14.5.7.36 TPTCj_DFBIDXi

Table 14-471. TPTCj_DFBIDXi

Address Offset	0x310 + (0x40*i)		Instance	IVA2.2 TPTC0
Physical address	0x01C1 0310 + (0x40*i)		Instance	IVA2.2 TPTC1
Physical address	0x01C1 0710 + (0x40*i)		Instance	IVA2.2 TPTC1
Description	Dst FIFO i Set B-Dim Idx			
Type	R			

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DBIDX																SBIDX															

Bits	Field Name	Description	Type	Reset
31:16	DBIDX	Dest B-Idx for Dest FIFO Register Set. Value copied from PBIDX: B-Idx offset between Destination arrays: Represents the offset in bytes between the starting address of each destination array (recall that there are BCNT arrays of ACNT elements). DBIDX is always used, regardless of whether DAM is Increment or FIFO mode.	R	0x0000
15:0	SBIDX	Dest B-Idx for Dest FIFO Register Set. Value copied from PBIDX: B-Idx offset between Source arrays: Represents the offset in bytes between the starting address of each source array (recall that there are BCNT arrays of ACNT elements). SBIDX is always used, regardless of whether SAM is Increment or FIFO mode.	R	0x0000

Table 14-473. TPTCj_DFMPPRXYi

Address Offset	0x314 + (0x40*i)																Instance	IVA2.2 TPTC0															
Physical address	0x01C1 0314 + (0x40*i)																Instance	IVA2.2 TPTC0															
Physical address	0x01C1 0714 + (0x40*i)																Instance	IVA2.2 TPTC1															
Description	Dst FIFO i Mem Protect Proxy																																
Type	R																																

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																						SECURE	PRIV	Reserved				PRIVID			

Bits	Field Name	Description	Type	Reset
31:10	Reserved	Read returns 0.	R	0x000000
9	SECURE	Secure Level: SECURE = 0: Nonsecure access SECURE = 1: Secure access DFMPPRXYi.SECURE is always updated with the value from the configuration bus secure field on any/every write to Program Set BIDX Register (trigger register). The SECURE value for the SA Set and DF Set are copied from the value in the Program set along with the remainder of the parameter values. The secure attribute is issued on the VBusM read and write command bus such that the target endpoints can perform memory protection and security checks based on the SECURE level of the external host that sets up the DMA transaction.	R	0
8	PRIV	Privilege Level: PRIV = 0: User level privilege PRIV = 1: Supervisor level privilege DFMPPRXYi.PRIV is always updated with the value from the configuration bus Privilege field on any/every write to Program Set BIDX Register (trigger register). The PRIV value for the SA Set and DF Set are copied from the value in the Program set along with the remainder of the parameter values. The privilege ID is issued on the VBusM read and write command bus such that the target endpoints can perform memory protection checks based on the PRIV of the external host that sets up the DMA transaction.	R	0
7:4	Reserved	Read returns 0.	R	0x0
3:0	PRIVID	Privilege ID: DFMPPRXYi.PRIVID is always updated with the value from configuration bus Privilege ID field on any/every write to Program Set BIDX Register (trigger register). The PRIVID value for the SA Set and DF Set are copied from the value in the Program set along with the remainder of the parameter values. The privilege ID is issued on the VBusM read and write command bus such that the target endpoints can perform memory protection checks based on the privid of the external host that sets up the DMA transaction.	R	0x0

15.1 Display Interface Subsystem Overview

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

The display interface subsystem provides the logic to display a video frame from the memory frame buffer (either SDRAM or SRAM) on a liquid-crystal display (LCD) panel or a TV set. The display subsystem integrates the following elements:

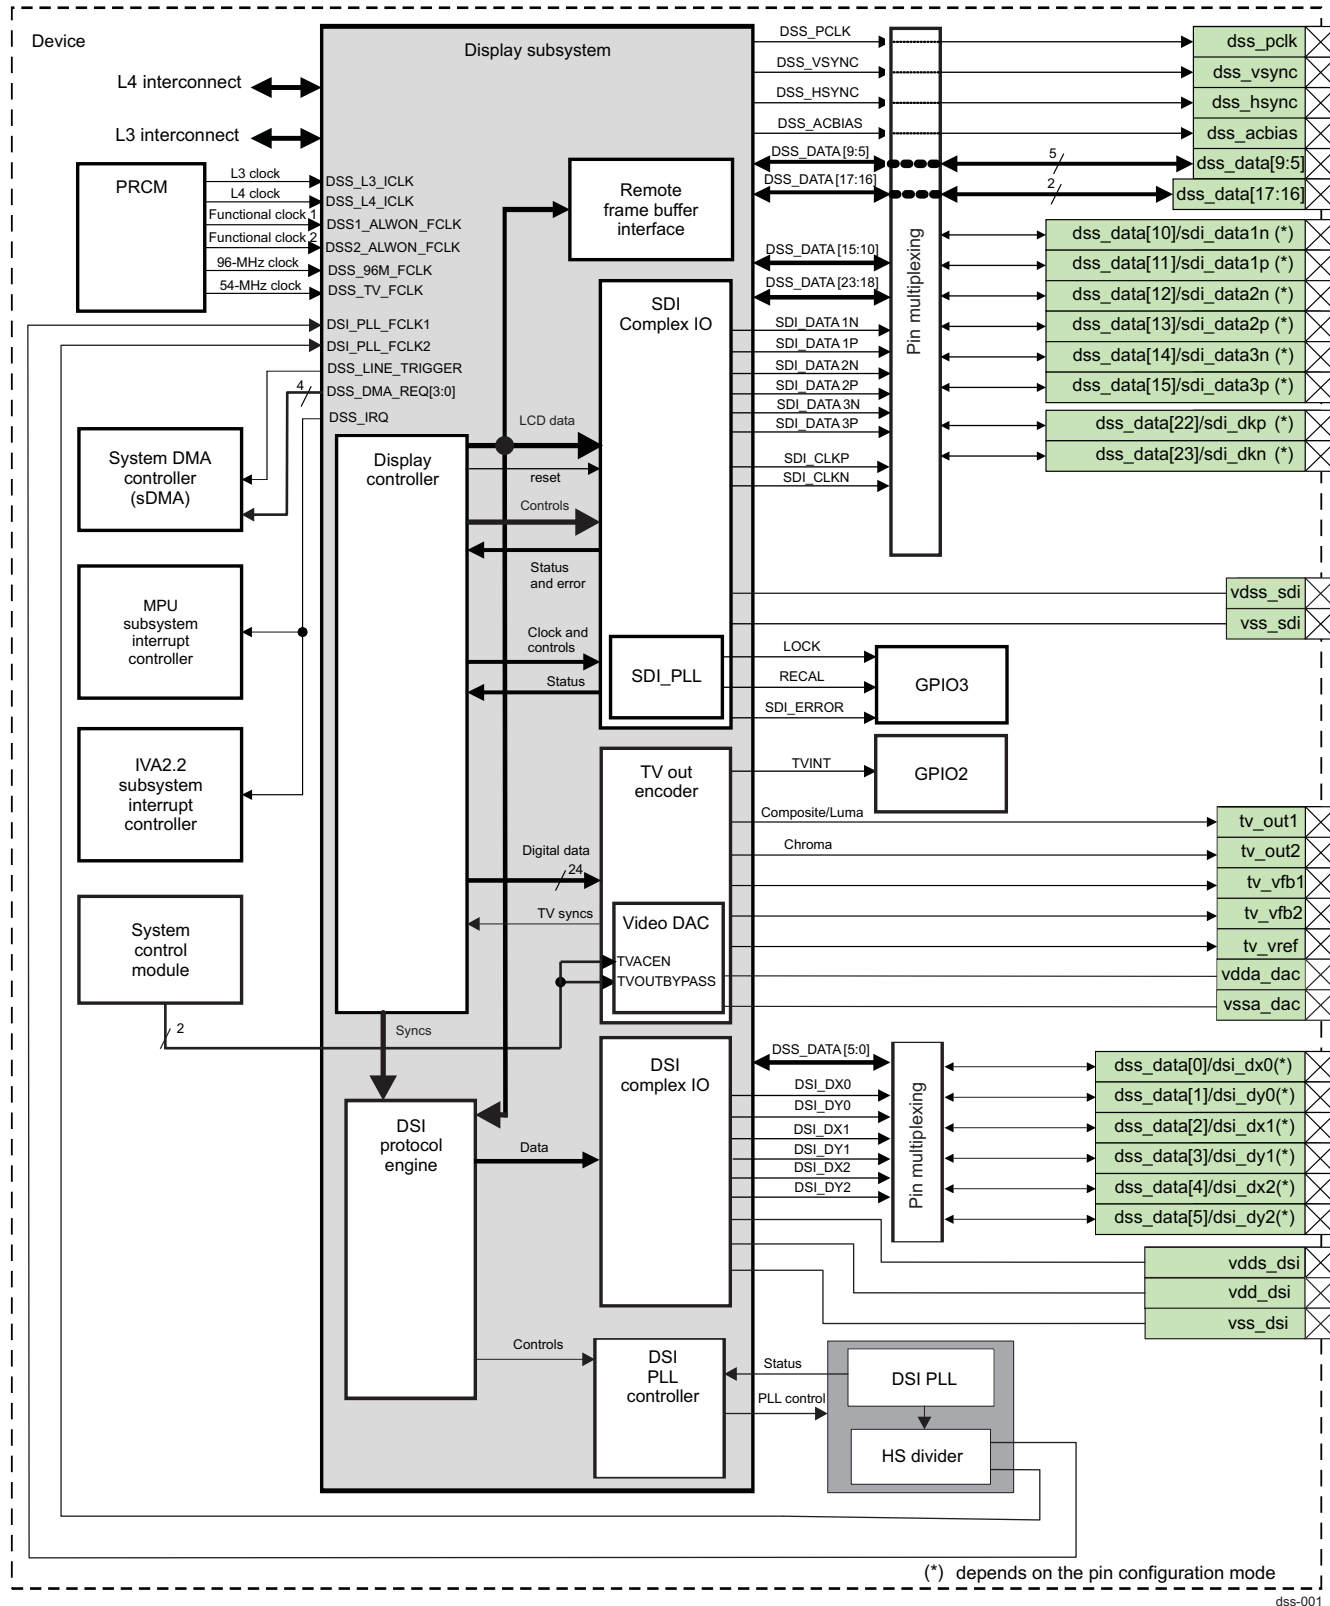

- Display controller (DISPC) module
- Remote frame buffer interface (RFBI) module
- Serial display interface (SDI) complex input/output (I/O) module with the associated phased-locked loop (PLL)
- Display serial interface (DSI) complex I/O module and a DSI protocol engine
- DSI PLL controller that drives a DSI PLL and high-speed (HS) divider
- NTSC/PAL video encoder

The display controller and the DSI protocol engine are connected to the L3 and L4 interconnect; the RFBI and the TV out encoder modules are connected to the L4 interconnect.

Note: The SDI module, the DSI complex I/O module, and the DSI PLL controller are not connected to an L3 or L4 interconnect. Specific display subsystem registers manage their programmable features.

Figure 15-1 shows a block diagram of the display subsystem.

Figure 15-1. Display Subsystem Highlight

dss-001

Note: For more information about connecting the LOCK, RECAL, SDI_ERROR, and TVINT signals through the GPIO2 and GPIO3 modules, see the *GPIO* chapter.

The display subsystem includes the following main features:

- Display controller
 - Display modes
 - Programmable pixel display modes (1, 2, 4, 8, 12, 16, and 24 bits-per-pixel [BPP] modes)
 - Programmable display size supported:
 - XGA - 1024x768 VESA Timings at 60 fps (pixel clock = 63.5 MHz)
 - WXGA - 1280x800 VESA timings at 59.91 fps (pixel clock = 71MHz)
 - SXGA+ - 1400x1050 Direct drive of LCD with minimal blanking at 50 fps (pixel clock = 75MHz)
 - HD 720p - 1280x720 CEA 861-D TIMINGS at 60 fps (pixel clock = 74.25 MHz)
 - 256 x 24-bit entries palette in red, green, and blue (RGB)
 - Programmable pixel rate up to 75 MHz

Note: The panel size is programmable and can be any width that is a multiple of 8 pixels (line length) in the range [1:2048] pixels (in the case of the RFBI mode, the minimum transfer size is a byte). The maximum resolution is 2048 (lines) x 2048 (pixels).

- Display support
 - Four types of displays are supported: Passive (super-twist nematic [STN]) and active (thin-film transistor [TFT]) colors, passive (STN), and active (TFT) monochromes.
 - 4-/8-bit monochrome passive matrix panel interface support (15 grayscale levels supported using dithering block)
 - 8-bit color passive matrix panel interface support (3375 colors supported for a color panel using dithering block)
 - 12-/16-/18-/24-bit active matrix panel interface support (replicated or dithered encoded pixel values)
 - Remote frame buffer support through the RFBI module
 - Partial display through the RFBI module
 - Second 24-bit digital output
 - Multiple-cycle output format on 8-/9-/12-/16-bit interface time division multiplexing (TDM)
- Signal processing
 - Overlay support for graphics (ARGB, RGBA, RGB or Color Look Up Table (CLUT)) and video1 (YCbCr 4:2:2, or ARGB, RGBA, RGB), video2 (YCbCr 4:2:2, or ARGB, RGBA, RGB)
 - Programmable video resizer independent horizontal and vertical resampling: Upsampling (up to x8) and downsampling (down to 1/4), maximum input width of 1024 pixels in 5-tap mode, and 2048 pixels in 3-tap configurations; no limitation on the input height
 - Rotation 90-, 180-, and 270-degrees
 - Transparency color key (source and destination)
 - Synchronized buffer update
 - Programmable video color space conversion YCbCr 4:2:2 into RGB
 - Hardware cursor
 - Gamma curve support on LCD output
 - Multiple-buffer support
 - Mirroring support
 - Programmable color phase rotation (CPR)
 - Alpha blending support (no rescaling in ARGB or RGBA formats)
- Advanced
 - Self-refresh using the DMA FIFO
 - Arbitration between high/low priority (graphics video1 and video2)

- FIFO handcheck in RFBI mode
- Power modes: Low-power saving modes
- RFBI (MIPI DBI protocol)
 - Access to remote frame buffer (RFB) direct microprocessor unit (MPU) interface
 - Sends commands to the RFB panel through the L4 interconnect
 - Sends data to the RFB panel, received from the display controller or from the MPU through the DISPC pixel data bus
 - Reads data/status from the RFB to the L4 interconnect
 - RFB interface
 - 8-/9-/12-/16-bit 8086-series parallel interface
 - Two programmable configurations for two devices connected to the RFBI module
 - Data formats
 - Programmable pixel modes (12-/16-/18-/24-BPP modes in RGB format)
 - Programmable output formats on one/multiple cycles per pixel (data from the display controller and from the L4 interconnect)
 - Interconnect/FIFO
 - One slave port with DMA request and Interconnect FIFO of 24x32-bit depth (for write access to DSS.RFBI_DATA register only)
 - One Video Port FIFO of 8x24-bit depth receiving data from the Display Controller.
- SDI
 - TI Flatlink™3G display interface support
 - Pin multiplexing allows simultaneous operation with a single 9-bit RFBI-driven display (no support for simultaneous dual RFBI panel and SDI.)

The SDI module is not available on all devices. See Chapter 1, *OMAP35x Family* section, to check availability of this module.

Note: The SDI pins are multiplexed with LCD parallel outputs.

- MIPI DSI
 - Transfer pixels and data received on the video port or L4 interconnect to the display through the DSI D-PHY
 - The maximum resolution supported on the video port is XGA at 60 fps with 24-bit pixels (maximum pixel clock of 67 MHz) for low voltage
 - Supports video mode and command mode
 - Bidirectional data link support (only one data lane is used in reverse direction in command mode)
 - Supports up to two data configurable lanes, in addition to the clock signaling (minimum of one data link and maximum of two, depending on speed, signal integrity requirements, and number of displays)
 - Maximum data rate of 800 Mbps per data pair
 - Data splitter for 2-data lane configuration
 - ECC and check-sum generation
 - Burst support for the video mode
 - RGB16, RGB18 (packed and non-packed), and RGB24 formats supported for video mode
 - Serial configuration port (SCP) for the DSIPHY complex I/O and DSI PLL
 - Connection to the D-PHY complex I/O through PPI
 - Data interleaving support for one synchronous stream (video mode) from the display controller and up to three interleaved asynchronous streams (command mode) from the interconnect concurrently
 - Data interleaving supports up to four interleaved asynchronous streams (command mode) from the interconnect or video port when there is no video mode
 - MIPI DCS support (transparent to the protocol engine, no decoding and interpretation of the information from and to the peripheral)
 - Supports selection between low-power state and HS mode between HS packet transfers

- Generic data type support.

Note: The DSI pins are multiplexed with LCD parallel outputs. The DSI module is not available on all devices. See Chapter 1, *OMAP35x Family* section, to check availability of this module.

- Video encoder
 - NTSC/PAL encoder outputs with the following standards:
 - NTSC-J, M
 - PAL-B, D, G, H, I
 - PAL-M
 - CGMS-A as described in the CEA-608-x Standard.
 - Input data interface compatible with the following protocols:
 - 24-bit input bus compatible with external sync
 - RGB 4:4:4
 - Dual output data 10-bit interface for internal digital-to-analog converter (DAC) that supports:
 - Composite video (CVBS)
 - Separate video (S-video)
 - TV output data supports ITU-R BT 470-7 recommendation standard for consumer market
 - Master clock input 13.5 MHz, 27 MHz (supports ITU-R 601 sampling for NTSC/PAL), and 54 MHz
 - Programmable horizontal sync, vertical timing, and waveforms
 - Programmable subcarrier frequency and SCH
 - Internal color bar test pattern generation
 - 2x/4x oversampling
 - Supports square pixel sampling (NTSC: 12.27 MHz, 24.54 MHz, 49.09 MHz PAL: 14.75 MHz, 29.5 MHz, 59 MHz)

CAUTION

In square pixel mode, an external clock generator is required to provide sampling frequencies.

- TV detection gating pulse generation

15.2 Display Subsystem Environment

This section describes the two main functions handled by the display subsystem:

- LCD support
- TV display support

15.2.1 LCD Support

LCD panels can be connected to the display subsystem of the device using parallel and/or serial interfaces.

15.2.1.1 Parallel Interface

In parallel interface, the paths of the display subsystem modules are the display controller and the RFBI.

The display controller provides the required control signals to interface the memory frame buffer (SDRAM or SRAM) directly to the external displays. The display controller is connected to the memory through the L3 interconnect and has its own DMA (with embedded FIFOs) to read data from the system memory. The L3 interconnect is the master port, while the L4 interconnect is the slave port of the display subsystem.

The display controller has two I/O pad modes at the module level:

- RFBI mode (RFBI enabled), which implements the MIPI DBI protocol
- Bypass mode (RFBI disabled), which implements the MIPI DPI protocol

The DSS.DISPC_CONTROL[16:15] GPOUT[1:0] bits control selection of the display subsystem modules (see [Table 15-1](#)).

Table 15-1. I/O Pad Mode Selection

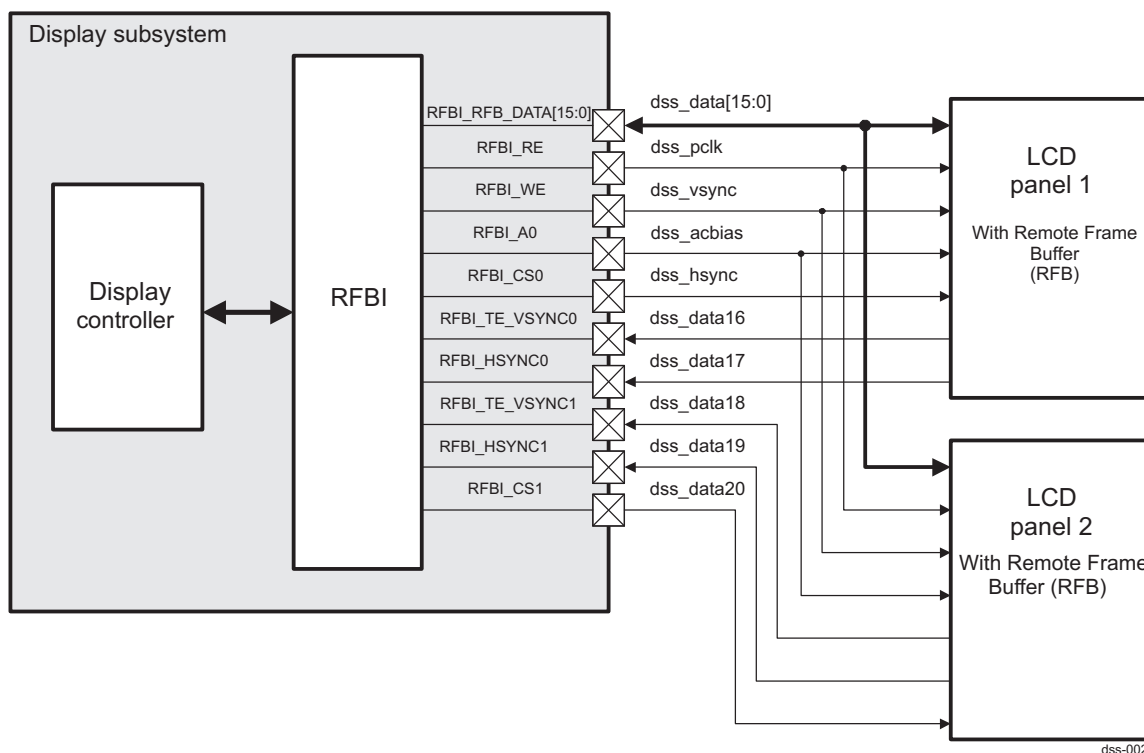

GPOUT1	GPOUT0	Mode Selection
0	0	Reset
0	1	RFBI mode
1	0	Invalid
1	1	Bypass mode

The remote frame buffer (RFB) of the LCD panel is directly connected to the RFBI module of the device. The RFBI controls the reads/writes from/to the RFB. The RFBI receives the output from the DISPC (which takes data from internal memory) and generates the signals to control the LCD panel. Through the RFBI, the MPU can send commands or parameter/display data to the LCD panel and directly set the DISPC registers to read/write the data from/to the memory in the LCD panel. The RFBI can manage up to two LCD panels when the serial interface is not used.

15.2.1.1.1 Parallel Interface in RFBI Mode (MIPI DBI Protocol)

Figure 15-2 shows the LCD support parallel interface in RFBI mode (example for 16-bit data interface).

Figure 15-2. LCD Support Parallel Interface (RFBI Mode)

Note: If the SDI is used, the second display device connected to RFB#1 is limited to 9-bit data.

Configure the DSS.RFBI_CONTROL[3:2] CONFIGSELECT field to drive signals for LCD 1 only, LCD 2 only, or both LCD 1 and LCD 2.

Table 15-2 describes the interface signals to/from the LCD panel in RFBI mode.

Table 15-2. LCD Interface Signals (RFBI Mode)

Signal Name	Type ⁽¹⁾	Description
RFBI_RFB_DATA[15:0]	I/O	RFBI I/O data
RFBI_RE	O	Read access signal
RFBI_WE	O	Write access signal
RFBI_A0	O	Command/data selection signal
RFBI_CS0	O	Chip-select (CS) signal for LCD 1
RFBI_CS1	O	CS signal for LCD 2
RFBI_TE_VSYNC0	I	Tearing effect (TE) synchronization signal (TE or VSYNC for LCD panel 1)
RFBI_HSYNC0	I	HSYNC from LCD panel 1
RFBI_TE_VSYNC1	I	TE synchronization signal (TE or VSYNC for LCD panel 2)
RFBI_HSYNC1	I	HSYNC from LCD panel 2

⁽¹⁾ I = Input, O = Output, I/O = Input/Output

- **RFBI_RFB_DATA[15:0]:** The pixel data comprises the RFBI pixel data (bits 15:0). A write/read command must be sent to the LCD panel to send/read the data.
Before any data access, the application must send commands and parameters when it is necessary to configure an LCD panel. The data is used as input in read operations during production test and also to read the status of the registers in the LCD panel and pixels from the embedded frame buffer in the LCD panel module. RFBI_RFB_DATA is multiplexed at the chip-level boundary with dss_data [15:0].
- **RFBI_RE:** This is the read-enable signal used to indicate when a read from the embedded memory in the LCD panel is ongoing. The RFBI registers describe the behavior of the read signal (off/on/cycle time). The polarity of the read-enable signal is programmable. This signal is multiplexed at the chip-level boundary with dss_pclk. The read is used to get status/data information from the LCD panel.
- **RFBI_WE:** The write-enable signal is used to indicate when a write is ongoing. The RFBI registers describe the behavior of the write signal (off/on/cycle time). The polarity of the write-enable signal is programmable. This signal is multiplexed at the chip-level boundary with dss_vsync.
- **RFBI_A0:** The signal is asserted to indicate its status: Command or data. The polarity is programmable and the status of the signal depends on the RFBI registers written by the application (CMD/READ/STATUS/PARAM/PIXEL). The register in use by the hardware defines the status of RFBI_A0. The order of the writes/reads to the RFBI registers CMD/READ/STATUS/PARAM/PIXEL defines the transitions of A0. This signal is multiplexed at the chip-level boundary with dss_acbias.
- **RFBI_CSx:** The signal is the chip-select (CSx) asserted to indicate which LCD panel is selected and must be ready to receive/transmit commands and data. When RE or WE is on, CSx must not be changed ($x = 0$ for LCD panel 1; $x = 1$ for LCD panel 2). CS0 is multiplexed at the chip-level boundary with dss_hsync, and CS1 is multiplexed at the chip-level boundary with dss_data[20].
- **RFBI_TE_VSYNCx:** Based on the trigger mode selected, the signal is the TE pulse signal or the LCD panel VSYNC (vertical synchronization) pulse signal. RFBI_TE_VSYNCx is used by the TE logic as the synchronization signal to send the pixel to the LCD panel.
To select the trigger mode, configure the DSS.RFBI_CONFIG[3:2] TRIGGERMODE field (0x0: Internal trigger mode with the DSS.RFBI_CONTROL[4] ITE bit, 0x1: External trigger mode with the TE signal RFBI_TE_VSYNCx, 0x2: External trigger mode with the RFBI_TE_VSYNCx, and RFBI_HSYNCx signals with the programmable line counter).
These signals are multiplexed at the chip-level boundary with dss_data[16] (RFBI_TE_VSYNC0) and dss_data[18] (RFBI_TE_VSYNC1) (LCD panel 1: $x = 0$; LCD panel 2: $x = 1$).
- **RFBI_HSYNCx:** The HSYNC pulse signals indicate to the RFBI module when horizontal synchronization occurs. The polarity of the HSYNC signals is programmable. The minimum pulse width of the signal is two L4 cycles. RFBI_HSYNC is used by the TE logic as a synchronization signal to send the pixel to the LCD panel. These signals are multiplexed at the chip-level boundary with dss_data[17] (RFBI_HSYNC0) and dss_data[19] (RFBI_HSYNC1) (LCD panel 1: $x = 0$; LCD panel 2: $x = 1$).

15.2.1.1.1.1 Description of the Tearing Effect Pulse Signal

The externally generated TE synchronization signal is a logical OR or AND operation between the HSYNC and VSYNC signals (see [Figure 15-3](#)). The logical operation (OR or AND) depends on the HSYNC and VSYNC signals polarity. The VSYNC signal indicates to the RFBI module when vertical synchronization occurs; the HSYNC signal indicates to the RFBI module when horizontal synchronization occurs.

Figure 15-3. External Generation of TE Signal Based on Logical OR Operation Between HSYNC and VSYNC (Active-High)

dss-003

The RFBI module detects the VSYNC and HSYNC pulses embedded in the received signal. VSYNC is detected based on the minimum pulse width defined by the DSS.RFBI_VSYNC_WIDTH register. VSYNC is not triggered by an inactive-to-active edge.

HSYNC is detected based on the minimum pulse width defined by the DSS.RFBI_HSYNC_WIDTH register. HSYNC is not triggered by an inactive-to-active edge.

The signal is generated from external logic based on the VSYNC/HSYNC of the LCD panel. The automatic trigger can be programmed based on the RFBI_TE signal or use a bit field in the RFBI registers to start data capture.

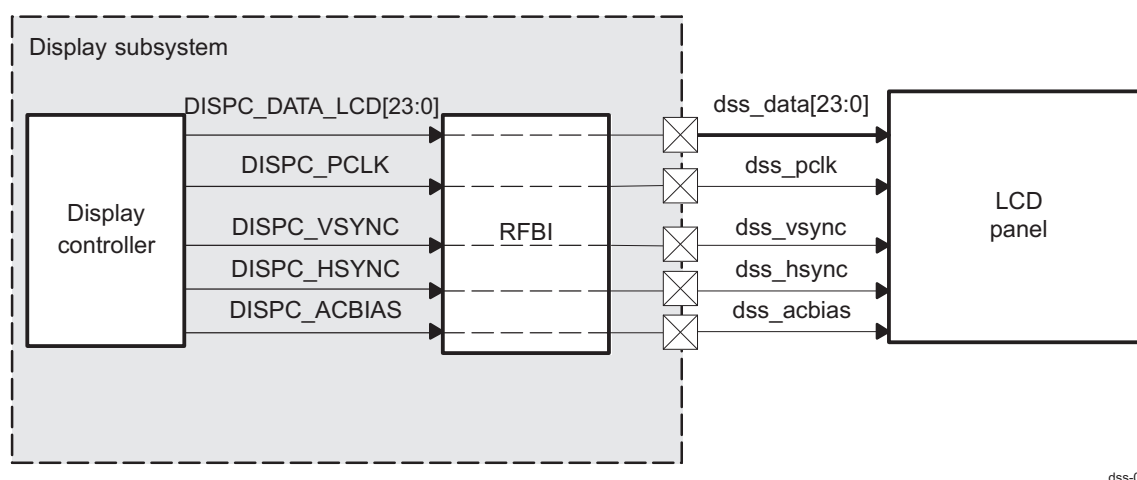

The polarity of the TE signal is programmable. The HSYNC and VSYNC pulses embedded in the TE signal have the same polarity, which is active high for an ORed signal and active low for an ANDed signal. The minimum pulse width of the signal is two L4 cycles. Hardware resets the line counter when the VSYNC occurs and increments it at every HSYNC. When the line counter reaches the programmable line number, the transfer to the LCD panel begins.

15.2.1.1.2 Parallel Interface in Bypass Mode (MIPI DPI Protocol)

When bypass mode is enabled, the display controller must be set to use it.

Figure 15-4 shows the LCD support parallel interface in bypass mode.

Figure 15-4. LCD Support Parallel Interface (Bypass Mode)

dss-004

Note: In bypass mode, the SDI and the parallel interface cannot be used at the same time.

Table 15-3 describes the interface signals to/from the LCD panel in bypass mode.

Table 15-3. LCD Interface Signals (Bypass Mode)

Signal Name	Type ⁽¹⁾	Description
DISPC_DATA_LCD[23:0]	O	LCD data from the display controller module
DISPC_PCLK	O	Pixel CLK from the display controller module
DISPC_VSYNC	O	VSYNC from the display controller module
DISPC_HSYNC	O	HSYNC from the display controller module
DISPC_ACBIAS	O	ACBIAS from the display controller module

⁽¹⁾ I = Input, O = Output, I/O = Input/Output

- DISPC_DATA_LCD[23:0]: The panel pixel data comes directly from the display controller module. DISPC_DATA_LCD is connected at the chip-level boundary with dss_data[23:0].
- DISPC_PCLK: This signal is the pixel clock that comes directly from the display controller. This signal is multiplexed at the chip-level boundary with dss_pclk.
- DISPC_VSYNC: Uses the vertical synchronization signal from the display controller. The LCD frame clock (VSYNC) toggles after all the lines in a frame are transmitted to the LCD panel and a programmable number of line clock cycles has elapsed both at the beginning and at the end of each frame. This signal is multiplexed on the chip-level boundary with dss_vsync.
- DISPC_HSYNC: Uses the horizontal synchronization signal from the display controller. The LCD line clock (HSYNC) toggles after all pixels in a line are transmitted to the LCD panel and a programmable number of pixel clock wait-states elapse, both at the beginning and at the end of each line. This signal is multiplexed on the chip-level boundary with dss_hsync.
- DISPC_ACBIAS: Uses the ac-bias signal from the display controller.
 - In passive matrix technology, the ac-bias signal is configured to transition each time a programmable number of line clocks occurs. To prevent a dc charge within the screen pixels, the power and ground supplies of the panel are periodically switched. The DISPC signals the panel to switch the polarity by toggling the ac-bias pin.
 - In active matrix technology, the ac-bias signal acts as an output-enable signal to indicate when data must be latched using the pixel clock. This signal is multiplexed on the chip-level boundary with dss_acbias.

15.2.1.1.3 LCD Output and Data Format for the Parallel Interface

This section describes the pixel data bus and shows timing diagrams of transactions and synchronizations in both RFBI and bypass modes.

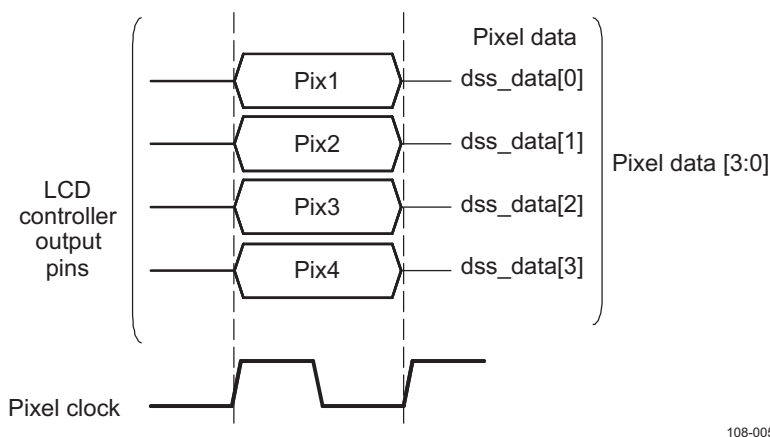

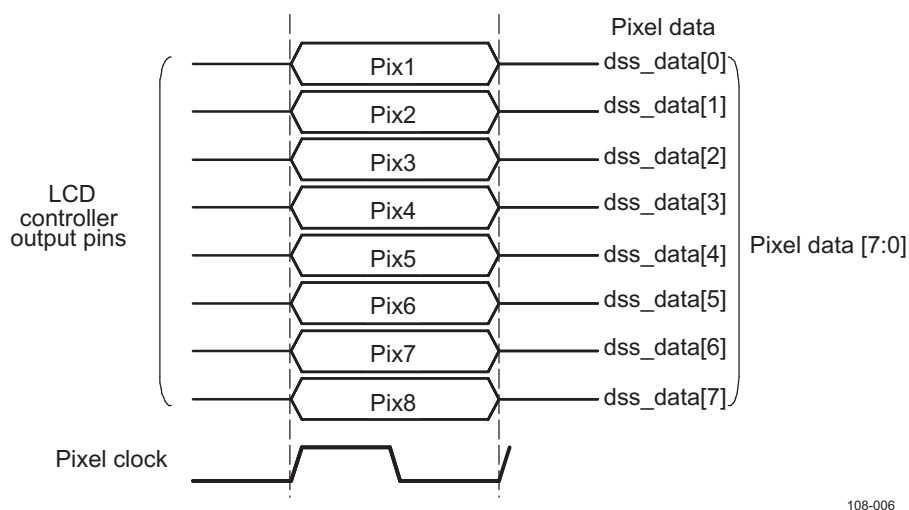

Figure 15-5 through Figure 15-11 show the pixel data bus for bypass mode, depending on the use of 4-, 8-, 12-, 16-, 18-, or 24-pixel data output pins. In RFBI mode, the pixel data bus is reformatted in accordance with the input and output data bus width.

Table 15-4 indicates the number of displayed pixels per pixel clock cycle based on the type of display panel.

Table 15-4. Number of Displayed Pixels per Pixel Clock Cycle Based on Display Type

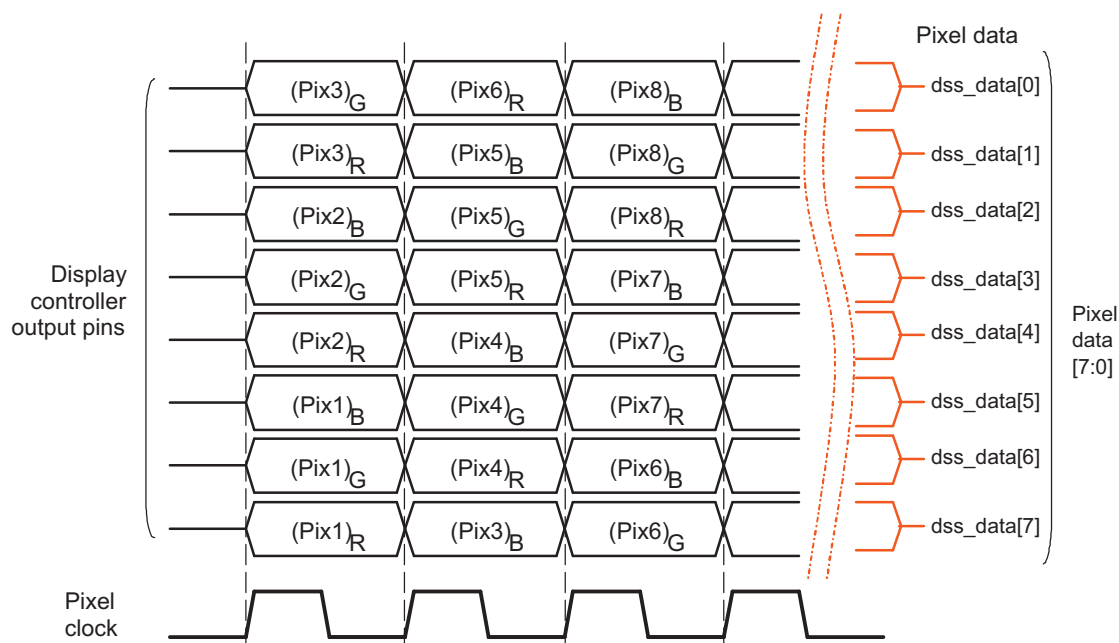

Display Panel	Number of Displayed Pixels per Pixel Clock Cycle
Monochrome 4-bit	4
Monochrome 8-bit	8
Passive matrix color	8/3
Active matrix	1

- Passive matrix technology, Monochrome mode
Monochrome displays use either a 4-bit or 8-bit interface. Each bit represents one pixel (on or off), which means that either 4 or 8 pixels are sent to the LCD at each pixel clock.
Figure 15-5 and Figure 15-6 show 4- and 8-bit monochrome displays, respectively.

Figure 15-5. LCD Pixel Data Monochrome4 Passive Matrix

Figure 15-6. LCD Pixel Data Monochrome8 Passive Matrix

- Passive matrix technology, Color mode
Color passive displays use 8-bit data input lines. In a given pixel clock cycle, each line represents one color component (red, green, or blue).
[Figure 15-7](#) shows an 8-bit color passive matrix display.

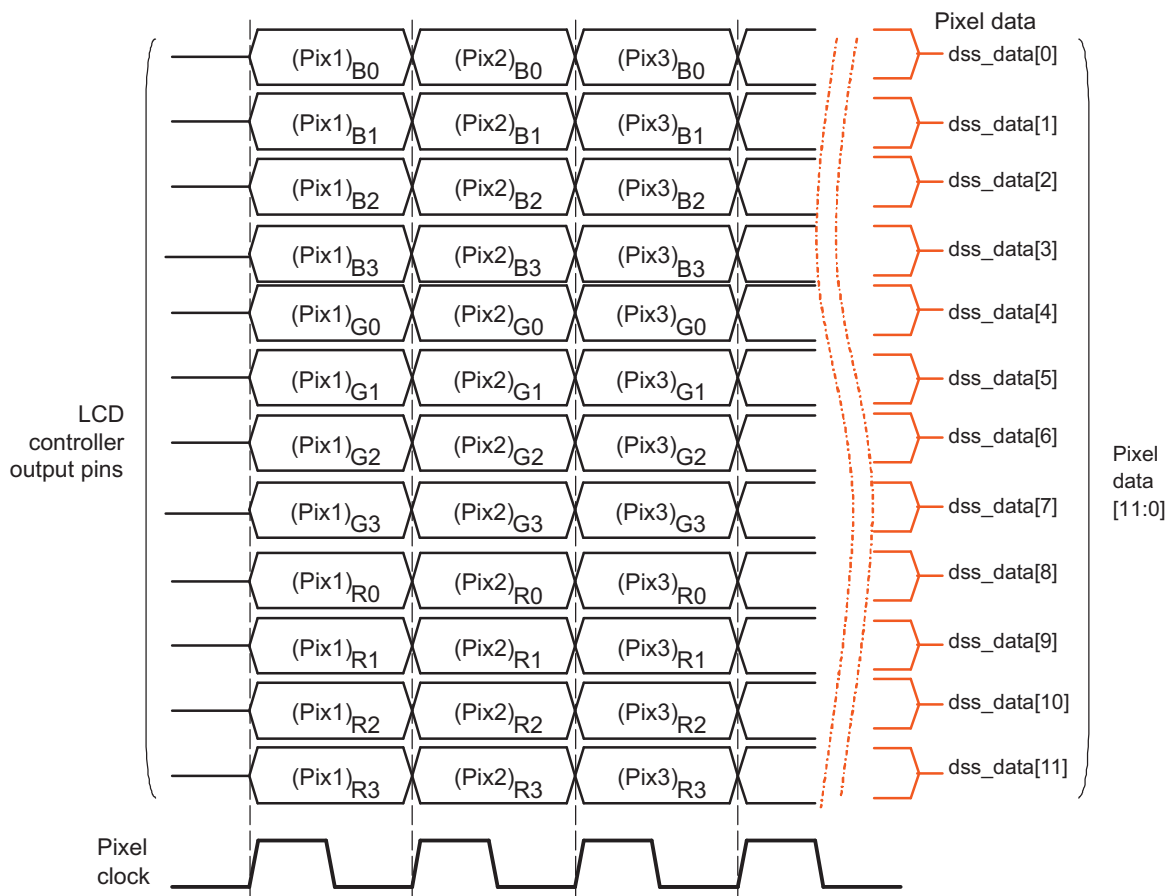

Figure 15-7. LCD Pixel Data Color Passive Matrix

108-007

- **Active matrix technology**
Active matrix displays bypass the STN dithering logic block and the output FIFO. Each line represents one pixel.
[Figure 15-8](#) through [Figure 15-11](#) show 12-, 16-, 18-, and 24-active matrix displays, respectively.

15.2.1.1.4 Transaction Timing Diagrams

- Timing diagrams in flow control mode
 - Stall Signal

The stall signal is used in RFBI and DSI modes. In the case of RFBI mode, it is used to indicate when the display controller should stop sending data over the LCD output interface. The RFBI module asserts the stall signal to stop data output by the display controller. It is deasserted to indicate when new data should be outputted by the display controller.

Figure 15-12. RFBI Data Stall Signal Diagram

dss-134

To avoid underflow of the DMA FIFO, the FIFO handcheck feature can be enabled by setting the `DSS.DISPC_CONFIG[16]` `FIFOHANDCHECK` bit to 1. The fullness of the FIFOs associated with the pipelines used for the LCD output is checked when the STALL signal is inactive before providing data to the pipeline. This prevents emptying the FIFO when the RFBI module requests data and there is not enough data in the display controller DMA FIFO. This feature should be enabled only when the RFBI mode is used (`DSS.DISPC_CONTROL[11]` `RFBIMODE` bit set to 1). When the FIFO handcheck feature is activated, the pixel transfer to the RFBI module during STALL inactivity period can be stopped (no `DISPC_PCLK` pulse) and restarted when there is enough data in the FIFO. The FIFO handcheck ensures that underflow can not occur for the pipelines associated with the LCD output in RFBI mode. Figure 15-13 details the RFBI data stall with FIFO handcheck mode activated.

Figure 15-13. RFBI Data Stall Signal Diagram With Handcheck

– RFBI timing diagrams

Table 15-5 lists the programmable timing fields. Figure 15-14 through Figure 15-16 show timing diagrams of read/write transactions to the LCD panel for the RFBI mode.

Table 15-5. Programmable Timing Fields in RFBI Mode

Timing Name	Register Field	Description
CSOnTime	DSS.RFBI_ONOFF_TIME[3:0] CSONTIME (with i = 0 or 1)	CS assertion time from start access time
CSOffTime	DSS.RFBI_ONOFF_TIME[9:4] CSOFFTIME (with i = 0 or 1)	CS deassertion time from start access time
WeCycleTime	DSS.RFBI_CYCLE_TIME[5:0] WECYCLETIME (with i = 0 or 1)	The time when A0 becomes valid until write cycle completion
WEOnTime	DSS_RFBI_ONOFF_TIME[13:10] WEONTIME (with i = 0 or 1)	WE assertion delay time from start access time
WEOffTime	DSS_RFBI_ONOFF_TIME[19:14] WEOFFTIME (with i = 0 or 1)	WE deassertion delay time from start access time
RECycleTime	DSS.RFBI_CYCLE_TIME[11:6] RECYCLETIME (with i = 0 or 1)	The time when A0 becomes valid until read cycle completion
REOnTime	DSS_RFBI_ONOFF_TIME[23:20] REONTIME (with i = 0 or 1)	RE assertion delay time from start access time
REOffTime	DSS.RFBI_ONOFF_TIME[29:24] REOFFTIME (with i = 0 or 1)	RE assertion delay time from start access time
CSPulseWidth	DSS.RFBI_CYCLE_TIME[17:12] CSPULSEWIDTH (with i = 0 or 1)	The time when write cycle time or read cycle time completes

- Timing diagrams in bypass mode

Figure 15-17 through Figure 15-32 show timing diagrams of synchronization signals and pixel clock in bypass mode for both passive matrix and active matrix panels. The display controller directly drives these signals, which are related to the programmable fields described in Table 15-6.

Table 15-6. Programmable Fields in Bypass Mode

Name	Register	Description
PPL	DSS.DISPC_SIZE_LCD[10:0] PPL field value + 1	Pixels per line
LPP	DSS.DISPC_SIZE_LCD[26:16] LPP field value + 1	Lines per panel
HBP	DSS.DISPC_TIMING_H[27:20] HBP field value + 1	Horizontal back porch
HFP	DSS.DISPC_TIMING_H[15:8] HFP field value + 1	Horizontal front porch
HSW	DSS.DISPC_TIMING_H[5:0] HSW field value + 1	Horizontal synchronization pulse width

Table 15-6. Programmable Fields in Bypass Mode (continued)

Name	Register	Description
VBP	DSS.DISPC_TIMING_V[27:20] VBP field value	Vertical back porch
VFP	DSS.DISPC_TIMING_V[15:8] VFP field value	Vertical front porch
VSW	DSS.DISPC_TIMING_V[5:0] VSW field value + 1	Vertical synchronization pulse width
ONOFF	DSS.DISPC_POL_FREQ[17] ONOFF bit	DISPC_HSYNC and DISPC_VSYNC pixel clock control
RF	DSS.DISPC_POL_FREQ[16] RF bit	DISPC_HSYNC and DISPC_VSYNC pixel clock edge control
IEO	DSS.DISPC_POL_FREQ[15] IEO bit	Invert DISPC_ACBIAS
IPC	DSS.DISPC_POL_FREQ[14] IPC bit	Invert DISPC_PCLK
IHS	DSS.DISPC_POL_FREQ[13] IHS bit	Invert DISPC_HSYNC
IVS	DSS.DISPC_POL_FREQ[12] IVS bit	Invert DISPC_VSYNC

- Active matrix timing configuration 1
 - DSS.DISPC_POL_FREQ[17] ONOFF bit = 0
 - DSS.DISPC_POL_FREQ[16] RF bit = 0
The DISPC_HSYNC and DISPC_VSYNC signals are driven on the opposite edge of DISPC_PCLK from the pixel data.
 - DSS.DISPC_POL_FREQ[15] IEO = 0
The DISPC_ACBIAS signal is active high.
 - DSS.DISPC_POL_FREQ[14] IPC = 0
The pixel data are driven on the rising edge of DISPC_PCLK.
 - DSS.DISPC_POL_FREQ[13] IHS = 0
The DISPC_HSYNC signal is active high.
 - DSS.DISPC_POL_FREQ[12] IVS = 0
The DISPC_VSYNC signal is active high.

15.2.1.2 SDI Serial Interface

This section describes SDI module. This module is not available on all devices. See Chapter 1, the *OMAP35x Family* section, to check availability of this module.

In the serial interface, the modules in the display subsystem path are the display controller and the SDI with its associated PLL. The display controller provides the required control signals to interface the memory frame buffer (either SDRAM or SRAM) directly to the external displays. The display controller is connected to the memory through the L3 interconnect and has its own DMA to read the data from the system memory.

The SDI module is an additional display output mode that facilitates the connection of displays over relatively few conductors.

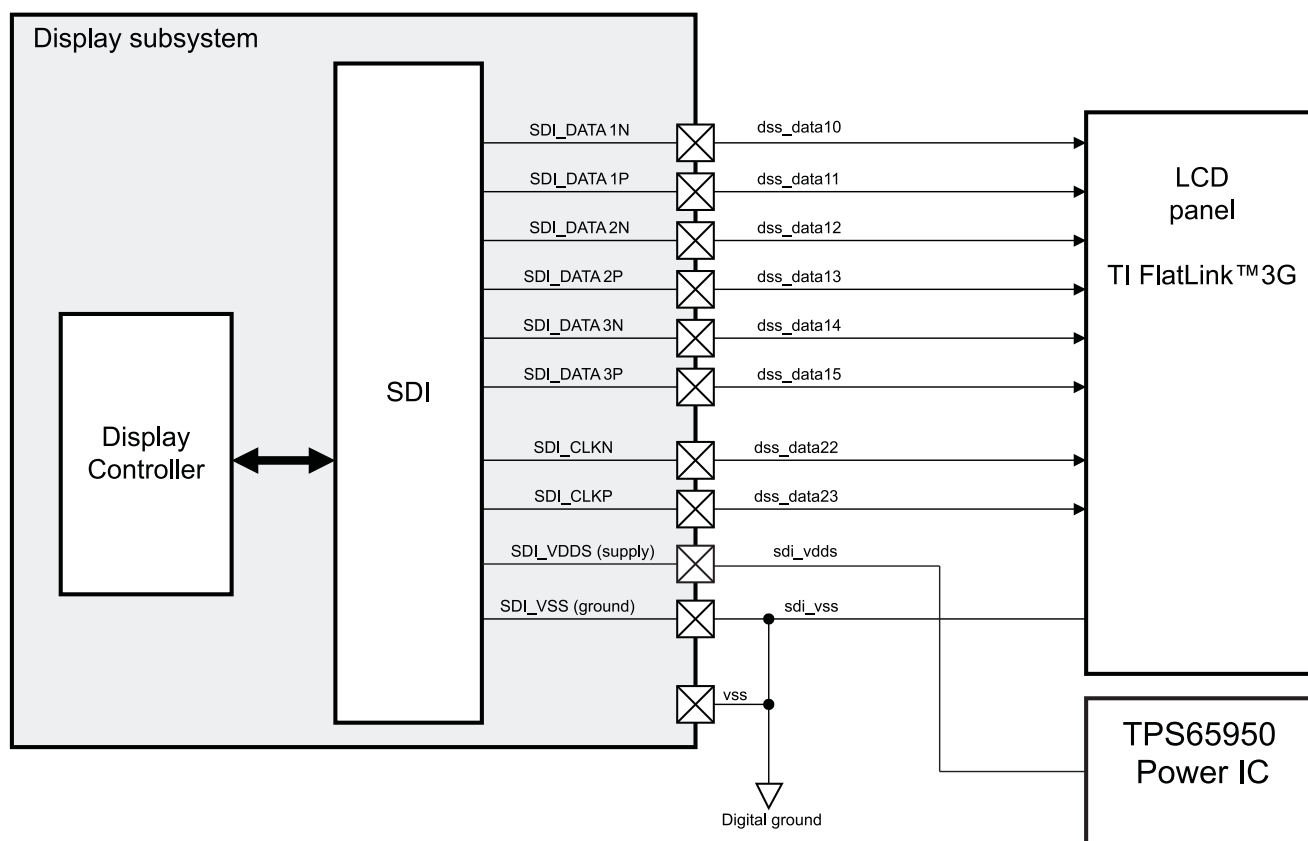

The SDI module implements the TI FlatLink™3G protocol and converts the conventional parallel display signals (including pixel data) from the display controller to serial form. Texas Instruments provides a global solution with OMAP device associated to a programmable 27-bit serial display interface receiver - SN65LVDS302 receiver for 3-data pair, SN65LVDS304 receiver for 2-data pair and SN65LVDS306 receiver for 1-data pair. For more details on these devices, please visit www.ti.com.

The SDI module contains a PLL to multiply the pixel clock by an appropriate factor. The resulting serialized data is then transmitted on 1 to 3 differential data pairs and an additional clock pair that has a reference transition at the boundary between pixels.

Note: Only one 9-bit RFBI driven display can be run at the same time as the SDI.

Figure 15-33 shows a typical connection between the SDI module and a compliant panel display.

Figure 15-33. Typical SDI Connection

dss-031

CAUTION

When routing the PCB, ensure that the connections between the OMAP device and the LCD panel meet TI FlatLink3G specifications.

Notes:

- The SDI pins are multiplexed in mode 1 with some LCD parallel pins. See the *System Control Module* chapter for more details on the pad multiplexing.
- The connection from the sdi_vss pin of the device to the digital ground of the PCB must be as short as possible.
- The sdi_vdds dedicated power supply is provided by a power IC. Texas Instruments provides a global solution with OMAP device associated to TPS65950 power IC. For more details on TPS65950 power IC, contact your TI representative.

Table 15-7 describes the interface signals between the SDI module of the OMAP device and the LCD panel.

Table 15-7. Interface Signals Between the SDI Module and LCD Panel

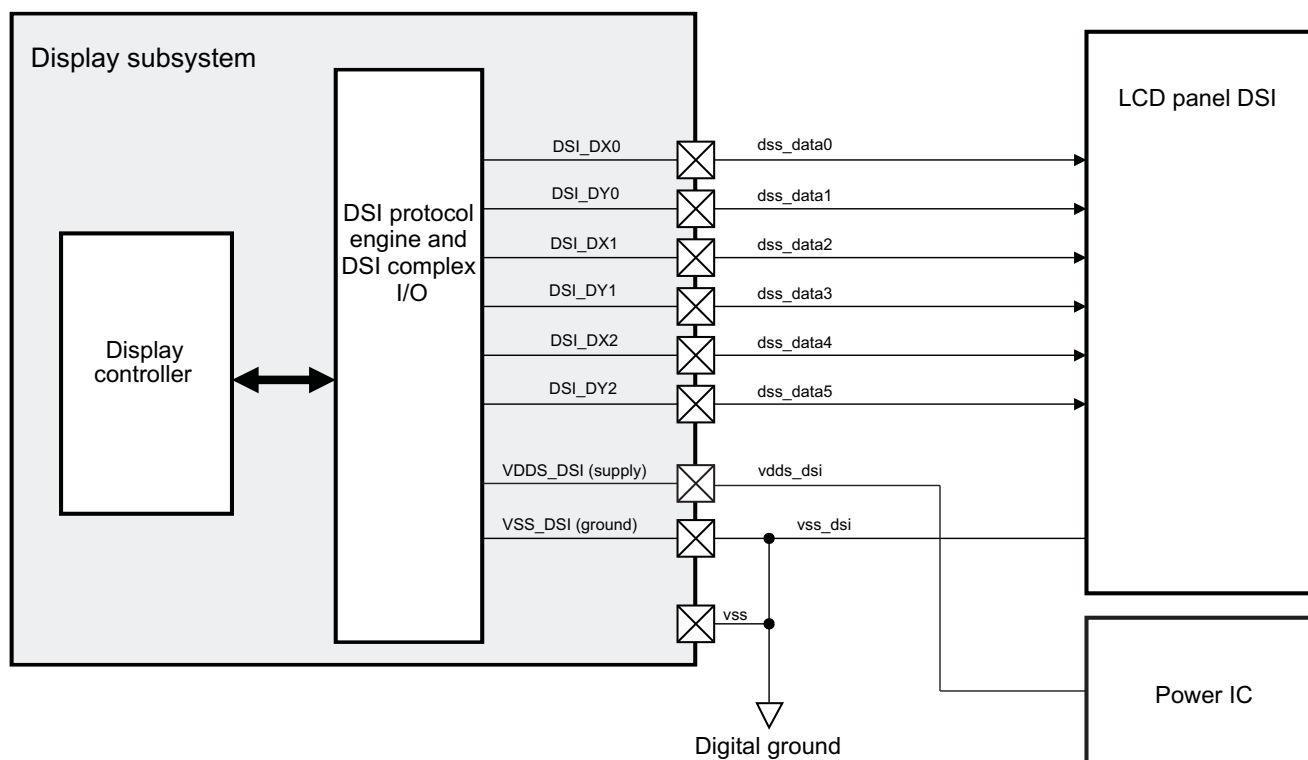

Signal Name	Type ⁽¹⁾	Description
SDI_DATA1N	O	First pair of differential data signals
SDI_DATA1P		
SDI_DATA2N	O	Second pair of differential data signals
SDI_DATA2P		
SDI_DATA3N	O	Third pair of differential data signals
SDI_DATA3P		
SDI_CLKN	O	Pair of differential clock signals
SDI_CLKP		
SDI_VDDS	PWR	Dedicated vdds power supply for SDI module
SDI_VSS	PWR	Dedicated vss ground for SDI module

⁽¹⁾ O=Output PWR=Power

15.2.1.3 DSI Serial Interface

Figure 15-34 shows a typical connection between the DSI modules and a compliant panel display.

Figure 15-34. Typical DSI Connection

dss-194

Note: The DSI pins are multiplexed in mode 1 with some LCD parallel pins. See the *System Control Module* chapter for more details on the pad multiplexing.

15.2.2 LCD Support With MIPI DSI 1.0 Protocol and Data Format

This section details briefly the MIPI DSI1.0 protocol and data format. For more details, see the MIPI DSI specification v1.0 (1.01.00r03) [2] with in addition the MIPI DSI Release note dated 26 July 2006 [13].

15.2.2.1 Physical Layer

Table 15-8 shows the DSI interface I/O.

Table 15-8. I/O Description for DSI Serial Interface

Signal Name		I/O ⁽¹⁾	Description	Value at Reset
dsi_dx0	line 1	I/O	Serial data/clock input/output	N/A
dsi_dy0				
dsi_dx1	line 2	I/O	Serial data/clock input/output	N/A
dsi_dy1				
dsi_dx2	line 3	I/O	Serial data/clock input/output	N/A
dsi_dy2				

⁽¹⁾ I/O = Input/Output

Note: Each serial line (line 1, line 2, and line 3) can be used as clock lane or data lane. All polarities are supported. The MIPI DSI 1.0 protocol requires at least one clock line and one data lane.

Lanes support four operating modes:

- HS mode: High-speed transmit mode
- LP mode: Low-power transmit mode
- ULPS: Ultra-low power state used between two transmissions
- Off mode: Lane is off.

15.2.2.1.1 Data/Clock Configuration

From the device point of view, the DSI interface consists of six input/output signals representing three differential signals: The serial clock and one or two serial data. The minimum configuration is one data pair and one clock pair.

- The data signal carries the bit-serial data. The DSI transmitter in the host sends the data in-quadrature with the DDR clock in high speed mode otherwise the clock is extracted from the received data in low speed mode. The data is transmitted byte-wise least significant bit first.
- The clock signal carries the DDR clock signal in High speed transmission.
- Software users should configure the order of the data lanes to indicate the byte order while splitting the byte stream for each D-PHY into bytes.

[Table 15-9](#) details all the DSI lanes configuration.

Table 15-9. DSI Lane Configuration

DSI D-PHY Lane Configuration	1	2	3	Description
Mode CLK + DATA1	CLK	DATA1	Not used	Single Data Lane
	CLK	Not used	DATA1	
	DATA1	CLK	Not used	
	Not used	CLK	DATA1	
	DATA1	Not used	CLK	
	Not used	DATA1	CLK	
Mode CLK + DATA1 + DATA2	CLK	DATA1	DATA2	Two Data Lanes
	CLK	DATA2	DATA1	
	DATA1	CLK	DATA2	
	DATA2	CLK	DATA1	
	DATA1	DATA2	CLK	
	DATA2	DATA1	CLK	

Notes:

- The byte on Dn is sent before the byte on Dn+1, all the combinations of data and clock are supported through the programming of the DSS.DSI_COMPLEXIO_CFG1 register. The CLOCK_POSITION and CLOCK_POL fields configure which lane transmits the clock and define its polarity. Four fields (DATA1_POSITION, DATA1_POL, DATA2_POSITION, and DATA1_POL) configure the data lanes and their polarity. The DATA2_POSITION field can be set to 0; in this case, only the data lane defined in the DATA1_POSITION field is used, and data is transmitted on only one clock lane and one data lane.
- The configuration of the DSI complex I/O (number of data lanes, position, differential order) should not be changed while DSS.DSI_CLK_CTRL[20] LP_CLK_ENABLE bit is set to 1. In order for the hardware to take into account a new configuration of the complex I/O (done in DSS.DSI_COMPLEXIO_CFG1 register), it is recommended to follow this sequence: First set the DSS.DSI_CTRL[0] IF_EN bit to 1, then reset the DSS.DSI_CTRL[0] IF_EN to 0, then set DSS.DSI_CLK_CTRL[20] LP_CLK_ENABLE to 1 and finally set again the DSS.DSI_CTRL[0] IF_EN bit to 1. If the sequence is not followed, the DSI complex I/O configuration is unknown.
- Only DATA1 is bi-directional in command mode. The low-power received information is always sent by the display panel using DATA1. Since any lane of the DSI complex I/O can be configured as data lane DATA1, all lanes of the complex I/O are bi-directional

15.2.2.1.2 ULPS

Each lane can be put in ultra-low-power state (ULPS) by software configuration. The ULPS mode requires all the following conditions:

- The lane should be in stop state
- For data lanes, no data must be pending in the DSI module
- For data lane 1, no BTA should have been sent. The DSI module should have the control of the bus.

The control of each lane is independently controlled by the DSS.DSI_COMPLEXIO_CFG2 register.

15.2.2.2 Video Port (VP) Interface

Note: The signals described in this section are internal and not bounded outside the device. This section aims at helping the software user to understand the internal connections between the display controller (DISPC) and the DSI protocol engine.

Table 15-10 summarizes the video interface signals. This interface is used to connect the display controller to the DSI protocol engine to send real time data stream. Note that only the active matrix timings are supported by DSI protocol engine. The HSYNC/VSYNC/DE/DATA signals are driven on rising or falling edge of the pixel clock (VP_PCLK).

Table 15-10. Video Interface for DSI Protocol Engine

Signal Name	Type ⁽¹⁾	Description
VP_HSYNC	I	Horizontal sync signal
VP_VSYNC	I	Vertical sync signal
VP_DATA[23:0]	I	Parallel output data: Bits 0 to 23
VP_PCLK	I	Pixel clock. In case of STALL configuration, it is used to indicate when new data is on the data bus during on clock period of VP_CLK
VP_DE	I	Data Enable
VP_STALL	O	The stall signal should be deasserted to receive pixel and asserted to stop receiving pixel. (It can be used only while the display controller is configured in RFBI mode only, in that mode the HSYNC and VSYNC are not generated)

⁽¹⁾ I = Input, O = Output, I/O = Input/Output

Table 15-10. Video Interface for DSI Protocol Engine (continued)

Signal Name	Type ⁽¹⁾	Description
VP_CLK	I	Display Controller internal clock. It is a free running clock. The VP_CLK is a divided clock from VP_PCLK.

Notes:

- The polarity of VP_HSYNC and VP_VSYNC are programmable by setting the DSS.DSI_CTRL register
- The maximum frequency for VP_CLK is 173 MHz at nominal voltage and 96 MHz at low voltage
- The clocks VP_CLK and VP_PCLK can have the same frequency.
- The number of bits to be captured on the video port is defined in the DSS.DSI_CTRL[7:6] VP_DATA_BUS_WIDTH field.

The data received on the video port can be stored into the line buffer memories or sent directly on the DSI interface in two cases:

- The line buffer size is too small compared to the line from the display controller
- There is no line buffer instantiated. In case there is no line buffer, the burst mode as defined as frequency burst mode, can not be used. Only the transparency burst mode is supported.

Note: The DSS.DSI_CTRL[13:12] LINE_BUFFER field defines the number of lines to be used for transferring data from the video port to the DSI link.

15.2.2.2.1 Video Port Used for Video Mode

In case of video port used for video mode, the VP_STALL is not used. Table 15-11 indicates the active signals on the video port.

Table 15-11. Video Interface in the Context of Video Mode

Signal Name	Type ⁽¹⁾	Description
VP_HSYNC	I	Horizontal sync signal
VP_VSYNC	I	Vertical sync signal
VP_DATA[23:0]	I	Parallel output data: Bits 0 to 23
VP_PCLK	I	Pixel clock.
VP_DE	I	Data Enable
VP_CLK	I	It is a free running clock which is the display controller functional clock. The maximum frequency is 173MHz at nominal voltage and 96 MHz at low voltage.

⁽¹⁾ I = Input, O = Output, I/O = Input/Output

Three video modes are available:

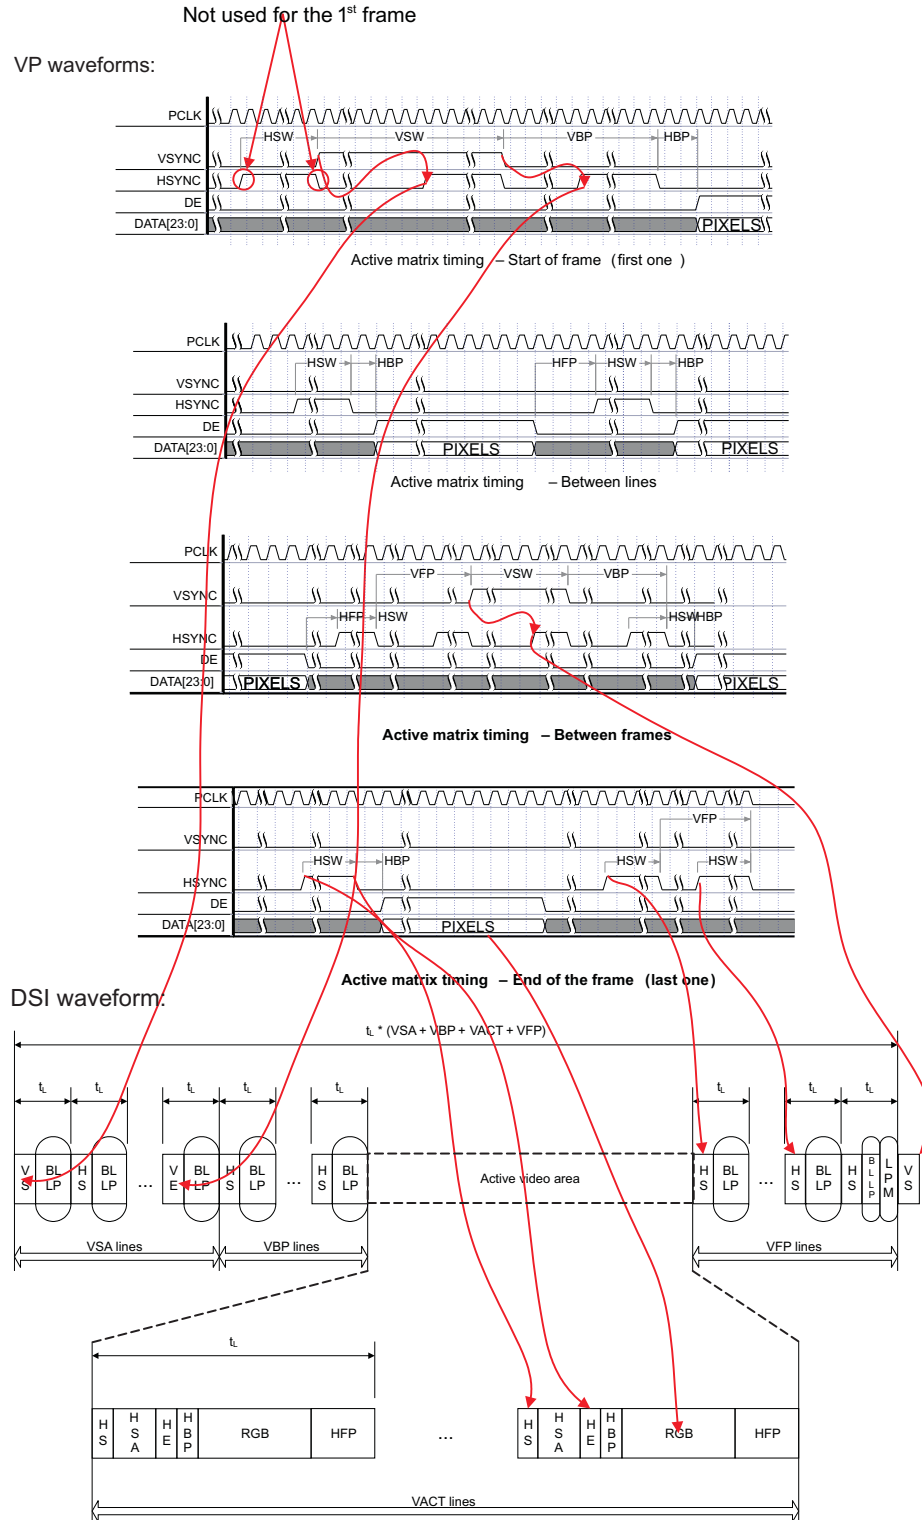

- No line buffer: The data received on the video port are directly output of the DSI port without buffering. The VP_CLK should match the DSI high-speed (HS) clock to get the exact same throughput on the two ports (the two clocks should be generated using the same PLL, the subsystem should provide such configuration)
- One line buffer:
 - The data can be transferred as described in "No line buffer" configuration
 - the data are first stored into the line buffer, when all the data for one line are received; the DSI protocol engine sends the whole line. All the synchronization packets occur at the same time as previous mode. Only the time when RGB packets are sent is delayed.
- Two line buffers:
 - The data can be transferred as described in "one line buffer" configuration
 - One line is stored when the second line is output on the DSI port. It allows burst capability. The

synchronization packets are not modified when bursting the RGB packets. While receiving the first line of the frame, there is no RGB packets sent since the line buffers are empty. To send the last line of the frame, a dummy line should be provided by the display controller to flush the line buffers.

Note: If more active lines are received on the video port than the number defined in the DSS.DSI_VM_TIMING3[15:0] VACT field, the extra lines are discarded by the DSI protocol engine. These lines are considered as blanking lines.

Figure 15-35, Figure 15-36 and Figure 15-37 show these three video modes.

Figure 15-35. DSI Video Mode Without Burst (No-Line Buffer)

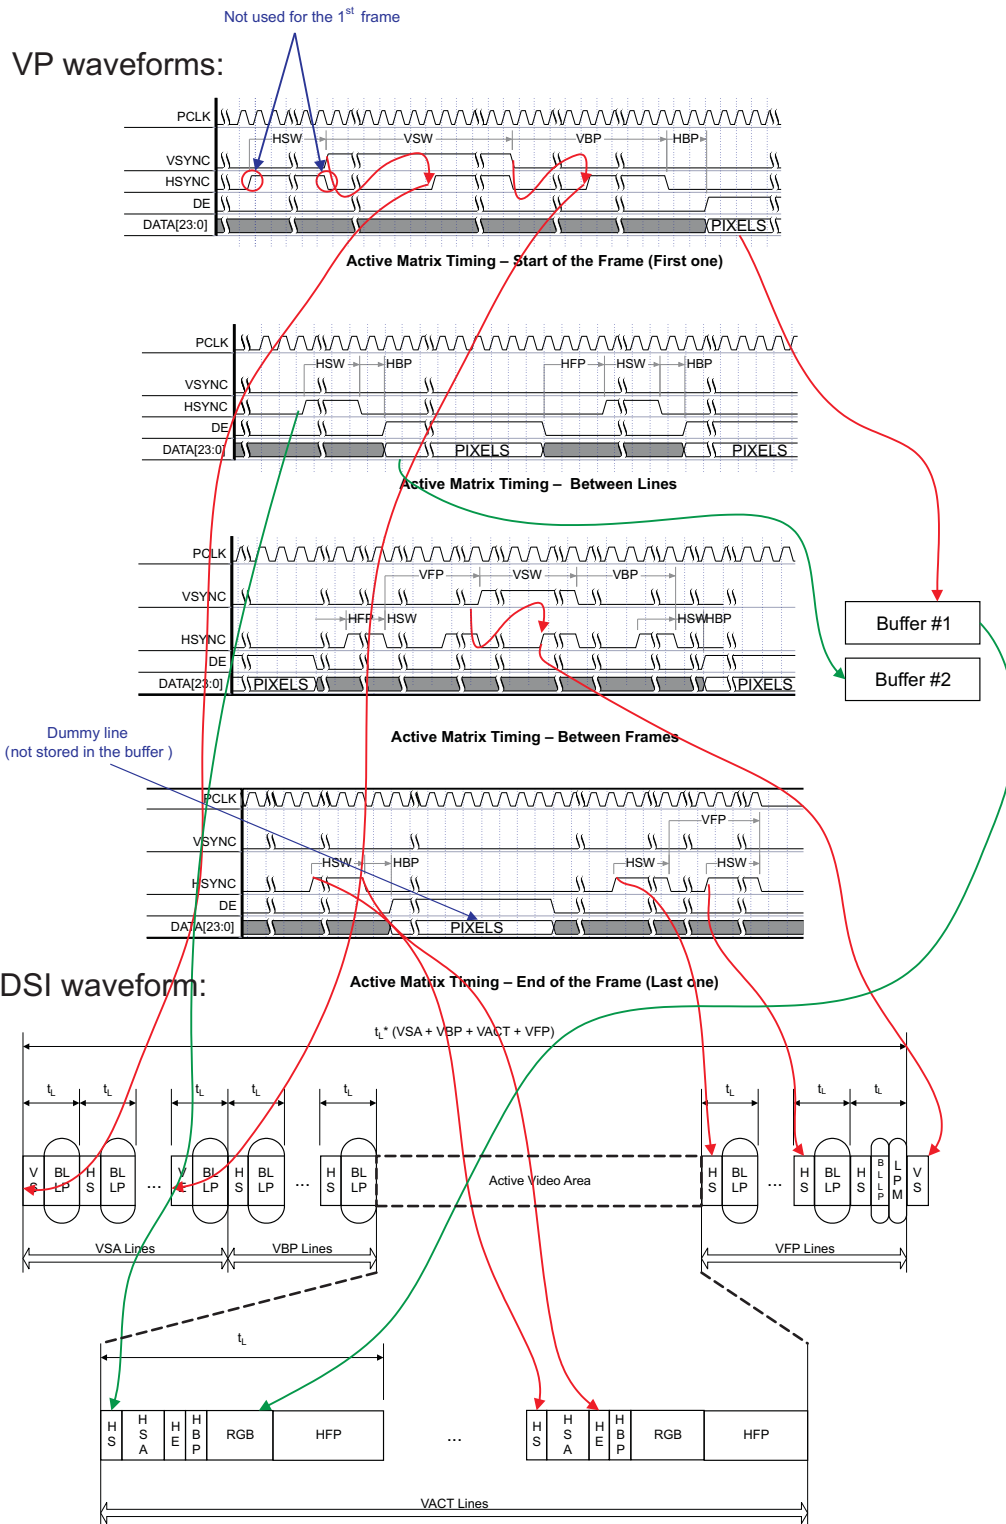

dss-136

Figure 15-36. DSI Video Mode Without Burst (One-Line Buffer)

dss-137

Figure 15-37. DSI Video Mode With Burst (Two-Line Buffers)

dss-138

Note: In the figures above:

- When HSync start and Hsync end short packets are not generated (HSA does not exist), HBP signal must be different than 0.
- The software should ensure that VBP is always defined in such a way that there is at least one HSYNC during VBP.

In case the signal VP_DE is not asserted during enough VP_PCLK cycles to be able to capture the number of bytes defined in the word count of the header, the module must send the valid data received on the video port followed by bytes of 0s to match the required number of bytes to transmit. The VP_PCLK should be present during all extra cycles where the DSI protocol engine is expecting pixels.

If the VP_DE signal is asserted during too many VP_PCLK cycles, the module should stop capturing the data on the video port while the number of bytes to capture as defined in the word count field of the header is reached.

The HS should check that the received synchronization events on video port (VSYNC and HSYNC) are inside the synchronization window based on expected timings. If the timings (internal and received) are out of sync, the interrupt for out of sync should be generated and the interface should be disabled (DSS.DSI_CTRL[0] IF_EN bit is automatically reset by hardware). The unsynchronization window is defined by the DSS.DSI_VM_TIMING2[27:24] WINDOW_SYNC field.

15.2.2.2.2 Video Port Used on Command Mode

In case of video port used for command mode, the VP_HSYNC, VP_VSYNC and VP_DE signals are not used. Table 15-12 indicates the active signals on the video port.

Table 15-12. Video Interface in the Context of Command Mode

Signal Name	Type ⁽¹⁾	Description
VP_DATA[23:0]	I	Parallel output data: Bits 0 to 23
VP_PCLK	I	One pulse is generated every time new data is output on the data bus
VP_STALL	O	The stall signal should be deasserted to receive pixel and asserted to stop receiving pixel. (It can be used only while the display controller is configured in RFBI mode only, in that mode the HSYNC and VSYNC are not generated)
VP_CLK	I	Display controller internal clock: It is a free running clock which is the display controller functional clock. The maximum frequency is 173MHz at nominal voltage and 96 MHz at low voltage.

(1) I = Input, O = Output, I/O = Input/Output

Note: The stall signal should be deasserted to receive pixel and asserted to stop receiving pixel.

Figure 15-38 and Figure 15-39 shows the VP_STALL signal assertion and deassertion on both rising and falling edges.

Figure 15-38. Stall Timing With Pixel on Rising Edge

dss-187

Figure 15-39. Stall Timing With Pixel on Falling Edge

To stop the transfer the VP_STALL signal must be asserted when the last data is output. The data can be output on the rising or falling edge of the VP_PCLK through some registers in the Display Controller module. The case with data output on falling edge of VP_PCLK is supported by the DSI protocol engine.

The clock VP_PCLK is generated from VP_CLK, these two clocks are balanced. Assertion and deassertion of VP_PCLK is done on rising edge of the VP_CLK. The width of the VP_PCLK pulse depends on the configuration of the clock divisor in the display controller (DSS.DISPC_DIVISOR[7:0] PCD field). In the DSI protocol engine, the information is defined in the DSS.DSI_CTRL[4] VP_CLK_RATIO bit and should be aligned with the display controller configuration.

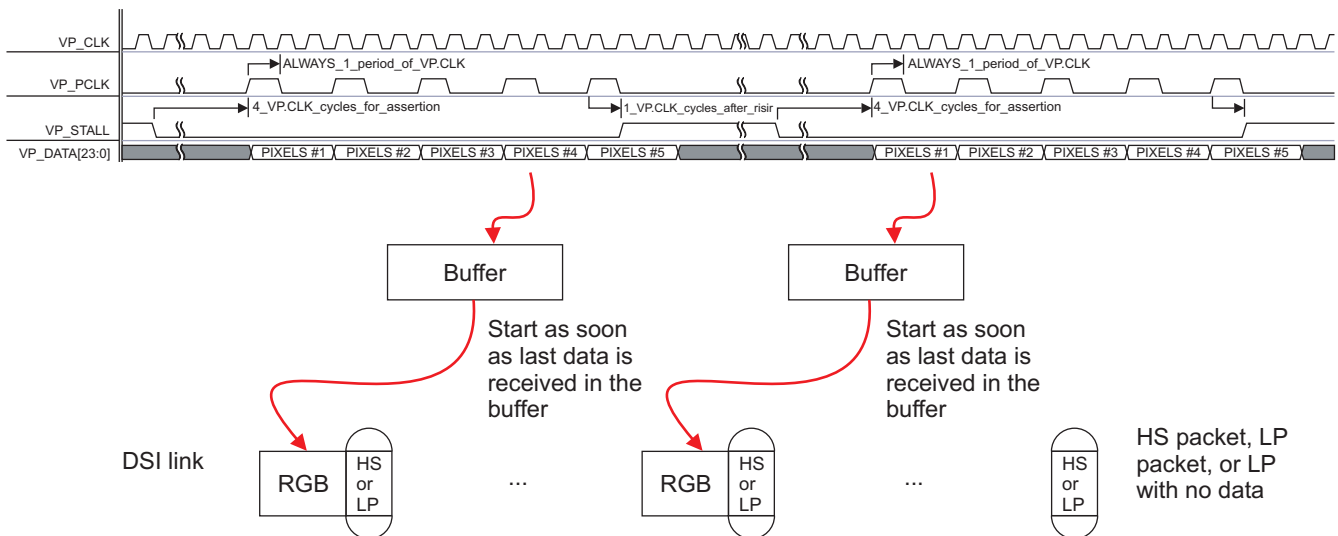

The deassertion of the VP_STALL signal should occur at least 4 VP_CLK cycles before assertion of VP_PCLK. The assertion of VP_STALL should occur one cycle VP_CLK after deassertion of VP_PCLK for the last pixel to be transferred. The VP_CLK clock is generated by the Display controller under software control. It can be kept running between VP_STALL assertion and deassertion period.

The word count (WC) defined in the DSS.DSI_VCn_LONG_PACKET_HEADER register for the virtual channel associated with the video port, indicates the number of bytes to receive (one line or two lines can be used depending on the WC and size of the line buffer). The total size defined in the WC of the header register can not exceed the size of the line buffer multiplied by the number of buffer lines.

The stall assertion/deassertion depends on the number of bytes to be received considering the size of the video port bus defined DSS.DSI_CTRL[7:6] VP_DATA_BUS_WIDTH field.

Figure 15-40 shows the data flow for command using the video port.

Figure 15-40. Data Flow for Command Mode Using Video Port

Two command modes are available:

- One line buffer: The data are stored in the line buffer before being sent
- Two line buffers: The two lines are used in the word count defined in the DSS.DSI_VCn_LONG_PACKET_HEADER register is bigger than the size line otherwise one line buffer is used.

Note: In command mode, the video port can only be used in one or two line buffer configuration. The no-line buffer configuration is not allowed.

The packets can be sent using High-Speed or Low-Speed.

15.2.2.2.3 Burst Mode

When the burst mode is enabled, the video port receives data from the display controller at the pixel clock. The DSI protocol engine buffers the data in its own line FIFO (double line buffer of 1024 x 24-bit pixels maximum). The read speed of the line can be the double of the pixel clock to increase the blanking time of the video mode and to allow command mode traffic to be interleaved during the blanking period. The burst mode is using a dual-line buffer.

The DSI port can output data from one line buffer while the second one is accessed by the video port. The two processes are concurrent but they do not access the same line at the same time. The DSI transfer can start only when the whole video port line is transferred into a line buffer. The switch is controlled by the VP_HS signal on the video port side and by internal signal on the DSI port indicating that the last data for the current line has been written into the line buffer.

Note: The line buffers are used to store the pixels only. The synchronization codes are not stored in the line buffers. They should be sent according to the video port timings.

15.2.2.3 Multilane Layer

Peripherals typically do not have substantial bandwidth requirements for returning data to the host processor. To keep designs simple and improve interoperability, all DSI-compliant systems should only use Lane 1 in LP Mode for returning data from a peripheral to the host processor.

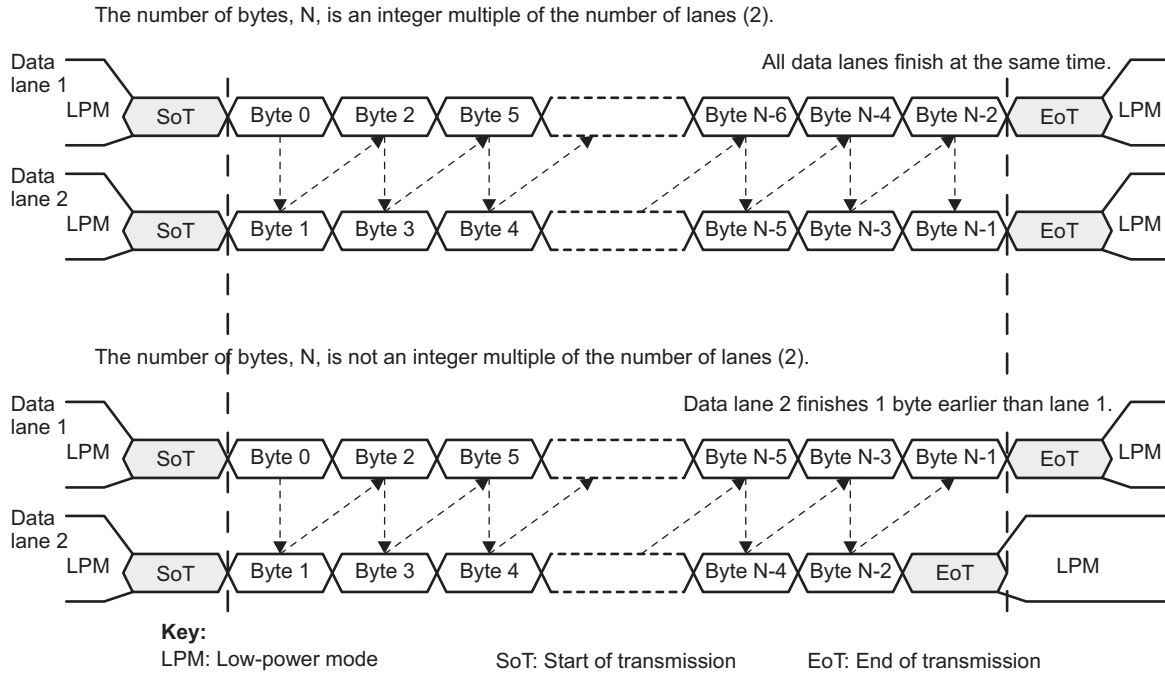

15.2.2.3.1 SoT and EoT in Multilane Configurations

Since a HS transmission is composed of an arbitrary number of bytes that may not be an integer multiple of the number of lanes, some lanes may run out of data before others. Therefore, the Lane Management layer, as it buffers up the final set of less-than-N bytes, deasserts its "valid data" signal into all lanes for which there is no further data. Although all Lanes start simultaneously with parallel SoTs, each lane operates independently and may complete the HS transmission before the other lanes, sending an EoT one cycle (byte) earlier.

15.2.2.3.2 Lane Splitter

The lane splitter can split the byte stream into 2 lines (for 1 lane, the splitter is bypassed). [Figure 15-41](#) and [Figure 15-42](#) show the byte position into each serial link for 1, and 2 data lane configuration. The byte stream starts always from the lane 1. It finishes on one of the lanes depending on the number of bytes to send and the number of lanes. The splitter module is only used when packets are sent using High Speed mode (HS). In Low Power mode (LP), only one data lane is used (Lane 1).

Figure 15-41. Two Data Lane Configuration

dss-140

Figure 15-42. One Data Lane Configuration

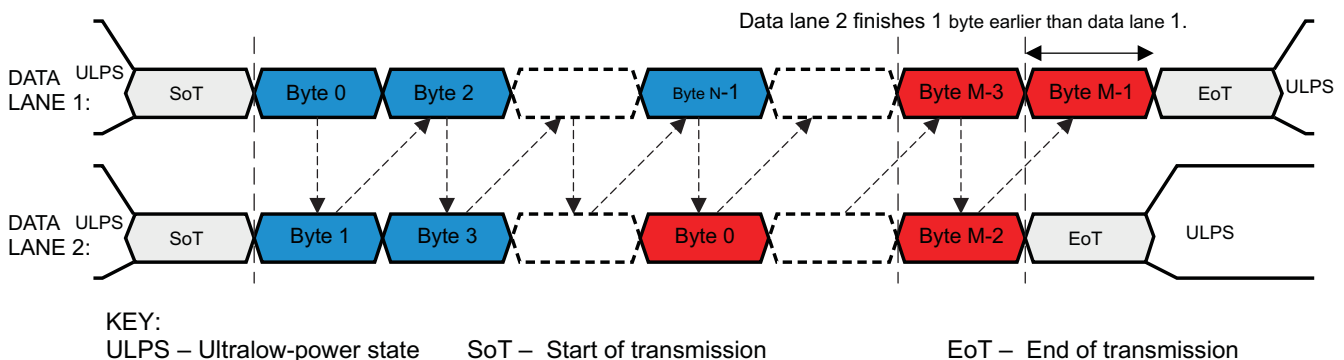

dss-141

In case of back-to-back packets, the byte stream is considered by the splitter module as a single packet. [Figure 15-43](#) shows the example of two packets sent back to back. N bytes for the first packet and M bytes for the second one.

Figure 15-43. Two Packets Using Two-Data Lane Configuration (Example)

The number of bytes transmitted $N + M$ for the 1st and 2nd packets is NOT an integer multiple of the number of data lanes:

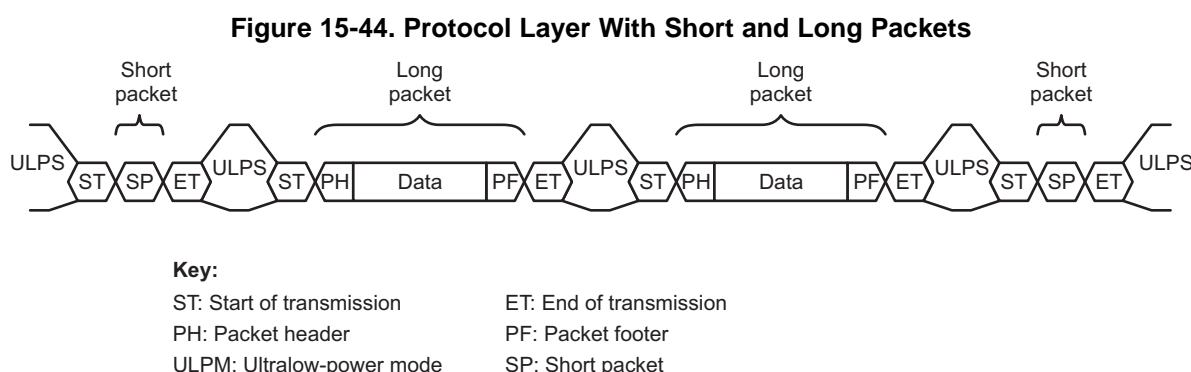

dss-142

15.2.2.4 Protocol Layer

The low level protocol (LLP) is a byte oriented protocol. It supports short and long packet formats. The DSI protocol layer defines how the display data is transported onto the physical layer. Packets can be sent using High speed mode or Low speed mode. It is selected through DSI registers. The feature set of the DSI protocol layer is:

- Transport of arbitrary data (Payload independent)
- 8-bit word size
- Support for up to four interleaved virtual channels on the same link
- Special packets for frame start, frame end, line start and line end information
- Descriptor for the type, pixel depth and format of the application-specific payload data
- Error Correction Code (ECC) for 1-bit error correction or 2-bit error detection in the header
- 16-bit Checksum Code for error detection

Figure 15-44 shows the protocol layer with short and long packets.

dss-143

15.2.2.4.1 Short Packet

Figure 15-45 shows the structure of the Short packet. A Short packet should contain an 8-bit Data ID followed by two command or data bytes and an 8-bit ECC; a Packet Footer should not be present. Short packets should be four bytes in length. The Error Correction Code (ECC) byte allows single-bit errors to be corrected and 2-bit errors to be detected in the Short packet.

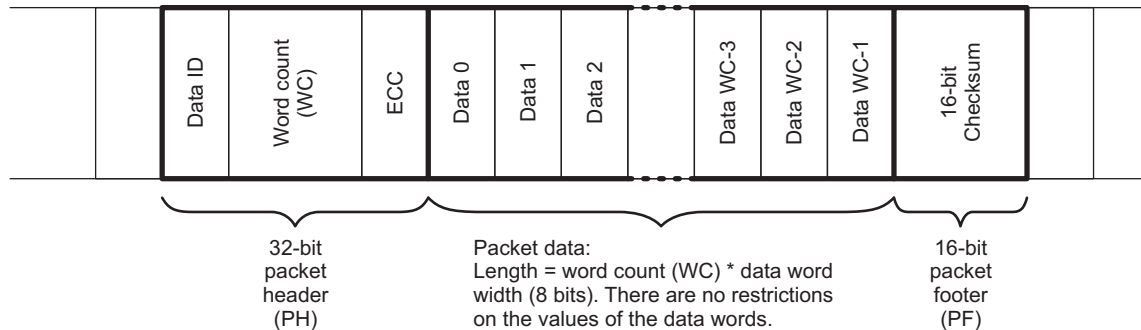

dss-144

Note: The short packets can be sent in Low power mode or in High speed mode.

15.2.2.4.2 Long Packet

Figure 15-46 shows the structure of the Low Level Protocol Long Packet. A long packet should consist of three elements: A 32-bit packet header (PH), an application-specific Data Payload with a variable number of bytes, and a 16-bit Packet Footer (PF). The packet header is further composed of three elements: An 8-bit Data Identifier, a 16-bit Word Count, and 8-bit ECC. The Packet Footer has one element, a 16-bit checksum. Long packets can be from 6 to 65,541 bytes in length.

Figure 15-46. Long Packet Structure

dss-145

- The Data Identifier defines the Virtual Channel for the data and the Data Type for the application specific payload data.
- The Word Count defines the number of bytes in the Data Payload between the end of the packet header and the start of the Packet Footer. Neither the packet header nor the Packet Footer should be included in the Word Count.
- The Error Correction Code (ECC) byte allows single-bit errors to be corrected and 2-bit errors to be detected in the packet header. This includes both the Data Identifier and Word Count fields.

After the end of the packet header, the receiver reads the next Word Count * bytes of the Data Payload. Within the Data Payload block, there are no limitations on the value of a data word, that is, no embedded codes are used. Once the receiver has read the Data Payload it reads the Checksum in the Packet Footer. The host processor should always calculate and transmit a Checksum in the Packet Footer. Peripherals are not required to calculate a Checksum. Also note the special case of zero-byte Data Payload: If the payload has length 0, then the Checksum calculation results in (0xFFFF). If the Checksum is not calculated, the Packet Footer should consist of two bytes of all zeros (0x0000). In the generic case, the length of the Data Payload should be a multiple of bytes. In addition, each data format may impose additional restrictions on the length of the payload data, e.g. multiple of four bytes. Each byte is transmitted least significant bit first. Payload data may be transmitted in any byte order restricted only by data format requirements. Multibyte elements such as Word Count and Checksum should be transmitted least significant byte first.

Note: The long packets can be sent in Low power mode or in High speed mode.

15.2.2.4.3 Data Identifier

The Data Identifier byte contains the Virtual Channel Identifier (VC) value and the Data Type (DT) value as illustrated in Figure 15-47. The Virtual Channel Identifier is contained in the two MS bits of the Data Identifier Byte. The Data Type value is contained in the six LS bits of the Data Identifier Byte. DI[7:6]: These two bits identify the data as directed to one of four virtual channels. DI[5:0]: These six bits specify the Data Type.

Figure 15-47. Data Identifier Structure

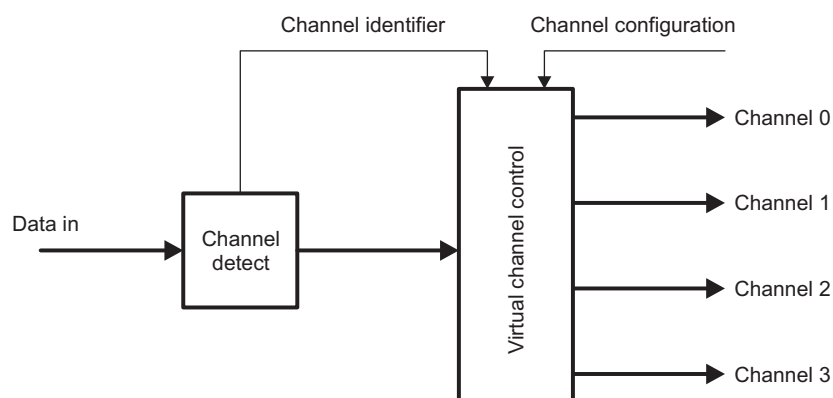

dss-146

15.2.2.4.4 Virtual Channel ID - VC Field, DI[7:6]

The host can service up to four peripherals with tagged commands or blocks of data, using the Virtual Channel ID field of the header for packets targeted at different peripherals. The Virtual Channel ID enables one serial stream to service two or more virtual peripherals by multiplexing packets onto a common transmission channel. Note that packets sent in a single transmission each have their own Virtual Channel assignment and can be directed to different peripherals. The virtual channel ID is defined in the DSS.DSI_VCn_SHORT_PACKET_HEADER and DSS.DSI_VCn_LONG_PACKET_HEADER registers for respectively short and long packets. It should not be modified by hardware. There is one set of registers for each virtual channel. Each set of registers defines the characteristics of the traffic between the host and the display associated to the virtual channel.

Figure 15-48 shows the virtual channel controller.

Figure 15-48. Virtual Channel Controller

dss-147

15.2.2.4.5 Data Type Field DT[5:0]

The Data Type field specifies whether the packet is a Long or Short packet type and the packet format. The Data Type field, along with the Word Count field for Long packets, informs the receiver of how many bytes to expect in the remainder of the packet. This is necessary because there are no special packet start /end sync codes to indicate the beginning and end of a packet. This permits packets to convey arbitrary data, but it also requires the packet header to explicitly specify the size of the packet.

15.2.2.4.6 Pixel Data Formats in Video Mode

The host can send different pixels format in video mode. Table 15-13 summarizes the pixel formats supported by the DSI interface in video mode.

Table 15-13. Pixel Data Format in Video Mode

Mode	Description
RGB888 (using 24-bit container)	RGB888
RGB666 (using 24-bit container)	RGB666
RGB666 (18-bit packet using 18-bit container)	RGB666_PACKET
RGB565 (using 16-bit container)	RGB565

15.2.2.4.7 Synchronization Codes

Each frame can be identified by two synchronization codes: One for the start of vertical synchronization pulse (VSSC) and one for the end of the vertical synchronization pulse (VSEC). Each line can be identified by two synchronization codes: One for the start of horizontal synchronization pulse (HSSC) and one for the end of the horizontal synchronization pulse (HSEC). The synchronization events may not be required by the display (peripheral): They are optional. Users can program which sync events are generated to the display from the timings received from the display controller in video mode. When data are received on the slave port, the synchronization codes are not automatically generated by the protocol engine. They can be provided on the L4 interconnect port by writing to the registers with limited timing control. It is highly recommended to use the video port from the display controller to receive the synchronization events to generate automatically the short synchronization packets to the peripheral. When the DSI protocol engine detects that the VSYNC signal from the display controller transition from inactive to active state, the VSSC short packet replaces the following HSSC corresponding to the following HSYNC synchronization short packet (if the generation is enabled). When the transition from active to inactive state is detected, the VSEC short packet is generated (if the generation is enabled) replacing the HSSC synchronization packet corresponding to the following HSYNC. When the DSI protocol engine detects that the HSYNC signal from the display controller transition from inactive to active state, the HSSC short packet is generated (if the generation is enabled). When the transition from active to inactive state is detected, the HSEC short packet is generated (if the generation is enabled). For the first frame, any HSYNC and data received on the video port prior to the first VSYNC should be ignored. Since the first VSYNC sent to the display is also recognized as a HSYNC for the first line, there should not be any HSYNC sent for the first line. To send the synchronization codes, the DSI protocol engine uses the short packets. [Table 15-14](#) summarizes the 6-bit data type synchronization code values.

Table 15-14. Synchronization Codes

Synchronization Code	Value	Comments
V Sync. Start Code (VSSC)	0x1	Optional
V Sync. End Code (VSEC)	0x11	Optional
H Sync. Start Code (HSSC)	0x21	Optional
H Sync. End Code (HSEC)	0x31	Optional

15.2.2.4.8 Blanking

To keep the DSI link in HS state while using the video mode, during blanking periods, the long Blanking packets are sent to the display. The DSS.DSI_VM_TIMINGi (i between 1 and 7) registers define the size of the long Blanking packets after:

- Horizontal Sync Start code (short packet)
- Horizontal Sync End code(short packet)
- Vertical Sync Start code(short packet)
- Vertical Sync End code(short packet)
- Pixels (long packet)

[Table 15-15](#) defines the short packet values for the synchronization packets:

Table 15-15. Sync Short Packet Values

Virtual Channel ID	Sync code	Header (1st byte)	Header (2nd byte): WC LSB	Header (3rd byte): WC MSB	Header (ECC)
0x0	0x1	0x1	0x0	0x0	See note following this table
	0x11	0x11			
	0x21	0x21			
	0x31	0x31			
0x1	0x1	0x41			
	0x11	0x51			
	0x21	0x61			
	0x31	0x91			
0x2	0x1	0x81			
	0x11	0x81			
	0x21	0xA1			
	0x31	0xB1			
0x3	0x1	0xC1			
	0x11	0xD1			
	0x21	0xC1			
	0x31	0xF1			

Notes:

- If the ECC is enabled by setting the DSS.DSI_VCn_CTRL[8] ECC_TX_EN bit to 1 for the virtual channel in video mode, the ECC value is then calculated otherwise 0x00 is used for the blanking long packets and sync short packets. If the CRC is enabled by setting the DSS.DSI_VCn_CTRL[7] CS_TX_EN bit to 1 for the virtual channel in video mode, the Check-sum value is then calculated otherwise 0x00 is used for the blanking long packets.
- In other cases, when the DSS.DSI_VCn_CTRL[7] CS_TX_EN bit is set to 0, the value 0x00 is always used for the CRC (long packets). When the DSS.DSI_VCn_CTRL[8] ECC_TX_EN bit is set to 0, the value 0x00 is used for the ECC for short and long packets except when the header is provided by register since the ECC field is available in the register. It can be used to generate invalid ECC value when the header is provided by register.

The link (lane(s) and clock separately) can be put in ULPS mode. While using the blanking values defined above, the packets (short and long packets) are considered in HS mode.

The timing parameters: VSA, VBP, VFP, HAS, HBP, HFP, VACT and t_L are defined in the DSS.DSI_VM_TIMINGx (x between 1 and 7) register. HAS, HBP, HFP, and t_L are defined using the byte clock unit (PPI Byte clock) and also in Low power clock cycles (TxClkEsc). VSA, VBP, VFP, and VACT are defined in term of number of lines. When the HS Blanking packets are sent during the blanking periods, the parameters are used to determine the blanking packet payload size (taking in account the 4-byte header and the 2-byte check sum)

The configuration of the display controller timing generator should be used when the display controller timings are used to generate the DSI HS video mode transfer.

Special care should be taken in the case of the last line of the frame. The LPM transition is required when the link is in HS mode for the whole frame.

When BTA is sent for the data packets, the following blanking period can not be used for sending any data from TX FIFO. When the blanking period starts with one HS packet from one VC, it can only be followed by another HS packet from the same VC or by trigger (BTA for example). When there is no more HS data to send for this VC, the lane is in LPM. When the blanking period starts with one LS packet from one VC, it can only be followed by another LS packet from the same VC or another VC or by trigger (BTA for

example) or by extra LS NULL packets. If the trigger has been sent, it is not possible to send any more data. When there is no more data from the TX FIFO to send in LS mode or the trigger has been sent, the lane is put in LPM. If the lanes should be kept in HS mode during blanking periods (except for last blanking period of the frame), the HS blanking packets should be used. In case one trigger is sent at the beginning of the blanking period, the rest of the blanking period is in ULPS.

Figure 15-49. DSI Video Mode: Nonburst Transfer With VE and HE

dss-148

Figure 15-50. DSI Video Mode: Nonburst Transfer Without VE and HE

dss-149

Note: HSA timing is not used and does not need to be programmed when HE short packet is not generated.

Figure 15-51. DSI Video Mode: Burst Transfer Without VE and HE

dss-150

Note: HSA timing is not used and does not need to be programmed when HE short packet is not generated.

In the last two figures, if HSync Start short packet is not generated (HSA does not exist), HBP should be different than 0.

15.2.2.4.10 Virtual Channels

The DSI protocol layer transports virtual channels. The purpose of virtual channels is to separate different data flows, which are interleaved in a same data stream. Each virtual channel is identified by a unique channel identification number in the header of the packet. The channel identification number is encoded in the 2-bit code. The DSI protocol engine determines the channel identifier number to be used for generating the packet header and multiplexes the interleaved data streams. The DSI protocol engine supports multiple concurrent virtual channels: Up to 4. [Table 15-16](#) summarizes the virtual channel values used for each channel.

Table 15-16. Virtual Channel Values

Virtual Channel Number	Value
Virtual Channel 0	0x0
Virtual Channel 1	0x1
Virtual Channel 2	0x2
Virtual Channel 3	0x3

In the case of multiple displays connected to the single DSI port on the host, a hub may be used to root the data stream to the appropriate display based on the virtual channel ID. Typically, virtual channel id 0x0 is used for the primary display and 0x1 for the secondary. The hub may have its own virtual channel id in order to provide communication capability between the host and the hub.

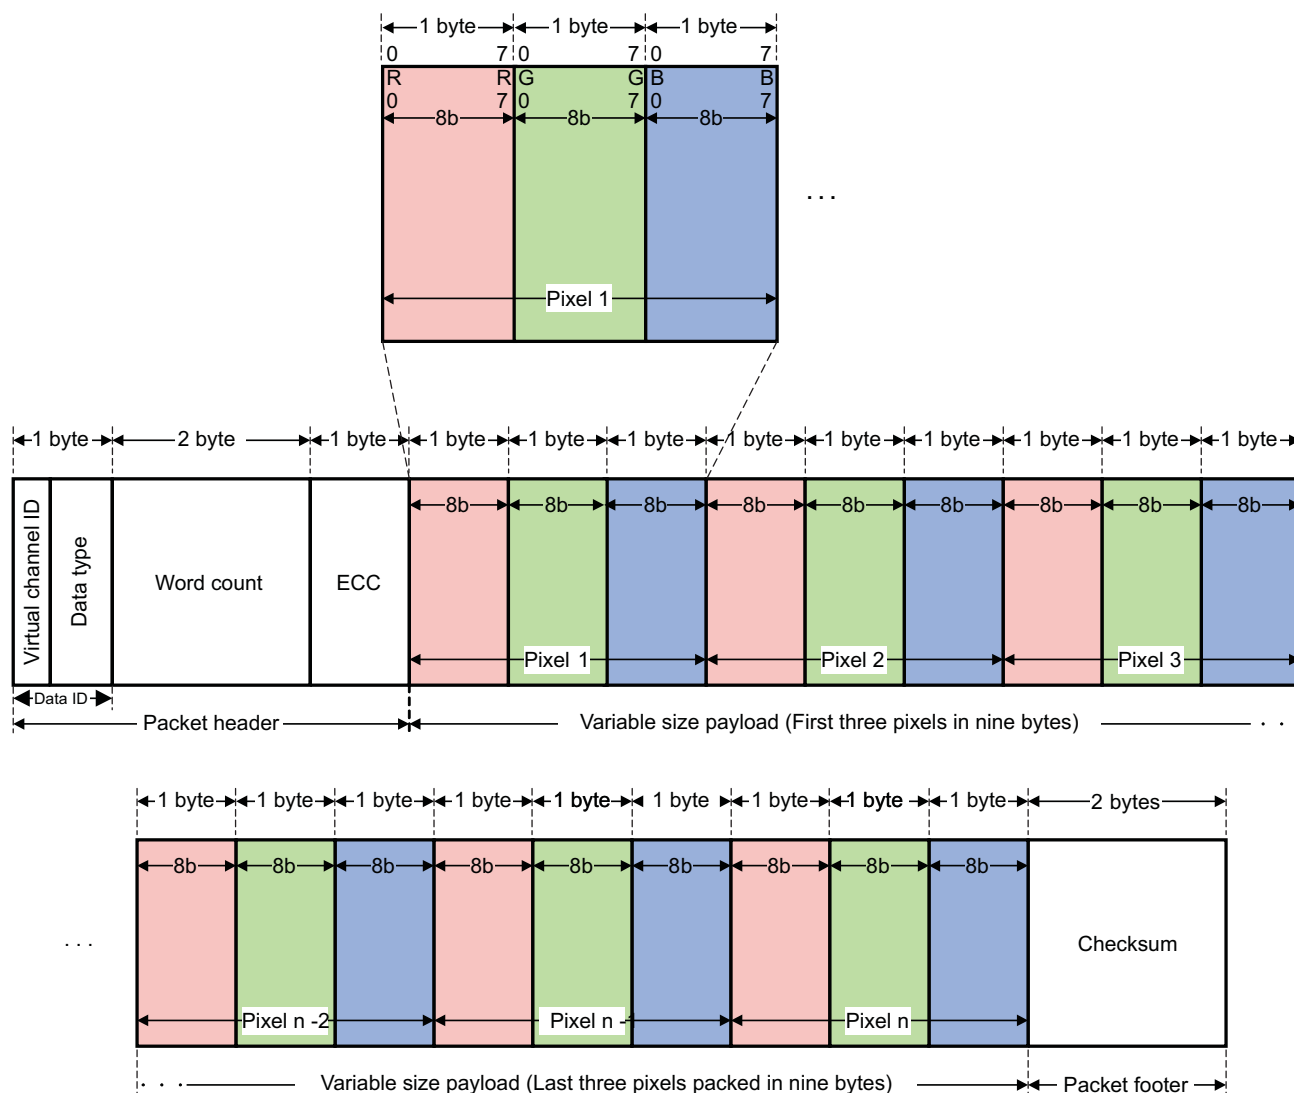

15.2.2.5 Pixel Data Formats

This section summarizes how the DSI supported pixel data formats in case of video mode are transmitted over the serial interface. For pixel formats in case of command mode, refer to MIPI DCS document. The DSI protocol engine is able to cope with all data formats given that the data line length sent through the DSI physical protocol is a multiple of a pixel. This condition is required for the DSI protocol engine to work properly.

15.2.2.5.1 24 Bits per Pixel - RGB Color Format, Long Packet

Figure 15-55 shows the RGB888 format.

Figure 15-55. 24 bits per Pixel RGB Color Format, Long Packet

dss-154

Packed Pixel Stream 24-Bit Format is a Long packet. It is used to transmit image data formatted as 24-bit pixels to a video mode display module. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes and a two-byte Checksum. The pixel format is red (8 bits), green (8 bits) and blue (8 bits), in that order. Each color component occupies one byte in the pixel stream; no components are split across byte boundaries. Within a color component, the LSB is sent first, the MSB last.

15.2.2.5.2 18 Bits per Pixel (Loosely Packed) - RGB Color Format, Long Packet

Figure 15-56 details the RGB666 format.

Figure 15-56. 18 Bits per Pixel (Loosely Packed) RGB Color Format, Long Packet

dss-155

In the 18-bit Pixel Loosely Packed format, each R, G, or B color component is six bits but is shifted to the upper bits of the byte, such that the valid pixel bits occupy bits [7:2] of each byte. Bits [1:0] of each payload byte representing active pixels are ignored. As a result, each pixel requires three bytes as it is transmitted across the Link. This requires more bandwidth than the packed format, but requires less shifting and multiplexing logic in the packing and unpacking functions on each end of the Link. This format is used to transmit RGB image data formatted as pixels to a video mode display module that displays 18-bit pixels. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes and a two-byte Checksum. The pixel format is red (6 bits), green (6 bits) and blue (6 bits) in that order. Within a color component, the LSB is sent first, the MSB last.

15.2.2.5.3 18 Bits per Pixel (Packed) - RGB Color Format, Long Packet

Figure 15-57 details the RGB666_PACKED format.

Figure 15-57. 18 Bits per Pixel (Packed) RGB Color Format, Long Packet

dss-156

Packed Pixel Stream 18-Bit Format (Packed) is a Long packet. It is used to transmit RGB image data formatted as pixels to a video mode display module that displays 18-bit pixels. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes and a two-byte Checksum. Pixel format is red (6 bits), green (6 bits) and blue (6 bits), in that order. Within a color component, the LSB is sent first, the MSB last. With this format, it is strongly recommended that the total line width be a multiple of four pixels (nine bytes).

15.2.2.5.4 16 Bits per Pixel - RGB Color Format, Long Packet

Figure 15-58 details the RGB565 format.

Figure 15-58. 16 Bits per Pixel RGB Color Format, Long Packet

Packed Pixel Stream 16-Bit Format is a Long packet used to transmit image data formatted as 16-bit pixels to a video mode display module. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes and a two-byte checksum. Pixel format is five bits red, six bits green, five bits blue, in that order. Note that the "Green" component is split across two bytes. Within a color component, the LSB is sent first, the MSB last.

15.2.3 LCD Output With TI FlatLink3G Data Format for the SDI Module

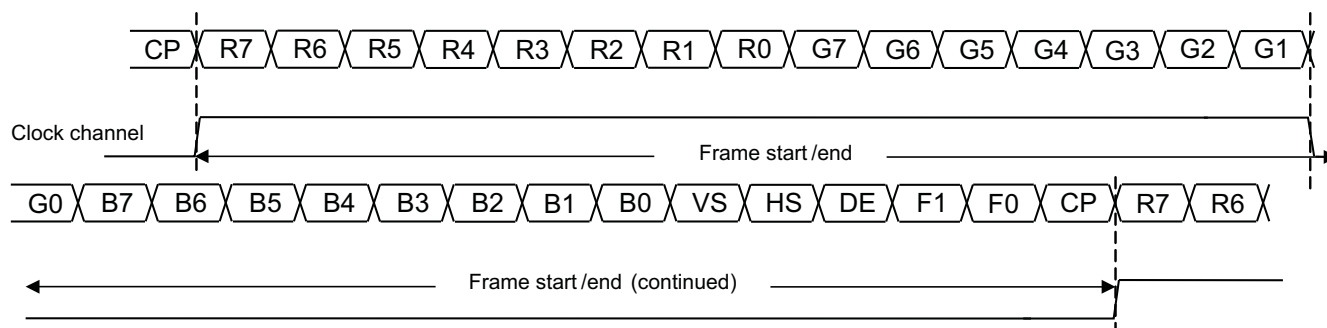

This section describes SDI module. This module is not available on all devices. See Chapter 1, the *OMAP35x Family* section, to check availability of this module.

The parallel-to-serial conversion of the 24-BPP pixel data depends on the number of data channels in use.

Figure 15-59 through Figure 15-61 summarize the pixel order for each data format of the TI FlatLink3G LCD panel.

The following apply to Figure 15-59 through Figure 15-61:

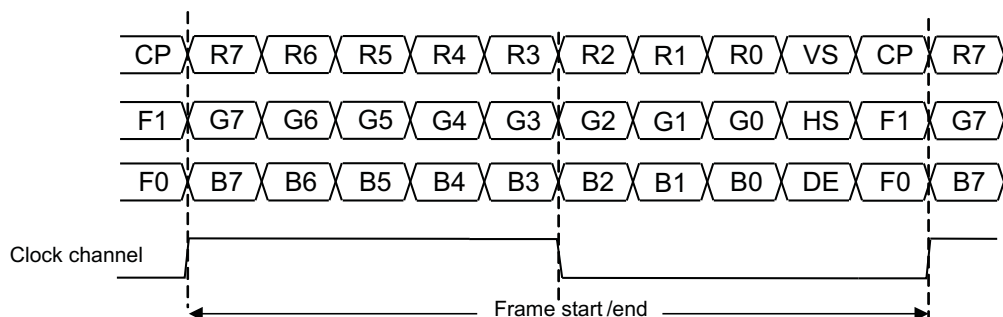

- VS: Vertical synchronization
- HS: Horizontal synchronizations
- DE: Data enable
- CP: Pixel parity. Parity of the whole 30-bit data is odd
- F1, F0: Reserved bits for the TI FlatLink3G protocol
- Clock Channel: Differential clock signal between SDI_CLKP and SDI_CLKN

Figure 15-59. 24 Bits Per Pixel With One Data Channel

dss-032

Figure 15-60. 24 Bits Per Pixel With Two Data Channels

dss-033

Figure 15-61. 24 Bits Per Pixel With Three Data Channels

dss-034

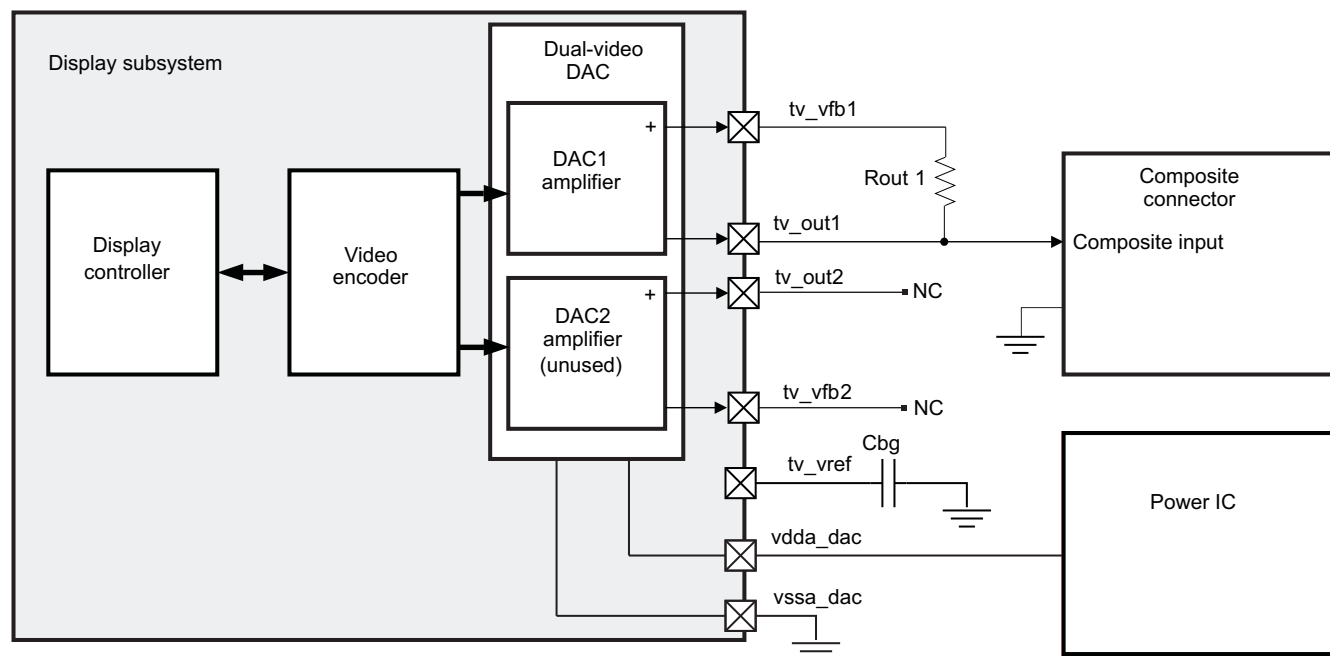

Note: The range of the data rates permitted is 120 Mbps per pair minimum (4 MHz pixel clock, one data pair) to 650 Mbps per pair maximum (65 MHz pixel clock, three data pairs).

15.2.4 TV Display Support

The TV display path includes the following modules:

- Display controller
- Video encoder
- Dual 10-bit DAC with video amplifiers

The display controller module receives synchronization signals from the video encoder and synchronously sends pixel data to the video encoder with these signals. The digital output of the display controller is always a 24-bit RGB value based on a pixel request from the video encoder.

Figure 15-63. TV Display Interface (Composite Mode)

dss-191

Note: In composite video mode, the video DAC2 chroma output must be disabled by setting the DSS.VENC_OUTPUT_CONTROL[2] CHROMA_ENABLE bit to 0.

Table 15-17 describes the interface signals to/from the TV set for the TV display support.

Table 15-17. TV Display Interface Pins

Pin Name	Type ⁽¹⁾	Description
tv_out1	O	Analog luma or composite video output. An external resistor is connected between this node and tv_vfb1 pin. The nominal value of Rout1 is 1650 Ohm. Note that this is the output node that drives the load (75 Ohm).
tv_out2	O	Analog chroma video output. An external resistor is connected between this node and tv_vfb2 pin. The nominal value of Rout2 is 1650 Ohm. This is the output node that drives the load (75 Ohm).
tv_vfb1	O	Amplifier feedback node. An external resistor is connected between this node and tv_out1. The nominal value of Rout1 is 1650 Ohm.
tv_vfb2	O	Amplifier feedback node. An external resistor is connected between this node and tv_out2. The nominal value of Rout2 is 1650 Ohm.
tv_vref	O	Reference output voltage from internal bandgap. A decoupling capacitor must be connected for optimum performance. tv_vref is generated internally to the OMAP device.
vdda_dac	Power	Analog supply voltage for the dual video DAC
vssa_dac	Power	Analog ground for the dual video DAC

⁽¹⁾ O = Output, Power = Power pin

CAUTION

- tv_out1 and tv_out2 are very high-frequency analog signals and must be routed with extreme care. As a result, the path of these signals should be as short as possible, and as isolated as possible from other interfering signals.
- During board design, the onboard traces and parasites must be matched for the two channels. tv_vfb1 and tv_vfb2 pins are the most sensitive pins in the TV out system. The onboard parasitic capacitance associated with these two pins should be less than 0.5 pF. Low onboard resistance is required for the traces that connect the Rout1/Rout2 to the tv_vfb1/tv_vfb2 and TV OUT pins (tv_out1 and tv_out2). The resistance on those trace affects output impedance matching. Therefore, Rout1 and Rout2 resistors are suggested to be placed as close as possible to the OMAP device pins. The onboard traces lead to the TV OUT pins must have a characteristic impedance of 75-Ohm starting from the closest possible place to the OMAP device pin output. For typical values of Rout1, Rout2, Cout, and Cbg, see the device data manual.
- If the TV output is not used, the analog pins tv_ref and vssa_dac must be grounded. To avoid current leakage, the following bits must be set to 0:
 - DSS.DSS_CONTROL[5] DAC_POWERDN_BGZ
 - DSS.VENC_OUTPUT_CONTROL[2:0]
 - PRCM.CM_FCLKEN_DSS[2] EN_TV
 - CONTROL.CONTROL_DEVCONF[18] TVOUTBYPASS

Texas Instruments provides a global solution with an OMAP device associated with a TPS65950 power IC. The power pin vdda_dac is software controlled by the power IC. For more details on the TPS65950 device, contact your TI representative.

15.2.4.1 TV Output and Data Format

The output data to the TV set are the analog composite data from the DAC. The following video standards are supported:

- NTSC-J, M
- PAL-B, D, G, H, I, N
- PAL-M
- PAL-N
- PAL-Nc

15.2.4.2 Digital-to-Analog Converter

The DAC includes the following main features:

- 1.0 V-to-1.3 V digital power supply, 1.8 V analog power supply
- 10-bit resolution
- DNL within 1 least-significant bit (LSB) and INL within 1 LSB
- Sample rate of up to 60 megasamples per second (MSPS)
- Support composite/S-video dc or ac coupled output
- Full-scale voltage output: 0.88 Vpp with a 75-Ohm load
- Internal TV detect feature
- Signal to Noise Ratio (SNR) is 54dB (taking into account the ac coupling)
- Suitable for low-power wireless application; total power: 10 mA (no load in dc coupled mode)
- Power-down mode with less than 3μA standby current
- Differential gain error and differential phase error: 1.5 percent and 1, respectively

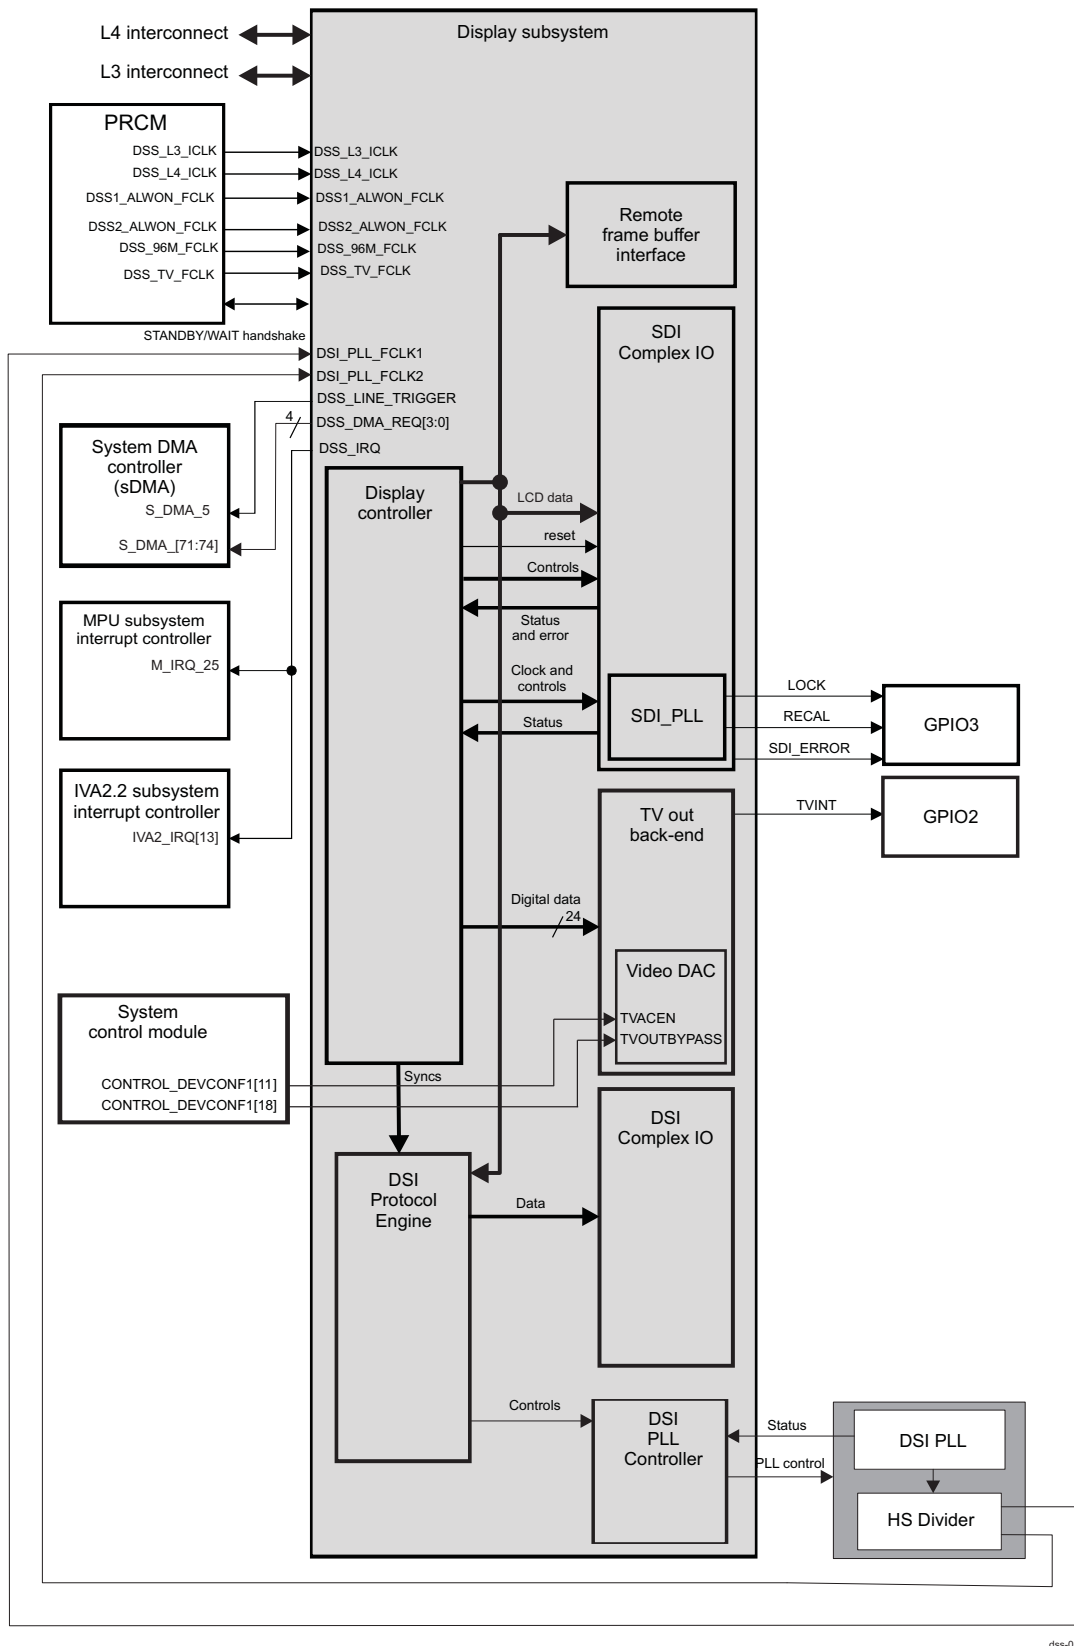

Note: To enhance the TV color display, it is highly recommended to set the DSS.DSS_CONTROL[4] DAC_DEMEN bit.

15.3 Display Subsystem Integration

This section describes the integration of the display subsystem and details clocks, resets, hardware requests, and power modes.

[Figure 15-64](#) shows the integration of the display subsystem in the device.

Figure 15-64. Display Subsystem Integration

dss-036

15.3.1 Clocking, Reset, and Power-Management Scheme

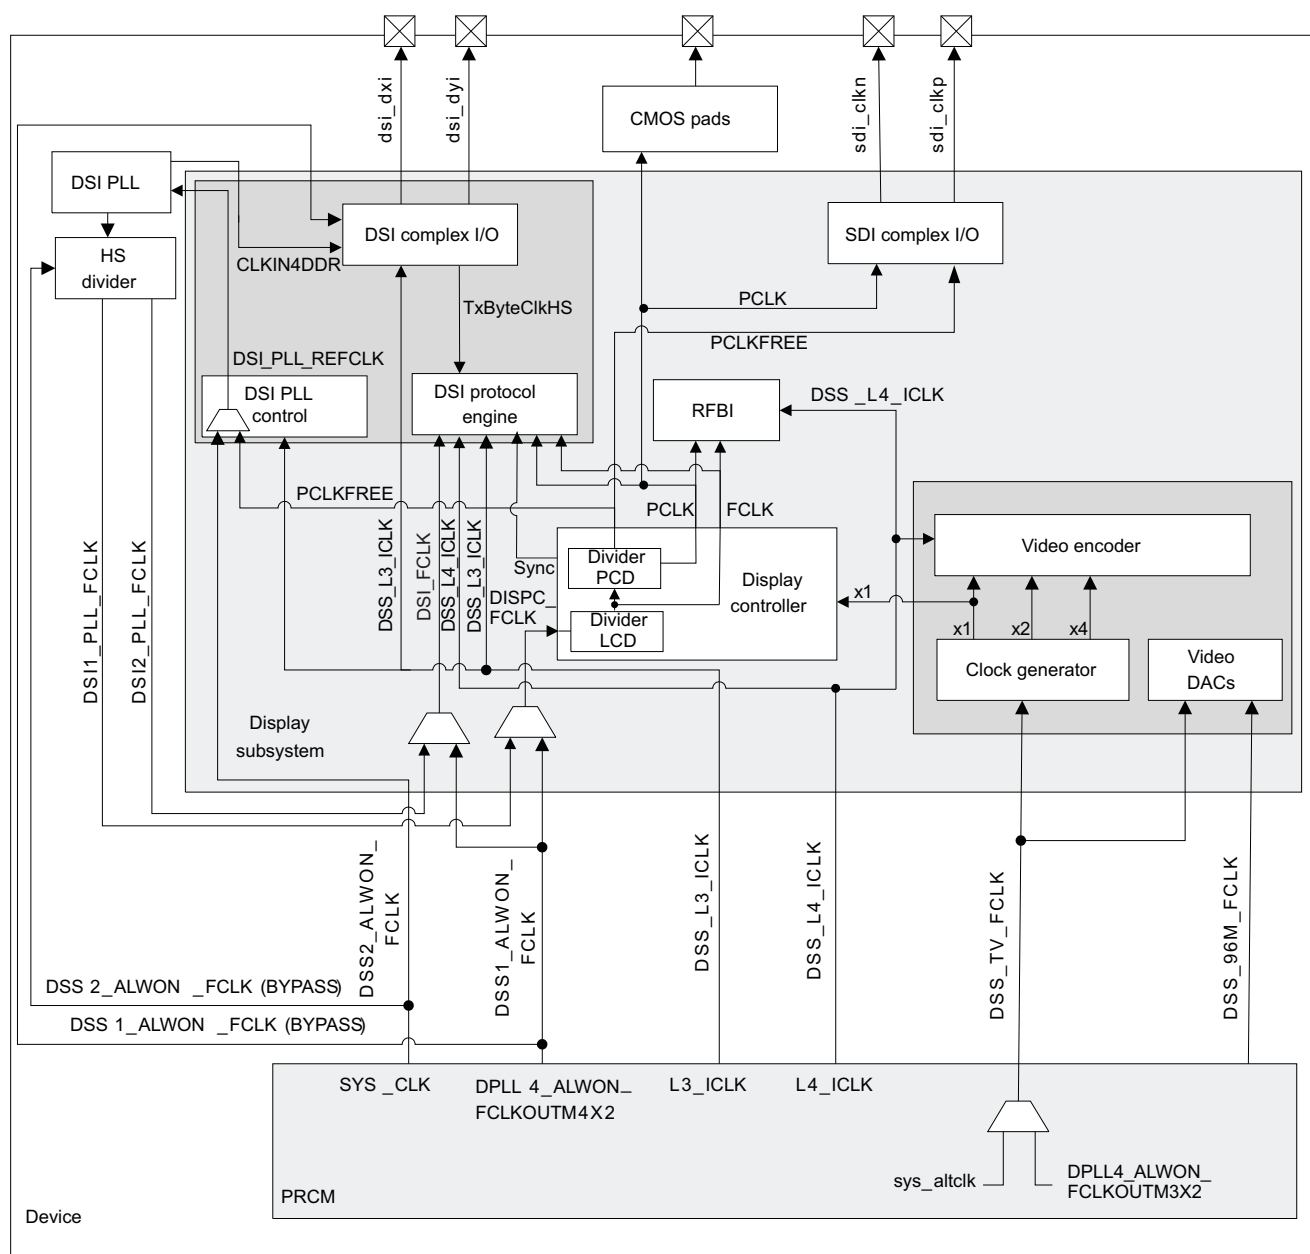

15.3.1.1 Clocks

The power, reset, and clock management (PRCM) module provides five clock signals to the display subsystem: The L3 interface clock (DSS_L3_ICLK) and the L4 interface clock (DSS_L4_ICLK) with frequencies respectively equal to the L3 interconnect clock and the L4 interconnect clock; two configurable functional clocks (DSS1_ALWON_FCLK and DSS2_ALWON_FCLK); and two other functional clocks (DSS_TV_FCLK and DSS_96M_FCLK).

The DSI PLL provides two functional clock signals to the display subsystem: DSI1_PLL_FCLK and DSI2_PLL_FCLK.

Figure 15-65 details the clock tree for the display subsystem.

Figure 15-65. Display Subsystem Clock Tree

dss-158

Note: A synchronization signal is sent by the display controller (DISPC) to the DSI protocol engine. This signal named DISPC_UPDATE_SYNC is used to inform the DSI protocol engine that it needs to be unsynchronized with the display controller.

Table 15-18 describes the different clocks with their possible frequency values.

Table 15-18. Display Subsystem Clocks

Clock Signal	Attribute	Module	Frequency	Comment
DSS_L3_ICLK	L3 interface clock	DSS	(See the <i>PRCM</i> chapter)	L3 interface clock from PRCM
DSS_L4_ICLK	L4 interface clock	DSS	(See the <i>PRCM</i> chapter)	L4 interface clock from PRCM
DSS1_ALWON_FCLK	Functional clock	DISPC, DSI protocol engine	Up to 173 MHz at nominal voltage	From PRCM: DPLL4 (source: DPLL4_ALWON_FCLK)
DSS2_ALWON_FCLK	Functional clock	DSI PLL	12/13/19.2/26/38.4 MHz	From PRCM: SYS_CLK
DSI1_PLL_FCLK	Functional clock	DISPC, DSI protocol engine	Up to 173 MHz at nominal voltage	From SDI PLL and HS divider
DSI2_PLL_FCLK	Functional clock	DSI protocol engine	Up to 173 MHz at nominal voltage	From SDI PLL and HS divider
DSS_TV_FCLK	Functional clock	DSS, video mode DAC	54 MHz or sys_alt_clk (up to 59 MHz)	From PRCM: DPLL4 (source: DPPLL4_ALWON_FCLK) or External input clock (See the <i>PRCM</i> chapter)
DSS_96M_FCLK	Functional clock	Video DAC	96 MHz	From PRCM: 96M_FCLK

To enable or disable each functional clock, set the following bit (1: Enable, 0: Disable):

- PRCM.CM_FCLKEN_DSS[0] EN_DSS1 bit to enable DSS1_ALWON_FCLK
- PRCM.CM_FCLKEN_DSS[1] EN_DSS2 bit to enable DSS2_ALWON_FCLK
- PRCM.CM_FCLKEN_DSS[2] EN_TV bit to enable DSS_TV_FCLK and DSS_96M_FCLK

To enable or disable the DSS_L3_ICLK and DSS_L4_ICLK interface clock, write (1: Enable, 0: Disable) in the PRCM.CM_ICLKEN_DSS[0] EN_DSS bit.

Note: Note that it is not possible to gate/stop L3 clock and keep L4 clock running.

- L3 and L4 interface clock

The DSS_L3_ICLK clock is used only by the display controller interface to fetch the pixel data. The DSS_L4_ICLK is used to access the L4 interconnect for configuring all the display subsystem registers.

Note: A clock generated internally from the L3 interface clock allows the submodules to be configured and is the functional clock for the RFBI. The SDI module is configured through the display subsystem register, as well as all display subsystem registers.

- Display controller functional clocks

The display controller can use either the DSS1_ALWON_FCLK or the DSI1_PLL_FCLK functional clock.

To select the DSS1_ALWON_FCLK functional clock (the default clock selected after reset), write 0 in the DSS.DSS_CONTROL[0] DISPC_CLK_SWITCH bit; to select the DSI1_PLL_FCLK functional clock, write 1 in the DSS.DSS_CONTROL[0] DISPC_CLK_SWITCH bit.

Note: The DSS1_ALWON_FCLK and DSI1_PLL_FCLK functional clocks must be active (the PRCM.CM_FCLKEN_DSS[0] EN_DSS1 and DSI PLL programmed correctly) to switch from one functional clock to another. The new functional clock is effective when the next vertical blanking interval occurs. This is true only if the DSS.DISPC_CONTROL[5] GOLCD bit is set to 1.

Depending on the DPLL4 input clock frequency, the DSS1_ALWON_FCLK can be adjusted by setting the PRCM.CM_CLKSEL_DSS[4:0] CLKSEL_DSS1 field.

- DSI PLL functional clock (DSI_PLL_REFCLK)
The DSI PLL controller module can use either the DSS2_ALWON_FCLK (from PRCM) or PCLKFREE (from DISPC) functional clock. To select the DSS2_ALWON_FCLK functional clock (default clock selected after reset), write 0 in the DSS.DSI_PLL_CONFIGURATION2[11] DSI_PLL_CLKSEL bit; to select the PCLKFREE functional clock, write 1 in the DSS.DSI_PLL_CONFIGURATION2[11] DSI_PLL_CLKSEL bit.
- DSI protocol engine functional clocks (DSI_FCLK)
The DSI protocol engine can use either the DSS1_ALWON_FCLK (from PRCM) or DSI2_PLL_FCLK (from DSI PLL) functional clock. To select the DSS1_ALWON_FCLK functional clock (default clock selected after reset), write 0 in the DSS.DSS_CONTROL[1] DSI_CLK_SWITCH bit; to select the DSI2_PLL_FCLK functional clock, write 1 in the DSS.DSS_CONTROL[1] DSI_CLK_SWITCH bit.

Note: It is possible to switch between these two clocks even when both of them are not active.

- There are five clock domains in the DSI module:
 - Byte clock domain:
TxByteClkHS is generated from the bit clock and converted into byte clock. The maximum frequency is 100 MHz (all OPPs). It is generated by the DSI complex I/O.
 - Functional Clock domain
The DSI_FCLK is the functional clock for the DSI Protocol engine module. The maximum frequency is 173 MHz (nominal voltage) and 124 MHz (low voltage). It should be always higher than Byte clock, L4 interconnect clock and video port clock. The software should correctly configure the clocks.
 - L4 interface clock domain
The DSS_L4_ICLK is used in the L4 interconnect port domain. The maximum frequency is 166 MHz at nominal voltage and 83 MHz at low voltage.
 - The video port domain
The pixel clock (PCLK) on the video port is used by the video port domain to capture the pixels from the display controller. The maximum frequency of VP_CLK used as the functional clock for the video port domain is 173 MHz at nominal voltage and 96 MHz at low voltage. In case the video port is used for video mode, the clocks from the display controller to the DSI protocol engine should have been generated using a clock from the PLL used to generate HS Byte clock (from the DSI-PHY).
 - Serial Configuration Port (SCP) and Power Control (PWR) interfaces
The DSS_L4_ICLK is the functional clock.

Notes:

- There is no clock domain for RxClkEsc since it is used as an enable and not as a clock by the DSI protocol engine module
 - The clock domains are asynchronous (except for L4 interconnect port and SCP/PWR since they both use DSS_L4_ICLK). The clocks used for the L4 interconnect port and SCP/PWR interface should be balanced.
- Video encoder functional clock
The DSS_TV_FCLK is divided into three balanced clocks, depending on the clock mode selected (see [Table 15-19](#)).

Table 15-19. Possible Digital Clock Division for the Video Encoder

Clock Output	Clock Mode	
	Clock mode 0	Clock mode 1
Video encoder clock 4x	DSS_TV_FCLK	DSS_TV_FCLK or 0 (gated)
Video encoder clock 2x	DSS_TV_FCLK/2	DSS_TV_FCLK
Video encoder clock 1x	DSS_TV_FCLK/4	DSS_TV_FCLK/2

Note: Clock mode 1 can be used for power saving purposes or if a 27-MHz external clock is provided to the video encoder.

The DSS_TV_FCLK can be adjusted depending on the DPLL4 input clock frequency by setting the PRCM.CM_CLKSEL_DSS[12:8] CLKSEL_TV field. If the DPLL4 is selected, the DSS_TV_FCLK is provided by the DPLL4_ALWON_FCLKOUTM3X2 clock.

Note: If the DSS_TV_FCLK is not provided by DPLL4 but rather by the sys_alt_clk pin, an external clock generator must be connected to this pin. In this case, a 54-MHz clock is needed for PAL or NTSC 601, a 49.04-MHz clock is needed for NTSC square pixel and a 59-MHz clock is needed for PAL square pixel.

- **Dual video DAC clocks**
The dual video DAC uses two distinct clocks: The DSS_TV_FCLK and the DSS_96M_FCLK. The video data are latched on the positive edge of the DSS_TV_FCLK clock. On the other hand, the video DAC uses DSS_96M_FCLK fixed-frequency clock internally as the clock input for the switch capacitor resistor.
- **SDI functional clock**
The display controller provides the functional clocks PCLK (pixel clock) and PCLKFREE (pixel clock free-running) of the SDI module, which is derived from the functional clock of the display controller. The functional clock of the SDI module drives the phase-locked loop SDI_PLL that multiplies and divides the PCLK frequency by two programmable factors for the serial connection. This section describes SDI module. This module is not available on all devices. See Chapter 1, the *OMAP35x Family* section, to check availability of this module.

Note: When using the SDI, configure the PCLK in the free-running mode by setting the DSS.DISPC_CONTROL[27] PCLKFREEENABLE bit to 1.

15.3.1.2 Resets

15.3.1.2.1 Hardware ResetSDI Clock Source/Frequency Change Sequence Part A

The display subsystem receives its reset signal DSS_RST (the reset signal of the display subsystem [DSS] power domain) from the PRCM module.

15.3.1.2.2 Software Reset

The display subsystem can receive a software reset propagated through all of the submodules and used to initialize the display subsystem. To apply the reset, write the DSS.DSS_SYSCONFIG[1] SOFTRESET bit (1: Reset; 0: Normal). The DSS.DSS_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1.

Note: The display controller, the DSI protocol engine, and the RFBI modules also have their own software reset functionality. To access this reset, access the DSS.DISPC_SYSCONFIG[1] SOFTRESET bit for the display controller, the DSS.DSI_SYSCONFIG[1] SOFTRESET bit for the DSI protocol engine, and the DSS.RFBI_SYSCONFIG[1] SOFTRESET bit for the RFBI module.

To properly reset these modules, 0x2 is the only valid value to write in these registers.

CAUTION

All the interface and functional clocks, even for the TV output, must be provided to the display subsystem to update the RESETDONE status bit correctly.

15.3.1.3 Power Domain

The display subsystem modules are on the Display subsystem (DSS) power domain and on the VDD2 voltage domain, except the dual video DACs, which are on the analog VDDADAC voltage domain.

15.3.1.4 Power Management

15.3.1.4.1 Clock Activity Mode

The display controller clocks can be configured as one of the following clock activity modes:

- DSS.DISPC_SYSCONFIG[9:8] CLOCKACTIVITY field set to 0x0 (reset value): The interface and functional clocks can be switched off.
- DSS.DISPC_SYSCONFIG[9:8] CLOCKACTIVITY field set to 0x1: The functional clocks can be switched off and the interface clocks are maintained during the wake-up period.
- DSS.DISPC_SYSCONFIG[9:8] CLOCKACTIVITY field set to 0x2: The interface clocks can be switched off and the functional clocks are maintained during the wake-up period.
- DSS.DISPC_SYSCONFIG[9:8] CLOCKACTIVITY field set to 0x3: The interface and functional clocks are maintained during the wake-up period.

The DSI protocol engine clocks can be configured in one of the following clock activity modes:

- DSS.DSI_SYSCONFIG[9:8] CLOCKACTIVITY field set to 0x0 (reset value): The interface and functional clocks can be switched off.
- DSS.DSI_SYSCONFIG[9:8] CLOCKACTIVITY field set to 0x1: The functional clocks can be switched off and the interface clocks are maintained during the wake-up period.
- DSS.DSI_SYSCONFIG[9:8] CLOCKACTIVITY field set to 0x2: The interface clocks can be switched off and the functional clocks are maintained during the wake-up period.
- DSS.DISPC_SYSCONFIG[9:8] CLOCKACTIVITY field set to 0x3: The interface and functional clocks are maintained during the wake-up period.

The DSS power domain clock activity status is logged in the PRCM.CM_CLKSTST_DSS[0] CLKACTIVITY_DSS status bit. When set to 0, there is no domain clock activity. When set to 1, the DSS power domain clock is active.

Note: The display subsystem interface clock can be dependent on the DSS power domain state. This is configured with PRCM.CM_AUTOIDLE_DSS[0] AUTO_DSS bit:

- When the AUTO_DSS bit is set to 0 (reset value): The display subsystem interface clock is not related to the DSS power domain state transition.
- When the AUTO_DSS bit is set to 1: The display subsystem interface clock is automatically enabled or disabled along with the DSS power domain state transition.

15.3.1.4.2 Autoidle Mode

The RFBI, display controller, DSI protocol engine, and L4 interfaces can internally gate their clocks to decrease power consumption, if no transaction is present on the related bus. The following bits must be set to enable this functionality:

- DSS.DISPC_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display subsystem
- DSS.RFBI_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the RFBI
- DSS.DISPC_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display controller
- DSS.DSI_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the DSI protocol engine
- DSS.DISPC_CONFIG[9] FUNCGATED bit (1: Functional clocks gated enabled; 0: Functional clocks gated disabled) for the display controller

Note: All the bits listed above (except FUNCGATED bit) are set to 1 by default. It is highly recommended to set all the bits to 1 to save power.

15.3.1.4.3 Idle Mode

The display controller, DSI protocol engine, and RFBI can be configured into one of the following acknowledgment modes:

- Force-idle mode: The module immediately enters the idle state on receiving a low-power mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state. Set the DSS.DISPC_SYSCONFIG[4:3] SIDLEMODE field to 0x0 (reset value) for display controller, set the DSS.DSI_SYSCONFIG[4:3] SIDLEMODE field to 0x0 (reset value) for DSI protocol engine, and, finally, the DSS.RFBI_SYSCONFIG[4:3] SIDLEMODE field to 0x0 (reset value) for RFBI.
- No-idle mode: The module never enters the idle state. Set the DSS.DISPC_SYSCONFIG[4:3] SIDLEMODE field to 0x1 for display controller, set the DSS.DSI_SYSCONFIG[4:3] SIDLEMODE field to 0x1 for DSI protocol engine, and, finally, the DSS.RFBI_SYSCONFIG[4:3] SIDLEMODE field to 0x1 for RFBI.
- Smart-idle mode:
 - Display controller: After receiving a low-power-mode request from the PRCM module, the display controller module enters the idle state when all the following conditions are satisfied:
 - All asserted output interrupts are acknowledged (no interrupt pending)
 - The display controller does not use anymore the L4 interface clock (DSS_L4_ICLK)
 - DSI Protocol engine: After receiving a low-power-mode request from the PRCM module, the DSI protocol engine enters the idle state when all the following conditions are satisfied:
 - All asserted output interrupts are acknowledged (no interrupt pending)
 - The DSI protocol engine does not use anymore the L4 interface clock (DSS_L4_ICLK)
 - The SCP and PWR transactions are completed
 - No data in the TX FIFO (data waiting in the FIFO to be sent to the peripheral)

To configure the display subsystem in smart-idle mode, set the DSS.DISPC_SYSCONFIG[4:3] SIDLEMODE field to 0x2 for display controller, set the DSS.DSI_SYSCONFIG[4:3] SIDLEMODE field to 0x2 for DSI protocol engine, and, finally, the DSS.RFBI_SYSCONFIG[4:3] SIDLEMODE field to 0x2 for RFBI.

Once the idle handshake protocol is over:

- The DSS L4 interface clock (DSS_L4_ICLK) can be shutdown at any time.
- Any transaction on the L4 configuration port is ignored.

15.3.1.4.4 SDI Idle Mode

To save power consumption, the PLL (SDI_PLL) of the SDI module can be configured in one of the operation modes shown in [Table 15-20](#) when not locked.

Table 15-20. SDI PLL Operation Modes

SDI_PLL Operation Mode	Stop mode Low power ⁽¹⁾	Stop mode Low power ⁽¹⁾	Idle bypass Low power	Idle bypass Fast relock	Limp
	Output clock stopped Lowest power standby	Output clock stopped Fastest start-up time	Output clock at PCLK rate Lowest power standby	Output clock at PCLK rate Fastest start-up time	Output at full speed
DSS.DSS_PLL_CONTROL[0] SDI_PLL_IDLE	0	0	1	1	1 or PCLK stops
DSS.DSS_PLL_CONTROL[20] SDI_PLL_LOWCURRSTBY	1	0	1	0	X
DSS.DSS_PLL_CONTROL[17] SDI_PLL_STOPMODE	1	1	1	1	0

⁽¹⁾ Recommended

15.3.1.4.5 Wake-Up Mode

The Display Controller (DISPC) supports the wake-up protocol. The mode is selected by programming the appropriate value in the DSS.DISPC_SYSCONFIG[2] ENWAKEUP bit. The wake-up signal is asserted when the DISPC is in idle mode and when anyone of the following events occur:

- Graphics pipe is enabled and data fetch is not completed for graphics window, and the number of data bytes in FIFO is less than the low threshold programmed value.
- Video1 pipe is enabled and data fetch is not completed for video1 window, and the number of data bytes in FIFO is less than the low threshold programmed value.
- Video2 pipe is enabled and data fetch is not completed for video2 window, and the number of data bytes in FIFO is less than the low threshold programmed value.
- The current pixel is the last pixel displayed on the LCD panel if it is not the last frame.
- The current pixel is the last pixel displayed on the digital panel if it is not the last frame.

If software users set the DSS.DISPC_CONFIG[17] FIFOFILLING bit, when one of the active pipe reaches the low threshold and should refill the FIFO for the current frame, the other pipes also refill their own FIFOs, even if the low threshold has not been reached. This is used to improve the probability of increasing the time when there is no access to the L3 interconnect (MStandby asserted, affects power savings).

Once the wake-up signal is asserted, the WAKEUP interrupt request is generated. The wake-up signal is deasserted when the idle request is no longer activated.

15.3.1.4.6 Standby Mode

As part of the system-wide power-management scheme, the display controller can enter standby mode. To configure the display controller, write the DSS.DISPC_SYSCONFIG[13:12] MIDDLEMODE field (00: Forced standby; 01: No standby; 10: Smart standby) in one of the following standby modes:

- Forced standby mode (default mode): The module enters standby mode when the module is disabled.
- No standby mode: The module never enters standby mode.
- Smart standby mode: The module enters standby state when the DISPC module is disabled or when all the three following events occur:
 - Graphics pipe is disabled or graphics pipe is enabled but data fetch completed for graphics window, or graphics pipe is enabled and data fetch is not completed and number of data bytes in FIFO is greater than the high threshold programmed value.
 - Video1 pipe is disabled or video1 pipe is enabled but data fetch completed for video1 window, or video1 pipe is enabled and data fetch is not completed and number of data bytes in FIFO is greater than the high threshold programmed value.
 - Video2 pipe is disabled or video2 pipe is enabled but data fetch completed for video2 window, or video2 pipe is enabled and data fetch is not completed and number of data bytes in FIFO is greater

than the high threshold programmed value.

When in standby mode, the display controller does not generate transactions on the L3 master port. Standby is active when the PRCM module confirms this mode.

The display subsystem standby mode activity can be monitored with the PRCM.CM_IDLEST_DSS[0] ST_DSS status register. When this register is read to 0, the display subsystem is accessible and the interface clock running; when it is read to 1, the display subsystem is in standby mode.

15.3.1.4.6.1 Conditions to Exit Standby Mode

The following conditions allow the subsystem to exit standby mode:

- Forced standby mode: Standby mode is exited when the display controller is enabled.
- Smart standby mode: Standby mode is exited when any one of the following events occurs:
 - Graphics pipe is enabled and data fetch is not completed for graphics window, and number of data bytes in FIFO is less than the low threshold programmed value.
 - Video1 pipe is enabled and data fetch is not completed for video1 window, and number of data bytes in FIFO is less than the low threshold programmed value.
 - Video2 pipe is enabled and data fetch is not completed for video2 window, and number of data bytes in FIFO is less than the low threshold programmed value.

15.3.1.4.6.2 Standby Transition Dependency

The sleep transition of the DSS power domain can be dependent or not with respect to MPU domain. This is configured by PRCM.CM_SLEEPDEP_DSS[1] EN_MPU bit:

- When the EN_MPU bit is set to 0 (reset value): The DSS power domain sleep dependency with the MPU power domain is disabled. The DSS power domain will not enter idle unless the MPU power has previously entered idle.
- When the EN_MPU bit is set to 1: The DSS power domain sleep dependency with the MPU power domain is enabled. The DSS power domain will enter idle regardless of the power domain state of the MPU.

The sleep transition of the DSS power domain may, or may not depend on the IVA2.2 domain, depending on the configuration of the PRCM.CM_SLEEPDEP_DSS[2] EN_IVA2 bit:

- When the EN_IVA2 bit is set to 0 (reset value): The DSS power domain sleep dependency on the IVA2.2 power domain is disabled.
- When the EN_IVA2 bit is set to 1: The DSS power domain sleep dependency on the IVA2.2 power domain is enabled.

15.3.1.4.6.3 Standby Procedure Description

When the display subsystem initiates a standby procedure, it also initiates an standby/wait handshake protocol with the PRCM module that lets the PRCM cut the display subsystem clocks. Depending on the PRCM setting, two modes are available:

- Manual mode
 - DSS1_ALWON_FCLK is shut down when the PRCM.CM_FCLKEN_DSS[0] EN_DSS1 bit is set to 0 and the display subsystem is in standby mode.
 - DSS2_ALWON_FCLK is shut down when the PRCM.CM_FCLKEN_DSS[1] EN_DSS2 bit is set to 0 and the display subsystem is in standby mode.
 - DSS_L3_ICLK and DSS_L4_ICLK are controlled together. They are shut down when the PRCM.CM_ICLKEN_DSS[0] EN_DSS bit is set to 0 and the display subsystem is in standby mode.

CAUTION

Do not stop DSS1_ALWON_FCLK, or DSS2_ALWON_FCLK clock (if used) if the display subsystem is not disabled.

CAUTION

DSS_TV_FCLK does not depend on the display subsystem standby state. Ensure correct clock management for DSS_TV_FCLK.

The clocks are reactivated when the related bits are set to 1 and the display subsystem exits from standby. For more information, see the *Power, Reset, and Clock Management* chapter.

- Hardware- or software-supervised mode

The DSS-power state-transition between active and inactive states can be either hardware or software supervised. This is programmed with the PRCM.CM_CLKSTCTRL_DSS[1:0] CLKTRCTRL_DSS field:

- When the CLKTRCTRL_DSS field is set to 0x0 (reset value), the automatic transition is disabled
- When the CLKTRCTRL_DSS field is set to 0x1, the software-supervised sleep transition is started on the DSS power domain.
- When the CLKTRCTRL_DSS field is set to 0x2, the software-supervised wake-up transition is started on the DSS power domain.
- When the CLKTRCTRL_DSS field is set to 0x3, the automatic transition is enabled. Any transition on the DSS power domain is supervised by the hardware.

15.3.1.4.6.4 Display Subsystem Standby Mode, Power-Saving Use Cases

- Setup
 - Set the display subsystem in smart standby mode.
 - Manually enable DSS_L3_ICLK and DSS_L4_ICLK.
 - Manually enable DSS1_ALWON_FCLK or DSS2_ALWON_FCLK.
 - Manually enable DSS_TV_FCLK if the video encoder is used.
 - Set the PRCM.CM_CLKSTCTRL_DSS[1:0] CLKTRCTRL_DSS field to 0x3 (autocontrol mode supervised by hardware).
- Shut down the display subsystem.
 - Disable the display subsystem.
 - Manually disable DSS1_ALWON_FCLK, DSS2_ALWON_FCLK, DSS_TV_FCLK, DSS_L3_ICLK, and DSS_L4_ICLK.

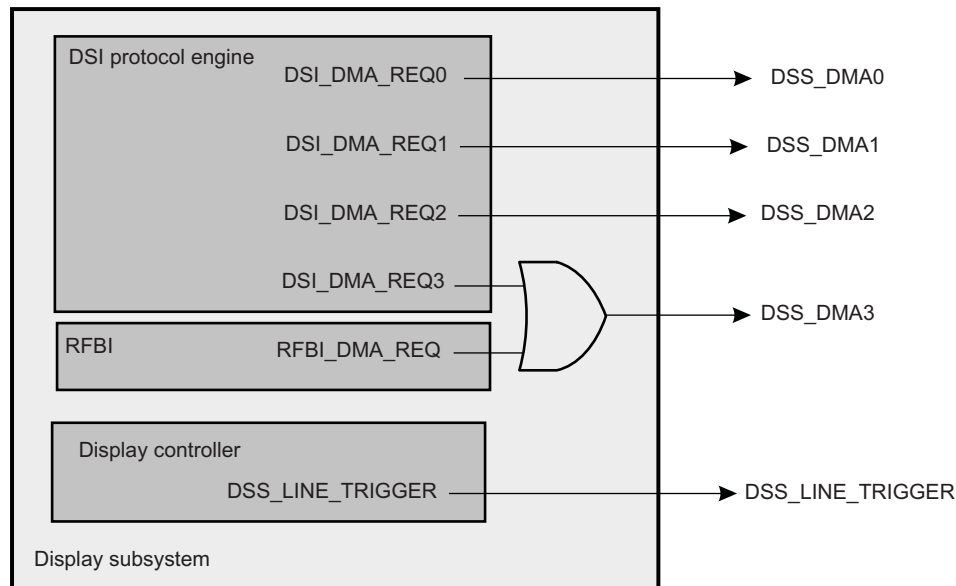

For more details on low-power programming settings, see [Section 15.6.2](#).

15.3.2 Hardware Requests

15.3.2.1 DMA Requests

The display controller, the DSI protocol engine, and the RFBI generate some DMA requests to the sDMA. [Figure 15-66](#) details the DMA tree.

Figure 15-66. Display Subsystem DMA Tree

dss-159

Table 15-21. DSS DMA Requests Description

DMA Request Name	DSS Module	Mapping	Description
DSS_LINE_TRIGGER	DISPC	S_DMA_5	See Section 15.3.2.1.1
DSI_DMA_REQ0	DSI protocol engine	S_DMA_71	See Section 15.3.2.1.2
DSI_DMA_REQ1	DSI protocol engine	S_DMA_72	See Section 15.3.2.1.2
DSI_DMA_REQ2	DSI protocol engine	S_DMA_73	See Section 15.3.2.1.2
DSI_DMA_REQ3	DSI protocol engine	S_DMA_74	See Section 15.3.2.1.2
RFBI_DMA_REQ	RFBI	S_DMA_74	See Section 15.3.2.1.3

Note: The DMA requests from the RFBI module (RFBI_DMA_REQ) and the DSI protocol engine (DSI_DMA_REQ3) are merged on line DSS_DMA3. The software should only use DSS_DMA3 on one module at a time (RFBI or DSI protocol engine).

15.3.2.1.1 Display Controller DMA Request (Line Trigger)

One DMA synchronization line (DSS_LINE_TRIGGER) is connected to the sDMA by the sDMA controller (S_DMA_5) input line. This DMA request is not a classical one but a synchronization signal from the display subsystem to the sDMA informing the sDMA that a programmable number of lines are output to the LCD, and that the system memory can be updated. This request is related to an interrupt event described in [Section 15.3.2.2, Interrupt Requests](#). This allows the sDMA channel to be synchronized with the Display subsystem internal DMA controller. In other words, it allows to synchronize a memory to memory frame buffer update based on the scan line of the frame buffer in system memory (SDRAM or SRAM) by the display controller. The DSS_LINE_TRIGGER DMA request is generated at a programmable line number defined in DSS.DISPC_LINE_NUMBER[10:0] LINENUMBER field.

15.3.2.1.2 DSI Protocol Engine DMA Request

The DSI DMA requests are used to allow automatic transfer by the sDMA or MPU (with less efficiency and through-put capability) from the DSI RX FIFO to the system memory and from the system memory to the DSI TX FIFO. Two independent DMA requests for RX FIFO and TX FIFO for the same virtual channel are supported.

15.3.2.1.3 RFBI DMA Request

The RFBI_DMA_REQ is used to receive data into the RFBI FIFO. The DMA request is always generated when there is enough room in the FIFO to accept the full burst.

15.3.2.2 Interrupt Requests

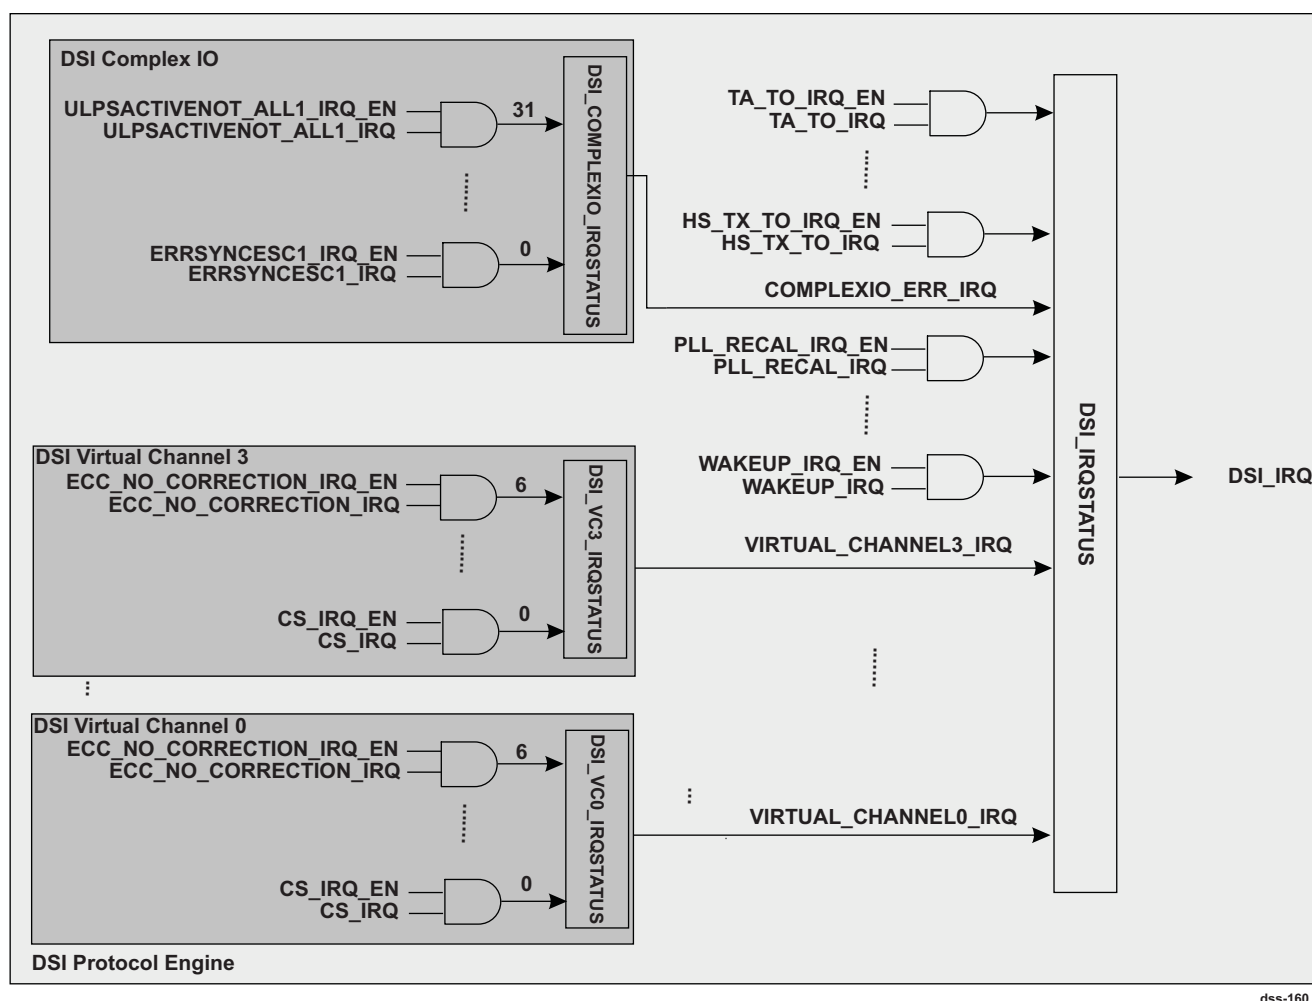

The DSI protocol engine, the DSI complex I/O (DSI_IRQ), and the display controller (DISPC_IRQ) generate one interrupt request each. The DSI_IRQ and DISPC_IRQ lines are merged together in a single interrupt line.

One interrupt line (DSS_IRQ) is connected to two interrupt controllers:

- MPU interrupt controller (M_IRQ_25 input line)
- IVA interrupt handler (IVA2_IRQ[13] input line)

Figure 15-67 shows the interrupt tree for the DSI protocol engine and DSI complex I/O in detail.

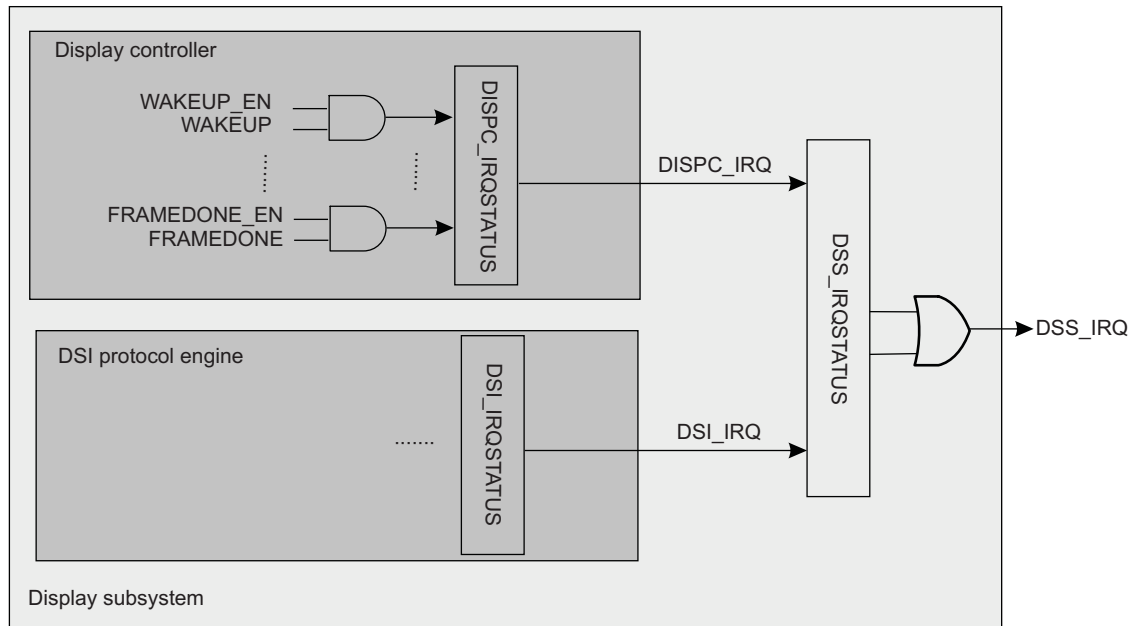

Figure 15-67. DSI Interrupt Tree

dss-160

Figure 15-68 details the interrupt tree for the DISPC and the display subsystem.

Figure 15-68. DISPC and DSS Interrupts Tree

dss-161

15.3.2.2.1 DISPC Interrupt Request

The interrupt line indicates when one or more events are detected by the hardware. Each event is independently maskable by setting the DSS.DISPC_IRQENABLE register.

To check when a particular interrupt event occurs and to reset a particular event, the DSS.DISPC_IRQSTATUS register must be accessed. This register regroups all the status of the module internal events that generate an interrupt (read 0: No interrupt occurred; read 1: Interrupt occurred; write 1: Status bit reset). See Section 15.7, *Display Subsystem Registers*, for more information on checking and clearing interrupt events.

Table 15-22 lists the display subsystem interrupt events.

Table 15-22. Display Subsystem Interrupts

Interrupt Name	Description
FRAMEDONE	Active frame is complete and LCD output is disabled.
VSYNC	VSYNC interrupt occurred at the end of the frame.
EVSYNC_EVEN ⁽¹⁾	EVSYNC_EVEN interrupt occurred at the end of the frame. (EVSYNC is received and the field polarity is even.)
EVSYNC_ODD ⁽¹⁾	EVSYNC_ODD interrupt occurred at the end of the frame. (EVSYNC is received and the field polarity is odd.)
ACBIASCOUNTSTATUS	The ac-bias transition counter decremented to 0.
PROGRAMMEDLINENUMBER	The LCD reached the user-programmed line number.
GFXFIFOUNDERFLOW	The input graphics FIFO goes underflow.
GFXENDWINDOW	The screen reached the end of the graphics window. All data for the graphics window are fetched from memory and displayed on the screen.
PALETTEGAMMALOADING	The palette/gamma table is loaded.
OCPELLOW	L3 interconnect sent SResp = ERR.
VID1FIFOUNDERFLOW	The input video1 FIFO goes underflow.

⁽¹⁾ EVYNC interrupts (EVSYNC_EVEN and EVSYNC_ODD) are external interrupts received by the display controller and generated by the video encoder (VENC) module.

Table 15-22. Display Subsystem Interrupts (continued)

Interrupt Name	Description
VID1ENDWINDOW	The screen reached the end of video1 window. All data for the video window are fetched from the memory and displayed on the screen.
VID2FIFOUNDERFLOW	The input video2 FIFO goes underflow.
VID2ENDWINDOW	The screen reached the end of video2 window. All data for the video window are fetched from the memory and displayed on the screen.
SYNCLOST	Interrupt occurs when VSYNC width/front or back porches are not wide enough to load the pipelines with data (LCD output).
SYNCLOSTDIGITAL	Interrupt occurs when the display controller is not ready to output data when a digital request occurs. This interrupt informs that the timings of the NTSC/PAL video encoder are not set correctly.
WAKEUP	Occurs when the wakeup signal is asserted

Note: To clear a synchronization lost interrupt, follow this sequence:

1. Clear the DSS.DISPC_CONTROL[0] LCDENABLE (LCD: SYNCLOST interrupt) or DSS.DISPC_CONTROL[1] DIGITALENABLE (TV: SYNCLOSTDIGITAL interrupt) bits.
Check the interrupts.
LCD: Verify that a FRAMEDONE interrupt occurs.
TV : Verify that EVSYNC_EVEN or EVSYNC_ODD interrupts occur.
2. Set the DSS.DSS_SYSCONFIG[1] SOFTRESET bit to reset the display subsystem.
3. Set the display subsystem registers again.

Note: The SYNCLOSTDIGITAL interrupts, which occur before the first VSYNC pulse signal (from the video encoder), should not be considered.

After the first VSYNC pulse signal, the SYNCLOSTDIGITAL interrupt status bit must be cleared by writing 1 in the DSS.DISPC_IRQSTATUS[15] SYNCLOSTDIGITAL bit; then the SYNCLOSTDIGITAL interrupt can be enabled by setting the DSS.DISPC_IRQENABLE[15] SYNCLOSTDIGITAL bit.

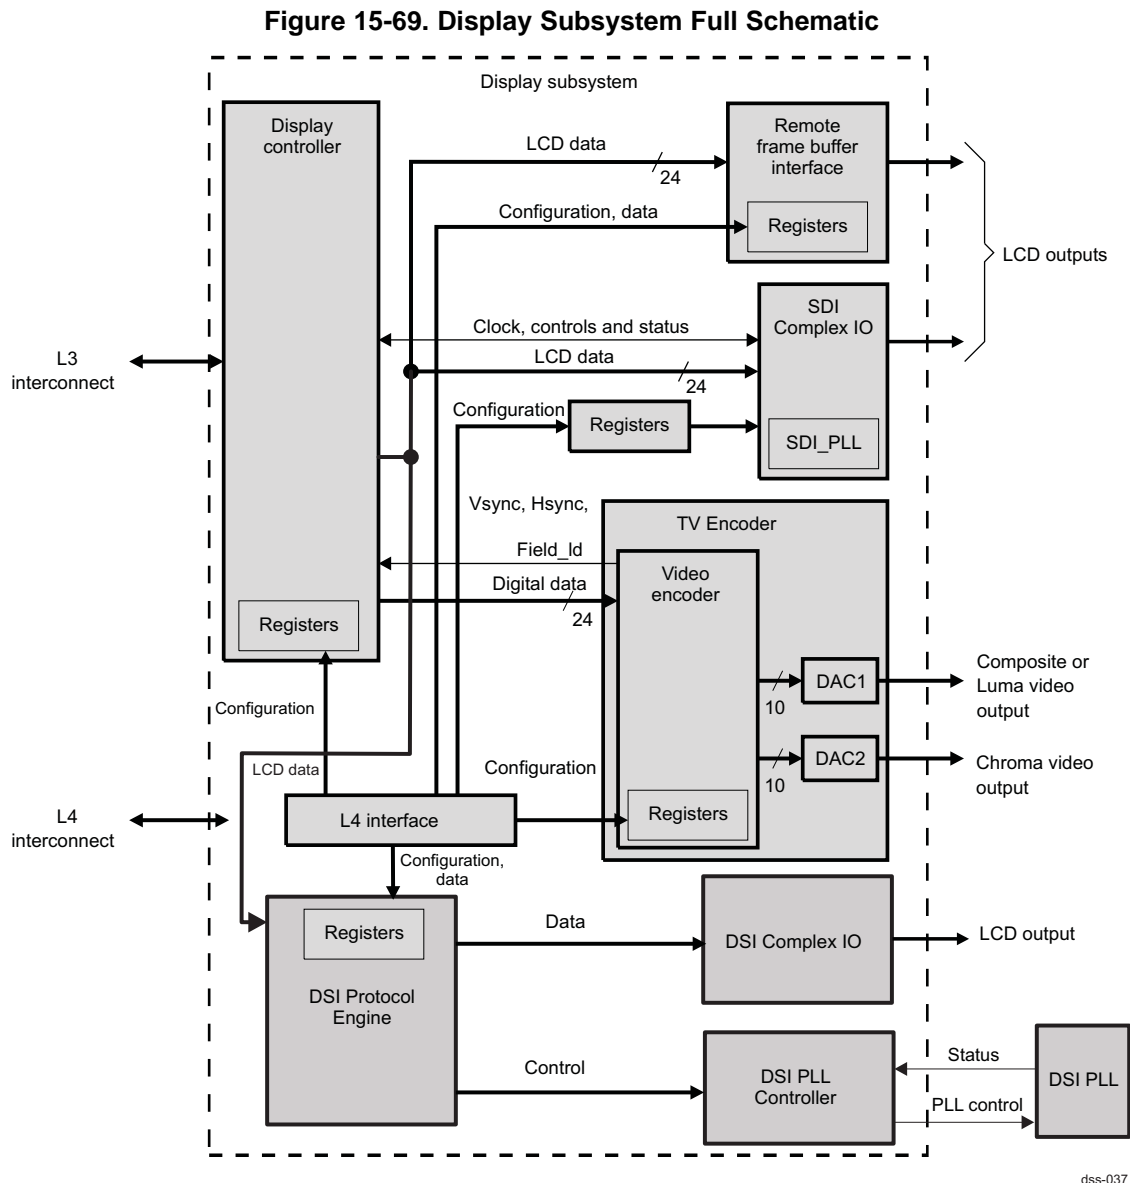

15.4 Display Subsystem Functional Description

This section describes the functionalities of the LCD and TV display supports by describing the following modules: Display controller, DSI protocol engine, DSI PLL controller, DSI complex I/O, RFBI, SDI, and video encoder.

The functionalities of the display controller are common to both LCD and TV data paths; the RFBI and SDI functionalities are LCD-specific; and the video encoder functionalities are specific to the TV set.

15.4.1 Block Diagram

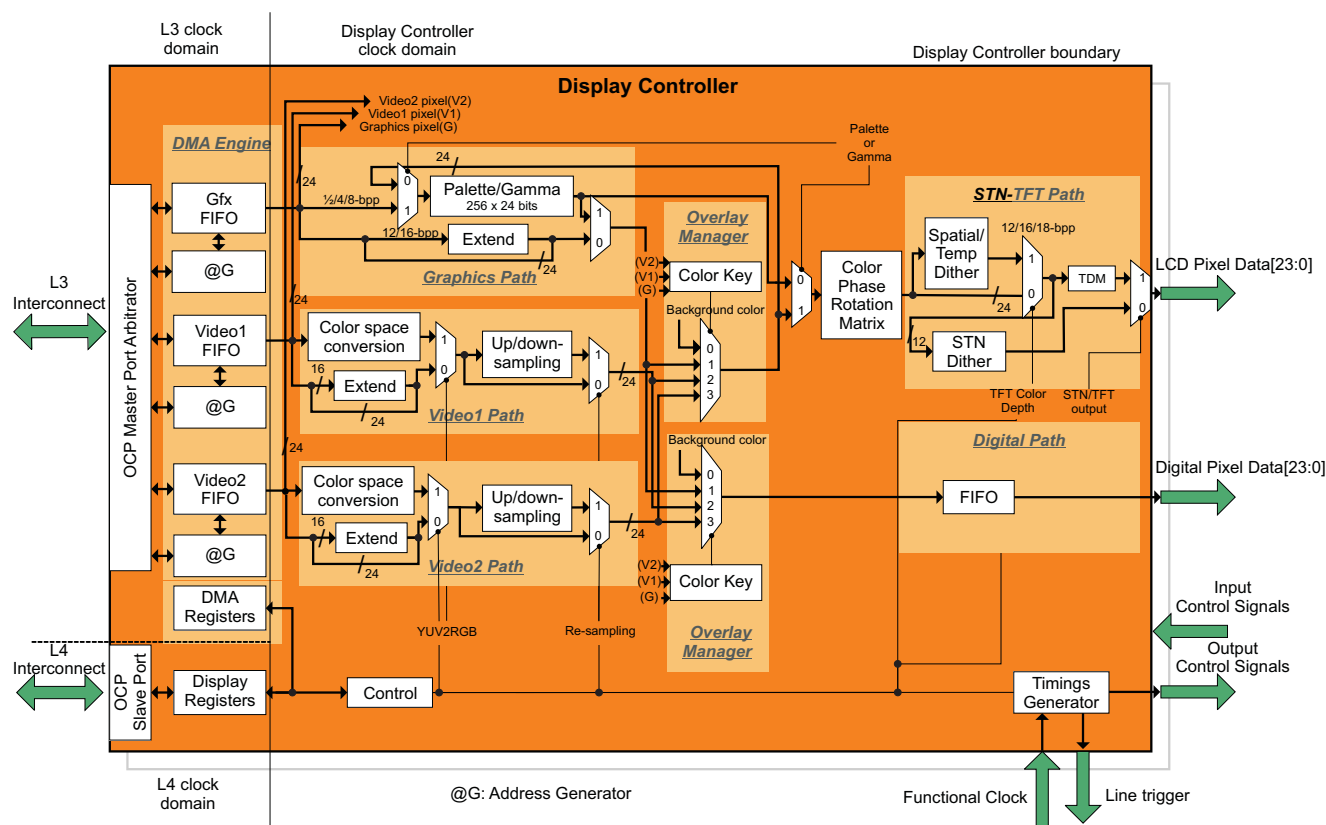

Figure 15-69 is a schematic of the display subsystem.

15.4.2 Display Controller Functionalities

The display controller can read and display the encoded pixel data stored in memory (see Figure 15-70).

Figure 15-70. Display Controller Architecture Overview

dss-038

Several processes can be configured to manage the graphics pipeline (palette, gamma table correction) and video pipeline (color space conversion, upsampling, downsampling, overlay, and transparency features).

The internal timing generator logic generates the LCD input signals. The external timing generator generates the appropriated signals to drive the digital output. The data from the two overlay managers are sent on the two concurrent 24-bit buses outside the display controller module. The memory accessed by the display controller is either the SDRAM memory or the SRAM memory.

15.4.2.1 Display Modes

15.4.2.1.1 LCD Output

The display subsystem supports two types of display technologies (both monochrome and color modes):

- Passive matrix displays
- Active matrix displays

The passive matrix display mode supports 3375 possible colors, allowing 16, 256, or 3375 colors to be displayed in each frame, depending on the color depth. The monochrome LCD has 15 grayscale levels available.

In active matrix display mode, the configuration of colors depends on the color depth:

- 24 BPP supports 16,777,216 colors.
- 18 BPP supports 262,144 colors.
- 16 BPP supports 65,536 colors.
- 12 BPP supports 4096 colors.

15.4.2.1.2 Digital Output

The digital output is always a 24-bit RGB value based on an external pixel request.

15.4.2.2 Graphics Pipeline

The graphics pipeline is connected to the graphics FIFO controller for the input port and to the two overlay managers (LCD and digital). It consists of one 256-entry palette and some programmable replication logic. The replication logic is used to convert the RGB pixels, excluding the RGB24 format, into RGB24 format based on user programming (replication of the most-significant bits [MSBs] for the RGB24 LSBs or use of 0s). The first unit connected to the input port of the graphics pipeline is the replication logic used for RGB pixels, then the second unit is the palette for concerned pixels.

15.4.2.2.1 Graphics Memory Format

The supported formats for the graphics layer are color lookup table (CLUT) bitmaps (1-, 2-, 4-, and 8-BPP) and true color bitmaps in RGB formats (12-, 16-, and 24-BPP [packet and nonpacket RGB24]) and in ARGB or RGBA formats (ARGB 16-, and 32-BPP, and RGBA 32-BPP) as follows:

- BITMAP 1-BPP data memory organization (CLUT) (Little Endian)

- BITMAP 1-BPP data memory organization (CLUT) (Little Endian + Nibble Mode)

- BITMAP 1-BPP data memory organization (CLUT) (Big Endian)

- BITMAP 1-BPP data memory organization (CLUT) (Big Endian + Nibble Mode)

- BITMAP 2-BPP data memory organization (CLUT) (Little Endian)

- BITMAP 2-BPP data memory organization (CLUT) (Little Endian + Nibble Mode)

- BITMAP 2-BPP data memory organization (CLUT) (Big Endian)

- BITMAP 2-BPP data memory organization (CLUT) (Big Endian + Nibble Mode)

- BITMAP 4-BPP data memory organization (CLUT) (Little Endian)

- BITMAP 4-BPP data memory organization (CLUT) (Little Endian + Nibble Mode)

- BITMAP 4-BPP data memory organization (CLUT) (Big Endian)

- BITMAP 4-BPP data memory organization (CLUT) (Big Endian + Nibble Mode)

- BITMAP 8-BPP data memory organization (CLUT) (Little Endian)

- BITMAP 8-BPP data memory organization (CLUT) (Big Endian)

- RGB 12-BPP data memory organization (Little Endian)

- RGB 12-BPP data memory organization (Big Endian)

- RGB 16-BPP data memory organization (Little Endian)

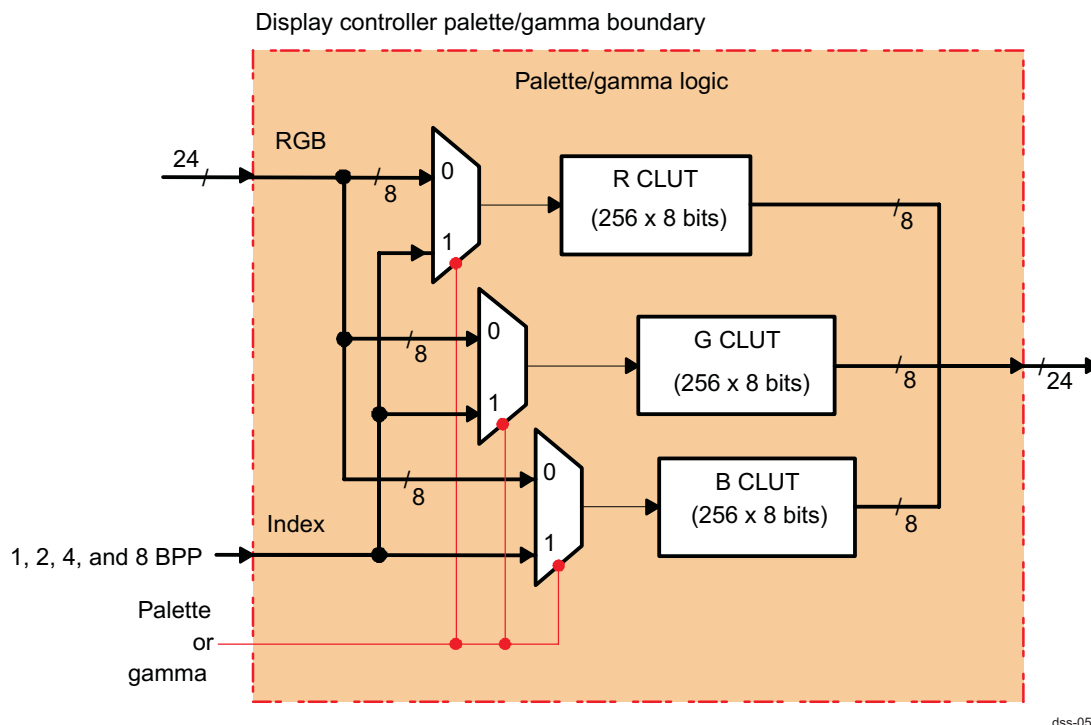

- RGB 16-BPP data memory organization (Big Endian)

15.4.2.2.2 Color Look-Up Table/Gamma Table

The graphics path supports the palette/gamma table. [Figure 15-71](#) shows the internal architecture of the color look-up/gamma table.

The palette is split into three memories of 256-bit x 8-bit entries. For bitmap (CLUT) indexes, the same value (1-, 2-, 4-, or 8-BPP) indexes the three memories. For gamma curve correction, each R, G, and B component indexes the corresponding memory to combine the three gamma curve values into a 24-bit value. The table can be reloaded every frame, once or never (at the beginning of the frame before fetching the pixels for the graphics and/or video windows).

Figure 15-71. Palette/Gamma Correction Architecture

dss-054

15.4.2.2.1 Color Look-Up Table

The palette mode uses the encoded pixel values from the input graphics FIFO as pointers to index the 24-bit-wide palette: 1-BPP pixels address 2 palette entries, 2-BPP pixels address 4 palette entries, 4-BPP pixels address 16 palette entries, and 8-BPP pixels address 256 palette entries.

When a palette entry is selected by the encoded pixel value, the content of the entry is sent to the color/grayscale space/time base passive matrix dithering circuit, or to the color time base active matrix dithering circuit.

In the color mode, the value within the palette is made up of three 8-bit fields, one for each color component (red, green, and blue). For color operation, an individual frame is limited to a selection of 256 colors (the number of palette entries). In the monochrome mode, only one 8-bit value is present.

After passing through the palette, 256 grayscales and 16,777,216 colors are numbers obtained. A redundancy introduced in the dithering logic step reduces these numbers when displaying. For passive matrix panels, the colors are limited to 15 grayscales and 3375 colors.

- Passive matrix technology
The palette is bypassed in 12, 16, and 24 BPP. The palette is not used.
- Active matrix technology
The palette is bypassed in 12, 16, and 24 BPP, allowing up to $2^{24} = 16,777,216$ colors to be displayed.

15.4.2.2.2 Gamma Table

In the gamma curve mode, the selected encoded pixel values based on the color keys from the video or graphics paths are sent to the gamma curve table. The mode is available only if the color look-up palette is not used for graphics. The output of the gamma curve processing is always sent to the LCD output. It is not available on digital output.

Each component of encoded pixel value is used as a pointer to index 1 out of 256 24-bit gamma curve entries in the table. Each 8-bit component is replaced with the 8-bit table value corresponding to an R, G, or B component.

15.4.2.2.2.1 Replication Logic

The replication logic increases the color depth of the graphics and video encoded pixels (from true color RGB 12-, and 16-BPP to 24-BPP). The encoded value is shifted to the 24-bit alignment. The MSB bits are copied to the LSB missing ones. Then the graphics are merged with the video data based on the transparency color keys. When the replication logic is not selected, the encoded pixel values are shifted to the MSB boundary of the 24-bit format. The missing bit values are filled up with 0s.

This is an example for RGB16 extension:

- Original 16-BPP data:

dss-T055

- If replication logic is ON:

dss-T056

- If replication logic is OFF:

dss-T057

15.4.2.3 Video Pipeline

The video pipeline is connected to the video FIFO controller for the input port and to the two overlay managers (LCD and digital). It consists of the Re-Sampling unit, the Color Space Conversion Unit, and some programmable replication logic. The replication logic is used to convert the RGB pixels, excluding the RGB24 format, into RGB24 format based on user programming (replication of the MSBs for the RGB24 LSBs or use of 0s). The first unit connected to the input port of the video pipeline is the Re-Sampling Unit, then the replication logic used for RGB pixels, then the Color Space Conversion Unit for YUV422 pixels.

15.4.2.3.1 Video Memory Formats

The display subsystem supports the following formats for the video layer: YUV2, UYVY, RGB12, RGB16, RGB24 (non-packed and packed formats), ARGB16 (video channel 2 only), ARGB32 (video channel 2 only), and RGBA32 (video channel 2 only).

- YUV2 4:2:2 data memory organization (Big Endian)

dss-T072

15.4.2.3.2 Color Space Conversion

The color space conversion module converts the video-encoded pixel values from YCbCr 4:2:2 format into RGB24. [Figure 15-72](#) and [Figure 15-73](#) detail the YCbCr 4:2:2 conversion to YCbCr 4:4:4 depending on the rotation parameters.

Figure 15-72. YCbCr 4:2:2 to YCbCr 4:4:4 (0- or 180-Degree Rotation)

dss-061

Figure 15-73. YCbCr 4:2:2 to YCbCr 4:4:4 (90- or 270-Degree Rotation)

dss-060

The interpolation of the missing chrominance component is given by the equation in [Figure 15-74](#).

Figure 15-74. Interpolation of the Missing Chrominance Component

$$Cb_n(YCbCr\ 444) = \frac{Cb_{n-1}(YCbCr\ 422) + Cb_{n+1}(YCbCr\ 422)}{2} \text{ (n odd)}$$

$$Cr_n(YCbCr\ 444) = \frac{Cr_{n-1}(YCbCr\ 422) + Cr_{n+1}(YCbCr\ 422)}{2} \text{ (n odd)}$$

dss-E062

First, to convert the YCbCr 4:2:2 encoded pixel values into YCbCr 4:4:4 format, the missing chrominance samples (Cb and Cr) are interpolated using the average values of the two closest values on the same line (1/2, 1/2) or are repeated from the second pixel in the same 32-bit container.

- In case of rotation 0-degree, for the last pixel, the chrominance samples are duplicated using the values from the previous pixel; otherwise, the chrominance samples are averaged using the two adjacent values.
- In case of 180-degree rotation, for the first pixel the chrominance samples missing are duplicated from the adjacent pixel; otherwise, the chrominance samples are averaged using the two adjacent values.
- In case of rotation 90- and 270-degree, the missing chrominance components are duplicated from the adjacent pixel in the same 32-bit container.

In case of 5-tap configuration for the vertical filtering, the missing chrominance samples are always duplicated using the second chrominance samples in the same 32-bit value.

Then the pixels are converted from YCbCr color space into the RGB color space, because the output format of the color space conversion is RGB24 (8-bit value per component: Red, green, and blue). The following matrices show the 11-bit coefficients registers used to convert from YCbCr 4:4:4 into RGB24. The user sets the coefficients according to the standard used to encode the pixel data in YCbCr color space.

In case of resampling, the YUV422 format is converted into YUV444. The YUV422-to-YUV444 processing is bypassed in the color space conversion unit.

If the active range for the luminance samples (Y) is [16235] and [16240] for the chrominance samples (Cb and Cr), the values of R, G, and B output components are clipped to the range [0:255]. The equation shown in [Figure 15-75](#) gives the 11-bit coefficients of the YCbCr to RGB color space conversion.

Figure 15-75. YCbCr to RGB Registers (VIDFULLRANGE=0)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y - 16 \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dss-E063

If the active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [0:255], the values of R, G, and B output components are clipped to the range [0:255]. The equation shown in [Figure 15-76](#) gives the 11-bit coefficients of the YCbCr-to-RGB color space conversion.

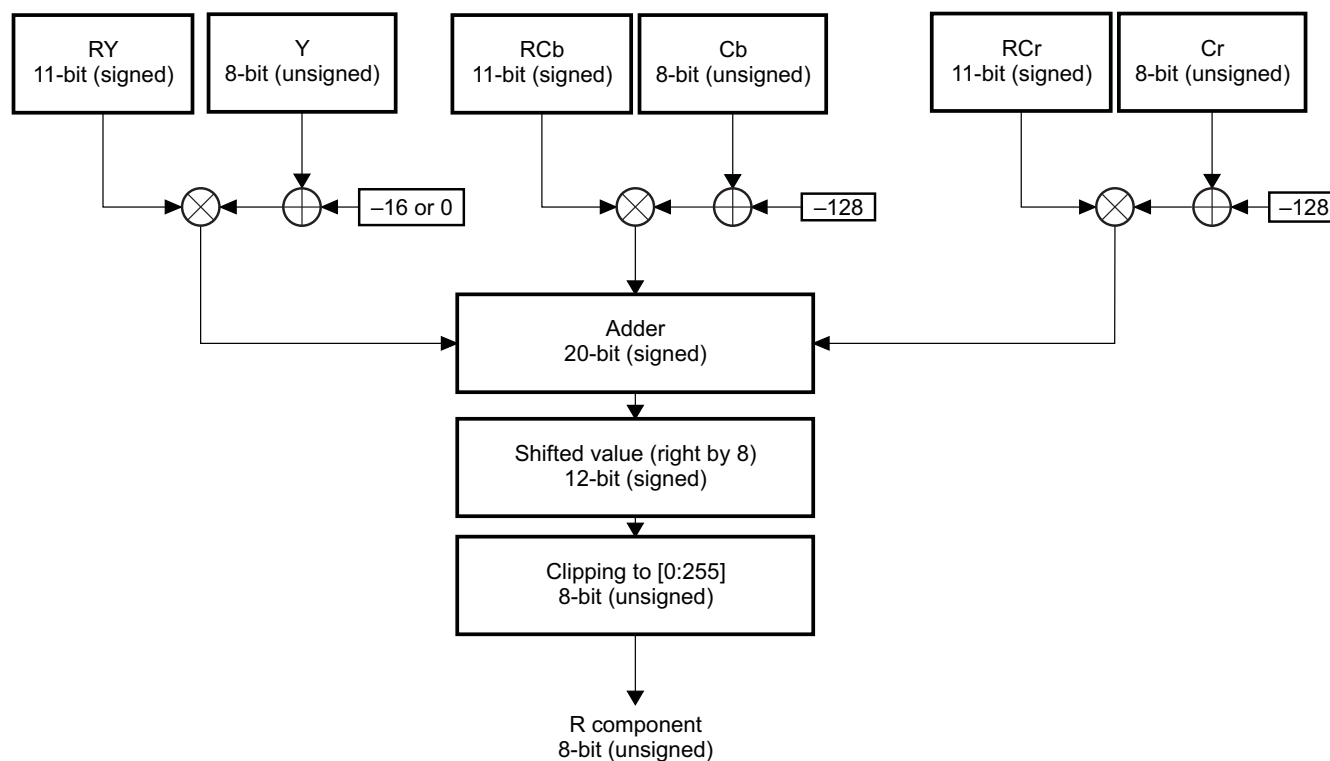

Figure 15-76. YCbCr to RGB Registers (VIDFULLRANGE=1)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dss-E064

[Figure 15-77](#) describes the computation for the calculation of the R component. The same computation applies for the G and B components:

Figure 15-77. Color Space Conversion Macro-Architecture

dss-065

15.4.2.3.3 Hardware Cursor

The video layer can be used to display the hardware cursor. The encoded pixel data for the cursor image are in RGB12, RGB16 or RGB24 formats and the color space conversion block is bypassed. The transparency color key can be used when a non rectangle shape is used.

The alpha blending can be used to show a partial transparent cursor. When the alpha blender is enabled, the graphics layer is on top of the video layers. The cursor uses the graphics layer. The pixel alpha blending or the transparency color key can be used.

15.4.2.3.4 Up-/Down-Sampling

The video layer has a dedicated resizing block to upsample and downsample the video-encoded pixels. The supported input formats from memory are RGB24, RGB16, and YUV422 (RGB12 and all the alpha formats like ARGB and RGBA are not supported). The user must set the right size and position of the original video before resizing for the upsampled/downsampled video to be inside the display screen boundaries.

The filtering applies on each component independently (R, G, and B).

For the horizontal up-/downsampling, the equation is (R component with five taps):

$$R_{out}(n) = \left(\sum_{i=-2}^{i=2} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7 \quad \text{dss-E066} \quad (15-1)$$

For the vertical up-/downsampling, the equation is (R component with three taps):

$$R_{out}(n) = \left(\sum_{i=-1}^{i=1} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7 \quad \text{dss-E067} \quad (15-2)$$

For the vertical up-/downsampling, the equation is (R component with five taps):

$$R_{out}(n) = \left(\sum_{i=-2}^{i=2} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7 \quad \text{dss-E068} \quad (15-3)$$

R_{out}: R component output

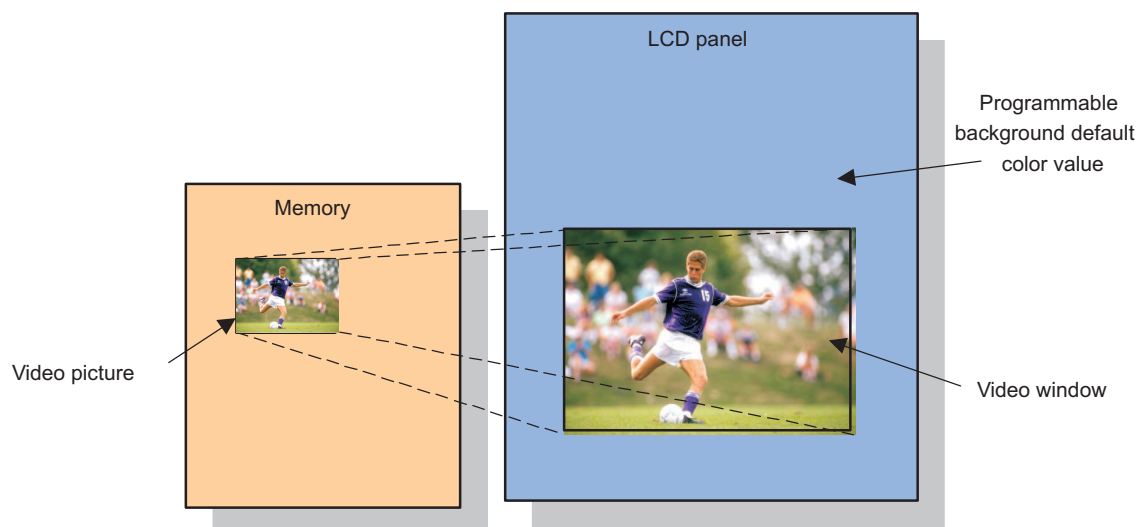

C_i(Φ)
dss-E069 : FIR filter coefficients

R_{in}: R component input

The pixel (n + 1) is older than pixel (n). The line (n + 1) is older than line (n).

Note: The coefficients *C_i(Φ)* depend on the phase between input and output pixels.

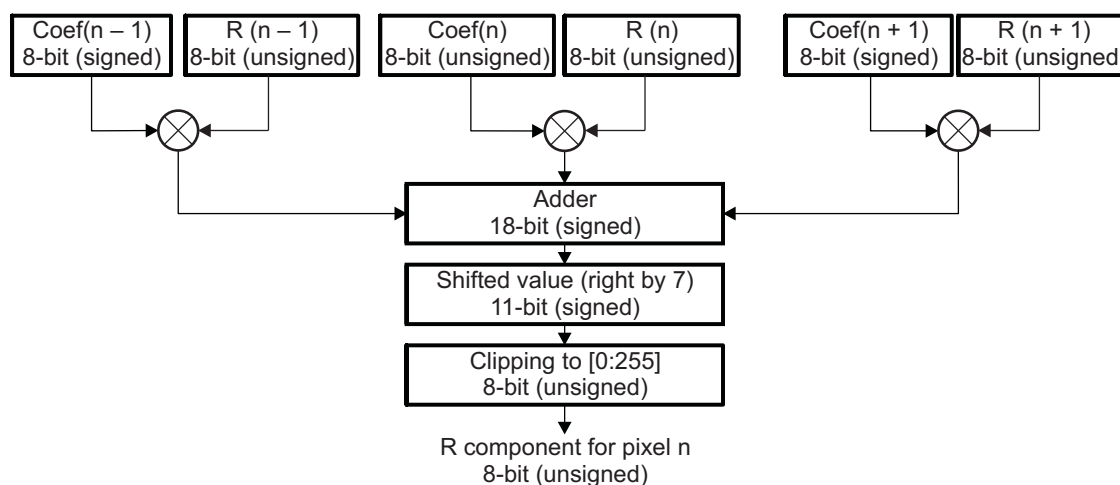

Figure 15-78 shows an example of video upsampling.

Figure 15-78. Video Upsampling

dss-070

Filter Description

The up/downsampling filter is a poly-phase filter with five taps and eight phases for the horizontal filter and a programmable number of taps (three or five) and eight phases for vertical filter. The upsampling ratio is up to x8. The downsampling ratio using 3-tap configuration is /2. The downsampling ratio using 5-tap configuration is /4. The vertical filter is first applied to the encoded input pixel data; and then the horizontal filter is applied on the resulting pixel values to generate the output pixel values. Figure 15-79 shows the computation for the R component in the case of three coefficients (vertical filtering). The same computation applies to the G and B components.

Figure 15-79. Resampling Macro-Architecture (3-Coefficient Processing)

dss-071

Down-Sampling Limitations

The maximum functional clock frequency after LCD divisor logic is 173 MHz at nominal voltage and 96 MHz at low voltage. While downsampling by 1/4, the picture size is SDTV resolution (708 x 576). The resampled picture resolution is QCIF (177 x 144) while downsampling by 1/4 and CIF (354 x 288) while downsampling by 1/2. Table 15-23 lists the required functional clock frequencies for several LCD panel resolutions.

Table 15-23. Functional Clock Requirement - Active Matrix LCD Output - SDTV Input Size - VESA Timings

LCD Resolution	Pixel Clock Frequency (MHz)	Minimum Functional Clock Frequency (MHz)		
		Down-Sampling (3-tap) H+V 1:2		Down-Sampling (5-tap) H+V 1:4
		RGB16 - YUV422 - RGB24	RGB16 - YUV422	RGB24
QCIF (177 x 144)	2	8	Not supported	Not supported
CIF (354 x 288)	8	32	32	64
QVGA (320 x 240)	6	24	24	48
HVGA (480 x 320)	12	48	48	96
VGA (640 x 480)	24	96	96	Not supported
SVGA (800 x 600)	37	148 ⁽¹⁾	148 ⁽¹⁾	Not supported
XVGA (1024 x 768)	61	Not supported	Not supported	Not supported

⁽¹⁾ Not supported at low voltage

Table 15-24 indicates the maximum picture size while downsampling by 1/2 and 1/4.

Table 15-24. Maximum Input Size - Active Matrix LCD Output - VESA Timings

LCD Resolution	Pixel Clock Frequency (MHz)	Maximum Input Picture Size		
		Down-Sampling (3-tap) H+V 1:2		Down-Sampling (5-tap) H+V 1:4
		RGB16 - YUV422 - RGB24	RGB16 - YUV422	RGB24
QCIF (177 x 144)	2	CIF	Not supported	Not supported
CIF (354 x 288)	8	SDTV	SDTV-Square (768 x 576)	SDTV-Square
QVGA (320 x 240)	6	VGA	SDTV-Square	SDTV-Square
HVGA (480 x 320)	12	SDTV	SDTV-Square	SDTV-Square
VGA (640 x 480)	24	1280 x 960	SDTV-Square	SDTV-Square
SVGA (800 x 600)	37	1536 x 1152	SDTV-Square	SDTV-Square
XVGA (1024 x 768)	61	1536 x 1152	SDTV-Square	SDTV

15.4.2.4 Overlay Support

CAUTION

Enabling overlay optimization (setting the [DSS.DISPC_CONTROL](#) [12] [OVERLAYOPTIMIZATION](#) bit) if no overlay region effectively exists (the [DSS.DISPC_VIDn_ATTRIBUTES](#) [0] [VIDENABLE](#) bit is cleared, with n = 1, 2) leads to unpredictable behavior. The overlay optimization feature must be enabled only when an overlay area exists. Before enabling the overlay optimization, the [DSS.DISPC_GFX_WINDOW_SKIP](#)[31:0] [GFXWINDOWSKIP](#) field must be first set according to the video1 and graphics windows overlap.

The overlay mechanism consists of displaying more than one layer (graphics and video layers) using rules based on priority and transparency color keys.

When the pixel format is ARGB or RGBA, the color key match logic uses only the RGB value defined by ARGB or RGBA. The alpha blending factor is ignored.

The overlay managers are based on the same rules for priority and transparency color keys (see [Figure 15-82](#)).

Each data pipeline is assigned a single overlay related to a single display controller output.

The overlay manager is connected to all three outputs of the pipelines (graphics, video1 and video2). The output of the LCD overlay manger is connected to the Spatial/Temporal Dithering, and Passive Matrix units and back to the palette unit in the case of Gamma correction.

15.4.2.4.1 Priority Rule

The overlay manager can be configured in two distinct modes:

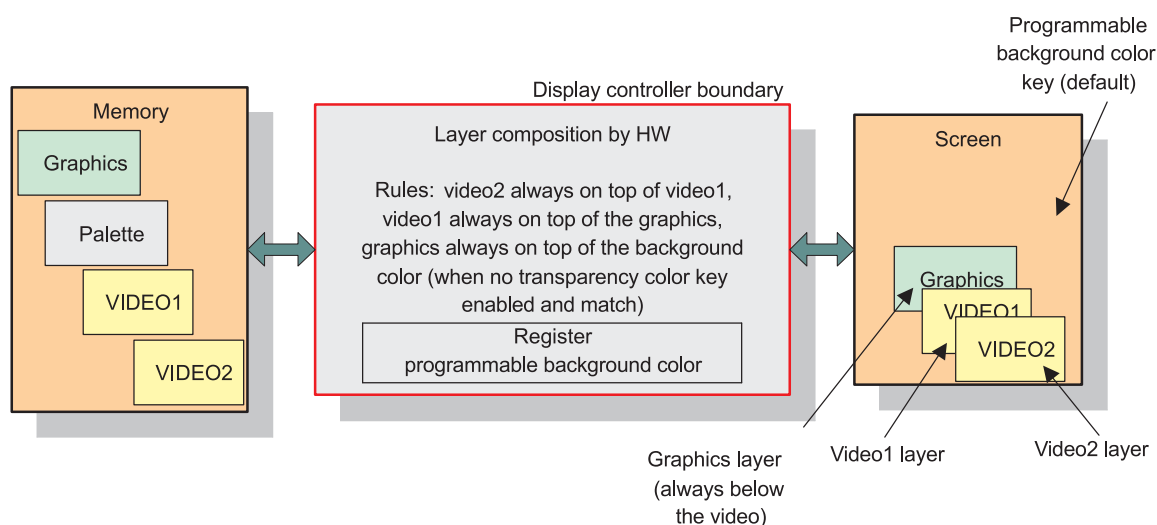

- Alpha mode (only source color key with the graphics layer)
- Normal mode (no alpha support)

The following rules apply in normal mode:

The video1 layer is always on top of the graphics layer. The video2 layer is always on top of the video1 and graphics. The display controller reads the data for each buffer from the system memory and, depending on the transparency color key values, displays either the pixels in the video layer, the pixels in the graphics layer, or the solid background color.

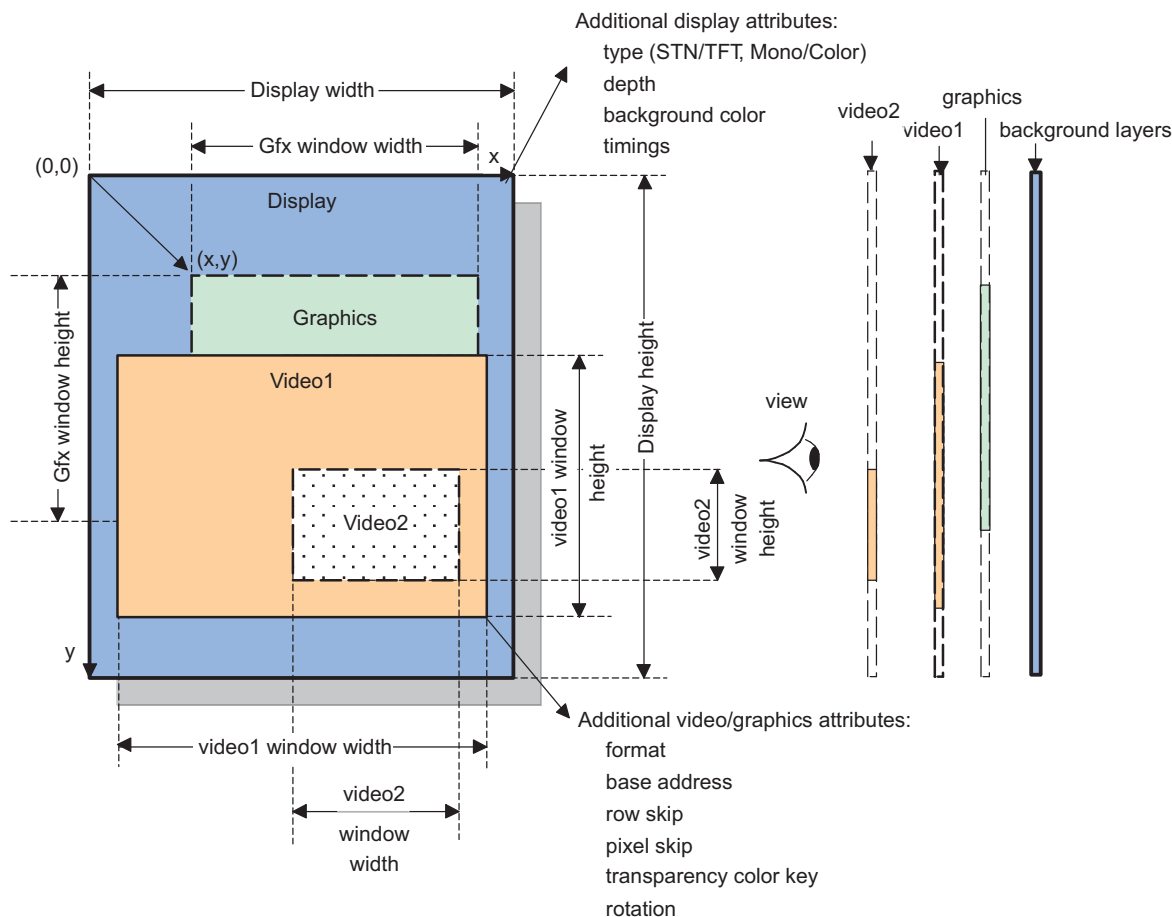

Each layer can have any size up to full-display screen. If there are no graphics or video-encoded pixels at a specific position, the programmable, solid background color appears (see [Figure 15-84](#)).

Figure 15-80. Overlay Manager in Normal Mode

dss-072

Figure 15-81. Display Attributes in Normal Mode

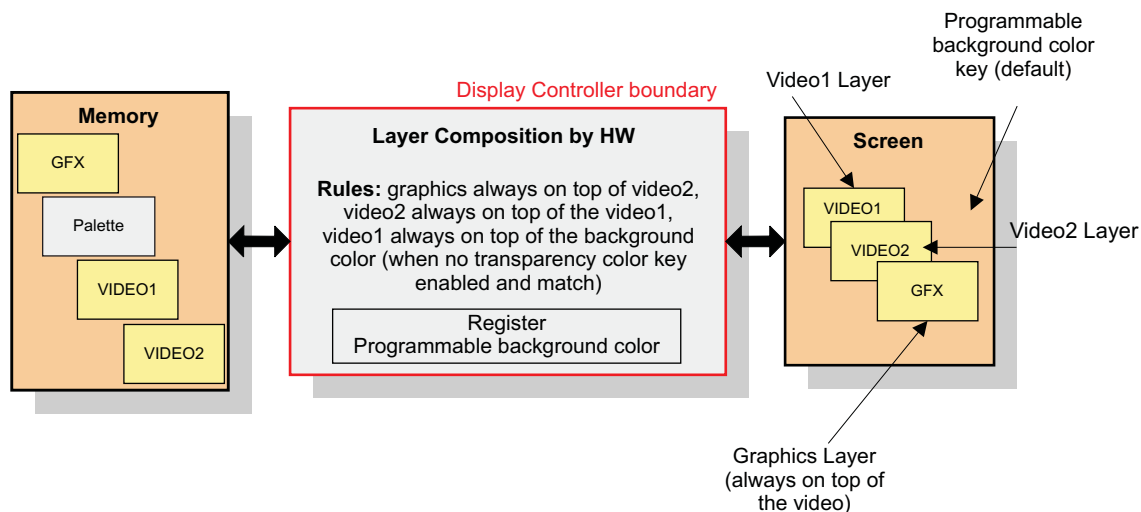

dss-073

The following rules apply in alpha mode:

The video2 layer is always on top of the video1 layer. The graphics layer is always on top of the video1 and video2. The display controller reads the data for each buffer from the system memory and, depending on the transparency color key values, displays either the pixels in the video layer, the pixels in the graphics layer, or the solid background color.

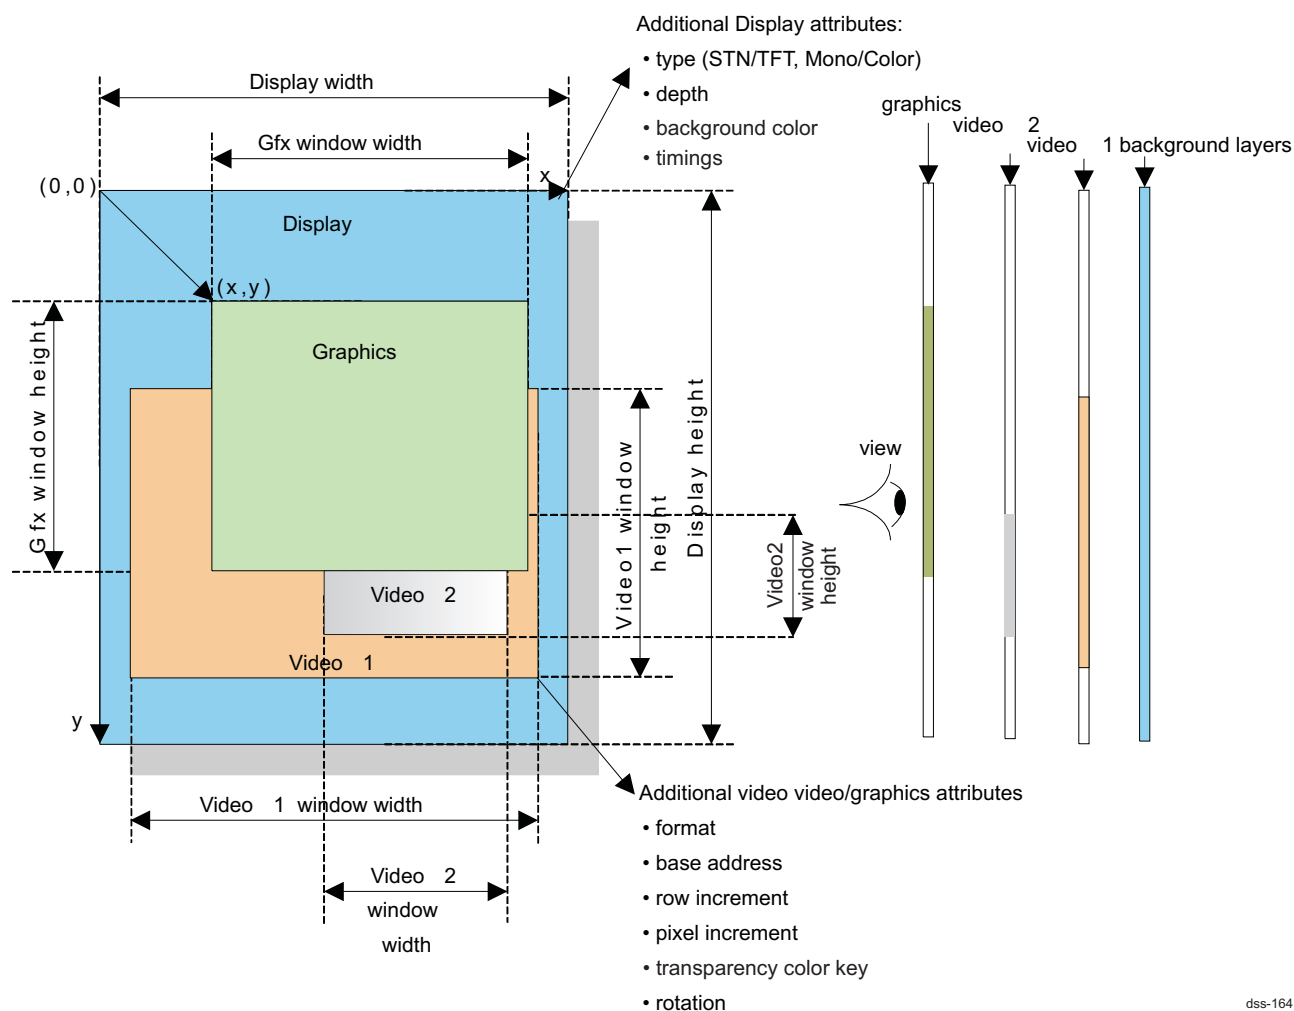

Each layer can have any size up to full-display screen. If there are no graphics or video-encoded pixels at a specific position, the programmable, solid background color appears (see [Figure 15-84](#)).

Figure 15-82. Overlay Manager in Alpha Mode

dss-163

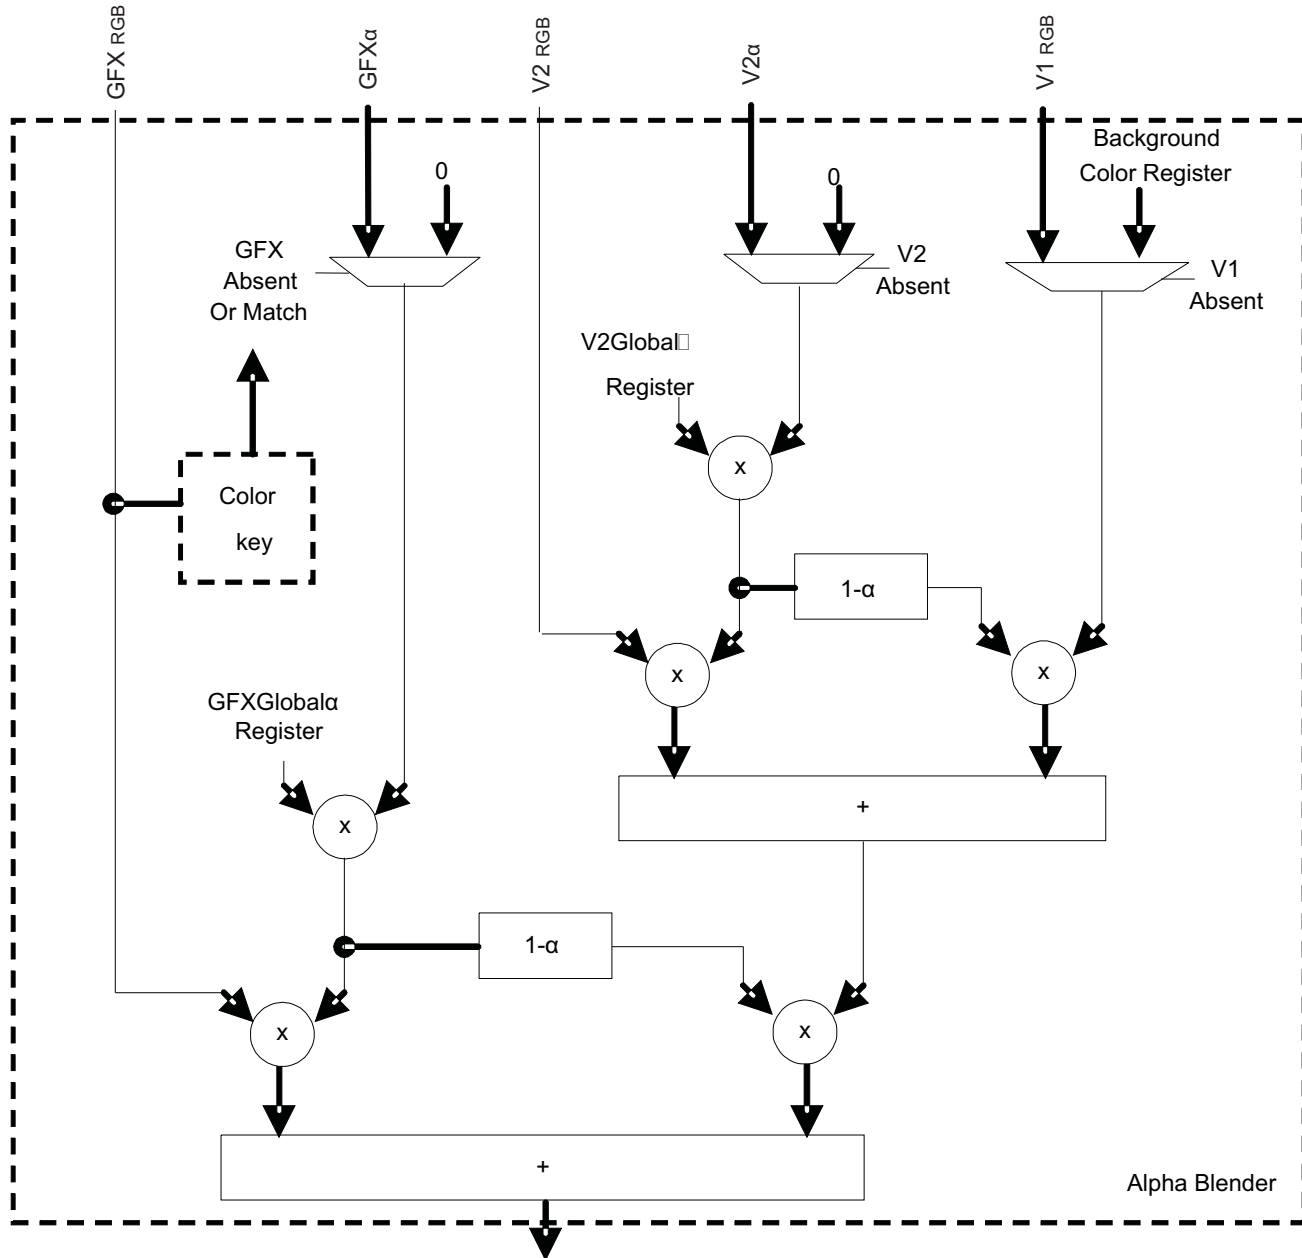

Figure 15-83. Display Attributes in Alpha Mode

dss-164

Figure 15-84 shows the alpha blending processing in detail.

Figure 15-84. Alpha Blending Macro Architecture

dss-165

Note: "1-alpha" operator corresponds to the basic 1's complement operation.

The alpha blending value is defined by the pixel value (ARGB or RGBA formats). A global alpha blending value can be defined and used in combination with the pixel alpha blending value. If the pixel format contains no alpha blending value, the pixel alpha value is considered to be 0xFF.

In case of ARGB-444, the alpha blending is defined using a 4-bit value. It is converted into an 8-bit value by duplicating the 4-bit value. Table 15-25 details the alpha blending 4-bit values and the corresponding blending percentage.

Table 15-25. Alpha Blending 4-Bit Values

Alpha Blending 4-Bit Value (ARGB-444)	Alpha Blending 8-Bit Value (Converted Value)	% Blending
0x0	0x00	100% (transparent)
0x1	0x11	93.33%
0x2	0x22	86.6%
...
0xE	0xEE	6.6%
0xF	0xFF	0% (opaque)

15.4.2.4.2 Transparency Color Keys

- The following features are available in normal mode:

The two transparency color keys are the video source transparency color key and the graphics destination transparency color key. The encoded pixel color value is compared to the transparency color key. For CLUT bitmaps, the palette index is compared to the transparency color key and not to the palette value pointed out by the palette index.

Note: The video source transparency color key and graphics destination transparency color key cannot be active at the same time.

- Video/graphics source transparency color key value

The video/graphics source transparency color key value defines the encoded pixel data considered as the transparent pixel. The encoded pixel values with the source color key value are pixels not visible on the screen, and the underlayer encoded pixel values or solid background color are visible.

The video source transparency color key can be used only if the color space conversion and the up-/down-scaling modules are disabled. The format of the data is RGB 16. (This feature handles the hardware cursor displayed by one of the video layers.)

To enable the video source transparency color key, set to 0x1 the DSS.DISPC_CONFIG[11] TCKLCDSELECTION bit for LCD output or the DSS.DISPC_CONFIG[13] TCKDIGSELECTION bit for digital output. Program the DSS.DISPC_CONFIG[10] TCKLCDENABLE bit (LCD output) or the DSS.DISPC_CONFIG[12] TCKDIGENABLE bit (digital output) to enable or disable the transparency color key.

An example is shown in [Figure 15-85](#): The video source transparency is applied on video1 (VID1) and video2 (VID2) layers. The pixels with the transparency color key are not displayed; instead, underlying layers are shown.

Figure 15-85. Video Source Transparency Example

dss-074

- Destination source transparency color key value

The destination transparency color key value defines the encoded pixels in the video layers to be displayed. The encoded pixel values with the destination color key value are pixels not visible on the screen because pixels at the same position in the video layers are visible. The destination transparency color key is applicable only in the graphics region when graphics and video overlap; otherwise, the destination transparency color key is ignored.

To enable the graphics destination transparency color key, set to 0x0 the DSS.DISPC_CONFIG[11] TCKLCDSELECTION bit for LCD output or the DSS.DISPC_CONFIG[13] TCKDIGSELECTION bit for digital output. Program the DSS.DISPC_CONFIG[10] TCKLCDENABLE bit (LCD output) or the DSS.DISPC_CONFIG[12] TCKDIGENABLE bit (digital output) to enable or disable the transparency color key.

An example is shown in Figure 15-86: The destination transparency is applied on graphics (GFX) layer and the pixels without the transparency color key are displayed over the overlying layers.

Figure 15-86. Destination Source Transparency Example

dss-075

- The following features are available in alpha mode:
Only the source transparency color key is available. The encoded graphics pixel color value is compared to the transparency color key. In the case of CLUT bit maps, the palette index is compared to the transparency color key and not the palette value pointed out by the palette index.

15.4.2.4.3 Overlay Optimization (Only Available in Normal Mode)

The display controller can be configured to take advantage of the fact that the graphics pixels under video window 1 are not visible when the transparency color key is not used. The optimization can be selected to reduce the bandwidth used to fetch the pixels for graphics. The color key must be disabled. The graphics pixels under the video window 1 are not fetched from system memory. At least the video window 1 and the graphics window must be enabled. The following graphic formats are supported: RGB (RGB16 and RGB24 packed and unpacked), YUV422, and BITMAP 8. The formats BITMAP 1, 2, and 4 are not supported. The video format can be RGB (RGB16, RGB24 packed and unpacked, and YUV422 formats). The DMA engine does not fetch the unnecessary graphics pixels to avoid extra bandwidth use. Only visible pixels from graphics and video buffers in system memory are fetched and displayed by the display controller.

15.4.2.5 Active/Passive Matrix Display Data Path

For active matrix display data path, the following blocks are serial and each of them can be bypassed:

- Color phase rotation
- Spatial/temporal dithering
- Multiple cycle data format

For passive matrix display data path, the following blocks are serial and each of them can be bypassed:

- Color phase rotation
- Spatial/temporal dithering
- Passive matrix technology

15.4.2.5.1 Color Phase Rotation

The Color Phase Rotation (CPR) can be used to correct the LCD output colorimetry in case of non pure white backlight.

The color phase rotation can be selected for passive matrix and active matrix panel. The logic is integrated after the LCD overlay manager or the palette while using the gamma correction and before the spatial/temporal dithering. The color phase rotation can be selected to correct the nonpure white backlight of the LCD module by using a programmable matrix to convert the 24-bit RGB pixel value into a new 24-bit RGB pixel value. The matrix is programmed through a set of nine 10-bit signed coefficients. The output of the calculation is clipped to [0:255]. The color phase rotation is processed by the equation shown in [Figure 15-87](#).

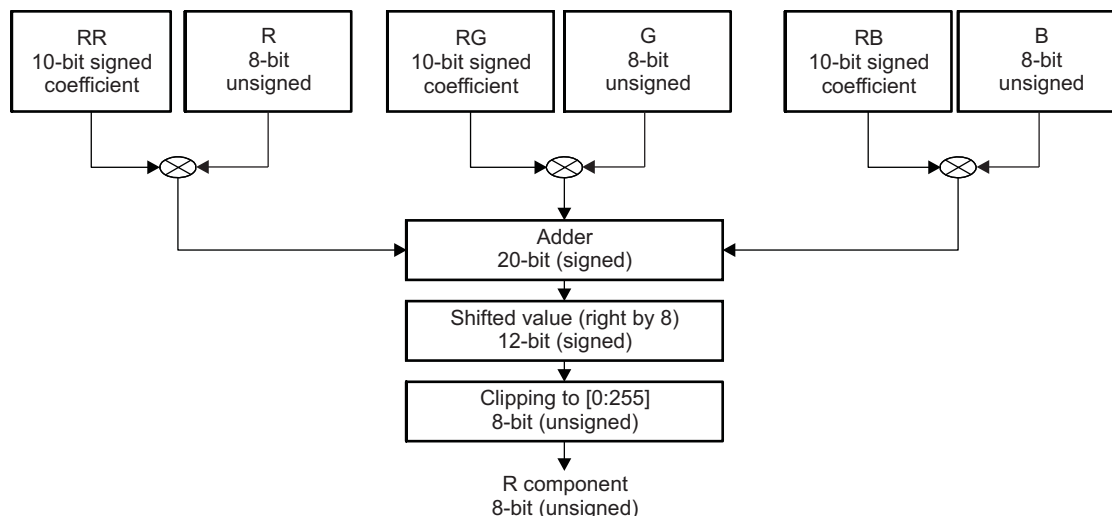

Figure 15-87. Color Phase Rotation Matrix

$$\begin{bmatrix} Rout \\ Gout \\ Bout \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RR & RG & RB \\ GR & GG & GB \\ BR & BG & BB \end{bmatrix} * \begin{bmatrix} Rin \\ Gin \\ Bin \end{bmatrix}$$

dss-E076

[Figure 15-88](#) shows the color phase rotation macro-architecture.

Figure 15-88. Color Phase Rotation Macro Architecture

dss-077

15.4.2.5.1.1 Spatial/Temporal Dithering

The spatial/temporal dithering logic can be selected for passive matrix and active matrix panel. The dithering logic is integrated after the color phase rotation and before the TDM and passive matrix units. The spatial/temporal dithering logic can be selected to enhance the quality of the passive matrix and active matrix outputs. The dithering logic can process the pixels over a single frame, two frames, or four frames. In the case of a single frame, only spatial processing is applied. In the case of multiple frames, spatial and temporal processing is applied to the pixels.

- **Passive Matrix Technology:** The passive matrix display dithering logic path is used. The spatial/temporal dithering logic can be selected. When selected, the pixels are preprocessed by the spatial/temporal dithering logic before the passive matrix display dithering logic. The output format of the spatial/temporal dithering logic is RGB 12-bit (not configurable).
- **Active Matrix Technology:** The encoded pixel values are used by spatial/temporal dithering logic to display the data in a lower color depth on the LCD panel. The spatial/temporal dithering algorithm is based on the (x,y) pixel position, the value of removed bits and the frame number. The picture quality is improved when enabling the spatial/temporal dithering logic. When spatial/temporal dithering is not enabled, the three MSBs of the pixel color components are output on the interface data bus if the interface data bus is smaller than the pixel format size. If the interface data bus is wider than the pixel format size, by programming the pixel components replication active/inactive, the MSB is replicated to the LSB of the interface data bus or the LSB is filled with 0s.

15.4.2.5.2 Passive Matrix Display Dithering Logic

- **Passive matrix technology**
After the graphics data are merged with the video data from the video layers depending on the transparency status, the result is sent to the color/grayscale space-/time-based dither generator. The monochrome data and each RGB color component are encoded on 4 bits, which are the 4 MSBs of the pixel-encoded component 8-bit value defined by the merge of the graphics data and the video data. These 4-bit values are used to select on the 16 intensity levels. The gray/color intensity is controlled by turning individual pixels on and off at varying period rates, making the average time the pixel is off longer than the average time the pixel is on, thus producing more intense grays/colors. The dithering generator also uses the intensity of adjacent pixels in the calculation to give the screen image a smooth appearance. The proprietary dither algorithm is optimized to provide a range of intensity values that matches the visual perception of color/gray graduations.
- **Active matrix technology**
The passive matrix dithering logic is always bypassed in active displays.

Note: If the interface data bus is smaller than the pixel format size, dithering logic can be enabled. If the interface data bus is wider than the pixel format size, the dithering logic cannot be enabled and replication feature can be used.

15.4.2.5.3 Passive Matrix Display Output FIFO

- Passive matrix technology
The display controller contains a 2-entry by 8-bit-wide output FIFO used to store pixel data before it is driven out to the LCD pins. Each time a modulated pixel value is output from the dither generator, it is placed into a serial shifter. The shifter can be configured to be 4 or 8 bits wide. Single-panel monochrome screens use either four or eight data lines; single-panel color screens use eight data pins.
- Active matrix technology
The output FIFO is bypassed in active matrix mode.

15.4.2.5.4 Multiple Cycle Output Format

The pixels after the active matrix display processing are formatted on one or multiple cycles (from one to three cycles). The interface width can be 8-, 9-, 12-, or 16-bit. On three cycles, two pixels can concatenate and send to the panel. When the TDM is disabled, the display controller outputs the pixels using the conventional formats: Passive matrix display/active matrix display monochrome/color.

The following example shows an output configuration based on the interface width (8-bit) and the pixel format output (24-bit) (also see [Table 15-26](#)):

- The DSS.DISPC_CONTROL[24:23] TDMCYCLEFORMAT field is set to 0x2 (three cycles for one pixel).
- The DSS.DISPC_DATA_CYCLEk (k=1) register is set to 0x00000008 (8 bits from pixel 1 for the first cycle).
- The DSS.DISPC_DATA_CYCLEk (k=2) register is set to 0x00000008 (8 bits from pixel 1 for the second cycle).
- The DSS.DISPC_DATA_CYCLEk (k=3) register is set to 0x00000008 (8 bits from pixel 1 for the third cycle).

Table 15-26. 8-Bit Interface Configuration/24-Bit Mode

	24-Bit Mode		
	1st Cycle	2nd Cycle	3rd Cycle
Data[7]	R0[7]	G0[7]	B0[7]
Data[6]	R0[6]	G0[6]	B0[6]
Data[5]	R0[5]	G0[5]	B0[5]
Data[4]	R0[4]	G0[4]	B0[4]
Data[3]	R0[3]	G0[3]	B0[3]
Data[2]	R0[2]	G0[2]	B0[2]
Data[1]	R0[1]	G0[1]	B0[1]
Data[0]	R0[0]	G0[0]	B0[0]

15.4.2.6 Video Line Buffer

The line buffer size is 1024 x 24-bit. There are six line buffers (1024 x 24-bit) that can be merged into three lines (2048 x 24-bit). [Table 15-27](#) lists the maximum width depending on the TAP configuration and the pixel format.

Table 15-27. Maximum Width Allowed

Vertical Tap	Pixel Format	Maximum Width (Pixels)
3	RGB16	2048
	RGB24	
	YUV422	
5	RGB16	1024
	RGB24	
	YUV422	

15.4.2.7 Synchronized Buffer Update

A synchronization mismatch between the frame buffer and the display refreshes, named tearing effect, can lead to images that appear to be stretched on the screen. To avoid this, a synchronization mechanism is needed between the display controller and the process that updates the buffer. An interrupt is generated when the display reaches a predefined line number. This PROGRAMMEDLINENUMBER interrupt is a level signal and stays active during the programmed line of the display.

15.4.2.8 Multiple Buffer Support

The user updates the base address of the buffer when the update of the working buffer has finished and is ready to be displayed. The register that contains the base address of the buffer is a shadow register that is read by the hardware at the next Vertical Front Porch (VFP).

15.4.2.9 Rotation

In case of SDRAM buffer, the display controller accesses the encoded pixels in burst, always considering the consecutive data in memory. The rotation engine (VRFB) in the SDRAM scheduler (SDRC) is in charge of translating the addresses from virtual to physical SDRAM addresses (see the *Memory Subsystem* chapter).

Note: It is highly recommended to use the VRFB Rotation engine when possible and not the Display Subsystem DMA engine for rotating frame buffer to have a good performance in the L3 interconnect and SDRAM memory efficiency.

The rotation using the SMS-VRFB rotation engine is supported for BITMAP8, RGB12 (16-bit container) and ARGB16, RGB16, ARGB16, RGB24 (using 32-bit container) and ARGB32 and RGBA32 and YUV422 (YUV2 and YUYV) . The formats not supported are BITMAP1, BITMAP2, BITMAP4 and RGB24 (using 24-bit container).

15.4.3 DSI Protocol Engine Functionalities

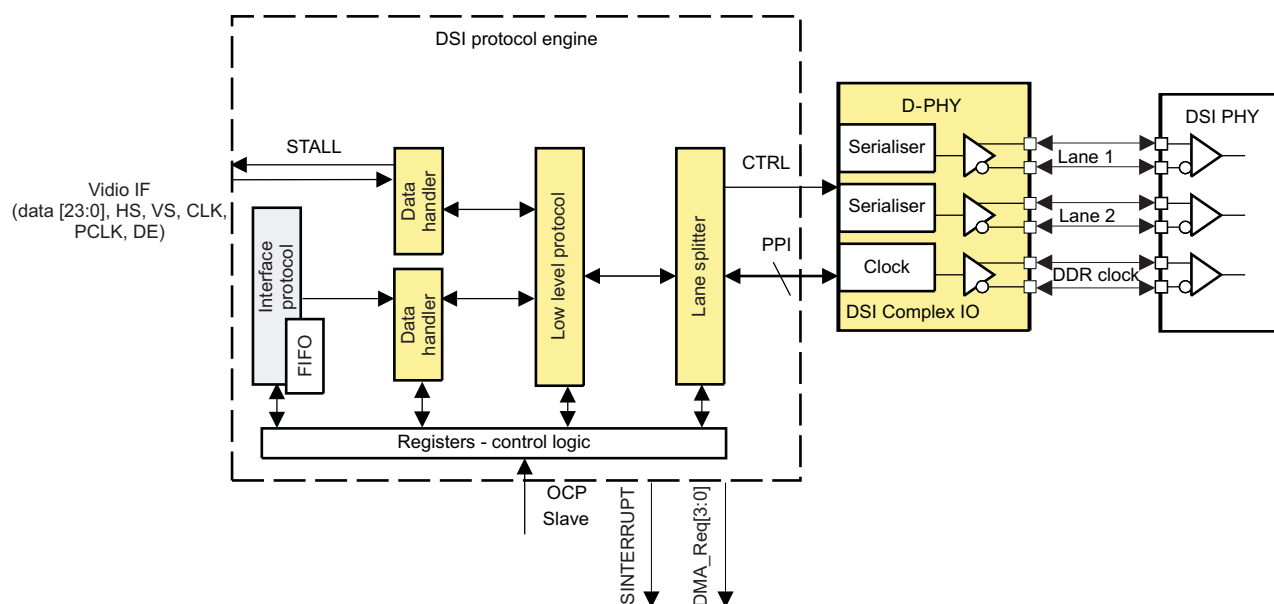

This section describes DSI module. This module is not available on all devices. See Chapter 1, the *OMAP35x Family* section, to check availability of this module.

The DSI protocol engine is based on the MIPI DSI specification v1.0. The DSI protocol engine integrates DSI interface to the display through the DSI D-PHY module, L4 interconnect interface and video interface from the display controller. The DSI D-PHY or complex I/O module is detailed in [Section 15.4.5](#). The interface between DSI protocol engine and DSI D-PHY is based on the PPI defined in the MIPI D-PHY specification. For more details, please refer to MIPI DSI1.0 specification. The DSI Transmitter (Protocol Engine + PHY) port can be connected to multiple displays using a single DSI host port. The DSI protocol engine controls the DSI PLL Control module detailed in [Section 15.4.4](#). The DSI Transmitter port can be used in video mode or/and command mode.

15.4.3.1 DSI Protocol Architecture

The DSI protocol engine receives data from the video port and/or the L4 interconnect slave port, encapsulates them with the virtual channel id, generates the ECC and check-sum, and splits the data into byte stream to the DSI PHY to be sent using the Low speed (LS) or High speed (HS) protocol. The DSI protocol engine receives data and acknowledge from the display using the same DSI link in case of bi-directional display. Multiple data streams can be interleaved to support multiple panels connected to the same host DSI port. [Figure 15-89](#) details the DSI protocol engine architecture.

Figure 15-89. DSI Protocol Engine

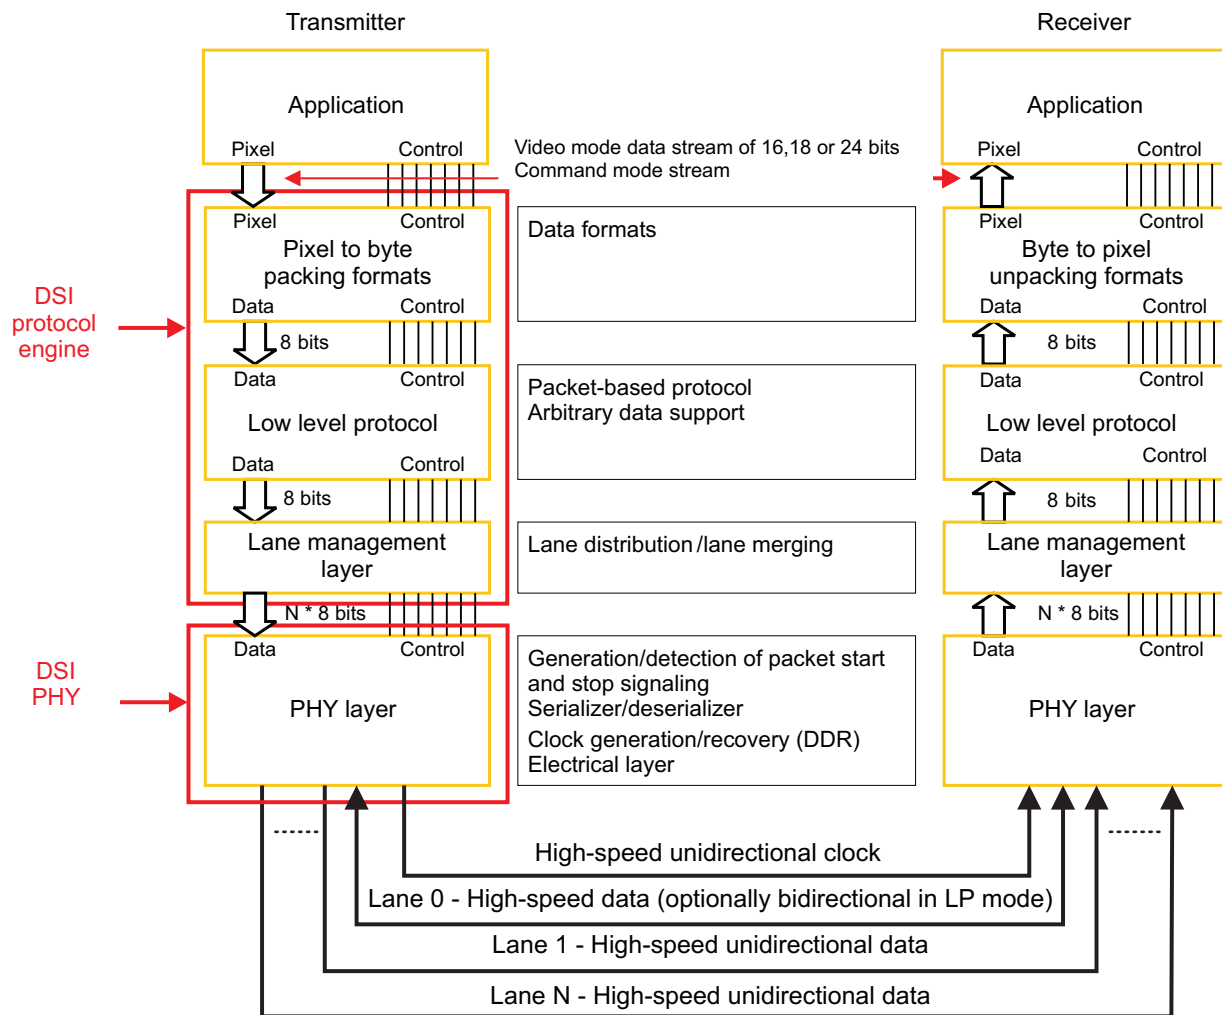

dss-166

Note: The order of the PHY pairs (clock and data lanes) is informative. Each PHY pair can be Clock or Data. The DSI complex I/O receives the configuration for pin order and the differential +/- in a pair from the settings in [DSS.DSI_COMPLEXIO_CFG1](#) register.

The DSI serial interface is a bi-directional differential serial interface with data/clock for the physical layer (configured in unidirectional link in case the display module is only unidirectional). The maximum DSI data transfer capacity is 800 Mbps per channel. The speed of the link can be software configured only when the DSI-PHY is in stop state or in ULPS.

[Figure 15-90](#) shows the DSI transmitter/receiver high-level data flow.

Figure 15-90. DSI Transmitter/Receiver Data Flow

dss-167

15.4.3.2 DSI Transfer Modes

There are two transfer modes supported by the DSI module:

- Video mode (VM): Pixels are received from the video port, there are some real time constraints (pixels should be sent at the pixel frequency required by the display module) for sending the data to the display;
- Command mode (CM): Pixels can be received from the video port or from the L4 interconnect, there are no real time constraints except that tearing effect should be avoided by starting the transfer at the right time during scan of the display and should be fast enough.

15.4.3.2.1 Video Mode

The video mode refers to the MIPI DPI standard. The sync events and pixels should be sent according to the display mode timings. Data are received from the video port. The display controller is in charge of fetching the data from the system memory and providing the data to the DSI protocol engine using the video port. The short packets used for the sync event are using precalculated 32-bit values. The long packets are constructed using the header defined in `DSS.DSI_VCn_LONG_PACKET_HEADER` registers.

15.4.3.2.2 Command Mode

The command mode refers to the MIPI DCS standard. The commands, parameters and pixels are sent to the display module with limited real time constraints (as defined in [Section 15.4.3.2.1](#)). The pixels can be provided on the video port by the display controller or on the L4 interconnect port.

The DSS.DSI_VCn_LONG_PACKET_HEADER registers are used for the header of long packets, the DSS.DSI_VCn_SHORT_PACKET_HEADER registers are used for the short packets.

The Error Correction Code (ECC) can be provided while writing the ECC value directly into the DSS.DSI_VCn_LONG_PACKET_HEADER and DSS.DSI_VCn_SHORT_PACKET_HEADER registers. The DSS.DSI_VCn_CTRL[8] ECC_TX_EN field indicates if the ECC value should be calculated or if the value written in the register should be used instead for command and video modes. In case of synchronization short packets for video mode, since the hardware generates the short packets without using DSS.DSI_VCn_SHORT_PACKET_HEADER registers, if the DSS.DSI_VCn_CTRL[8] ECC_TX_EN field is set to 1, the ECC is calculated otherwise the value zero is used. The feature is used to generate incorrect ECC for debug purpose and to ease the check for the link and peripheral error detection and correction.

For the payload, the DSS.DSI_VCn_LONG_PACKET_PAYLOAD registers are used. Each 32-bit PAYLOAD data is written into the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register from the MPU subsystem or system DMA. It is buffered to be able to send packets with higher rate than the L4 interconnect frequency can provide. The word count defined in the DSS.DSI_VCn_LONG_PACKET_HEADER registers is used to determine the number of bytes to be sent using the DSS.DSI_VCn_LONG_PACKET_PAYLOAD registers. The write into the DSS.DSI_VCn_LONG_PACKET_HEADER registers is required before accessing the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register. The hardware should be able to extract the length of the payload and be able to discard extra data sent using the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register. The hardware takes into account the write into the DSS.DSI_VCn_LONG_PACKET_HEADER register only if the virtual channel is enabled otherwise the write is ignored by hardware.

In the case of pixels received on the video port, only the DSS.DSI_VCn_LONG_PACKET_HEADER register is used. The video port pixels are used for the payload.

15.4.3.2.3 Video + Command Modes

The two modes can be interlaced to send two DSI streams to two types of panels: Video or command types. The number of concurrent video stream is limited to a single one. The number of concurrent command mode streams is limited to 4 when there is no video stream and 3 otherwise. In case there is one DSI stream using video mode, the command mode pixels should be provided on the L4 interconnect only.

15.4.3.2.4 Burst Modes

- **Frequency-burst mode** The frequency-burst mode is used to reduce the High-Speed (HS) period by increasing the clock frequency on the DSI link. It allows in some case, the power consumption reduction of the link. The non-HS period used typically to drive the main panel can be used to send data to the secondary panel or to allow feedback (acknowledge) from the primary and secondary panels. The DSI protocol engine needs to buffer a full line before sending the HS packets for the line. A double buffering mechanism is required to be able to send a line while the following one is being received on the video port.
- **Transparent-burst mode** The transparent-burst mode is used by increasing the pixel clock frequency generated by the display controller with in addition an increase of the horizontal blanking period.

15.4.3.3 Clock Requirements

The serial clock generated by the DSI host and sent to the display can be a continuous clock. The clock lane supports clock transmission even there is no data to send for displays that require continuous clock. It is software programmed through the DSS.DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit: This bit can be programmed only when the interface is disabled (that is, DSS.DSI_CTRL[0] IF_EN bit set to 0).

The peripheral can use two different kinds of clocks. The first one is the DDR clock provided on the clock lane. The second clock is some transitions on the data lane 1 even if there is no valid data to send using low power mode.

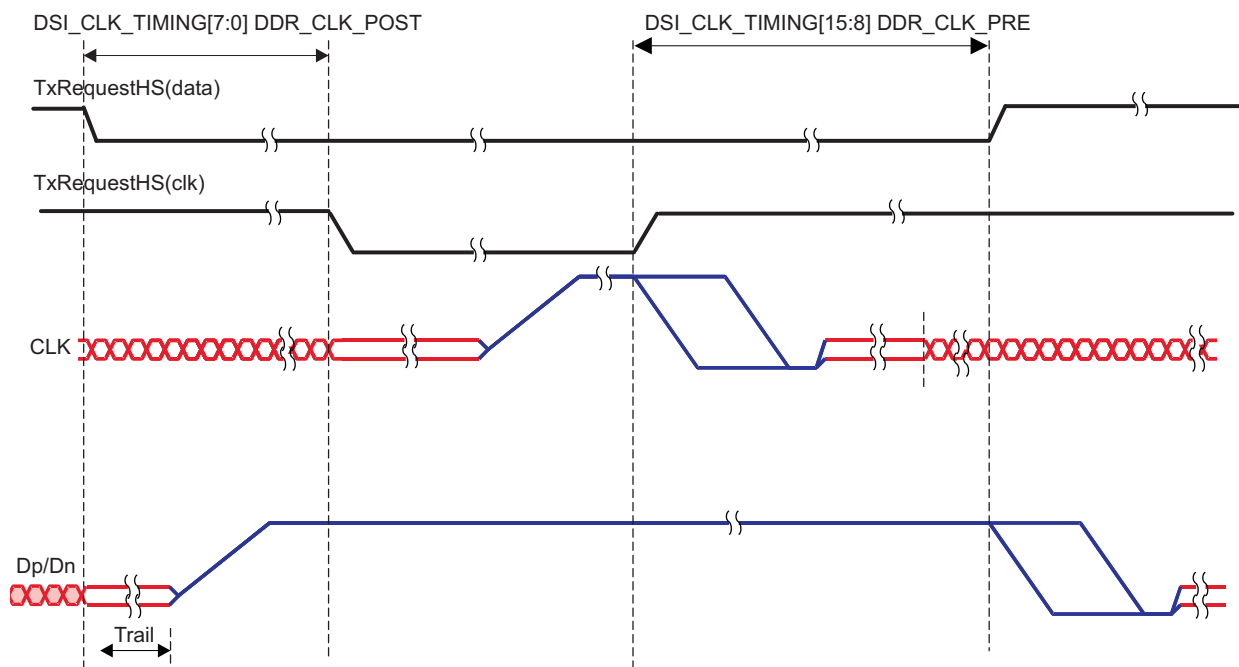

The LP clock (TxClkEsc) frequency provided to the DSI complex I/O is in the range of 67% to 150% of the peripheral Low-Power (LP) clock frequency. It is generated internally by the DSI protocol engine module using the DSI functional clock. The DSI functional clock is divided by 1, 2, 3, up to 8191 using the value programmed in the DSS.DSI_CLK_CTRL[12:0] LP_CLK_DIVISOR field. The LP clock generated from DSI functional clock should be in the range of 20 MHz down to 32 KHz. The duty cycle should be 50/50 (tolerance of 45/55 for maximum value).

The DSS.DSI_CLK_CTRL[20] LP_CLK_ENABLE bit is used to enable or disable the clock. When disabled, the value of DSS.DSI_CLK_CTRL[12:0] LP_CLK_DIVISOR field is ignored and does not need to be programmed by the software user.

15.4.3.3.1 DDR Clock Timing

This section describes the timing requirement when starting/stopping the DDR clock when the data lane state changes between LP to HS.

Figure 15-91. DDR Clock Start/Stop Timing

dss-168

Note: Delays between assertion/deassertion of PPI signals (TxRequestHS) and DSI complex I/O output are programmed by settings the DSS.DSI_CLK_TIMING[15:8] DDR_CLK_PRE and DSS.DSI_CLK_TIMING[7:0] DDR_CLK_POST fields

The DSS.DSI_CLK_TIMING[7:0] DDR_CLK_POST field value is used between deassertion of the Data request signal (TxRequestHS) for all enabled data lanes and DDR request signal (TxRequestHS) for the clock lane.

The DSS.DSI_CLK_TIMING[15:8] DDR_CLK_PRE field value is used between assertion of the DDR request signal (TxRequestHS) corresponding to the clock lane and the assertion of the Data request signal (at least one of the TxRequestHS for enabled data lanes)

15.4.3.3.2 Extra LP Transitions

Some DSI receivers require extra clock cycles in LP mode to process the data. The DSI protocol engine can be programmed to send automatically one NULL long packet. It applies only when no more data are ready to be sent from the internal FIFO to the peripheral on the last low speed transfer. The same value is used for all the virtual channels sending packets in low speed mode.

The size of the payload is defined by the DSS.DSI_CLK_CTRL[17:16] LP_NULL_PACKET_SIZE field. The header value depends on the virtual channel (VC) ID and the size of the payload as detailed in Table 15-28 and Table 15-29.

Table 15-28. Extra NULL Packet Header

Virtual Channel ID	Payload size (DSI_CLK_CTRL[17:16] LP_NULL_PACKET_SIZE)	Header (1st byte)	Header (2nd byte): WC LSB	Header (3rd byte): WC MSB	Header (ECC)
0x0	0	0x9	0x0	0x0	0x9
	1		0x1		0x13
	2		0x2		0x2F
	3		0x3		0x35
0x1	0	0x49	0x0		0x1F
	1		0x1		0x05
	2		0x2		0x39
	3		0x3		0x23
0x2	0	0x89	0x0		0x10
	1		0x1		0x0A
	2		0x2		0x36
	3		0x3		0x2C
0x3	0	0xC9	0x0		0x06
	1		0x1		0x1C
	2		0x2		0x20
	3		0x3		0x3A

Table 15-29. Extra NULL Packet Payload

Payload size (DSI_CLK_CTRL[17:16] LP_NULL_PACKET_SIZE)	Payload (1st byte)	Payload (2nd byte)	Payload (3rd byte)	Payload (CRC) LSB	Payload (CRC) MSB
0	NA	NA	NA	0xFF	0xFF
1	0	NA	NA	0x87	0x0F
2	0	0	NA	0xB8	0xF0
3	0	0	0	0x33	0x39

Notes:

- In Table 15-28 and Table 15-29, both ECC and checksum are enabled
- NA stands for not available

15.4.3.4 Power Management

The DSI protocol engine implements an handshake protocol on its L4 interconnect port with the PRCM. The DSI protocol engine provides a clock gating signal CIO_CLK_ICG to gate the L3 interface clock (L3_ICLK) provided by the PRCM to the DSI complex I/O. It allows reduction of the power consumption of the DSI complex I/O while the DSI link is not in used. To gate the L3_ICLK clock at DSI complex I/O level, set the DSS.DSI_CLK_CTRL[14] CIO_CLK_ICG bit to 1.

15.4.3.5 Serial Configuration Port (SCP) Interface

The SCP interface is used to transfer register values from the DSI protocol engine to the DSI PLL Control module and to the DSI complex I/O. It spends several cycles to serialize the data to be sent. Software users should take into account the delay in processing the transfer of the data from/to the slave port to/from the module.

15.4.3.5.1 Shadowing Register

The two first SCP registers for the DSI complex I/O address map should be implemented as shadow registers. The shadowing mechanism is enabled/disabled using the DSS.DSI_COMPLEXIO_CFG1[31] SHADOWING bit:

- When setting the DSS.DSI_COMPLEXIO_CFG1[31] SHADOWING bit to 1, the transfer of the values from the two first L4 interconnect port registers into the two first registers of the DSI complex I/O (DSS.DSIPHY_CFG0 and DSS.DSIPHY_CFG1) is done only when the DISPC_UPDATE_SYNC signal from the display controller is active and the DSS.DSI_COMPLEXIO_CFG1[30] GOBIT is set to 1. If there is no pending update for the two registers, when the DISPC_UPDATE_SYNC signal is asserted, the DSS.DSI_COMPLEXIO_CFG1[30] GOBIT bit is reset by hardware and there is no SCP transfer.
 - If there is only one register to update, only the corresponding new value is transferred. The second register in the DSI complex I/O is not updated. When the transfer is completed, the DSS.DSI_COMPLEXIO_CFG1[30] GOBIT is reset by hardware.
 - If the two registers need to be updated, the order of the transfer is first the register with lower address and then the second one. When the transfers are completed, the DSS.DSI_COMPLEXIO_CFG1[30] GOBIT is reset by hardware.

When there is an on-going transfer (read or write) to any SCP register, the transfer should complete prior to start the update of shadowing registers.

- When unsetting the DSS.DSI_COMPLEXIO_CFG1[31] SHADOWING bit to 0, if the transfer into the two first DSI complex I/O registers has already started, it should be finished

Note: When reading the shadow registers, the local value stored in the DSI protocol engine is returned if the update is pending otherwise the values stored in the DSI complex I/O are returned.

15.4.3.5.2 Busy Signal

The signal SCPBusy indicates that there is still some activity using the SCPClk provided by the PRCM. The SCPClk clock is the DSS_L3_ICLK clock.

15.4.3.6 Power Control

The DSI protocol engine can control and send power commands for both DSI complex I/O and DSI PLL controller modules.

15.4.3.6.1 Complex I/O Power Control Commands

15.4.3.6.1.1 Complex I/O Power Control Commands

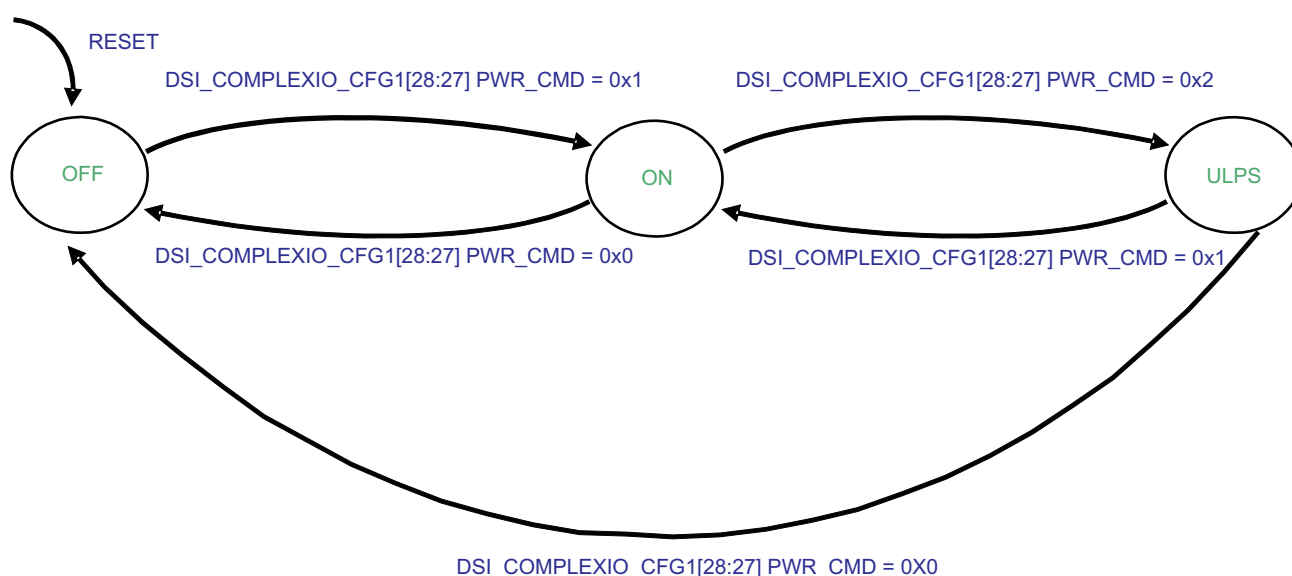

The DSI complex I/O can be set into three modes:

- **OFF:** In this power state, the complete DSI-PHY circuit is powered down. The internal LDO is OFF.
- **ON:** In this power state, the complete DSI-PHY circuit is powered on and functional.
- **Ultra Low Power State (ULPS):** In this power state, the ULPS exit detection circuit power switch is ON for the lanes which are in receive ULPS mode. For the lanes which are in transmit ULPS mode, the circuitry for weak pull-down is ON. The ultra low power state should only be used when all the three lanes are in ULPS (transmit or receive).

15.4.3.6.1.2 Complex I/O Power FSM

Figure 15-92 describes the power control FSM to control the power state of the complex I/O.

Figure 15-92. Complex I/O Power FSM

dss-169

The PwrCmdOff, PwrCmdUlp and PwrCmdOn commands control the state transition of the DSI complex I/O. Software users should set the DSS.DSI_COMPLEXIO_CFG1[28:27] PWR_CMD field to ask for a state change. The allowed transitions are: OFF -> ON and ON -> ULP and ULP -> OFF. The DSS.DSI_COMPLEXIO_CFG1[26:25] PWR_STATUS field gives a status on the current state of the DSI complex I/O.

CAUTION

- In automatic mode, the software should ensure that the DSI complex I/O in the ON mode (that is, ON command already sent) before sending requests to the complex I/O.
- In a command request to change to a state which is the current one (acknowledge has been received), the command is ignored (nothing is sent to the DSI complex I/O).
- To change state to ULP state, the user should ensure that all the three ULPSActiveNot signals are low. The ULPSActiveNot_ALL0_IRQ interrupt can be used by the software user to determine the state of the ULPSActiveNot signals. The change from ULP to ON state is required before starting the ULP exit sequence (refer to [Section 15.4.3.7.1](#) for details).

15.4.3.6.2 DSI PLL Power Control Commands

The DSI PLL controller module can be set into four modes:

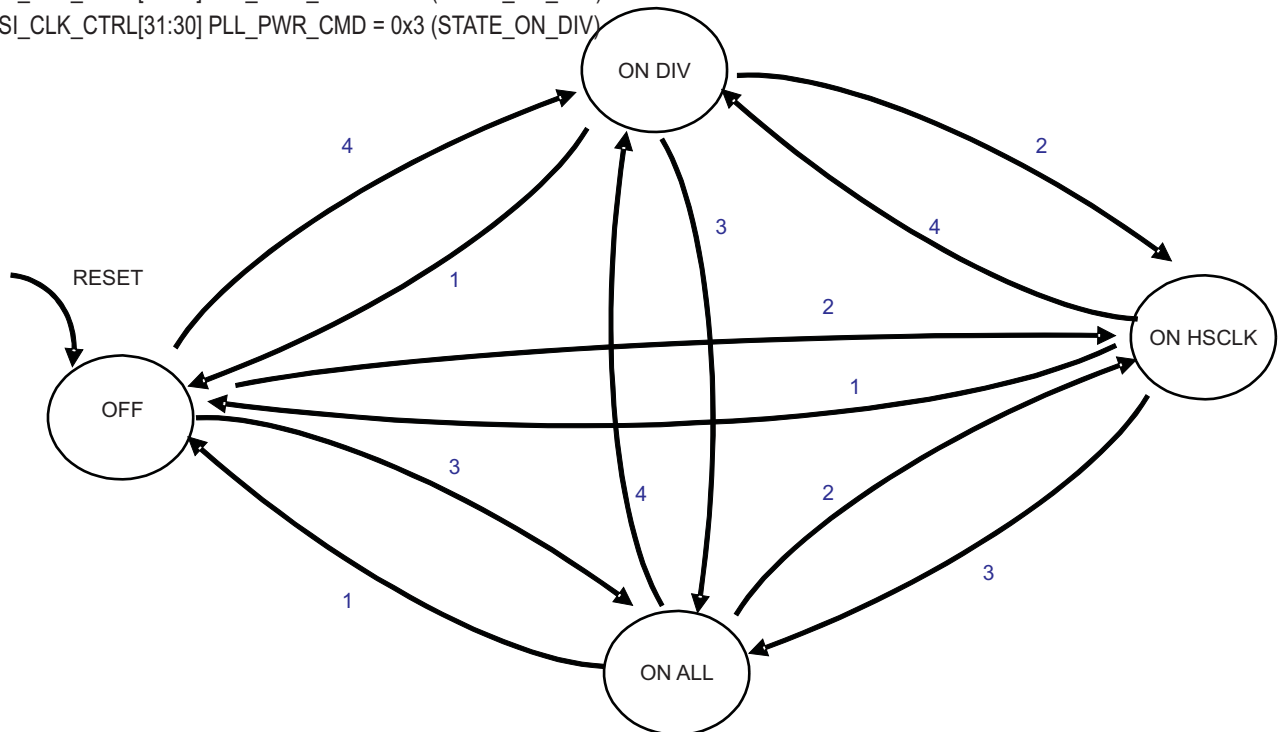

- OFF: The DSI PLL and HSDIVIDER are OFF.
- ON ALL: Both DSI PLL and HSDIVIDER are ON. The HS_CLK clock is provided to the DSI complex I/O and the second clock output is provided to the HSDIVIDER.
- ON HSCLK: The DSI PLL is ON. The HSDIVIDER is OFF. The HS_CLK clock is provided to the DSI complex I/O but the second clock output is not provided to the HSDIVIDER.
- ON DIV: Both DSI PLL and HSDIVIDER are ON. The HS_CLK clock is not provided to the DSI complex I/O but the second clock output is provided to the HSDIVIDER.

15.4.3.6.2.1 DSI-PLL Power FSM

Figure 15-93 shows the DSI PLL power FSM.

Figure 15-93. DSI PLL Power FSM

- 1 = DSI_CLK_CTRL[31:30] PLL_PWR_CMD = 0x0 (STATE_OFF)
 2 = DSI_CLK_CTRL[31:30] PLL_PWR_CMD = 0x1 (STATE_ON_HSCLK)
 3 = DSI_CLK_CTRL[31:30] PLL_PWR_CMD = 0x2 (STATE_ON_ALL)
 4 = DSI_CLK_CTRL[31:30] PLL_PWR_CMD = 0x3 (STATE_ON_DIV)

dss-170

The commands PLLPwrCmdOff, PLLPwrCmdOnAll, PLLPwrCmdOnDIV and PLLPwrCmdOnHSCLK controls the state transition of the DSI PLL control module. Software users should set the DSS.DSI_CLK_CTRL[31:30] PLL_PWR_CMD field to ask for a state change. The DSS.DSI_CLK_CTRL[29:28] PLL_PWR_STATUS field gives a status on the current state of the DSI PLL controller.

Note: In a command requests to change to a state which is the current one (acknowledge has been received), the command is ignored (nothing is sent to the DSI PLL Control module).

All the DSI PLL power is controller by the DSI protocol engine except the LDO power of the PLL and HSDIVIDER that can be controlled by the DSI PLL controller module. Indeed, the HSDIVIDER and PLL

SYSRESET signals can be forced by the DSI PLL controller module by setting respectively DSS.DSI_PLL_CONTROL[4] DSI_HSDIV_SYSRESET and DSS.DSI_PLL_CONTROL[3] DSI_PLL_SYSRESET fields. By setting these bits to 1, the SYSRESET signal is forced active (module is forced at reset state). When these bits are set to 0 (reset value), the SYSRESET signals are controlled by the DSI PLL power FSM.

15.4.3.6.2.1.1 DSI-PLL HS Clock Signals

The signal DSISStopClk is provided to the DSI PLL Control module. It indicates when the DSI Protocol engine does not need to use the High Speed transfer mode (HS mode) and PLL HS output (HS_CLK clock) can be stopped. The following conditions must also be met when DISPC_UPDATE_SYNC may be generated by the Display Controller, as that may also result in the PLL HS output being stopped.

When the interface is disabled (that is, DSS.DSI_CTRL[0] IF_EN bit set to 0), the signal DSISStopClk is asserted.

The assertion of the DSISStopClk depends on the following conditions:

- Clock lane TxRequestHS is deasserted (the DDR clock on the clock lane is not required anymore). The get TxRequestHS deassertion, all of the following conditions are required:
 - The DSS.DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit must be reset to 0 and no HS data transfer should be on going or already scheduled
 - No virtual channel active in video mode. No virtual channel using the video mode is enabled; if the virtual channel is enabled, the mode is command mode only (that is, DSS.DSI_VCn_CTRL[0] VC_EN bit set to 1 and DSS.DSI_VCn_CTRL[4] MODE bit set to 0)
 - No command mode requiring High speed transfer (one or more virtual channels using command mode can be active)
 - Or DSS.DSI_CTRL[0] IF_EN bit reset to 0 (if all previous conditions are not required)

The deassertion of the DSISStopClk depends on one of the following conditions (the DSI interface is enabled by setting the DSS.DSI_CTRL[0] IF_EN bit to 1):

- Clock lane TxRequestHS needs to be asserted (the DDR clock on the clock lane is required anymore).
- One video mode virtual channel active
- At least one virtual channel in command mode requiring High speed transfer
- The DSS.DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit is set to 1 by the software user (the DSS.DSI_CTRL[0] IF_EN bit should be reset to 0 for updating the DDR_CLK_ALWAYS_ON bit value)

The automatic assertion/deassertion is enabled by using the DSS.DSI_CLK_CTRL[18] HS_AUTO_STOP_ENABLE bit.

The manual mode can be used by setting/resetting the DSS.DSI_CLK_CTRL[19] HS_MANUAL_STOP_CTRL bit to assert/deassert the DSISStopClk signal.

15.4.3.6.2.1.2 DSI-PLL HS Clock FSM

Figure 15-94 shows the DSI PLL HS clock FSM.

Figure 15-94. DSI PLL HS Clock FSM

dss-171

When DSIStopClock is used there is a latency through other modules (DSI PLL controller and DSI-PHY) before TxByteClkHS is stopped. This latency needs to be accounted for to prevent any issue when DSIStopClock is deasserted soon after being asserted. This is done using a hardware timer programmed using the DSS.DSI_STOPCLK_TIMER[7:0] DSI_STOPCLK_LATENCY field. This timer is programmed in number of periods of the DSI Protocol functional clock (DSI_FCLK). At reset value, the timer is programmed with 0x80 (128) value.

CAUTION

The programmed value in DSS.DSI_STOPCLK_TIMER[7:0] DSI_STOPCLK_LATENCY field must be greater than: $((3 \times L3_ICLK \text{ period}) + (5 \times CLKIN4DDR \text{ period})) / (DSI_FCLK \text{ period})$

15.4.3.7 Timers

Note: Among the timers described in this section, only the HS TX, LP RX and turnRequests timers generates interrupts immediately when the timer value is null. For ForceTxStopMode timer, it ends counting instantly and ForceTxStopMode is not asserted.

15.4.3.7.1 Twakeup Timer

The T_{WakeUp} timer is not implemented in the DSI Protocol engine. The software must use general-purpose timer (GPTimer) to handle this. This timer is used for exiting ULP mode for the active lanes (clock and/or data lanes). The sequence to exit ULP is:

1. change the state of TxULPSExit for each lane to active
2. wait for the interrupt indicating that all lanes with TxULPSExit active have acknowledged by asserting ULPSActiveNot. This is done by reading the DSS.DSI_COMPLEXIO_IRQSTATUS ULPSACTIVENOT_ALLi_IRQ fields ($i = 0, 1$).

3. start the application wake-up timer (GPtimer)
4. wait for the time-out
5. change TxUlpsClk signals to in-active state for the clock lane and/or TxRtequestEsc in-active state for the data lane(s)

Note: The minimum time for the wake-up period is 1 ms.

To enter ULPS mode for clock lane, TxUlpsClk state should be change to active state. To enter ULPS mode for data lane, TxRequestEsc state should be changed to active state (TxUlpsEsc as well if it is not in active state already).

15.4.3.7.2 ForceTxStopMode FSM

The signal ForceTxStopMode is used at initialization time (DSI complex I/O). [Figure 15-95](#) describes the ForceTxStopMode FSM to assert/deassert ForceTxStopMode signal.

The DSI protocol engine asserts ForceTxStopMode by setting the DSS.DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO bit to 1. This bit can be reset by software or automatically by hardware when the time-out occurs.

At the same time the signal is asserted, the FSM asserts ForceTxStopMode signal. When the timer period is finished or the bit field DSS.DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO is reset by software, the ForceTxStopMode signal is deasserted.

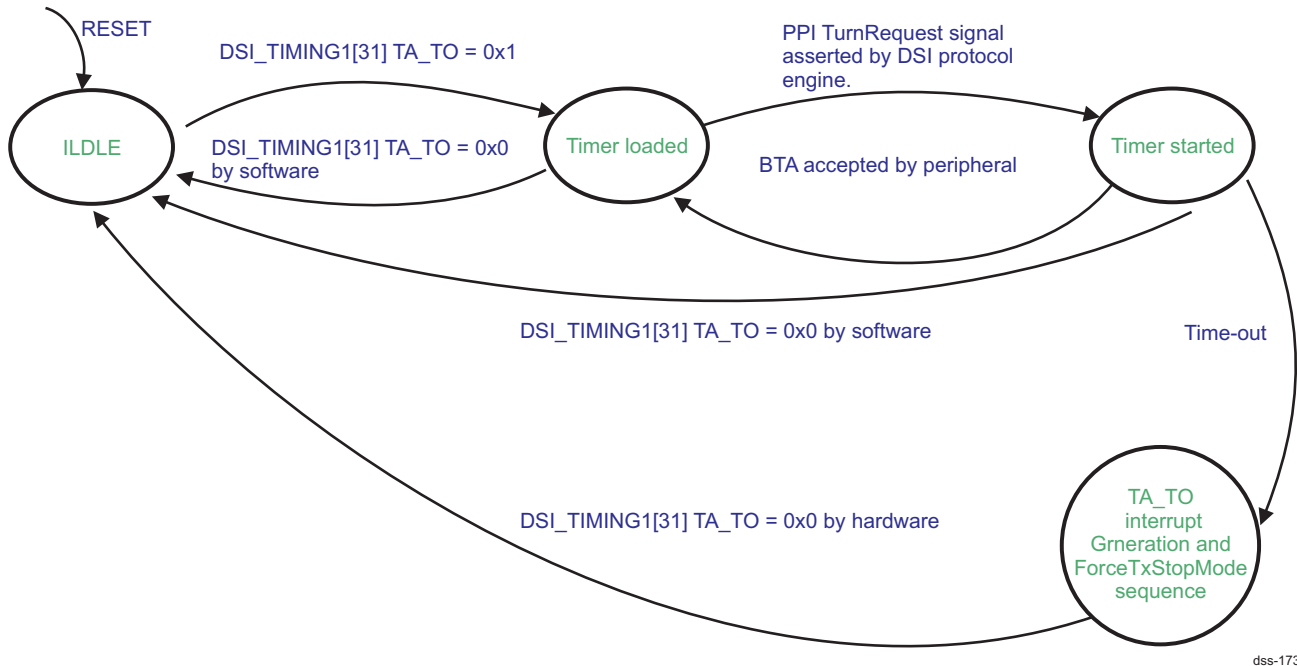

The calculation of the number of DSI_FCLK cycles assertion period is defined by:

Total period in DSI_FCLK cycles = DSI_TIMING1[12:0] STOP_STATE_COUNTER_IO x ((DSI_TIMING1[14] STOP_STATE_X16_IO x 15) + 1) x ((DSI_TIMING1[13] STOP_STATE_X4_IO x 3) + 1)

15.4.3.7.3 TurnRequest FSM

The signal TurnRequest is used to request turnaround. It is only valid for the data lane #1 since the other data lanes can not be used in the reverse direction to receive data from the DSI receiver. [Figure 15-96](#) describes the TurnRequest FSM to assert/deassert TurnRequest signal.

Figure 15-96. TurnRequest FSM

dss-173

The DSI protocol engine asserts TurnRequest signal during one TxClkEsc cycle when the turn-around is enabled. The DSS.DSI_TIMING1[31] TA_TO bit is set/reset by software to respectively enable/disable the timer for turnaround procedure failure. It can be reset by software or automatically by hardware when the time out occurs.

The timer is loaded with the value in number of DSI_FCLK cycles:

$$\text{DSI_TIMING1}[28:16] \text{ TA_TO_COUNTER} \times ((\text{DSI_TIMING1}[30] \text{ TA_TO_X16} \times 15) + 1) \times ((\text{DSI_TIMING1}[29] \text{ TA_TO_X8} \times 7) + 1).$$

When the interrupt is generated, the hardware should automatically assert ForceTXStopMode in order for the DSI-PHY to drive LP-11 stop state. The ForceTXStopMode timer is used to define the minimum duration of LP-11 state. The Stop State can be longer if there is no activity.

The hardware resets the ForceTXStopMode bit, followed by an internal logic reset except all register values and TX FIFO content, then resets the DSS.DSI_CTRL[0] IF_EN bit. The software should take action to recover by resetting the peripheral, for example, if it is not responding. It should wait for DSS.DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO and DSS.DSI_CTRL[0] IF_EN bits to be reset to 0 before starting the recovery sequence.

15.4.3.7.4 Peripheral Reset Timer

The peripheral reset timer is not implemented in the DSI protocol engine module. Such as the Twakeup timer, a general-purpose timer (GPTimer) should be used in case of reset of the peripheral to determine when the peripheral is ready again for operation.

15.4.3.7.5 HS TX Timer

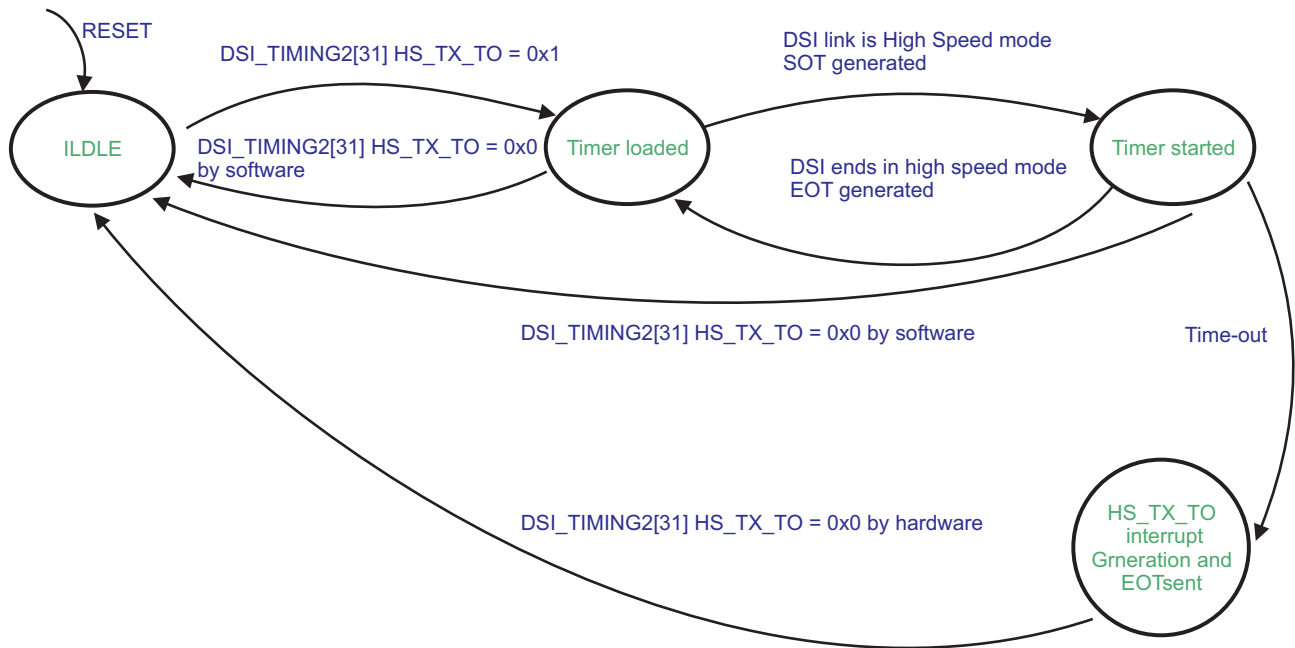

The HS TX timer is used to detect when the host has been in TX mode for too long. When time-out occurs, the EOT is forced. The timer is reloaded when a start of high speed transmission occurs. It is enabled/disabled by software through the DSS.DSI_TIMING2[31] HS_TX_TO bit. The interrupt HS_TX_TO_IRQ is generated when the timer expires. The DSS.DSI_IRQSTATUS[14] HS_TX_TO_IRQ bit is set to 1 when the HS TX time-out occurs.

The maximum time to be supported is 20 ms. It can be used to determine that at least once a frame in video mode, the HS mode is stopped to enter ULPS. Since the refresh rate can be up to 50 frames per second in video mode, the maximum time in HS is 20 ms.

The timer is loaded with the value in number of TxByteClkHS:

DSI_TIMING2[28:16] HS_TX_TO_COUNTER x ((DSI_TIMING2[30] HS_TX_TO_X16 x 15) + 1) x ((DSI_TIMING2[29] HS_TX_TO_X8 x 7) + 1)

Figure 15-97. High-Speed TX Timer FSM

dss-174

When the time-out occurs, the hardware should send EOT request in order for the DSI complex I/O to drive LP-11 stop state. This is followed by the generation of the interrupt. The hardware will perform an internal logic reset including the TX FIFO content, but excluding the register values and then resets the DSS.DSI_CTRL[0] IF_EN bit.

The software should wait for the DSS.DSI_CTRL[0] IF_EN bit to be reset to 0 before taking any recovery action by resetting for example the peripheral if it is not responding.

15.4.3.7.6 LP RX Timer

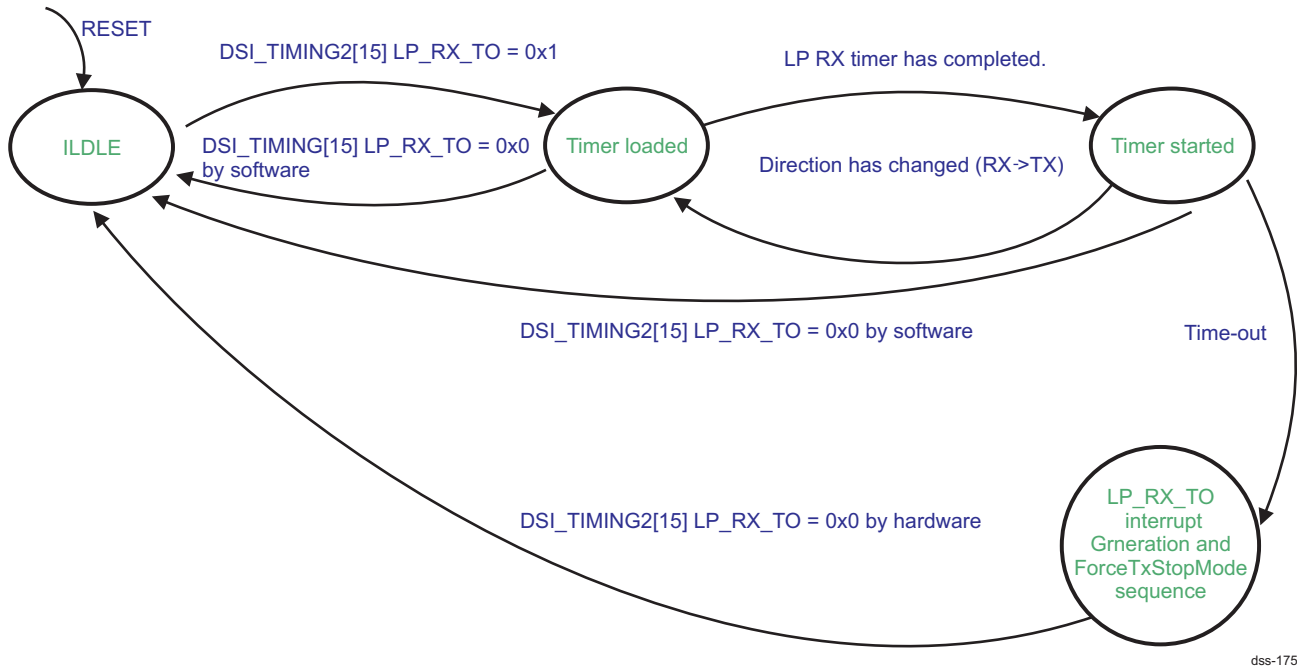

When the host is in Low power Receive mode after a bus turn-around, the LP RX timer is loaded. When the timer expires, the host requests the DSI complex I/O to drive LP-11. The interrupt LP_RX_TO_IRQ is generated when the timer expires. The DSS.DSI_IRQSTATUS[15] LP_RX_TO_IRQ bit is set to 1 when the LP RX time-out occurs.

The DSS.DSI_TIMING2[15] LP_RX_TO bit is set/reset by the software to respectively enable/disable the timer.

The timer is loaded with the value in number of DSI_FCLK cycles:

DSI_TIMING2[12:0] LP_RX_TO_COUNTER x ((DSI_TIMING2[14] LP_RX_TO_X16 x 15) + 1) x ((DSI_TIMING2[13] LP_RX_TO_X4 x 3) + 1)

Figure 15-98. Low-Power RX Timer FSM

dss-175

When the interrupt is generated, the hardware should automatically reset the DSS.DSI_TIMING2[15] LP_RX_TO bit and then assert ForceTxStopMode in order for the DSI complex I/O to drive LP-11 stop state. The ForceTxStopMode timer is used to define the minimum duration of LP-11 state. The Stop State can be longer if there is no activity.

The hardware resets the ForceTxStopMode bit, followed by an internal logic reset except all register values and TX FIFO content, then resets the DSS.DSI_CTRL[0] IF_EN bit. The software should take action to recover by resetting the peripheral, for example, if it is not responding. It should wait for the DSS.DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO and DSS.DSI_CTRL[0] IF_EN bits to be reset before starting the recovery sequence. The TX FIFO is not flushed (the FIFO is flushed only when DSS.DSI_VCn_CTRL[0] VC_EN is set to 1).

15.4.3.8 Bus Turnaround

The bus turn-around (BTA) is not automatically sent by default after each packet sent to the display(s). It is programmable independently for each virtual channel ID. The virtual channel can be enabled when DSS.DSI_VCn_CTRL[6] BTA_EN bit is set to 1 by software. The software should ensure that, when the BTA is sent to the peripheral, there is enough time allocated for the response and the BTA from the peripheral to host. When setting the DSS.DSI_VCn_CTRL[6] BTA_EN bit to 1, one BTA is sent manually to the peripheral. This manual mode can be used for packets in command or video mode.

CAUTION

The BTA should not be sent when the RX FIFO is not empty. The user should take care of emptying the RX FIFO before sending BTA to the peripheral. It is to ensure that when receiving new data from peripheral, all the allocated spaces for all the virtual channels are empty.

In automatic mode, the BTA is sent automatically at the end of short or long packets when respectively the DSS.DSI_VCn_CTRL[2] BTA_SHORT_EN or the DSS.DSI_VCn_CTRL[3] BTA_LONG_EN bits are set to 1.

Note: If the DSS.DSI_VCn_CTRL[2] BTA_SHORT_EN bit is enabled, the user can still set the DSS.DSI_VCn_CTRL[6] BTA_EN bit. Only one BTA is sent to the peripheral and the DSS.DSI_VCn_CTRL[6] BTA_EN bit is reset by hardware.

If the DSS.DSI_VCn_CTRL[3] BTA_LONG_EN bit is enabled, the user can still set the DSS.DSI_VCn_CTRL[6] BTA_EN bit. Only one BTA is sent to the peripheral and the DSS.DSI_VCn_CTRL[6] BTA_EN bit is reset by hardware.

If the DSS.DSI_VCn_CTRL[2] BTA_SHORT_EN and DSS.DSI_VCn_CTRL[3] BTA_LONG_EN bits are both enabled, the user can still set the DSS.DSI_VCn_CTRL[6] BTA_EN bit to send a BTA. Only one BTA is sent and the DSS.DSI_VCn_CTRL[6] BTA_EN bit is reset by hardware.

As explained previously, two modes can be used for each virtual channel ID:

- **Automatic:** After each packet, a bus turn-around is sent. To determine the size of the long packet, the protocol engine on the host side should read the word count defined in the header (in DSS.DSI_VCn_LONG_PACKET_HEADER register) and use it to determine the last data to be sent on the DSI link. For short packets, the size is always 4 bytes. Then the bus turn-around is sent to the peripheral. The word count is also used to determine how many bytes should be transferred from the 32-bit writes access to the payload register (DSS.DSI_VCn_LONG_PACKET_PAYLOAD register).
- **Manual:** In case of data transfer using the L4 interconnect port, while all data have been provided to the DSI protocol engine, the user can select bus turn-around for the last packet provided to the L4 interconnect port only by setting the bus turn-around enable bit (DSS.DSI_VCn_CTRL[6] BTA_EN) or for last packets and following ones by setting the automatic mode; in case of data transfer using the video port, the bus turnaround enable bit (DSS.DSI_VCn_CTRL[6] BTA_EN) can be selected at any time during the transfer of the packet. In case of video mode packets (data and synchronization events) the user can not determine when the BTA is sent relatively the video mode packets, so it is highly recommended to use manual BTA mode only for packets generated in command mode but it is possible to use BTA when for a virtual channel in video mode. In case of data provided on the video port, an interrupt for end of packet transfer (PACKET_SENT_IRQ) is provided to the user to know when the packet has been completely sent by the DSI complex I/O. The PACKET_SENT_IRQ can be monitored in DSI_VCn_IRQSTATUS[2] PACKET_SENT_IRQ status bit. The user can request BTA even if the space allocated in the TX FIFO for the corresponding VC is empty. It can be sent later on even if there was no packet sent before BTA request. The DSS.DSI_VCn_CTRL[6] BTA_EN bit should be reset by hardware if the BTA request has been sent even if the automatic mode for this specific type of packets is enabled.

The bus turn-around is supported for video mode packets and for command mode packets. It is not possible to send BTA during the blanking periods of the video mode when HS blanking packets should be sent - that is, when one of the following bits is set to 1: DSS.DSI_CTRL[20] BLANKING_MODE, DSS.DSI_CTRL[21] HFP_BLANKING_MODE, DSS.DSI_CTRL[22] HBP_BLANKING_MODE or DSS.DSI_CTRL[23] HSA_BLANKING_MODE. So in video mode, the BTA request is delayed until there is a blanking period without HS blanking packets.

TA Timer

When TurnRequest signal is asserted (always only for data lane #1), the TA_TO timer is started. If the direction signal is no changed according to the turn-around request, the TA_TO interrupt is generated. When the Direction signal is in output mode, any data on the input data bus should be ignored since the DSI is in transmission mode (data and triggers should be ignored). Refer [Section 15.4.3.7.3](#) to for more details on TA_TO timer.

15.4.3.9 PHY Triggers

Three triggers are used by the DSI protocol engine:

- reset from host to display
- tearing effect from display to host
- acknowledge

These triggers are supported only for data lane #1. The reset trigger is associated with the signal TxTriggerEsc1[3]. The tearing effect trigger is associated with the signal RxTriggerEsc1[2]. The acknowledge trigger is associated with the signal RxTriggerEsc1[1].

Note: The TX signals - TxTriggerEsc1[2], TxTriggerEsc1[1], and TxTriggerEsc1[0] - and the RX signals - RxTriggerEsc1[3], and RxTriggerEsc1[0] - are not used by DSI protocol engine.

15.4.3.9.1 Reset

The DSI protocol engine can use one of the triggers of the DSI-PHY to send a reset to the display. The DSS.DSI_CTRL[5] TRIGGER_RESET bit is set to 1 to send the trigger reset. When the software requires the trigger reset to be sent to the peripheral, the DSI protocol engine should reset its own logic but not the registers. The software can select between two reset modes:

- Immediate reset: All pending requests in TX FIFO not already taken into account for transfer scheduling, the RX FIFO requests, and the data from video port are ignored. Only the current transfer on DSI link and already scheduled ones are transmitted. All the other transfers are discarded.
- Synchronized reset: The mode is only valid if there is virtual channel using the video mode and if it is active. The principle is to wait for the current video frame to be transferred on the link. Any data on VP after the current frame are ignored.

To select the reset mode, software users must program the DSS.DSI_CTRL[14] TRIGGER_RESET_MODE.

CAUTION

For both reset modes, the hardware is responsible for flushing the FIFOs, synchronization buffers and line buffers before resetting the DSS.DSI_CTRL[0] IF_EN bit.

15.4.3.9.2 Tearing Effect

The tearing effect on the display is avoided by having synchronization information from the display. It is used only in command mode. In case of video mode, it is not functional. It is the user responsibility to select command mode for the virtual channel using the tearing effect feature.

The software is responsible for setting and sending the appropriate sequence to receive the tearing effect trigger from the peripheral. When receiving the tearing effect trigger, the DSI protocol engine should generate the TE_TRIGGER_IRQ interrupt with TE event if the interrupt is enabled. To enable the interrupt, set to 1 the DSS.DSI_IRQENABLE[16] TE_TRIGGER_IRQ_EN bit. The DSS.DSI_IRQSTATUS[16] TE_TRIGGER_IRQ status bit indicates if the interrupt event has been generated.

One or multiple virtual channels can be synchronized using the same tearing effect trigger. The DSS.DSI_VCn_TE[16] TE_EN bit should be set to indicate that the hardware should use the following TE trigger to start the transfer of the data from the related virtual channel. This bit is reset when all the data have been sent to the peripheral. The DSS.DSI_VCn_TE[17] TE_START bit should be used when the automatic mode enabled by setting the DSS.DSI_VCn_TE[16] TE_EN bit is not used. It allows the user to start the transfer manually based on application events or based on the TE trigger interrupt (TE_TRIGGER_IRQ).

The number of bytes to be transferred is defined by using the DSS.DSI_VCn_TE[15:0] TE_SIZE field. The TE_SIZE field is decremented for each payload byte (it does not include Check-sum) sent on the DSI link. The register content should not be modified by software during a transfer. The DSS.DSI_VCn_TE[15:0] TE_SIZE field should be set first to indicate that the following accesses to DSS.DSI_VCn_LONG_PACKET_HEADER register should be used for tearing effect transfer.

The data can be provided from two sources (selection by setting the DSS.DSI_VCn_CTRL[1] SOURCE bit):

- L4 interconnect port using DMA request: The DMA request DSI_DMA_REQi (i=0 to 3) to should be asserted only when TE trigger is received or when the DSS.DSI_VCn_TE[17] TE_START bit is set by user and should not be asserted anymore when all the bytes defined in DSS.DSI_VCn_TE[15:0] TE_SIZE field have been sent on the DSI link. The virtual channel is associated with a DMA request (from DSI_DMA_REQ0 to DSI_DMA_REQ3) by programming the number in the DSS.DSI_VCn_CTRL[23:21] DMA_TX_REQ_NB field. The DSS.DSI_VCn_LONG_PACKET_PAYLOAD register is used to provide the number of bytes defined by the DSS.DSI_VCn_TE[15:0] TE_SIZE field (the check-sum value is not provided in the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register). The size of the header is not taken into account in the number of bytes to transfer. The DSS.DSI_VCn_SHORT_PACKET_HEADER register is not used.
- Video port: The DMA request is not asserted. The data are captured in the line buffer using the STALL mechanism. In case there is no line buffer instantiated (that is, DSS.DSI_CTRL[13:12] LINE_BUFFER field set to 0), it is not possible to use the video port to provide data. The line buffer should be filled up according to the word count defined in the DSS.DSI_VCn_LONG_PACKET_HEADER register header. The value should be written before the TE trigger event is received or before the DSS.DSI_VCn_TE[17] TE_START bit is set to 1 by software. In case the total number of bytes defined by the DSS.DSI_VCn_TE[15:0] TE_SIZE field is not a multiple of the word count defined in the DSS.DSI_VCn_LONG_PACKET_HEADER register, all the packets have the same size defined by the WC of the header except the last transfer. The size of the last transfer is defined by the remaining bytes to send. Since the DSS.DSI_VCn_TE[15:0] TE_SIZE field is modified after each packet transfer, the size of the last packet is equal to the value of DSS.DSI_VCn_TE[15:0] TE_SIZE field just before the last transfer (the header and the payload check-sum sizes are not included in DSS.DSI_VCn_TE[15:0] TE_SIZE field).

When the transfer is completed, the value of the DSS.DSI_VCn_TE[15:0] TE_SIZE field is equal to 0. The software is responsible to ensure that the pending data in the TX FIFO for the corresponding virtual channel using TE are related to TE transfer. Any data in the TX FIFO that should be sent before reception of TE trigger should be sent before TE. This is done by not enabling TE trigger until all data for the corresponding VC have been sent to the peripheral. The software can check that the space allocated for the virtual channel in the TX FIFO is empty by reading the DSS.DSI_VCn_CTRL[5] TX_FIFO_NOT_EMPTY status bit.

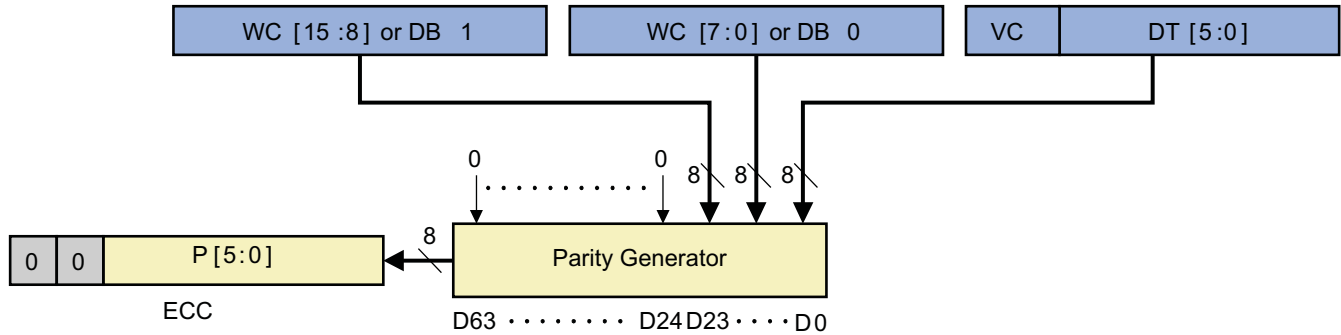

15.4.3.9.3 Acknowledge

The corresponding Acknowledge interrupt (ACK_TRIGGER_IRQ) should be generated upon reception of the acknowledge trigger. To enable the acknowledge interrupt, set the DSS.DSI_IRQENABLE[17] ACK_TRIGGER_IRQ_EN bit to 1. When the interrupt is generated, the DSS.DSI_IRQSTATUS[17] ACK_TRIGGER_IRQ status bit is set to 1.

15.4.3.10 ECC Generation

Note that the DSI protocol uses a four-byte packet header. Since ECC generation requires a fixed word length of 64-bits, the packet headers should be padded with additional bits to form a full eight-byte value for ECC generation and checking. The packet header less the ECC byte should occupy bits D[23:0] and the pad bits should occupy bits D[63:24]. All padding bits should be zero for the purpose of generating the ECC byte. ECC can be generated using a parallel approach as illustrated in [Figure 15-99](#).

Figure 15-99. 64-Bit ECC Generation on TX Side

dss-176

The ECC generation/check can be enabled and disabled by software. It is defined by a common bit for all the virtual channels:

- The DSS.DSI_CTRL[2] ECC_RX_EN bit enables/disables the ECC generation in the receive direction.
- The DSS.DSI_VcN_CTRL[8] ECC_TX_EN bit enables/disables the ECC generation in the transmit direction

15.4.3.11 Checksum Generation for Long Packet Payloads

Long packets are comprised of a packet header protected by an ECC byte and a payload of 0 to $2^{16} - 1$ bytes. To detect the errors during the transmission of Long packets, a checksum is calculated over the payload portion of the data packet. Note that, for the special case of a zero-length payload, the 2-byte checksum is set to 0xFFFF. The checksum can only indicate the presence of one or more errors in the payload. Unlike ECC, the checksum does not enable error correction. For this reason, checksum calculation is not useful for some unidirectional DSI implementations since the peripheral has no way for reporting errors to the host processor. Checksum generation and transmission is mandatory for host processors sending Long packets to peripherals. It is optional for peripherals transmitting Long packets to the host processor. However, the format of Long packets is fixed; the peripherals that do not support checksum generation should transmit two bytes having value 0x0000 in place of the checksum bytes when sending Long packets to the host processor. The host processor should disable checksum checking for received Long packets from peripherals that do not support checksum generation.

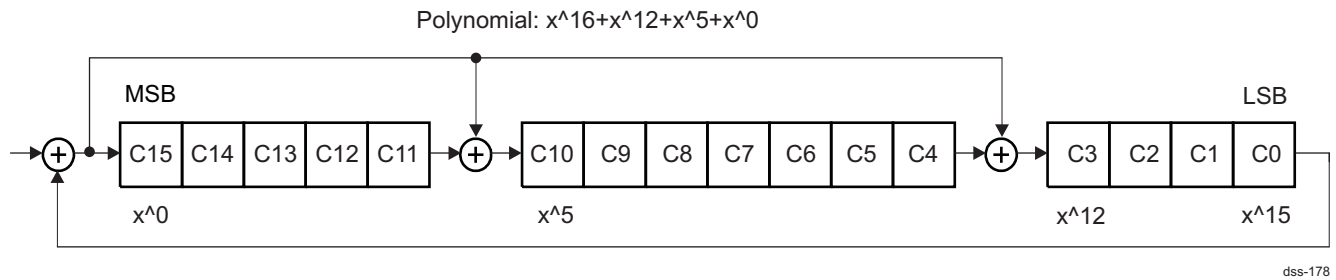

The checksum should be realized as a 16-bit CRC with a generator polynomial of $x^{16} + x^{12} + x^5 + x^0$. The LS byte is sent first, followed by the MS byte. Note that within the byte, the LS bit is sent first.

Figure 15-100. Checksum Transmission

dss-177

The CRC implementation is presented in [Figure 15-101](#). The CRC shift register is initialized to 0xFFFF before packet data enters. Packet data not including the packet header then enters as a bitwise data stream from the left, LS bit first. Each bit is fed through the CRC shift register before it is passed to the output for transmission to the peripheral. After all bytes in the packet payload have passed through the CRC shift register, the shift register contains the checksum. C15 contains the checksums MSB and C0 the LSB of the 16-bit checksum. The checksum is then appended to the data stream and sent to the receiver.

Figure 15-101. 16 Bit CRC Generation Using a Shift Register

The check-sum generation/check can be enabled and disabled by software. It is defined by a common bit for all the virtual channels:

- The DSS.DSI_CTRL[1] CS_RX_EN bit enables/disables the check-sum generation in the receive direction.
- The DSS.DSI_VCh_CTRL[7] CS_TX_EN bit enables/disables the check-sum generation in the transmit direction

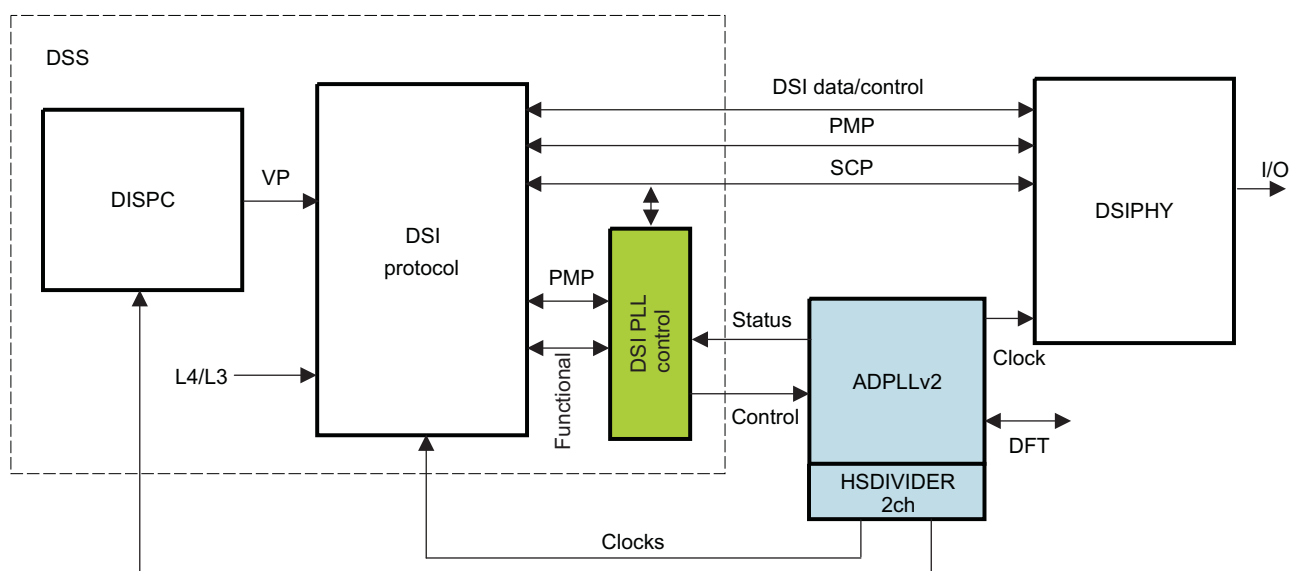

15.4.4 DSI PLL Controller Functionalities

This section describes functionality associated with the DSI module. This module is not available on all devices. See Chapter 1, the *OMAP35x Family* section, to check availability of this module.

15.4.4.1 DSI PLL Controller Overview

The DSI PLL controller module forms part of the Display Sub-system. Nevertheless, it uses the SCP (Serial Configuration Port) and PMP (Power Management Port) ports as the primary interfaces to the DSI protocol engine. The SCP interface is used to set the configuration of the DPLL and HSDIVIDER modules, primarily the various counter values. The PMP port is used to control the power state of the DPLL and HSDIVIDER modules. Figure 15-102 provides an overview of the DSI PLL controller module inside the Display Subsystem.

The DSI PLL is also used to generate the 74.25-MHz frequency used for HDTV applications.

Figure 15-102. DSI PLL Controller Overview

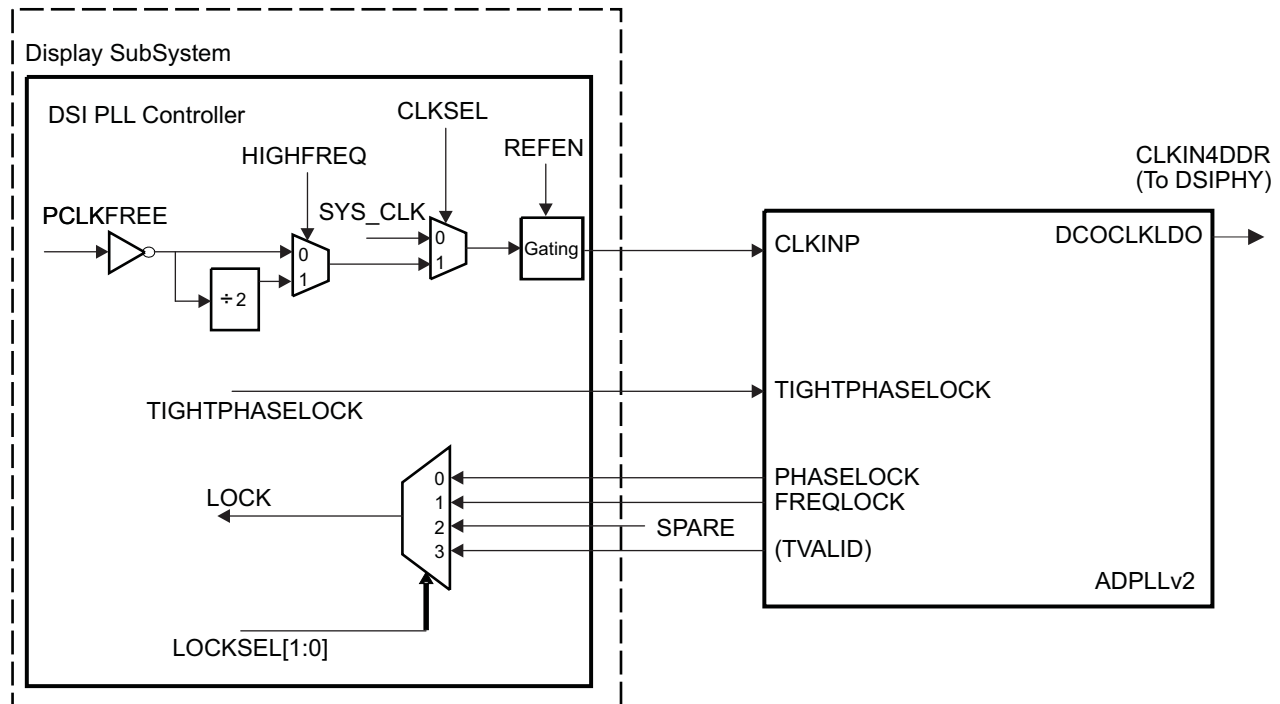

Note: The DSI PLL controller module does not have an interface to L4 interconnect. The programmable features are managed by registers mapped into the DSI protocol engine.

15.4.4.2 DSI PLL Controller Architecture

The DSI PLL is an ADPLLv2 module. The pixel clock (PCLK) frequency range is 2 to 65 MHz. This may be divided by 2 above 32 MHz (Above 21 MHz if N=0) to meet the PLL input reference (CLKINP) timing requirements. This is performed by setting the DSS.DSI_PLL_CONFIGURATION2[12] DSI_PLL_HIGHFREQ bit to 1.

Figure 15-103 shows the internal DSI PLL reference diagram.

Figure 15-103. DSI PLL Reference Diagram

Note: PCLK is inverted as the falling edge is the reference edge and ADPLLv2 uses positive edge as reference (F/F should be positive edge clock also)

dss-180

The DSI PLL clock output (DSI_PLL_HSCLK) corresponds to the CLKIN4DDR clock of the DSI complex I/O module.

The DSI PLL reference clock is the DSI_PLL_REFCLK clock. Depending on the setting in DSS.DSI_PLL_CONFIGURATION2[11] DSI_PLL_CLKSEL bit, the reference clock can be either the DSS2_ALWON_FCLK provided by the PRCM or the PCLKFREE provided by the DISPC module.

15.4.4.3 DSI PLL Operations

The DSI PLL configuration signals operate according to Table 15-30. Table 15-30 indicates the operation when the PLL is not locked.

Table 15-30. DSI PLL Operation Modes When Not Locked

DSI PLL Operation Mode	Stop mode Low power ⁽¹⁾	Stop mode Fast Relock ⁽¹⁾	Idle bypass
Mode Description	Output clocks stopped Lowest power standby	Output clocks stopped Fastest start-up time	Selects when PLL and HSDIVIDER bypass clocks are used
DSS.DSS_PLL_CONFIGURATION2[0] DSI_PLL_IDLE	0	0	1
DSS.DSS_PLL_CONFIGURATION2[6] DSI_PLL_LOWCURRSTBY	1	0	1
DSS.DSS_PLL_CONFIGURATION1[0] DSI_PLL_STOPMODE	1	1	X

⁽¹⁾ Recommended

When locked, the PLL output frequency is: Input frequency x M /(N+1)/HIGHFREQ where:

- M multiplier is programmed in DSS.DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM field.
- N divider is programmed in DSS.DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN field.
- HIGHFREQ divider by 2 is enabled by setting the DSS.DSI_PLL_CONFIGURATION1[12] DSI_PLL_HIGHFREQ bit to 1.

15.4.4.4 DSI PLL Controller Shadowing Mechanism

The configuration registers are accessed through the DSI protocol engine register space using SCP port. This includes all the configuration signals and the returning status signals.

CAUTION

All writes must be 32-bit operations as the SCP always transfers 32 bits. Any 16-bit or 8-bit operations may lead to unpredictable errors.

A shadow mechanism is implemented for appropriate register values so that configurations may optionally be updated in synchronism with the Display Controller (DISPC) and DSI protocol engine. The front porch time from the DISPC indicates the time when making the update of the value. All the required updated values must have been written before this signal is asserted. Refer to [Section 15.4.3.5.1](#) for more details.

15.4.4.5 Error Handling

The PLL lock and recalibration signals may be monitored to detect loss of lock or requirement to recalibrate (due to large temperature change since the last lock request):

- The DSS.DSI_PLL_STATUS[1] DSI_PLL_LOCK status bit gives the DSI PLL lock state.
- The DSS.DSI_PLL_STATUS[2] DSI_PLL_RECAL status bit informs if the PLL needs to be uncalibrated

These signals can also generate interrupts at DSI protocol engine level:

- The PLL_LOCK_IRQ interrupt indicates that the DSI PLL control module has sent a lock request to the DSI PLL. To monitor this event, read the DSS.DSI_IRQSTATUS[7] PLL_LOCK_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL_UNLOCK_IRQ interrupt indicates that the DSI PLL control module has sent an unlock request to the DSI PLL. To monitor this event, read the DSS.DSI_IRQSTATUS[8] PLL_UNLOCK_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL_RECAL_IRQ interrupt indicates that the DSI PLL control module has sent a recalibration request to the DSI PLL. To monitor this event, read the DSS.DSI_IRQSTATUS[9] PLL_RECAL_IRQ bit. Set this bit to 1 to clear the status bit.

15.4.5 DSI Complex I/O Functionalities

This section describes functionality associated with the DSI module. This module is not available on all devices. See Chapter 1, the *OMAP35x Family* section, to check availability of this module.

15.4.5.1 DSI Complex I/O Overview

The DSI complex I/O or DSI-PHY is a MIPI D-PHY compliant transceiver. It is used in the DSI interface between a mobile phone application device and a display module.

DSI-PHY is a complex I/O with 3 unidirectional (HS) Lane Modules. This includes 2 data lane modules and 1 clock lane module. Each lane module has 2 data pads (DX, DY). These data pads are connected with a complementary lane module on the DSI receiver device using point to point interconnect.

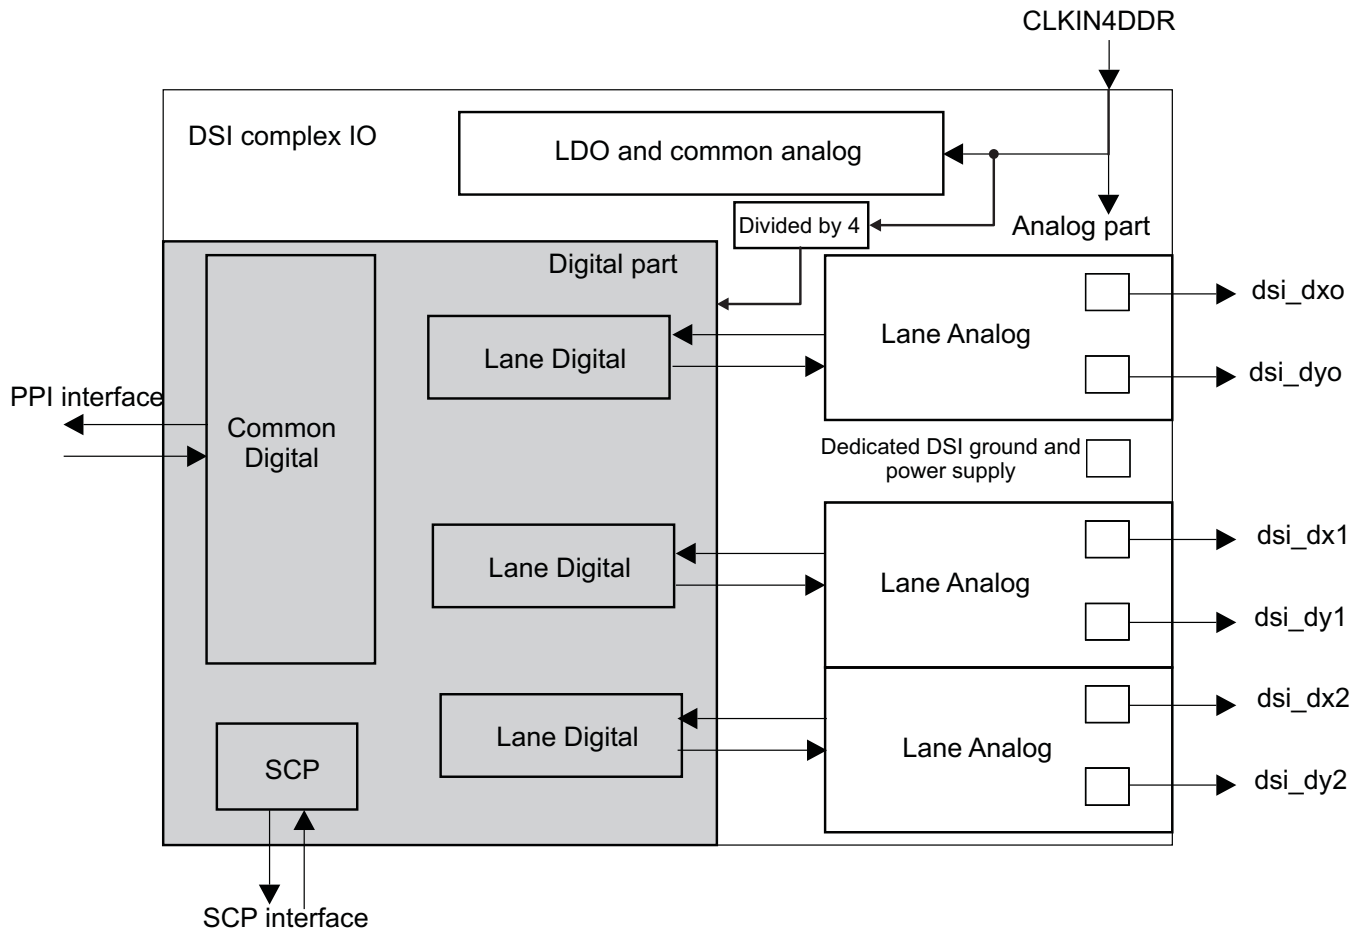

Lane modules support High speed burst mode. Forward direction and reverse direction escape modes are also supported. Escape modes maybe used for Low Power Data Transmission, among other things. DSIPHY lane modules correspond to CIL-MFDA and CIL-MCNN lane type defined by D-PHY specification.

The maximum data rate supported in High Speed Mode is 800Mbps per data lane. The lane module function and position is configurable, that is, any lane module can be chosen as clock lane module, and DX/DY data pad for each lane module can be configured as either DP or DN pins defined by D-PHY spec.

DSIPHY interacts with the higher layers of the DSI link through the PHY-Protocol Interface (PPI). DSIPHY does not include a PLL; a high frequency clock input is expected in HS mode (CLKIN4DDR). DSIPHY supports also Serial Configuration Protocol (SCP) to set various configuration and control registers. The DSIPHY supports GPIO operation on each of the six data pins.

15.4.5.2 DSI Complex I/O Architecture

[Figure 15-104](#) shows the top-level block diagram of DSIPHY. It has 3 lane module functions, and some common analog and digital functions. Each lane module has an analog and a digital part. The digital lane circuitry implements the protocol interface of MIPI D-PHY. It interacts with the DSI protocol engine.

Figure 15-104. DSI Complex I/O Architecture

dss-189

The internal input & output interfaces of DSIPHY are compliant with PHY-Protocol Interface (PPI) description of the MIPI D-PHY specification annex. The explanation of D-PHY interface and PPI protocol is in the MIPI D-PHY specification document.

The lane module analog circuit converts the digital levels to the LP and HS level signals for the link. It also converts the analog state of the link into digital levels.

For High Speed signals, the lane module analog also does the last stage untiming of HS data to obtain optimum quadrature with the HS clock.

DSIPHY has an internal LDO to generate 1.2V supply. This LDO requires an off-chip decoupling capacitor and hence a dedicated pin. DSIPHY expects a high frequency clock input in HS mode.

The clock input is required to have four times the frequency of the DDR clock, that is, twice the HS data rate. GPIO functions are supported on each ds_dxi and ds_dyi.

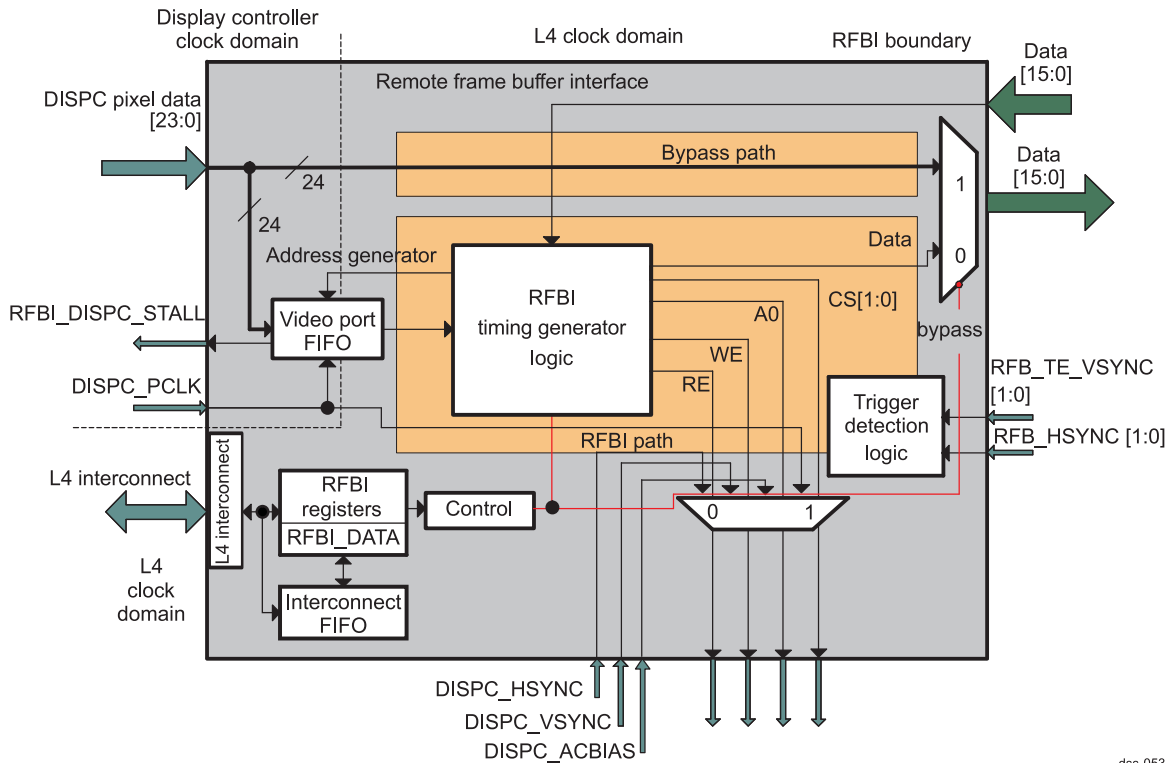

15.4.6 RFBI Functionalities

The RFBI module can capture the output pixel from the display controller and send the data to the RFB in the LCD panel. The application configures the RFBI module, sends commands, reads data, and configures the display controller to send data fetched from the system memory by the display controller DMA engine. The commands/data are sent using an 8-, 9-, 12-, or 16-bit parallel interface.

The display controller is configured to send the data in 12-, 16-, 18-, or 24-BPP format. In the video port FIFO, the encoded pixel values are in an LSB alignment.

Figure 15-105 shows an overview of the RFBI architecture.

Figure 15-105. RFBI Architecture Overview

15.4.6.1 RFBI FIFO

The input video port FIFO receives data from the display controller at the pixel clock. The data in the video port FIFO are read by the RFBI and are sent to the LCD panel. The video port FIFO is 24 bits wide and each pixel in 12-, 16-, 18-, and 24-BPP format is stored in the video port FIFO using one 24-bit value aligned on the 24-bit LSB. [Section 15.4.6.4, Output Parallel Modes](#), shows an example of an output configuration based on the interface width (16 bits) and the pixel format output (24 bits).

15.4.6.2 RFBI Interconnect FIFO

The interconnect FIFO receives the data from RFBI_DATA write requests to the L4 interconnect slave port. The data in the interconnect FIFO are read by the RFBI and sent to the LCD panel. The width of the interconnect FIFO is 32 bits. The size of the interconnect FIFO is 24 words of 32 bits (i.e 24 words of RFBI_DATA).

15.4.6.3 Input Pixel Formats

The supported pixel formats in the RFB module are: RGB24-888, RGB18-666, RGB16-565, and RGB12-444 as output from the display controller and from the L4 (for writing parameters). In both cases, the pixels are formatted in accordance with the configuration of the output interfaces (multiple cycles).

15.4.6.4 Output Parallel Modes

The RFBI output modes are 8-, 9-, 12-, and 16-bit interfaces. Any mode can be selected regardless of the pixel format. Set the right configuration in the cycle registers to define a valid configuration for each output cycle.

The following example is an output configuration based on the 16-bit interface width and the 24-bit pixel format ($i = 0$ or 1) (see also [Table 15-31](#)):

- The DSS.RFBI_CONFIGi[10:9] CYCLEFORMAT field is set to 0x3 (three cycles for two pixels).
- The DSS.RFBI_DATA_CYCLE1_i register is set to 0x00000010 (16 bits from pixel 1 for the first cycle).
- The DSS.RFBI_DATA_CYCLE2_i register is set to 0x00080808 (8 bits from pixel 1 and pixel 2 and alignment of 8 bits from pixel 2 for the second cycle).
- The DSS.RFBI_DATA_CYCLE3_i register is set to 0x00100000 (16 bits from pixel 2 for the third cycle).

Table 15-31. 16-Bit Interface Configuration/24-Bit Mode

	24-Bit Mode		
	1st Cycle	2nd Cycle	3rd Cycle
Data[15]	R0[7]	B0[7]	G1[7]
Data[14]	R0[6]	B0[6]	G1[6]
Data[13]	R0[5]	B0[5]	G1[5]
Data[12]	R0[4]	B0[4]	G1[4]
Data[11]	R0[3]	B0[3]	G1[3]
Data[10]	R0[2]	B0[2]	G1[2]
Data[9]	R0[1]	B0[1]	G1[1]
Data[8]	R0[0]	B0[0]	G1[0]
Data[7]	G0[7]	R1[7]	B1[7]
Data[6]	G0[6]	R1[6]	B1[6]
Data[5]	G0[5]	R1[5]	B1[5]
Data[4]	G0[4]	R1[4]	B1[4]
Data[3]	G0[3]	R1[3]	B1[3]
Data[2]	G0[2]	R1[2]	B1[2]
Data[1]	G0[1]	R1[1]	B1[1]
Data[0]	G0[0]	R1[0]	B1[0]

15.4.6.5 Unmodified Bits

In a cycle, if every bit in the interface does not have a pixel value, the status of the unused bits can be programmed to be 0, 1, or the previous value (I/O power consumption optimization).

15.4.6.6 Bypass Mode

In bypass mode, the RFBI path is bypassed and the display controller data and signals are sent directly to the output interface of the RFBI.

15.4.6.7 Send Commands

The commands are written through the L4 interconnect and into the DSS.RFBI_CMD register. After a command is sent, another one can be accepted by the module and set. If the processing of a command is not complete, the MPU access to change the command stalls.

15.4.6.8 Read/Write

Depending on the status of A0, WE, and RE, the commands and display/parameter data are written to the panel (handled by the state-machine for the commands/parameter data and stored in memory for the display data), or the display data/status values are read from the LCD panel (status and display data in the LCD panel memory). The polarity of A0 (RFBI_A0 signal), WE (RFBI_WE signal), RE (RFBI_RE signal), and CSx (RFBI_CSx signal, with x = 0, 1) is programmable.

Table 15-32 describes the read/write function.

Table 15-32. Read/Write Function Description

A0 (RFBI_A0)	WE (RFBI_WE)	RE (RFBI_RE)	Function Description
1	0	1	Display data write, parameter data write
1	1	0	Display data read
0	1	0	Status read
0	0	1	Command data write

A minimum of RFBI_Cs cycle time, as defined in Table 15-33, is required to keep the RFBI_CSx signal asserted between write transfers of multiple pixels.

Table 15-33 indicates the minimum cycle time for RFBI_CSx, depending on the source of pixels (display controller or L4 slave port) and the cycle format (1pixel/cycle, 1 pixel/2 cycles, 1 pixel/3 cycles, or 2 pixels/3 cycles).

Table 15-33. Minimum Cycle Time for CSx/WE Always Asserted

RFBI Performance	RFBI_CONFIGi[10:9] CYCLEFORMAT	RFBI_CONFIGi[8:7] L4FORMAT	Minimum Cycle Time (in Number of L4 Cycles)
L4 interconnect	1 pixel/cycle	1 pixel	5
	1 pixel/2 cycles	1 pixel	4
	1 pixel/3 cycles	1 pixel	4
	2 pixels/3 cycles	1 pixel	6
	1 pixel/cycle	2 pixels	4
	1 pixel/2 cycles	2 pixels	4
	1 pixel/3 cycles	2 pixels	4
	2 pixels/3 cycles	2 pixels	6
Display Controller	1 pixel/cycle	N/A	4
	1 pixel/2 cycles	N/A	3
	1 pixel/3 cycles	N/A	3
	2 pixels/3 cycles	N/A	6

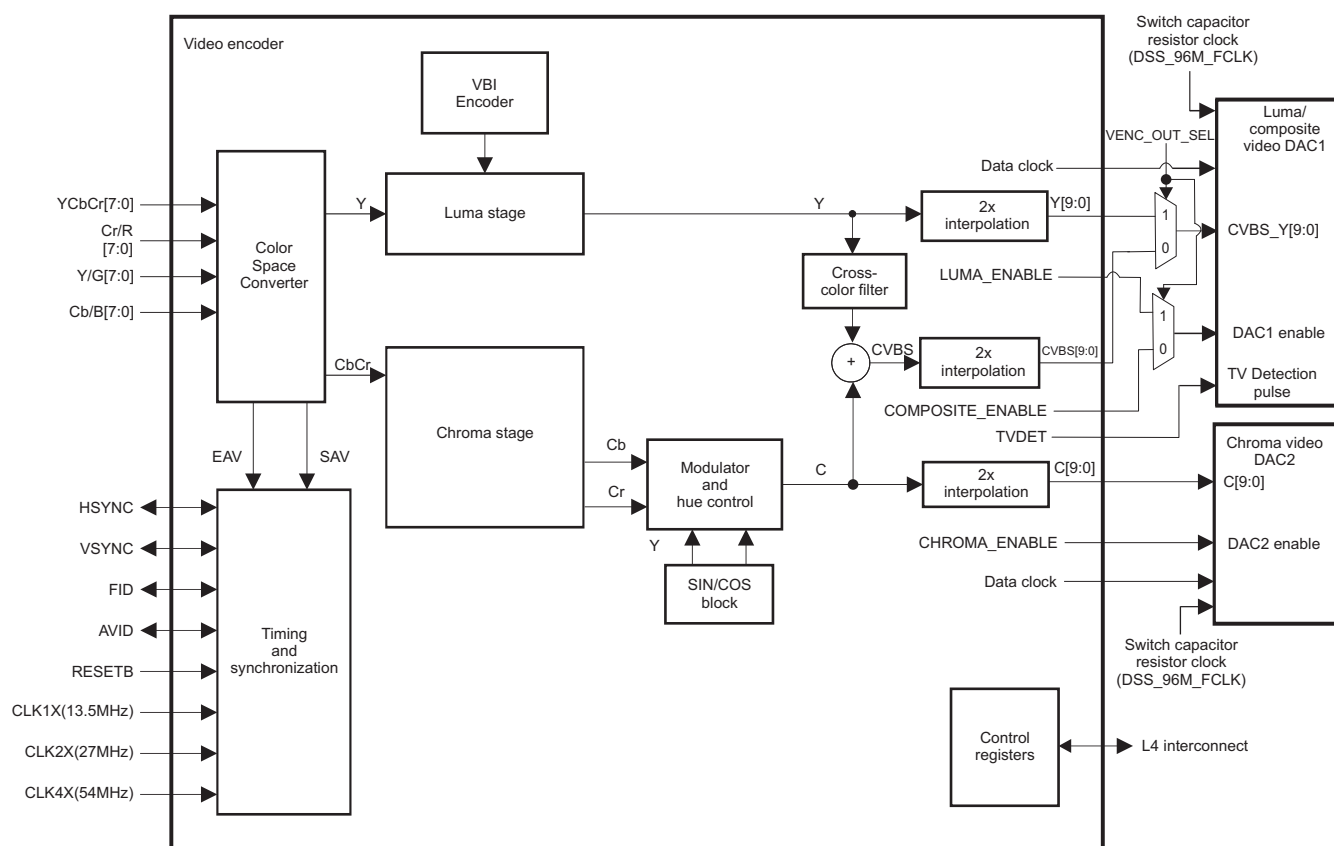

15.4.7 Video Encoder Functionalities

The input formats supported by the encoders are 24-bit 4:4:4 RGB. The encoder output is the DAC (for more information, see Section 15.2, *Display Subsystem Environment*). In the display subsystem, the input format from the display controller is always 24-bit RGB. The RGB-to-YCbCr color space converter converts the 24-bit RGB pixel data to 24-bit YCbCr data.

The remaining Cb and Cr color components enter the 2-to-1 chrominance decimation, which reduces by half the chrominance bandwidth and the amount of chrominance data. After the data manager, the encoder processes in 4:2:2 data path up to the 2x interpolation. A luma delay synchronizes luma to chrominance data.

Figure 15-106 shows an overview of the video encoder architecture.

Figure 15-106. Video Encoder Architecture Overview

dss-079

Note: Output video mode can be either composite video (CVBS output) or Separate video (s-video: Luma and chroma outputs):

- Composite video: DAC1 is used
- Separate video (luma/chroma): Both DAC1 (luma) and DAC2 (chroma) are used

The selection is programmed with DSS.DSS_CONTROL[6] VENC_OUT_SEL bit. Composite video is the default selection.

15.4.7.1 Test Pattern Generation

For diagnostic purposes, the data manager can be forced to output 100/100 color bar RGB/YCbCr data by setting the SVDS field VENC_F_CONTROL[7:6] register to 0x1.

Table 15-34. 100/100 Color Bar Table

COLOR	R	G	B	Y	Cb	Cr
White	255	255	255	235	128	128
Yellow	255	255	0	210	16	146
Cyan	0	255	255	170	166	16
Green	0	255	0	145	54	34
Magenta	255	0	255	106	202	222
Red	255	0	0	81	90	240
Blue	0	0	255	41	240	110
Black	0	0	0	16	128	128

15.4.7.2 Luma Stage

The luma stage includes a luma pipeline delay, luma shaping, 2x interpolation filter, and luma variable delay. The luma pipeline delay block is used to match luma path length to chroma path length. In the luma gain shaper, a programmable gain is first applied to the luminance data output. The luminance gain is defined by the DSS.VENC_GAIN_Y register. Horizontal sync, vertical sync, and setup insertion are then performed.

Black level and blank level are programmable through the DSS.VENC_BLACK_LEVEL and DSS.VENC_BLANK_LEVEL registers. All the transition edges of the luminance signal, such as sync edges and active video edges, are properly shaped and filtered to keep the bandwidth within the standards.

After all required components of the luminance signal are added, the resulting signal is low-passed and interpolated to 2x-pixel rate. This 2x interpolation simplifies the external analog reconstruction filter design and improves the signal-to-noise ratio.

15.4.7.3 Chroma Stage

The chroma stage includes a low-pass filter, first-stage 2x interpolation, chroma gain shaper, and second-stage 2x interpolation. A pair of programmable gains adjusts the time-multiplexed U/V signal. The gains for U and V are independently controlled by the DSS.VENC_GAIN_U and DSS.VENC_GAIN_V register bits.

15.4.7.4 Subcarrier and Burst Generation

The encoder uses a 32-bit subcarrier increment to synthesize the subcarrier. The value of the subcarrier increments required to generate the desired subcarrier frequency for NTSC and PAL format is found by:

$$S_CARR = \text{ROUND} ([F_{sc}/F_{clkenc}] \times 2^{32})$$

where:

F_{sc} = Frequency of the subcarrier

F_{clkenc} = Frequency of the internal video encoder

The DSS.VENC_S_CARR register controls the subcarrier frequency. The DSS.VENC_C_PHASE register controls the phase of the subcarrier. The phase of the color subcarrier is reset to DSS.VENC_C_PHASE. Table 15-35 presents the VENC_S_CARR register values depending the standard and pixel type used.

Table 15-35. VENC_S_CARR Register Recommended Values

Standard	Pixel Type	Subcarrier Frequency (Fsc) (MHz)	Fclkenc (MHz)	VENC_S_CARR register value (hexa)
NTSC-M, J	ITU-R601	3.579545	27	0x21F07C1F
PAL-M	ITU-R601	3.5756083125	27	0x21E6EFE3
PAL-B, D, G, H, I, N	ITU-R601	4.43361875	27	0x2A098ACB
PAL-Nc	ITU-R601	3.58205625	27	0x21E6EFE3
NTSC-M, J	Square pixel	3.579545	24.5454	0x25555555
PAL-M	Square pixel	3.579561149	24.5454	0x1F15C01E
PAL-B, D, G, H, I, N	Square pixel	4.43361875	29.50	0x26798C0C
PAL-Nc	Square pixel	3.58205625	29.50	0x1F15C01E

CAUTION

In square pixel mode, an external clock generator is needed to provide sampling frequencies (49.09 MHz for NTSC square pixel or 59 MHz for PAL square pixel).

The color subcarrier reset has four modes:

- No reset
- Reset every two lines
- Reset every two fields
- Reset every eight fields

The DSS.VENC_C_PHASE register can be used to adjust the SCH (subcarrier to horizontal sync phase). The DSS.VENC_BSTAMP_WSS_DATA[6:0] BSTAP field sets the amplitude of the color burst. The DSS.VENC_M_CONTROL[1] PAL bit enables phase alternation line encoding.

A phase switching subcarrier is generated to encode the chrominance signal when the DSS.VENC_M_CONTROL[1] PAL bit is set to 1. Otherwise, a normal subcarrier is generated. Phase alternation line refers to the encoding scheme in which the subcarrier alternates between two phases every scan line. Two possible alternation sequences are possible, and the DSS.VENC_M_CONTROL[5] PALPHS bit selects one of these sequences.

15.4.7.5 Closed Caption Encoding

The encoder can be programmed to encode closed-caption data and extended data in the selected line. The closed-caption data are sent to the encoder through the L4 interconnect. The data stream consists of 7-bit US-ASCII code and 1 odd-parity bit (see Table 15-36).

Table 15-36. Closed-Caption Data Format

MSB							LSB
Odd parity	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0

The standard service encodes closed caption in both fields; the extended service encodes closed caption in even fields. When set to 1, the DSS.VENC_L21_WC_CTL L21EN[0] bit enables closed-caption encoding in odd fields. When set to 1, the DSS.VENC_L21_WC_CTL L21EN[1] bit enables closed-caption encoding in even fields.

There is a 4-line offset between the value programmed in the DSS.VENC_LN_SEL[4:0] SLINE field and the scan line where closed caption is to be encoded. Program the value 0x11 to activate the closed caption on line 21. The DSS.VENC_LN_SEL[25:16] LN21_RUNIN field should be kept at reset value (0x10B). Four closed-caption data registers contain the data to be encoded. The DSS.VENC_LINE21[7:0] L21O and DSS.VENC_LINE21[15:8] L21O fields contain the first and the second bytes of closed-caption data to be encoded in the odd field. The DSS.VENC_LINE21[23:16] L21E and DSS.VENC_LINE21[31:24] L21E fields contain the first and the second bytes of data to be encoded in the even field.

Immediately after the closed-caption data is written to the registers, in either the odd field or even field, the corresponding closed-caption status bit (DSS.VENC_STATUS[4] CCE or DSS.VENC_STATUS[3] CCO) is reset to 0 to indicate that the closed-caption data is available in the closed-caption data registers and yet to be encoded.

Immediately after the closed-caption data is encoded, the DSS.VENC_STATUS[4] CCE bit or the DSS.VENC_STATUS[3] CCO bit is set to 1 to indicate that the closed-caption data has been encoded and is ready to accept new data. As seen in Figure 15-107, a null character is automatically inserted if the closed-caption data is not written to the closed-caption data registers in time for encoding.

The running clock frequency is controlled by the DSS.VENC_CC_CARR_WSS_CARR[15:0] FCC field which should be kept at reset value (0x2631) to get 5034960.5Hz (32xflin) for NTSC-601. The closed-caption running clock common frequencies are detailed in Table 15-37.

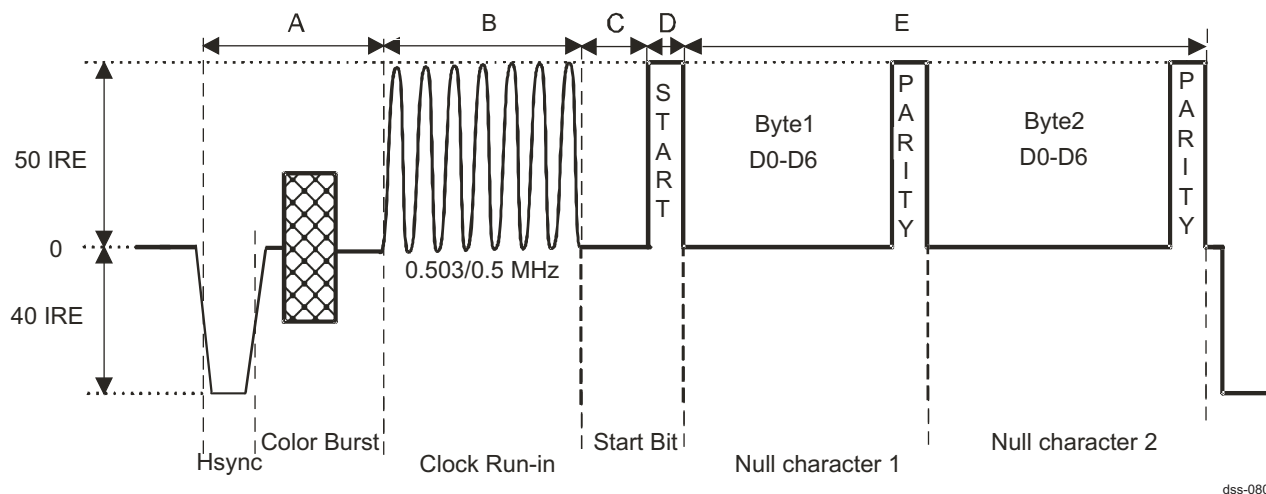

Table 15-37. Closed-Caption RunClock Frequency Settings

	NTSC-601	PAL-601	NTSC Square Pixel	PAL Square Pixel
VENC_CC_CARR_WSS_CARR[15:0] FCC field value	0x2631	0x25ED	0x2A03	0x22B6

The closed-caption data is encoded in nonreturn-to-zero (NRZ) format. Additionally, the data translates to the IRE scale as follows: 0 = 0 IRE; 1 = 50 IRE.

Figure 15-107 shows the parameters of closed-caption line data implemented in different standards.

Figure 15-107. Closed Captioning Timing

dss-080

Notes:

- The interval A is controlled by the DSS.VENC_LN_SEL[25:16] LN21_RUNIN field.
- The interval B is controlled by DSS.VENC_CC_CARR_WSS_CARR[15:0] FCC field.

Table 15-38. Closed-Caption Standard Timing Values

Intervals	Description	Timing Values for Encoding			Timing Values for Decoding		
		Minimal	Nominal	Maximal	Lower Bound	Nominal	Upper Bound
A	HSYNC to clock running	10.250 s	10.500 s	10.750 s	10.000 s	10.500 s	11.000s
B	Clock running		12.910 s			12.910 s	
C	Clock running to third start bit		3.972 s			3.972 s	
D	Start bit		1.986 s			1.986 s	
E	Data characters		31.778 s			31.778 s	

Note: All timing values listed in Table 15-38 are measured from the mid-point (half amplitude) on all edges.

For a complete description of closed-caption standard, please refer to CEA-608-C standard.

15.4.7.6 Wide-Screen Signaling (WSS) Encoding

The encoder can embed data, encoded in accordance with the IEC61880 and ITU-R 1119 data insertion standard, within the vertical blanking interval (VBI).

The encoder supports WSS data insertion on line 20 of every frame in the NTSC format. WSS data insertion is enabled by activating the DSS.VENC_L21_WC_CTL[14:13] EVEN_ODD_EN bit and by programming the VENC_BSTAMP_WSS_DATA[27:8] WSS_DATA field.

The running clock frequency is controlled by the DSS.VENC_CC_CARR_WSS_CARR[31:16] FWSS field. The wide-screen signaling running clock common frequencies are detailed in [Table 15-39](#)

Table 15-39. Wide-Screen Signaling RunClock Frequency Settings

	NTSC-601	PAL-601	NTSC Square Pixel	PAL Square Pixel
VENC_CC_CARR_WSS_CARR[31:16] FWSS field value	0x043F	0x2F72	0x04AC	0x2B6D

To select the line where the WSS data are encoded, program the DSS.VENC_L21_WC_CTL[12:8] LINE field.

CAUTION

The setting of the LINE[4:0] field value depends on the video standard:

- PAL mode: There is an one line offset, so program the wanted line number - 1. The recommended value is line $0x16 + 1 = 0x17$ (23rd line). Note that the default value is $0x14 + 1 = 0x15$ (21st line).
- NTSC mode: There is a four line offset, so program the wanted line number - 4. The recommended value is line $0x10 + 4 = 0x14$ (20th line). Note that the default value is $0x14 + 4 = 0x18$ (24th line).

The WSS encoding block assumes that a full 10-bit video range is used to determine the 70 percent of peak-white amplitude of a logic-1 bit. The encoder also supports WSS data insertion on line 23 in the PAL format. Both waveforms are shown in [Figure 15-108](#).

Figure 15-108. WSS Timing

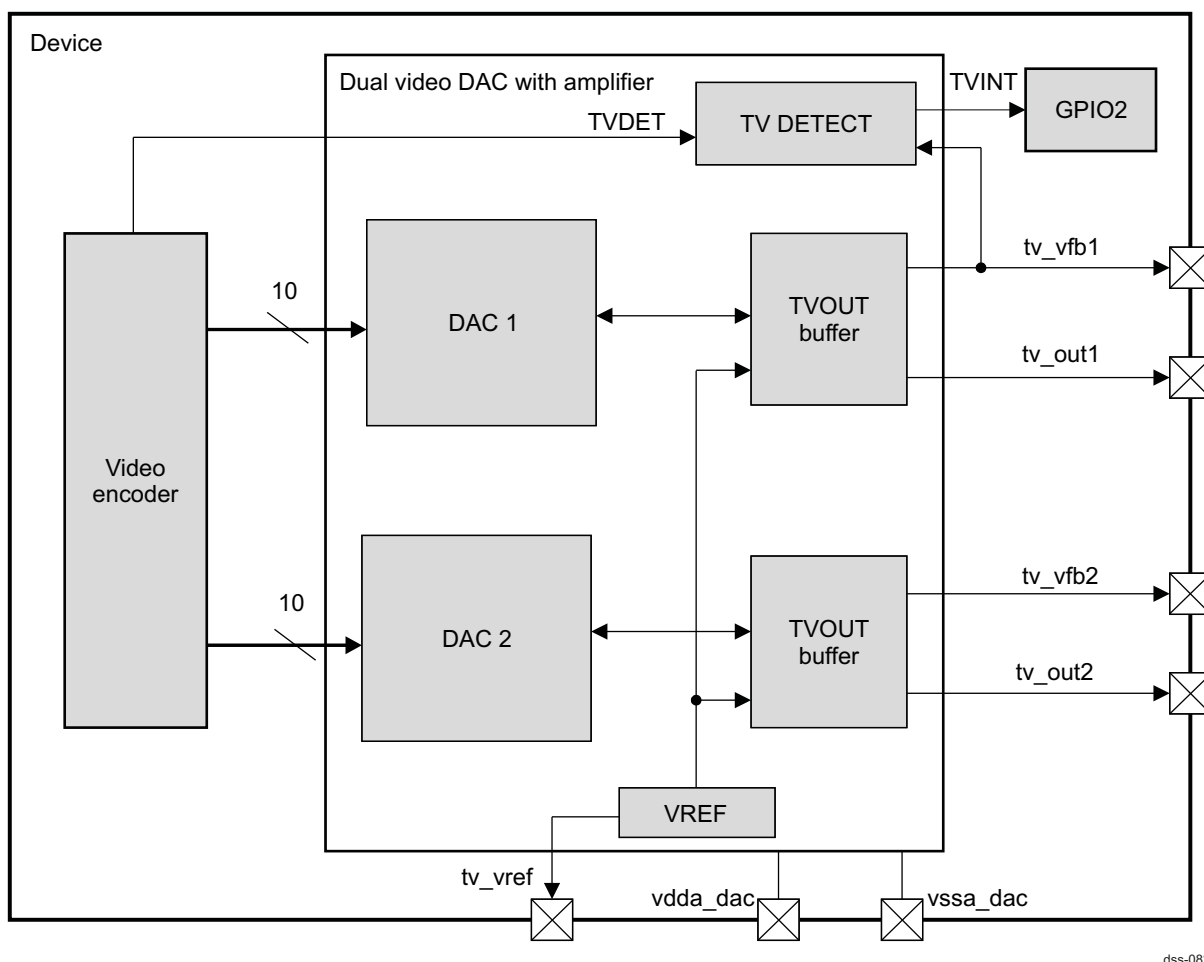

dss-081

15.4.7.7 Video DAC Architecture

Figure 15-109 shows the architecture of the dual 10-bit video DAC.

Figure 15-109. Dual 10-Bit Video DAC Architecture

pss-082

The display subsystem provides the necessary control signals to interface the memory frame buffer directly to external displays (TV sets). Two (one per channel) 10-bit current steering DAC is used to generate the video analog signal. The video mode DAC 1 (luma/composite) also includes the TV detection/disconnection and power-down mode features.

15.4.7.8 Video DC/AC Coupled TV Load

The dual 10-bit video DAC supports both dc-coupled and ac-coupled TV loads. The `CONTROL.CONTROL_DEVCONF1[11] TVACEN` bit is used to define which output coupling is used (0: Dc coupling; 1: Ac coupling). This bit is the first one to be programmed according to the TV load on the PCB board.

Note: When dc coupling is used, note that there is a 385-mV dc offset at the TVOUT output (tv_out1 for DAC1 and tv_out2 for DAC2).

15.4.7.9 TV Detection/Disconnection Pulse Generation and Usage

15.4.7.9.1 TV Detection/Disconnection Pulse Generation

The TV detect block is an integral part of the dual video DAC module.

Notes:

- The TV detection/disconnection feature is supported only for VDAC1.
- The TV disconnection feature is recommended for power saving purpose. The TV detection/disconnection is only operational when video out is active. Therefore to detect cable connection automatically, it is necessary to periodically activate the video out to test for cable presence.

This block compares the output (tv_out1) to reference (tv_vref) voltages, to sense the condition of the load. To operate, the TV detect requires two digital signals, TVACEN and TVDET. The TVACEN signal indicates to both TVOUT buffer and the TV detect circuit if the load is ac or dc coupling to adjust accordingly. TVDET is a digital pulse at the frequency of the TV sync pulses. The operation of the circuit is based on the difference in voltage levels in the output of the buffer depending of the load status. The TV detect block compares the output against a couple of references and the result is latched at the start of every sync pulse. The status is read later in with the TVDET pulse rising edge.

The following registers are used to set the TV detection/disconnection pulse:

- The DSS.VENC_TVDETGP_INT_START_STOP_X register defines which pixels are used to start and stop the pulse inside their respective line.
- The DSS.VENC_TVDETGP_INT_START_STOP_Y register defines which lines are used to start and stop the pulse.
- The DSS.VENC_GEN_CTRL[0] EN bit enables or disables the TVDET pulse (0: Disable; 1: Enable).
- The DSS.VENC_GEN_CTRL[16] TVDP bit sets the TVDET pulse polarity (0: Active low; 1: Active high).

15.4.7.9.2 TV Detection Procedure

The TV detection procedure is the following:

1. Initial setup:
 - Program the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y registers to define on which pixels and lines, respectively, the TVDET pulse will start and stop.
 - Set the DSS.VENC_GEN_CTRL[16] TVDP bit to 1 (reset value) for a TVDET pulse active high polarity.
 - Set the DSS.VENC_GEN_CTRL[0] EN bit to 1 to enable the TVDET pulse generation.
2. The TVDET signal is set to low by hardware according to the settings in the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y registers.
3. Set the VENC_OUTPUT_CONTROL[0] LUMA_ENABLE bit (in s-video mode) or the VENC_OUTPUT_CONTROL[1] COMPOSITE_ENABLE (in composite video mode) to 1 to enable the video DAC1 output.
4. Power up the VDDADAC voltage for VDAC and the TVOUT buffer (repeat every TV field during the horizontal synchronization). This is software controlled through an I²C interface connected to the power IC (TPS65950 device). For more details on the TPS65950 device, contact your TI representative.
5. The TVDET pulse is set high by hardware according to the settings in the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y registers.
6. Check the TVINT output signal: When TVINT is set to 1, the load is connected.

CAUTION

- If ac coupling is selected, two TVDET pulses are required to set high the TVINT signal. Due to the internal logic of the video DAC1, the TVINT signal is generated after the next positive edge of the TVDET signal that happens during the next VSYNC timing.
- If dc coupling is selected, only one TVDET pulse is required to set high the TVINT signal.

15.4.7.9.3 TV Disconnection Procedure

The TV disconnection procedure is the following:

1. Initial setup:
 - Program the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y registers to define on which pixels and lines, respectively, the TVDET pulse will start and stop.
 - Set the DSS.VENC_GEN_CTRL[16] TVDP bit to 1 (reset value) for a TVDET pulse active high polarity.
 - Set the DSS.VENC_GEN_CTRL[0] EN bit to 1 to enable the TVDET pulse generation.
2. The TVDET signal is set to low by hardware according to the settings in the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y registers.
3. The TVDET pulse is set high by hardware according to the settings in the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y registers.
4. Check the TVINT output signal: When TVINT is reset to 0, the load is disconnected.
5. Reset the VENC_OUTPUT_CONTROL[0] LUMA_ENABLE bit (in s-video mode) or the VENC_OUTPUT_CONTROL[1] COMPOSITE_ENABLE (in composite video mode) to 0 to disable the video DAC1 output.
6. Power-down the VDDADAC voltage for VDAC and the TVOUT buffer (repeat every TV field during the horizontal synchronization). This is software controlled through an I²C interface connected to the power IC (TPS65950 device). For more details on the TPS65950 device, contact your TI representative.

CAUTION

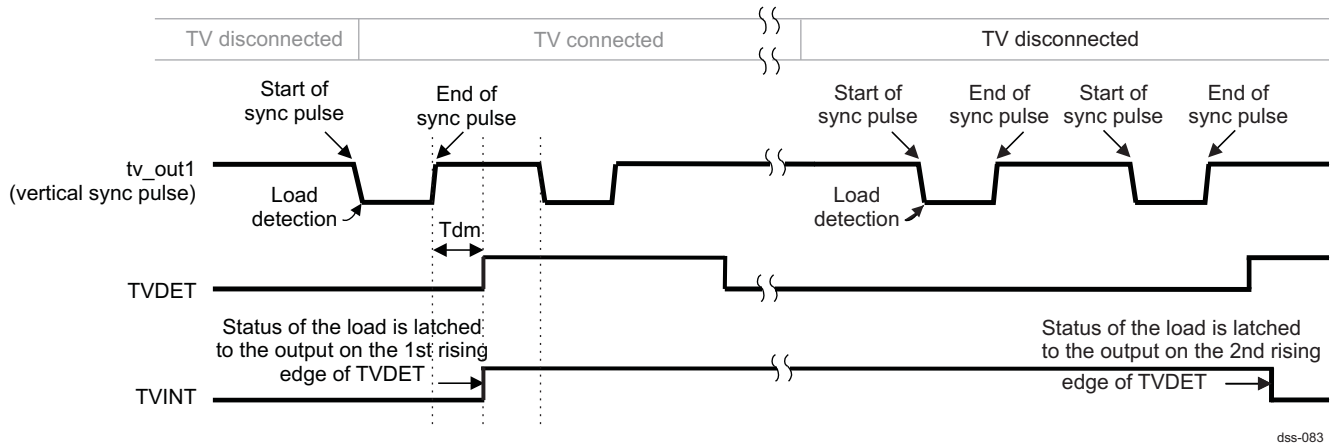

- If dc coupling is selected, two TVDET pulses are required to set low the TVINT signal. Due to the internal logic of the video DAC1, the TVINT signal is generated after the next positive edge of the TVDET signal that happens during the next VSYNC timing.
- If ac coupling is selected, only one TVDET pulse is required to set low the TVINT signal.

15.4.7.9.4 Recommended TV Detection/Disconnection Pulse Waveform

To enable the detection/disconnection of the load, the circuit requires that the TVDET pulse resembles the following waveform. As explained in [Section 15.4.7.9.2, TV Detection Procedure](#), and in [Section 15.4.7.9.3, TV Disconnection Procedure](#) by using the video encoder registers, the TVDET pulse polarity, start and stop is programmable. The only critical parameter is Tdm, which should be longer than the delay through the DAC and TVOUT buffer, which is at least 750 ns.

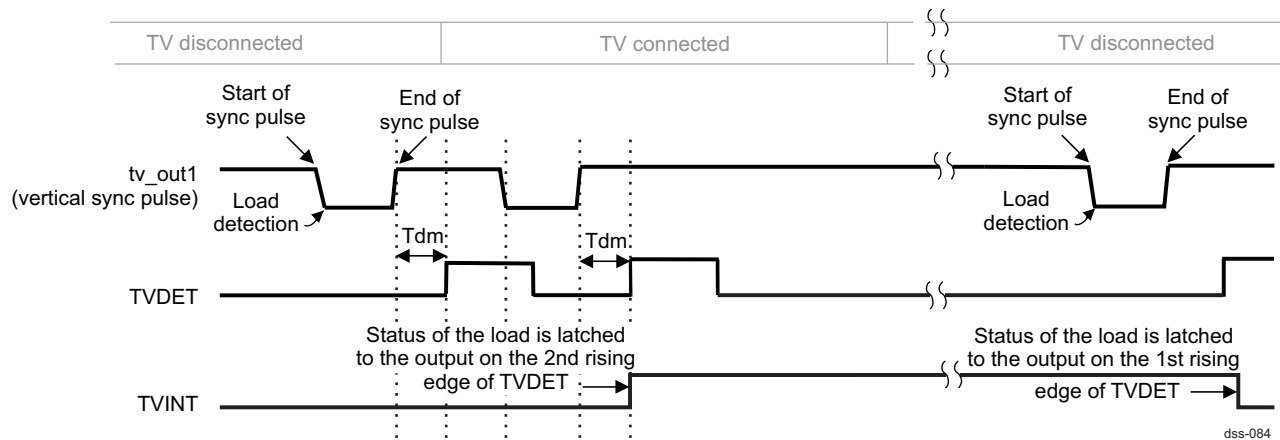

If dc-coupling is selected, the TVINT output signal for TV detection is latched at the rising edge of the first TVDET signal but the TVINT output signal for TV disconnection is latched after the next rising edge of the TVDET signal that happens during the next VSYNC timing. [Figure 15-110](#) shows the waveforms for the dc-coupling TV detect pulse (TVDET) when load is connected and disconnected.

Figure 15-110. DC-Coupling TV Detect Waveforms for TV Connected and Disconnected

If ac-coupling is selected, the TVINT output signal for TV detection is latched after the next rising edge of the TVDET signal that happens during the next VSYNC timing but the TVINT output signal for TV disconnection is latched at the rising edge of the first TVDET signal. Figure 15-111 shows the waveforms for the ac-coupling TV detect pulse (TVDET) when load is connected and disconnected.

Figure 15-111. AC-Coupling TV Detect Waveforms for TV Connected and Disconnected

Notes:

- When setting the DSS.VENC_TVDETPGP_INT_START_STOP_X register, the software user must ensure that the TVDET signal is in the active area. To avoid any problem, the TVDET signal must not be longer than one line.
- The activation of the TVDET signal will not have a visual impact on the tv_out1 output signal.

15.4.7.9.5 TV Detection/Disconnection Usage

The TV-detection/TV-disconnection is based on the difference in voltage levels in the output of the TV buffer depending on the load status. The operation is slightly different for ac and for dc operation. For dc operation, the tv_out1 voltage is compared against a voltage reference (tv_vref) that makes the comparator trigger in each sync pulse while the load is connected. For ac operation, the tv_out1 voltage is compared against a voltage reference (tv_vref) that makes the comparator trigger in each sync pulse while the load is disconnected. In both cases, the TVINT output signal produces a logic 1 when a load is connected and a logic 0 when a load is disconnected.

For dc-coupling mode, see Figure 15-112 and for ac-coupling mode, see Figure 15-113

Note: Because the video DAC and the video encoder must be awake for connection detection, consider that the video DAC can take up to 10 s to wake up.

Figure 15-112. GPIO Signal Waveform Proposal for TV Detection/Disconnection in DC-Coupling Mode

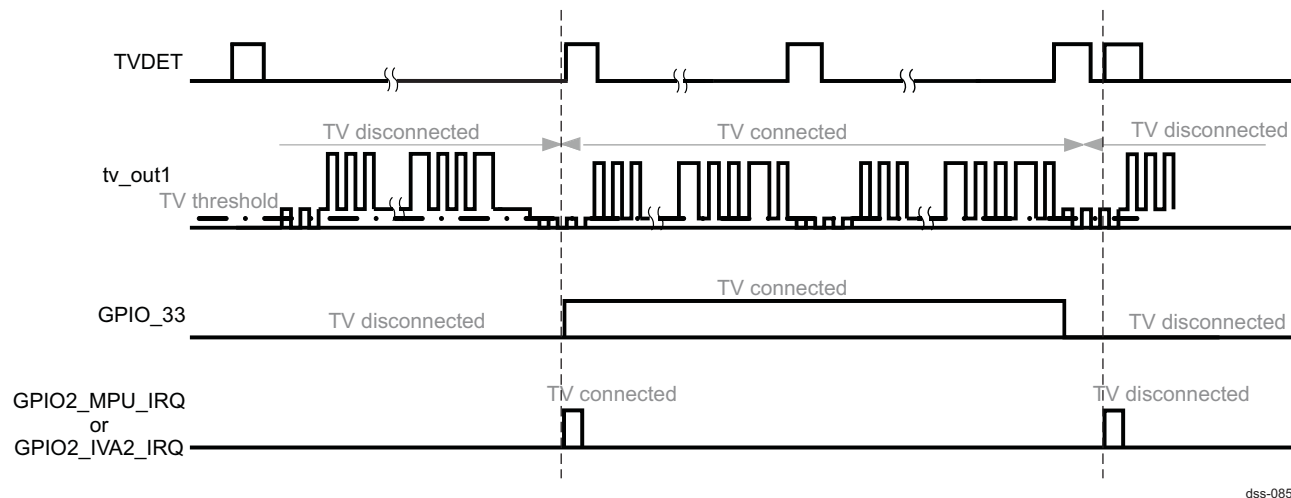

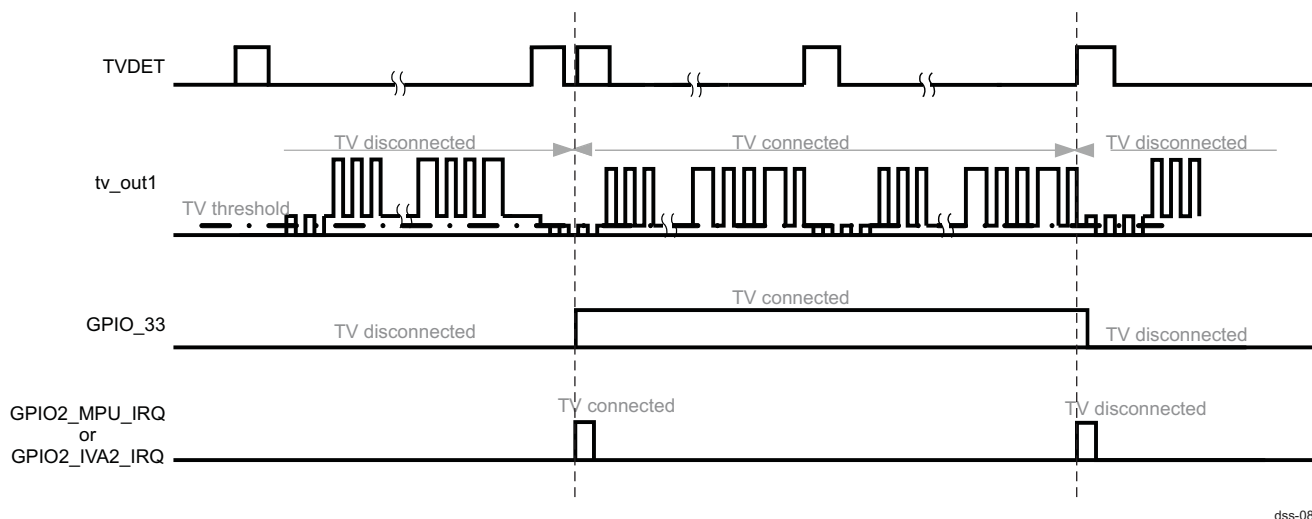

Figure 15-113. GPIO Signal Waveform Proposal for TV Detection/Disconnection in AC-Coupling Mode

15.4.7.10 Video DAC Bypass Mode

The dual 10-bit video DAC has a TVOUT buffer bypass mode that turns off the TVOUT buffer and redirects directly the DAC output to the VFB pins (tv_vfb1 for DAC1 and tv_vfb2 for DAC2).

This bypass mode is activated by setting the CONTROL.CONTROL_DEVCONF1[18] TVOUTBYPASS bit to 1. The reset value of the CONTROL.CONTROL_DEVCONF1[18] TVOUTBYPASS bit is 0 (that is, the TVOUT buffer is not bypassed).

Note: In bypass mode:

- both tv_vfb1 and tv_vfb2 pins require a RLOAD resistor connected to the ground. The typical value of the RLOAD resistor is 976 .

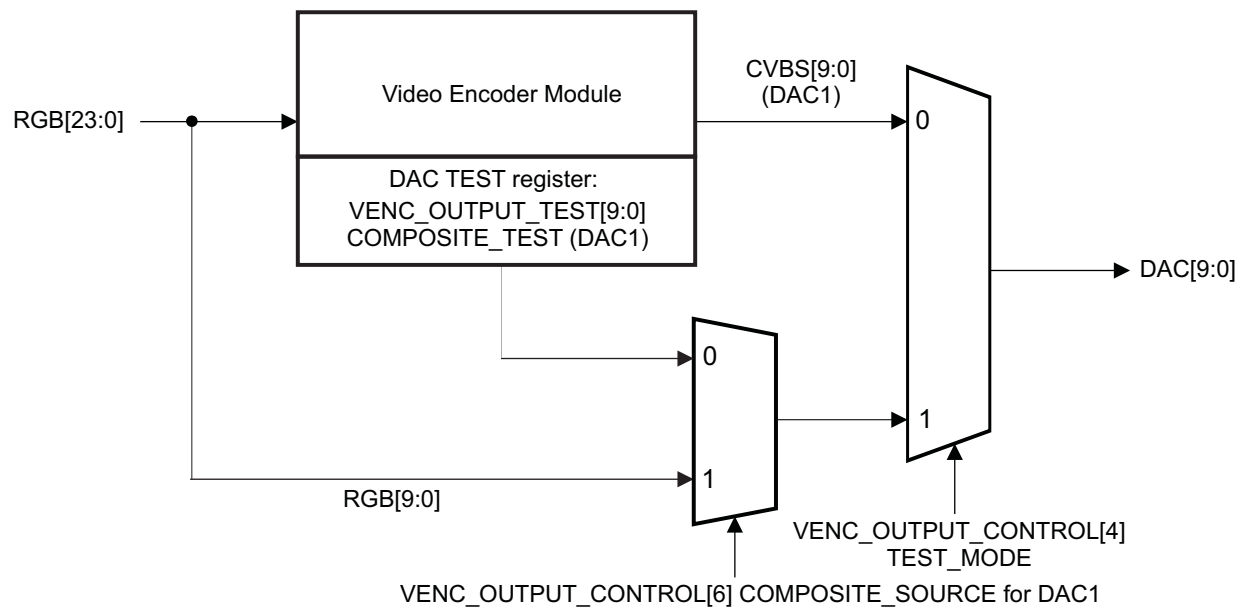

CAUTION

- The TV detect feature is not available in bypass mode.
- In bypass mode, external amplifiers are needed on the tv_vfb1 and tv_vfb2 pins.

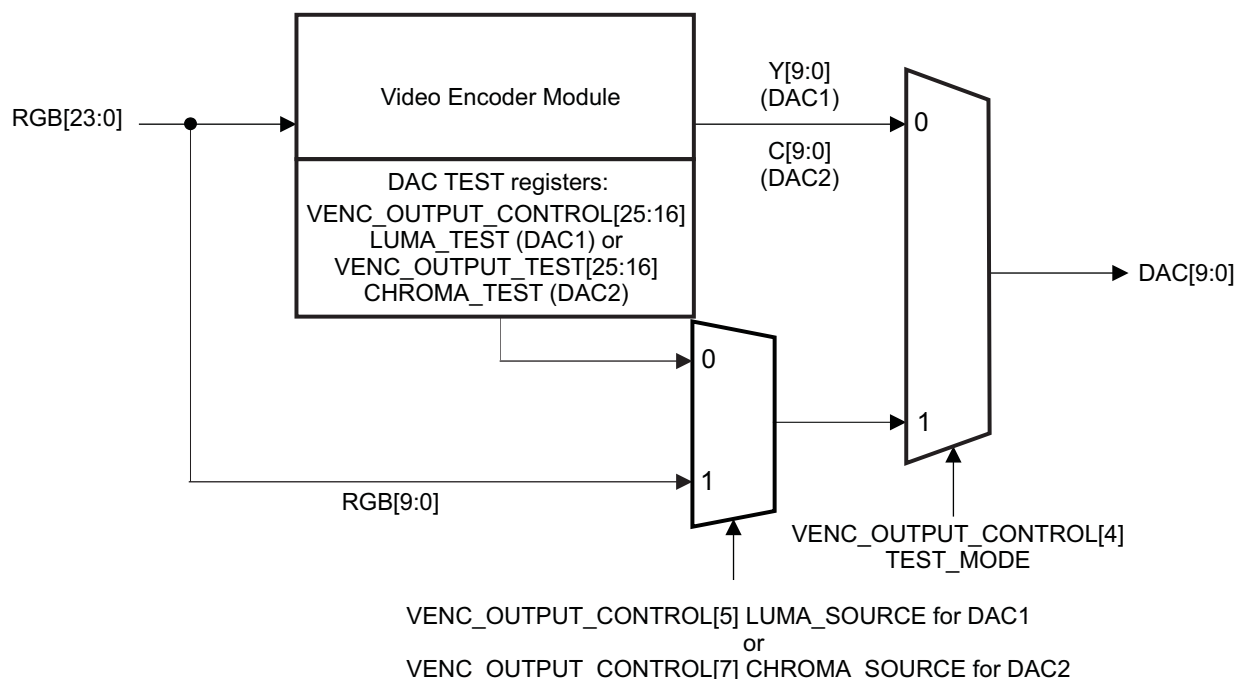

15.4.7.11 Video Dual-DAC Test Mode

The DAC can be tested for debug using either 10-bit external data or 10-bit internal register values directly connected to the DAC. See [Figure 15-114](#) for video DAC test in composite video mode, and see [Figure 15-115](#) for video DAC test in separate video mode.

Figure 15-114. DAC Test Mode in Composite Video Mode

dss-087

Figure 15-115. DAC Test Mode in Separate Video Mode

dss-088

- Use the DSS.VENC_OUTPUT_CONTROL[4] TEST_MODE bit to select between DAC normal mode (0x0) and DAC test mode (0x1).
- Use the DSS.VENC_OUTPUT_CONTROL[7] CHROMA_SOURCE bit for DAC2 and either the DSS.VENC_OUTPUT_CONTROL[6] COMPOSITE_SOURCE bit (in composite video mode) or the DSS.VENC_OUTPUT_CONTROL[5] LUMA_SOURCE bit (in s-video mode) for DAC1 to select the test mode:
 - 0x0: From the internal register DSS.VENC_OUTPUT_TEST[25:16] CHROMA_TEST bit field for DAC2 and either DSS.VENC_OUTPUT_TEST[9:0] COMPOSITE_TEST bit field (composite video) or DSS.VENC_OUTPUT_CONTROL[25:16] LUMA_TEST (s-video mode) for DAC1
 - 0x1: From the video port G[1:0], B[7:0]

Note: In the external data test mode (bypass mode), the display controller must provide the data (G[1:0], B[7:0]) externally. To do this, configure the video encoder to generate correct timing signals, without which the display controller cannot operate (even if the encoder core is bypassed from the data path perspective).

15.4.8 SDI Functionalities

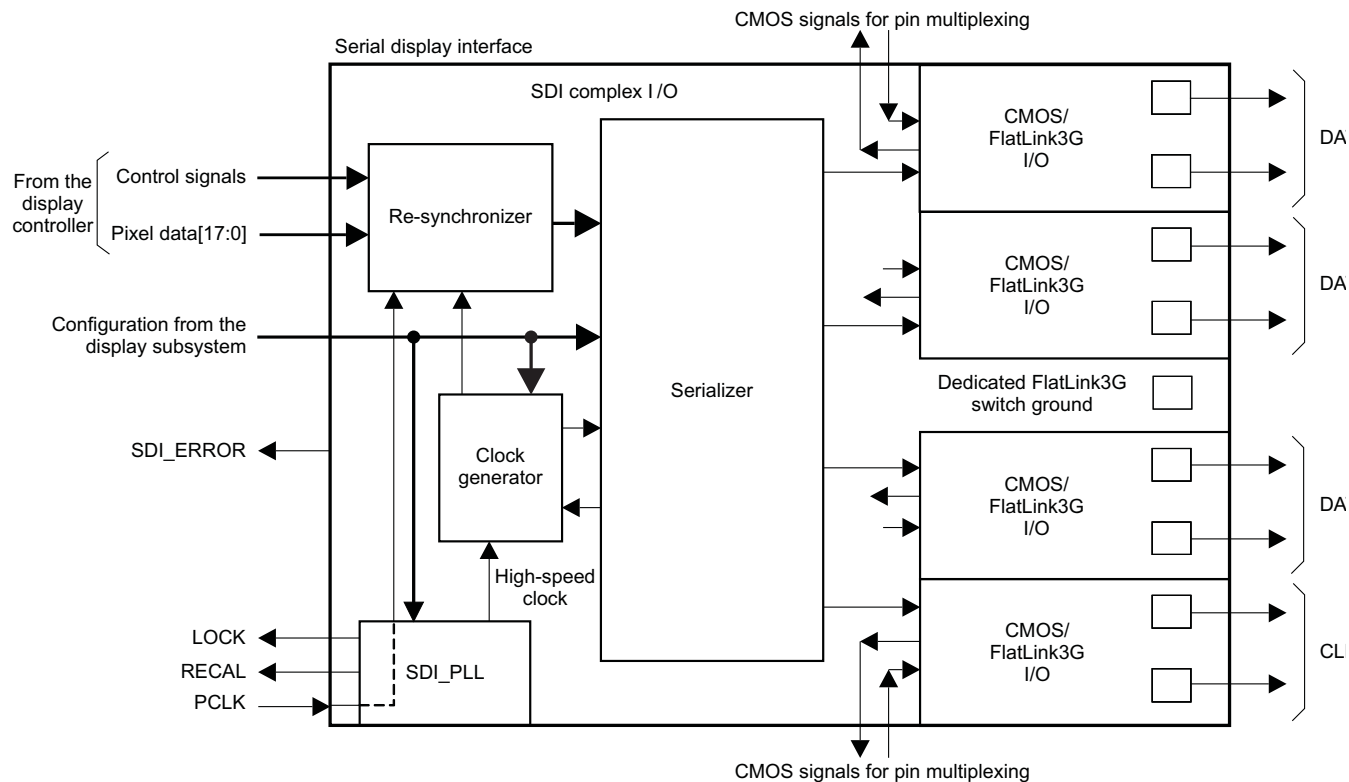

This section describes SDI module. This module is not available on all devices. See Chapter 1, the *OMAP35x Family* section, to check availability of this module.

The SDI interface has three main functions:

- A PLL (SDI_PLL) to multiply or divide the pixel clock frequency (PCLK) up to the required data rate. The pixel clock frequency range is 4-65 MHz. This clock may be divided by 2 above 32 MHz to meet the PLL input reference timing requirements.
- A specific IP block to output the data in the chosen serial format
- Output buffers to transmit the small swing differential signals

The last two functions are combined in the complex I/O module. [Figure 15-116](#) shows the SDI architecture.

Figure 15-116. SDI Architecture Overview

Notes:

- The RECAL status indicates when the SDI_PLL must be recalibrated (0: No recalibration is required; 1: Recalibration is required).
This status is connected to the GPIO_80 internal signal of the GPIO3 module. For additional information, see the *General-Purpose Interface* chapter.
- The LOCK status indicates when the SDI_PLL is locked (0: PLL not locked; 1: PLL locked). This status is connected to the GPIO_81 internal signal of the GPIO3 module. For additional information, see the *General-Purpose Interface* chapter.
For more information about lock and recalibration, see the *Power, Reset, and Clock Management* chapter.
- The SDI_ERROR status indicated when the SDI module is in error mode (0: No error; 1: SDI in error). This status allows monitoring error conditions, such as inconsistent configuration or internal loss of synchronization. It is connected to the GPIO_82 internal signal of the GPIO3 module. For additional information, see the *General-Purpose Interface* chapter.

15.5 Display Subsystem Basic Programming Model

This section describes how to configure the display subsystem for the desired functionalities and also describes the programming models of the display controller, the RFBI, the SDI and the video encoder.

The main configuration scenarios are:

- LCD panel support (bypass or RFBI mode)
Configure the RFBI module (only if in RFBI mode; otherwise, the default values must remain), and then configure the display controller to the desired functionalities before the activities start.
- TV set support
Configure the video encoder and then the display controller.
- Both LCD panel support (bypass or RFBI mode) and TV set support
Configure the RFBI module (only if in RFBI mode; otherwise, leave the default values), configure the video encoder, and then configure the display controller.
- TI FlatLink 3G-compliant LCD panel support
Configure the SDI, configure the video encoder, and then configure the display controller.

15.5.1 Display Subsystem Reset

The display subsystem can receive a software reset that is propagated through all of the submodules to initialize the subsystem. The following procedure describes a possible sequence:

1. To take the display subsystem out of reset, all clocks related to the display subsystem must be enabled and the DPLL4 must be enabled. The following clocks must be enabled to take the display subsystem out of reset:
 - PRCM.CM_FCLKEN_DSS[0] EN_DSS1 bit set to 1
 - PRCM.CM_FCLKEN_DSS[1] EN_DSS2 bit set to 1
 - PRCM.CM_FCLKEN_DSS[2] EN_TV bit set to 1
 - PRCM.CM_ICLKEN_DSS[0] EN_DSS bit set to 1
 Once the clocks are enabled as shown, the display subsystem can be taken out of reset.
2. Write 1 in the DSS.DSS_SYSCONFIG[1] SOFTRESET bit to apply the soft reset to the subsystem.
3. Read the DSS.DSS_SYSSTATUS[0] RESETDONE bit. If this bit is 1, the reset sequence is complete; otherwise, read this bit again (the reset sequence is not completed).

15.5.2 Display Subsystem Configuration Phase

The display subsystem configuration phase is important to configure the data flow for using the LCD panel or the TV set. Use the following flow:

1. To configure the top level of the functional clock of the display controller clock, set the DSS.DSS_CONTROL[0] DSS_CLK_SWITCH bit.
2. To configure the top level of the video encoder, set the DSS.DSS_CONTROL[2] VENC_CLOCK_MODE bit and the DSS.DSS_CONTROL[3] VENC_CLOCK_X4 bit for TV set support.
3. To configure the top level of the DAC, set the DSS.DSS_CONTROL[4] DAC_DEMEN bit for TV set support (if required).
4. Configure the TI FlatLink 3G-compliant LCD panel through the SPI interface to use the serial interface display.
5. Configure the RFBI module and/or the SDI module and/or the video encoder as needed.
6. Configure the display controller.

15.5.3 Display Controller Basic Programming Model

Some display controller registers are termed *shadow registers*, which are associated with the digital output and/or the LCD output. A shadow register change has no direct effect on the configuration of the display controller unless the DSS.DISPC_CONTROL[5] GOLCD bit is set for the LCD output and/or the DSS.DISPC_CONTROL[6] GODIGITAL bit is set for the digital output.

In the case of the digital output, after programming the shadow registers, the DSS.DISPC_CONTROL[6] GODIGITAL bit must be set to 1. If this bit is not set, the configuration of the display controller will have no effect. This setting indicates that all display controller shadow registers are programmed and that hardware can update the internal registers at the external EVSYNC.

In the case of the LCD output, after programming the shadow registers, the DSS.DISPC_CONTROL[5] GOLCD bit must be set to 1. If this bit is not set, the configuration of the display controller will have no effect. This setting indicates that all display controller shadow registers are programmed and that hardware can update the internal registers at the VFP start period.

Before setting either the DSS.DISPC_CONTROL[5] GOLCD or DSS.DISPC_CONTROL[6] GODIGITAL bit, ensure that the bit is cleared.

Table 15-40 lists the shadow registers.

Table 15-40. Shadow Registers

Shadow Register Name	Updated on VFP Start Period (LCD output)	Updated on External VSYNC (Digital output)
DSS.DISPC_CONTROL	X ⁽¹⁾	X ⁽¹⁾
DSS.DISPC_CONFIG	X	X
DSS.DISPC_DEFAULT_COLOR _m (m = 0)	X

15.5.3.1 Display Controller Configuration

The following registers define the display controller configuration:

- DSS.DISPC_SYSCONFIG
- DSS.DISPC_SYSSTATUS
- DSS.DISPC_IRQSTATUS
- DSS.DISPC_IRQENABLE

15.5.3.2 Graphics Layer Configuration

The graphics layer configuration is common to the LCD and the TV set.

15.5.3.2.1 Graphics DMA Registers

The following registers define the graphics DMA engine configuration:

- DSS.DISPC_CONTROL
- DSS.DISPC_GFX_BA_j
- DSS.DISPC_GFX_ATTRIBUTES
- DSS.DISPC_GFX_ROW_INC
- DSS.DISPC_GFX_PIXEL_INC
- DSS.DISPC_GFX_FIFO_THRESHOLD
- DSS.DISPC_GFX_TABLE_BA

The following fields define the attributes of the graphics DMA engine:

- Graphics layer enable (DSS.DISPC_GFX_ATTRIBUTES[0] GFXENABLE bit): The default value of this bit at reset time is 0x0 (Disabled). The graphics DMA engine fetches encoded pixels from the system memory only when the graphics layer is enabled (a valid configuration is programmed for the graphics layer). The graphics window is present and the graphics pipeline is active.
- Burst size (DSS.DISPC_GFX_ATTRIBUTES[7:6] GFXBURSTSIZE field): The default burst size at reset time is 4 x 32 bytes. The possible values are 4 x 32, 8 x 32, and 16 x 32 bytes. The burst size is initialized at boot time by the software and never changes as long as the display controller is enabled. This field indicates the maximum burst size for the specific pipeline. In case of misalignment, the DMA engine may issue single and/or smaller burst requests because the burst size must be aligned to the burst boundary.
- Preload configuration (DSS.DISPC_GFX_ATTRIBUTES[11] GFXFIFOPRELOAD bit): The default preload configuration uses the DSS.DISPC_GFX_PRELOAD register value (the reset value is 256 bytes) to define the number of bytes to be fetched from system memory into the display controller graphics FIFO. By programming the DSS.DISPC_GFX_ATTRIBUTES[11] GFXFIFOPRELOAD bit, the software user selects between preload register (with 256 bytes as the reset value) and the high threshold value for preload of the encoded pixels. For best performance, the configuration of thresholds is defined using the FIFO size (in bytes) minus 1 for the high threshold, and the FIFO size

(in bytes) minus the burst size (in bytes) for the low threshold, which provides 960, 992, and 1008, respectively, for burst sizes 16x32, 8x32, and 4x32. Note also that the preload value is defined based on the following display types:

- Active matrix (TFT) display: DSS.DISPC_GFX_PRELOAD[11:0] PRELOAD = 0x60 (value is 96)
- Color passive matrix (STN) display: DSS.DISPC_GFX_PRELOAD[11:0] PRELOAD = 0x72 (value is 114)
- Monochrome passive matrix (STN) display: DSS.DISPC_GFX_PRELOAD[11:0] PRELOAD = 0xE0 (value is 224)
- Base address of the graphics buffer in system memory (DSS.DISPC_GFX_BA_j registers): The default value of these two registers at reset time is 0x0. The horizontal resolution is one pixel because the base address is aligned on a pixel size boundary. In case of 4 BPP, the resolution is two pixels; for 2 BPP, resolution is four pixels; for 1 BPP, resolution is eight pixels; and for RGB24 packed format, the resolution is four pixels. The vertical resolution is one line. The register DSS.DISPC_GFX_BA0 defines the base address of the even field; and DSS.DISPC_GFX_BA1 defines the base of the odd field in the case of an external synchronization and based on the value of the input signal DISPC_FID and the polarity. To improve system throughput, the base address should be aligned on the burst size boundary.
- Graphics FIFO threshold (DSS.DISPC_GFX_FIFO_THRESHOLD register): The low threshold (DSS.DISPC_GFX_FIFO_THRESHOLD[11:0] GFXFIFOLOWTHRESHOLD) and the high threshold (DSS.DISPC_GFX_FIFO_THRESHOLD[27:16] GFXFIFOHIGHTHRESHOLD) values define the FIFO DMA behavior. When the low level is reached, one or more requests are issued to the L3-based interconnect to fill up the FIFO to reach the high threshold. The DMA engine then waits until the low level is reached to restart the requests. By setting the DSS.DISPC_CONFIG[14] FIFOMERGE bit to 1, the software user merges the three FIFOs (GFX, VID1 and VID2) into a single one. In this case, the low (DSS.DISPC_GFX_FIFO_THRESHOLD[11:0] GFXFIFOLOWTHRESHOLD) and the high threshold (DSS.DISPC_GFX_FIFO_THRESHOLD[27:16] GFXFIFOHIGHTHRESHOLD) values must be programmed with a multiplier factor of three (3 x value). Note that by default the FIFOs are not merged (DSS.DISPC_CONFIG[14] FIFOMERGE bit reset value is 0).
- Palette/gamma table used (DSS.DISPC_CONFIG[3] PALETTEGAMMATABL bit): The bit indicates if the palette must be loaded before the graphics data for the following frame. The bit is set by software and reset by hardware.
- Base address of the palette/gamma table buffer in system memory (DSS.DISPC_GFX_TABLE_BA register): The default value of this register at reset time is 0x0. The base address is aligned on a 32-bit address. Depending on the pixel size of graphics data (1, 2, 4, or 8 BPP), 16 (1, 2, or 4 BPP), or 256 (8 BPP) x 32-bit values are loaded from system memory into the internal table memory. To load the table when using the memory as a gamma table, the graphics pipeline is enabled and then disabled by the software when the palette loaded interrupt is generated. The overlay manager ignores the graphics pipe when the table is used as a gamma table.

Note: In case of RGB16 format and optimization enabled, the base address is aligned on a 32-bit boundary and the number of bytes to skip is a multiple of 4 bytes.

- Graphics Priority (DSS.DISPC_GFX_ATTRIBUTES[14] GFXARBITRATION): The default value at reset time is 0x0. It is used to change between normal priority (value of 0) to high priority (value of 1) to change priority for the graphics channel vs. video channels. It can be used to give higher priority to the pipelines with real time constraint vs. non real time pipelines. For e.g. pipelines associated to the LCD output in RFBI mode should have lower priority than pipelines associated to TV output.
- Graphics Self-Refresh (DSS.DISPC_GFX_ATTRIBUTES[15] GFXSELFREFRESH): The default value at reset time is 0x0. It is used to use the DMA FIFO without accessing the interconnect for multiple frames. Once, the data have been loaded to the DMA FIFO for displaying the frame, they are used for the following frames.

The sequence to activate the self-refresh is the following:

- Frame t: The bit field should be set at anytime during frame
- Frame t+1: Fetch of the data in the DMA FIFO and display of the frame
- Frame t+2: No access to the L3 interconnect, DMA FIFO uses to provide the pixels

The sequence to deactivate the self-refresh is the following:

- Frame t: No access to the L3 interconnect, DMA FIFO uses to provide the pixels, bit field can be

- changed at any time during the frame
- Frame t+1: Fetch of the data from system memory using the L3 interconnect

15.5.3.2.2 Graphics Layer Configuration Registers

The following registers define the graphics layer configuration:

- DSS.DISPC_CONFIG
- DSS.DISPC_GFX_POSITION
- DSS.DISPC_GFX_SIZE
- DSS.DISPC_GFX_ATTRIBUTES

The graphics layer is enabled/disabled by setting/resetting the DSS.DISPC_GFX_ATTRIBUTES[0] GFXENABLE bit. When the graphics layer is disabled, the graphics window does not exist on the screen and the graphics pipeline and DMA are inactive.

Set a valid configuration before enabling the graphics layer. After a register change, either the DSS.DISPC_CONTROL[6] GODIGITAL or DSS.DISPC_CONTROL[5] GOLCD bit must be set. The software must wait for the hardware to reset the bit before setting it. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

15.5.3.2.3 Graphics Window Attributes

The following fields define the attributes of the graphics window:

- Graphics format (DSS.DISPC_GFX_ATTRIBUTES[4:1] GFXFORMAT field): The default value of this field at reset time is 0x0 (BITMAP 1-BPP). The graphics format can be either: BITMAP1, BITMAP2, BITMAP4, or BITMAP8 (CLUT) or RGB12, RGB16, or RGB24 (true-color formats).
- Graphics window X-position (DSS.DISPC_GFX_POSITION[10:0] GFXPOSX field): The default value at reset time is 0x0. The window X-position is from 0 to 2047 columns. All integer values in the range [0:2047] are allowed.
- Graphics window Y-position (DSS.DISPC_GFX_POSITION[26:16] GFXPOSY field): The default value of this field at reset time is 0x0. The window Y-position is from 0 to 2047 rows. All integer values in the range [0:2047] are allowed.
- Graphics window width (DSS.DISPC_GFX_SIZE[10:0] GFXSIZEX field): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed for the following formats: 8 BPP, RGB12, RGB16, and RGB24. The width must be a multiple of eight pixels for 1 BPP, four pixels for 2 BPP, and two pixels for 4 BPP. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width of the graphics window (in bytes) is a multiple of the graphics burst size defined in the DSS.DISPC_GFX_ATTRIBUTES[7:6] GFXBURSTSIZE field (in bytes).

Note: When the RGB24 packed format is selected, the width must be a multiple of 12 bytes when the DSS.DISPC_GFX_ROW_INC register is not 1. When DSS.DISPC_GFX_ROW_INC register is 1, the width can be any size from 1 to 2048 pixels.

The entire pixels of the graphics window must be inside the LCD screen. Depending on the width of the buffer to be displayed in the graphics layer and the position, the width should be adjusted by software to limit the right edge of the window inside the screen.

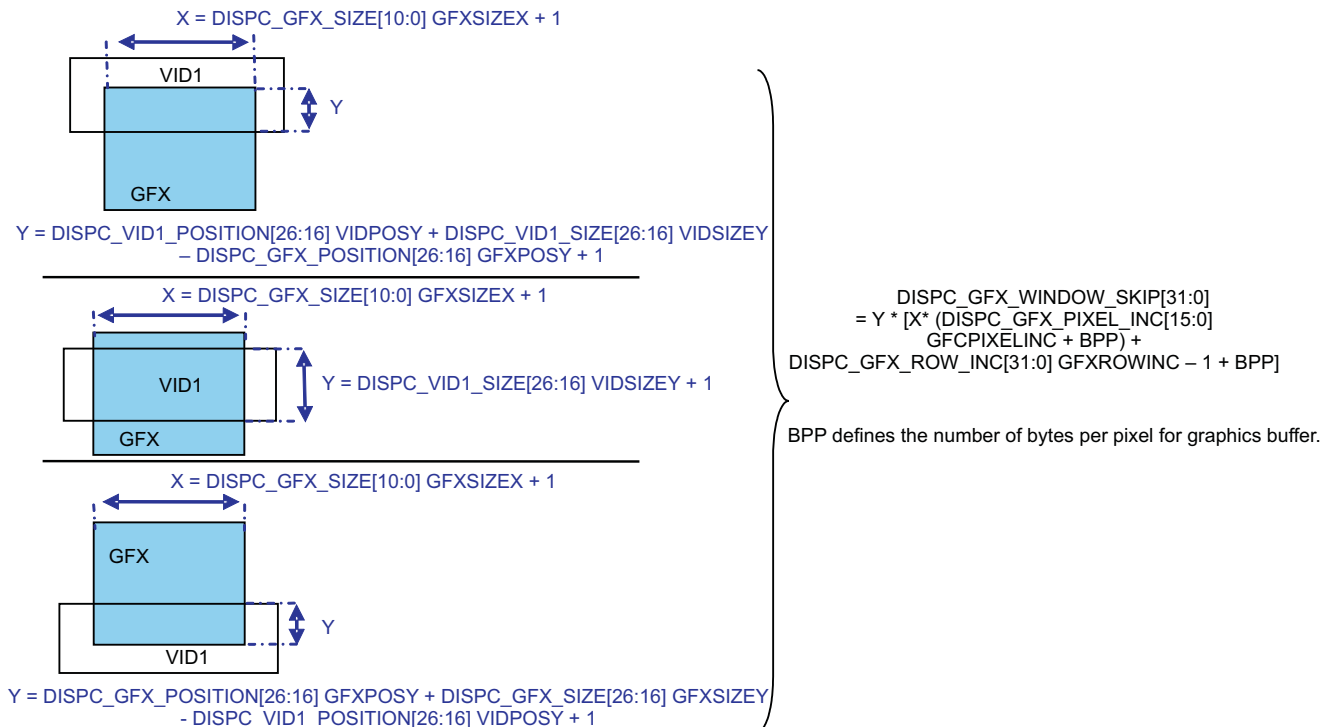

- Graphics window height (DSS.DISPC_GFX_SIZE[26:16] GFXSIZEY field): The default value at reset time is 0x0 (1 pixel). The window height is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The entire pixels of the graphics window must be inside the LCD screen. Depending on the height of the buffer to be displayed in the graphics layer and the position, the height should be adjusted by software to limit the bottom edge of the window inside the screen
- Graphics data nibble mode (DSS.DISPC_GFX_ATTRIBUTES[9] GFXNIBBLEMODE bit): This bit indicates the nibble mode of the graphics pixels. The default value at reset time is 0x0 (Disable).
- Graphics replication logic enable (DSS.DISPC_GFX_ATTRIBUTES[5] GFXREPLICATIONENABLE bit): The default value at reset time is 0x0 (Disable). The encoded pixel data in RGB format (RGB16) can be extended to 24-bit format with or without replication of the MSB part to fill up the LSB due to the

24-bit left alignment. If the replication logic is turned off, the LSB part is filled up with 0s.

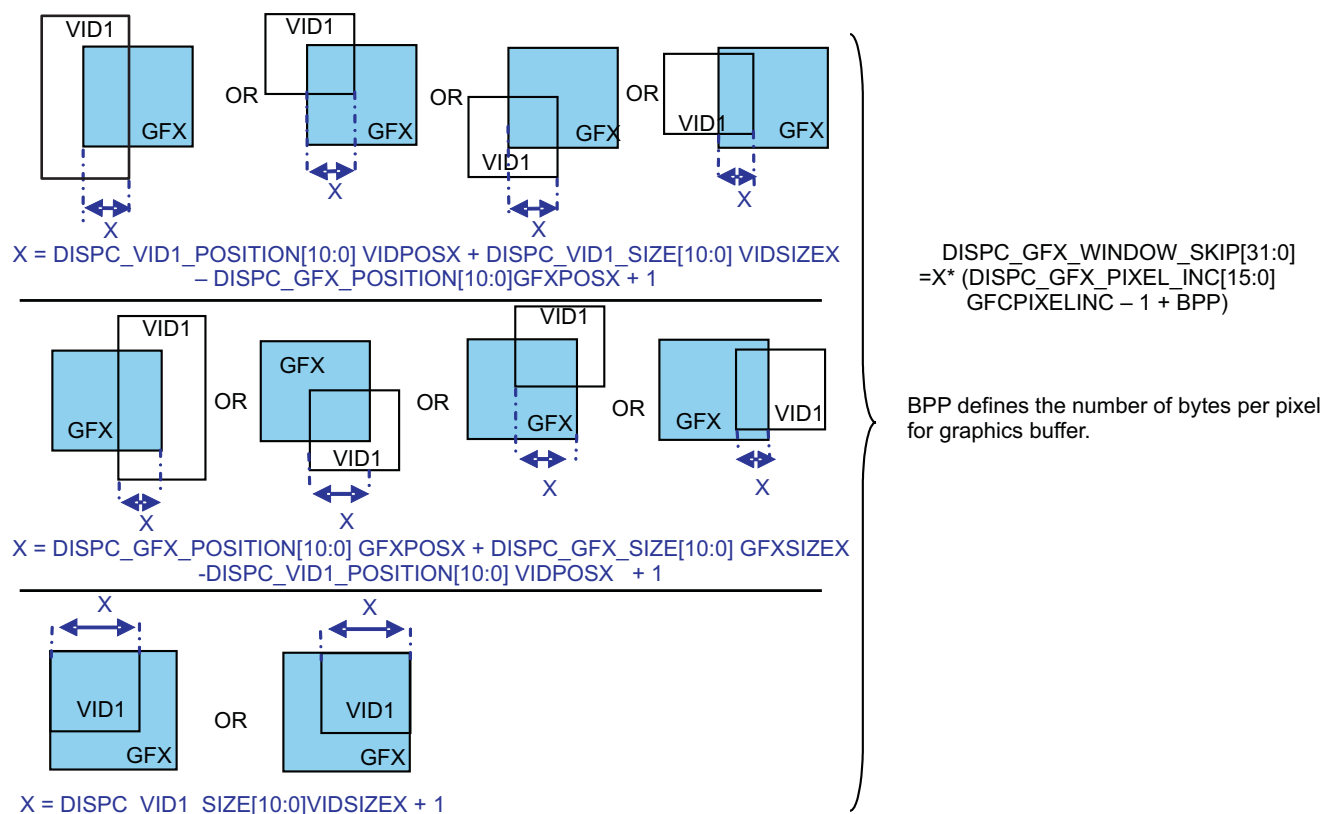

- Graphics window skip enable (DSS.DISPC_CONTROL[12] OVERLAYOPTIMIZATION bit): By setting/resetting the bit field, the overlay optimization is enabled or disabled. Before enabling the overlay optimization, the DSS.DISPC_GFX_WINDOW_SKIP[31:0] GFXWINDOWSKIP field must be set according to the video1 and graphics windows overlap. The default value at reset time is 0x0 (Disable). When video1 is not present, the DSS.DISPC_GFX_WINDOW_SKIP[31:0] GFXWINDOWSKIP field should be reset. When the color key is used, the DSS.DISPC_GFX_WINDOW_SKIP[31:0] GFXWINDOWSKIP field should be reset.
- Graphics window skip (DSS.DISPC_GFX_WINDOW_SKIP[31:0] GFXWINDOWSKIP field): The bit field represents the number of bytes to skip while fetching the graphics-encoded pixels when reaching the beginning of the video window. The optimization allows fetching only the visible graphics pixels. The color key cannot be selected because the graphics pixels under the video window are not present. The default value at reset time is 0x0 (0 byte).

Figure 15-117 through Figure 15-119 give examples of how to program the GFXWINDOWSKIP field for overlay optimization:

15.5.3.3 Video Layer Configuration

The video layer configuration is common to the LCD and the TV set.

15.5.3.3.1 Video DMA Registers

The following registers define the video DMA engine configuration:

- DSS.DISPC_CONTROL
- DSS.DISPC_VIDn_BA0

- [DSS.DISPC_VIDn_ATTRIBUTES](#)
- [DSS.DISPC_VIDn_ROW_INC](#)
- [DSS.DISPC_VIDn_PIXEL_INC](#)
- [DSS.DISPC_VIDn_FIFO_THRESHOLD](#)
- [DSS.DISPC_VIDn_PICTURE_SIZE](#)

The following fields define the attributes of the graphics DMA engine:

- Video layer enable ([DSS.DISPC_VIDn_ATTRIBUTES](#)[0] VIDENABLE bit): The default value of this bit at reset time is 0x0 (Disabled). The video DMA engine fetches encoded pixels from the system memory only when the video layer is enabled (a valid configuration is programmed for the video layer). The video window is present and the video pipeline is active.
- Burst size ([DSS.DISPC_VIDn_ATTRIBUTES](#)[15:14] VDBURSTSIZE field): The default burst size at reset time is 4 x 32 bytes. The possible values are 4 x 32, 8 x 32, and 16 x 32 bytes. The burst size is initialized at boot time by the software and never changes as long as the display controller is enabled. This field indicates the maximum burst size for the specific pipeline. In case of misalignment, the DMA engine may issue single and/or smaller burst requests, because the burst size must be aligned to the burst boundary.
- Preload configuration ([DSS.DISPC_VIDn_ATTRIBUTES](#)[19] VIDFIFOPRELOAD bit): The default preload configuration uses the [DSS.DISPC_VIDn_PRELOAD](#) register value (the reset value is 256 bytes) to define the number of bytes to be fetched from system memory into the display controller graphics FIFO. By programming the [DSS.DISPC_VIDn_ATTRIBUTES](#)[19] VIDFIFOPRELOAD bit, the software user selects between preload register (with 256 bytes as the reset value) and the high threshold value for preload of the encoded pixels. For best performance, the configuration of thresholds is defined using the FIFO size (in bytes) minus 1 for the high threshold, and the FIFO size (in bytes) minus the burst size (in bytes) for the low threshold, which provides 960, 992, and 1008, respectively, for burst sizes 16x32, 8x32, and 4x32. Note also that the preload value is defined based on the following display types:
 - Active matrix (TFT) display: [DSS.DISPC_VIDn_PRELOAD](#)[11:0] PRELOAD = 0xB0 (value is 176)
 - Color passive matrix (STN) display: [DSS.DISPC_VIDn_PRELOAD](#)[11:0] PRELOAD = 0x110 (value is 272)
 - Monochrome passive matrix (STN) display: [DSS.DISPC_VIDn_PRELOAD](#)[11:0] PRELOAD = 0x1B0 (value is 432)
- Base address of the video buffer in system memory ([DSS.DISPC_VIDn_BA](#)_j registers): The default value at reset time is 0x0. The horizontal resolution is one pixel because the base address is aligned on pixel size boundary. In case of YCbCr 4:2:2 formats, the resolution is 2 pixels. In case of RGB24 packed format, the resolution is 4 pixels. The vertical resolution is one line. The register [DSS.DISPC_VIDn_BA0](#) defines the base address of the even field, and [DSS.DISPC_VIDn_BA1](#) defines the base of the odd field in the case of an external synchronization and based on the value of the input signal DISPC_FID and the polarity. To improve system throughput, the base address should be aligned on the burst size boundary.
- Video FIFO threshold ([DSS.DISPC_VIDn_FIFO_THRESHOLD](#) register): The low threshold ([DSS.DISPC_VIDn_FIFO_THRESHOLD](#)[11:0] VIDFIFOLOWTHRESHOLD) and the high threshold ([DSS.DISPC_VIDn_FIFO_THRESHOLD](#)[27:16] VIDFIFOHIGHTHRESHOLD) values define the FIFO DMA behavior. When the low level is reached, one or more requests are issued to the L3-based interconnect to fill up the FIFO to reach the high threshold. The DMA engine then waits until the low level is reached to restart the requests. By setting the [DSS.DISPC_CONFIG](#)[14] FIFOMERGE bit to 1, the software user merges the three FIFOs (GFX, VID1 and VID2) into a single one. In this case, the low ([DSS.DISPC_VIDn_FIFO_THRESHOLD](#)[11:0] VIDFIFOLOWTHRESHOLD with n corresponding to the active video channel 1 or 2) and the high threshold ([DSS.DISPC_VIDn_FIFO_THRESHOLD](#)[27:16] VIDFIFOHIGHTHRESHOLD with n corresponding to the active video channel 1 or 2) values must be programmed with a multiplier factor of three (3 x value). Note that by default the FIFOs are not merged ([DSS.DISPC_CONFIG](#)[14] FIFOMERGE bit reset value is 0).
- Video buffer width ([DSS.DISPC_PICTURE_SIZE](#)[10:0] VIDORGSIZEX): The default value at reset time is 0x0 (1 pixel). The buffer width in system memory is from 1 up to 2048 pixels. All the integer values in the range [1:2048] are allowed. Software users must program this field to the value minus 1.
- Video buffer height ([DSS.DISPC_PICTURE_SIZE](#)[26:16] VIDORGSIZEY): The default value at reset time is 0x0 (1 pixel). The buffer height in system memory is from 1 up to 2048 pixels. All the integer

values in the range [1:2048] are allowed. Software users must program this field to the value minus 1.

15.5.3.3.2 Video Configuration Registers

The following shadow registers define video layer n (with n = 1 or 2) configuration:

- DSS.DISPC_CONFIG
- DSS.DISPC_VIDn_POSITION
- DSS.DISPC_VIDn_SIZE
- DSS.DISPC_VIDn_ATTRIBUTES
- DSS.DISPC_VIDn_FIR
- DSS.DISPC_VIDn_PICTURE_SIZE
- DSS.DISPC_VIDn_FIR_COEF_Hi (with i = 0 to 7)
- DSS.DISPC_VIDn_FIR_COEF_HVi (with i = 0 to 7)
- DSS.DISPC_VIDn_CONV_COEFi (with i = 0 to 4)
- The video layer n (with n = 1 or 2) is enabled/disabled by setting/resetting the DSS.DISPC_VIDn_ATTRIBUTES[0] VIDENABLE field. If the video layer is disabled, the video window does not exist on the screen and the whole video pipeline and DMA are inactive. Before enabling the video layer, a valid configuration must be set. After a register change, either the DSS.DISPC_CONTROL[6] GODIGITAL or DSS.DISPC_CONTROL[5] GOLCD bit must be set. The software must wait for the hardware to reset the bit before setting this bit. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

15.5.3.3.3 Video Window Attributes

The following fields define the attributes of video window n:

- Video format (DSS.DISPC_VIDn_ATTRIBUTES[4:1] VIDFORMAT field, with n = 1 or 2): The default value at reset time is 0x0 (BITMAP 1 BPP, nonsupported format by the video pipeline). The video format can be RGB16, RGB24, YUV2 4:2:2 co-DSS sited, and UYVY 4:2:2 co-sited.
- Video window X-position (DSS.DISPC_VIDn_POSITION[10:0] VIDPOSX field, with n = 1 or 2): The default value at reset time is 0x0 (first column starting on the left edge of the screen). The window X-position is from 0 to 2047 columns. All integer values in the range [0:2047] are allowed.
- Video window Y-position (DSS.DISPC_VIDn_POSITION[26:16] VIDPOSY field, with n = 1 or 2): The default value at reset time is 0x0 (first row starting at the top of the screen). The window Y-position is from 0 to 2047 rows. All integer values in the range [0:2047] are allowed.
- Video window width (DSS.DISPC_VIDn_SIZE[10:0] VIDSIZEX field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width (in bytes) of the video window is a multiple of the video burst size defined in the DSS.DISPC_VIDn_ATTRIBUTES[15:14] VDBURSTSIZE field (in bytes).

Note: When the RGB24 packed format is selected, the width must be a multiple of 12 bytes when the DSS.DISPC_VIDn_ROW_INC register is not 1. When the DSS.DISPC_VIDn_ROW_INC register is 1, the width can be any size from 1 to 2048 pixels.

The entire pixels of the video window must be inside the LCD screen. Depending on the width of the buffer to be displayed in the video layer and the position, the width should be adjusted by software to limit the right edge of the window inside the screen.

- Video window height (DSS.DISPC_VIDn_SIZE[26:16] VIDSIZEY field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window height is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The entire pixels of the video window must be inside the LCD screen. Depending on the height of the buffer to be displayed in the video layer and the position, the height should be adjusted by software to limit the bottom edge of the window inside the screen.
- Video picture width in system memory (DSS.DISPC_VIDn_PICTURE_SIZE[10:0] VIDORGSIZEX field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed with RGB16 and RGB24 video data. For

YUV2 4:2:2 and UYVY 4:2:2 formats, the width must be a multiple of two pixels. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width (in bytes) of the video picture is a multiple of the video burst size defined in the DSS.DISPC_VIDn_ATTRIBUTES[15:14] VIDBURSTSIZE field (in bytes).

- Video picture height in system memory (the DSS.DISPC_VIDn_PICTURE_SIZE[26:16] VIDORGSIZEY field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed.
- Video Priority (DSS.DISPC_VIDn_ATTRIBUTES[23] VIDARBITRATION): The default value at reset time is 0x0. It is used to change between normal priority (value of 0) to high priority (value of 1) to change priority for the video channel vs. other channels. It can be used to give higher priority to the pipelines with real time constraint vs. non real time pipelines. For e.g. pipelines associated to the LCD output in RFBI mode should have lower priority than pipelines associated to TV output.
- Video Self-Refresh (DSS.DISPC_VIDn_ATTRIBUTES[24] VIDSELFREFRESH): The default value at reset time is 0x0. It is used to use the DMA FIFO without accessing the interconnect for multiple frames. Once, the data have been loaded to the DMA FIFO for displaying the frame, they are used for the following frames.

The sequence to activate the self-refresh is the following:

- Frame t: The bit field should be set at anytime during frame
- Frame t+1: Fetch of the data in the DMA FIFO and display of the frame
- Frame t+2: No access to the L3 interconnect, DMA FIFO uses to provide the pixels

The sequence to deactivate the self-refresh is the following:

- Frame t: No access to the L3 interconnect, DMA FIFO uses to provide the pixels, bit field can be changed at any time during the frame
- Frame t+1: Fetch of the data from system memory using the L3 interconnect

15.5.3.3.4 Video Up-/Down-Sampling Configuration

The video horizontal up-/downsampling block for video pipeline n (with n = 1 or 2) is enabled/disabled by setting/resetting the DSS.DISPC_VIDn_ATTRIBUTES[5] VIDRESIZEENABLE bit.

The video vertical up-/downsampling block for video pipeline n is enabled/disabled by setting/resetting the DSS.DISPC_VIDn_ATTRIBUTES[6] VIDRESIZEENABLE bit.

Set a valid configuration before enabling the video up-/downsampling block.

Note: Vertical and horizontal downsampling are limited to a 1/4 resize factor.

After a register change, either the DSS.DISPC_CONTROL[6] GODIGITAL or DSS.DISPC_CONTROL[5] GOLCD bit must be set. The software must wait until the hardware resets this bit before setting it. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

The following fields define the configuration of the video up-/downsampling block for video pipeline n:

- Vertical up-/downsampling increment value (DSS.DISPC_VIDn_FIR[27:16] VIDFIRVINC field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$VIDFIRVINC[12:0] = 1024 \times \left(\frac{VIDORGSIZEY[10:0]}{VIDSIZEY[10:0]} \right) \quad (15-4)$$

dss-E093

Notes:

- If the VIDFIRVINC[11:0] field value is greater than 4096, it is clipped to 4096. If VIDSIZEY[10:0] equals 0x1, VIDSIZEY[10:0] is replaced by 0x2 in the previous equation.
 - The VIDORGSIZEY[10:0] and VIDSIZEY[10:0] field values must be programmed with the value desired minus 1.
-

- Horizontal up-/downsampling increment value (DSS.DISPC_VIDn_FIR[11:0] VIDFIRHINC field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$VIDFIRHINC[12:0] = 1024 \times \left(\frac{VIDORGSIZE[10:0]}{VIDSIZE[10:0]} \right) \quad \text{dss-E094} \quad (15-5)$$

Notes:

- If the VIDFIRHINC[11:0] field value is greater than 4096, it is clipped to 4096. If VIDSIZEX[10:0] equals 1, VIDSIZEX[10:0] is replaced by 2 in the previous equation.
 - The VIDORGSIZE[10:0] and VIDSIZEX[10:0] field values must be programmed with the value desired minus 1.
-
- Vertical up-/downsampling accumulator value (DSS.DISPC_VIDn_ACCUI[25:16] VIDVERTICALACCU field, with n = 1 or 2, l = 0 or 1): The unsigned integer value range is [0:1023]. The accumulator value indicates in which phase the vertical filtering starts. The value 0 indicates that 0 is the first phase used by the hardware to generate the first data (see Table 15-41).
 - Vertical up-/downsampling line buffer configuration (DSS.DISPC_VIDn_ATTRIBUTES[22] VIDLINEBUFFERSPLIT bit): The default value at reset time is 0x0 (line buffers are not split). The backward compatibility is maintained versus OMAP2420 and OMAP2430 devices. When the bit field is set, each line buffer is split into two line buffers to be able to use six line buffers instead of three.
 - Vertical up-/downsampling line buffer configuration (DSS.DISPC_VIDn_ATTRIBUTES[21] VIDVERTICALTAPS bit): The default value at reset time is 0x0 (3-tap configuration is used). If the bit field is reset, the 3-tap configuration is used. The backward compatibility is maintained versus OMAP2420 and OMAP2430 devices. When the bit field is set, the 5-tap configuration is used and the DSS.DISPC_VIDn_ATTRIBUTES[22] VIDLINEBUFFERSPLIT bit must be set to 1.
 - Vertical up-/downsampling line buffer configuration (DSS.DISPC_VIDn_ATTRIBUTES[20] VIDDMAOPTIMIZATION bit): The default value at reset time is 0x0 (no optimization). If the bit field is reset, the DMA engine fetches two pixels for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation. If the bit field is set, the DMA engine fetches one pixel for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation. The width and height of picture should be even to use the optimization.
 - Horizontal up-/downsampling accumulator value (DSS.DISPC_VIDn_ACCUI[9:0] VIDHORIZONTALACCU field, with n = 1 or 2, l = 0 or 1): The unsigned integer value range is [0:1023]. The accumulator value indicates in which phase the horizontal filtering starts. The value 0 indicates that 0 is the first phase used by the hardware to generate the first data (see Table 15-41).

Table 15-41. Vertical/Horizontal Accumulator Phase

Accumulator Value	Phases f
0	0
128	1
256	2
384	3
512	4
640	5
768	6
896	7

- Vertical up-/downsampling coefficients (DSS.DISPC_VIDn_FIR_COEF_HVi registers, with n = 1 or 2, i = 0 to 7): The 3-tap vertical up-/downsampling coefficients are defined in these registers. There are eight registers for the eight phases with three coefficients for each, or a total of 24 programmable coefficients for the vertical up-/downsampling block. Each register contains two 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one).

In addition, there are 2-tap vertical up/downsampling coefficients defined in DSS.DISPC_VIDn_FIR_COEF_Vi registers. There are 8 registers for the 8 phases with 2 coefficients

for each of them so a total of 16 programmable coefficients for the vertical up-/downsampling block used in addition of the 3-tap registers defined above. Each register contains two 8-bit signed coefficients. In case of 5-tap configuration, both sets of registers DSS.DISPC_VIDn_FIR_COEF_HVi and DSS.DISPC_VIDn_FIR_COEF_Vi are used. In case of 3-tap configuration, only one set of registers DSS.DISPC_VIDn_FIR_COEF_HVi is used.

- Horizontal up-/downsampling coefficients (DSS.DISPC_VIDn_FIR_COEF_Hi and DISPC_VIDn_FIR_COEF_HVi registers, with n = 1 or 2, i = 0 to 7): The DSS.DISPC_VIDn_FIR_COEF_Hi register and the DSS.DISPC_VIDn_FIR_COEF_HVi register define the 5-tap horizontal up-/downsampling coefficients. There are eight registers for the eight phases with five coefficients for each register, or a total of 40 programmable coefficients for the horizontal up-/downsampling block.

Each DSS.DISPC_VIDn_FIR_COEF_Hi register contains three 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one). Each DSS.DISPC_VIDn_FIR_COEF_HVi register contains one 8-bit signed coefficient.

The programmable coefficient for the FIR up-/downsampling method must be adjusted based on application needs. For more details on scaling programming settings, see [Section 15.6.1](#).

15.5.3.3.5 Video Color Space Conversion Configuration

The DSS.DISPC_VIDn_CONV_COEFi registers (with i = 0 to 4) has nine 11-bit coefficients defined for the programmable color space conversion block for video pipeline n (with n = 1 or 2).

The standard register coefficients are:

YCbCr-to-RGB Registers (VidFullRange=0)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y - 16 \\ Cr - 128 \\ Cb - 128 \end{bmatrix} \quad \text{dssE095} \quad (15-6)$$

YCbCr to RGB Registers (VidFullRange=1)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y \\ Cr - 128 \\ Cb - 128 \end{bmatrix} \quad \text{dss-E096} \quad (15-7)$$

[Table 15-42](#) lists the color space conversion register values.

Table 15-42. Color Space Conversion Register Values

Coefficients	BT.601-5	BT.601-5 range[0:255]	BT.709	BT.709 range [0:255]

15.5.3.4 Rotation/Mirroring Display Subsystem Settings

This section describes rotation/mirroring settings. The device provides flexible mechanisms for an efficient implementation of rotation using the display-subsystem, its DMA engine, and the rotation engine of the SMS module. Depending on whether the image data is located in on-chip SRAM or external SDRAM, either a DMA rotation or a VRFB rotation is used. When configuring the rotation, the image data format (RGB or YUV) must also be taken into account. The video pipelines also perform the interpolation of YUV image data and the color conversion from YUV into RGB format for displaying the images on an LCD screen.

15.5.3.4.1 Image Data Formats

In order to understand the programming of the rotation mechanisms described underneath, the supported representations of the image data in memory must also be considered. Differences exist between the supported formats on the graphics and video pipelines. The graphics pipeline supports RGB and RGB with a color look-up table (CLUT), whereas the video pipelines support two versions of YUV 4:2:2 and RGB16. In the case of YUV, the interpolation and color conversion hardware in the video pipelines converts the image data to the RGB format suitable for the LCD screen.

The graphics pipeline supports:

- 1-, 2-, 4-, and 8-bits-per-pixel color look-up table
- 12-, 16-, and 24-bits-per-pixel RGB

The video pipelines support the following data formats (always 2 bytes/pixel):

- RGB16
- YUV2
- UYVY

For more information on the graphics data formats, please refer to [Section 15.4.2.2, Graphics Pipeline](#).

For more information on the video data formats, please refer to [Section 15.4.2.3, Video Pipeline](#).

In the video pipeline, the YUV 4:2:2 format is converted into a full YUV 4:4:4 format by interpolation of the chrominance values from neighboring pixels. After this interpolation is completed, the conversion to the RGB format (suitable for displaying the image on the LCD screen) is performed.

For more information on YUV 4:2:2 to RGB conversion, please refer to [Section 15.4.2.3.2, Color Space Conversion](#).

15.5.3.4.2 Image Data from On-Chip SRAM

For image data located in the on-chip SRAM, the DSS DMA is used to perform 90-degree, 180-degree, and 270-degree rotation. This is done by using the double-indexed addressing mode of the DMA. This addressing mode allows a pixel and a row increment to be specified. These address increments are used after each pixel or each row (line), respectively. [Figure 15-120](#) illustrates the principle steps for a 90-degree rotation.

Figure 15-120. 90-Degree DMA Rotation Example

Table 15-43. 90-Degree DMA Rotation Example Description

Parameter	Description	Additional parameters for formulas
ba	Buffer Base Address in Memory	
IW	Image Width in pixels	$iw = IW - 1$
IH	Image Height in pixels	$ih = IH - 1$
ps	Pixel Size (in bytes)	

Figure 15-120 shows how the image is stored in memory and how it is read out to achieve a 90-degree rotated orientation. The first pixel for the 0-degree orientation is located at the buffer base address (ba). If the image is to be shown on an LCD screen with a 90-degree rotation, the readout starts at the 90-degree base address (1). In order to proceed from one pixel to the next in the same line in the rotated orientation, the pixel increment (2) must be applied. At the end of each line of the rotated view, the row increment (3) is the offset to advance to the beginning of the next line in the memory buffer.

Hence, by setting the three DMA parameters (base address, pixel increment, and row increment), a 90-degree rotation can be achieved, as can 180-degree and 270-degree rotation. Each of the parameters can also be combined with an optional mirroring on the vertical axis.

Following there is a description the setup required to perform the rotation via the DSS DMA. This rotation mechanism is used when the image data is stored in internal SRAM.

15.5.3.4.2.1 Rotation/Mirroring Registers

To set up the rotation and/or mirroring, the following registers must be programmed:

- Graphics pipeline (GFX):
 - DSS.DISPC_GFX_BA_j
 - DSS.DISPC_GFX_PIXEL_INC
 - DSS.DISPC_GFX_ROW_INC
 - DSS.DISPC_GFX_ATTRIBUTES
 - DSS.DISPC_GFX_POSITION
 - DSS.DISPC_GFX_SIZE
 - DSS.DISPC_GFX_FIFO_THRESHOLD
- Video pipelines (VID) 1 and 2:
 - DSS.DISPC_VID_n_BA_j
 - DSS.DISPC_VID_n_PIXEL_INC
 - DSS.DISPC_VID_n_ROW_INC

- DSS.DISPC_VIDn_ATTRIBUTES
- DSS.DISPC_VIDn_POSITION
- DSS.DISPC_VIDn_SIZE
- DSS.DISPC_VIDn_CONV_COEF0 to DSS.DISPC_VIDn_CONV_COEF4
- DSS.DISPC_VIDn_FIFO_THRESHOLD
- DSS.DISPC_xxx_BAi (i = 0 or 1): These registers contain the base address of the image data at which the DSS DMA transfer of the image starts. The register values depend on the rotation chosen (see [Table 15-44](#) for the formulas). When using the LCD interface, the registers DISPC_xxx_BA0 are used. The registers DISPC_xxx_BA1 are only used for the TV output.
- DSS.DISPC_xxx_PIXEL_INC[15:0]: This field contains the DMA addressing increment after each pixel. This field is used to perform the DSS DMA rotation (see [Table 15-44](#) for the formula).

Note: When the RGB24 packet format is selected, the only valid value is 1.

- DSS.DISPC_xxx_ROW_INC[31:0]: This field contains the DMA addressing increment after each row (line) of pixels. This field is used to perform the DSS DMA rotation (see [Table 15-44](#) for the formula).

Note: When the RGB24 packet format is selected, the valid values are 1 and any value multiples of 12 bytes (4x32 bit). When the value is a multiple of 12 bytes, the width must be a multiple of 12 bytes. When the value is 1, the width can be any size from 1 to 2048 pixels.

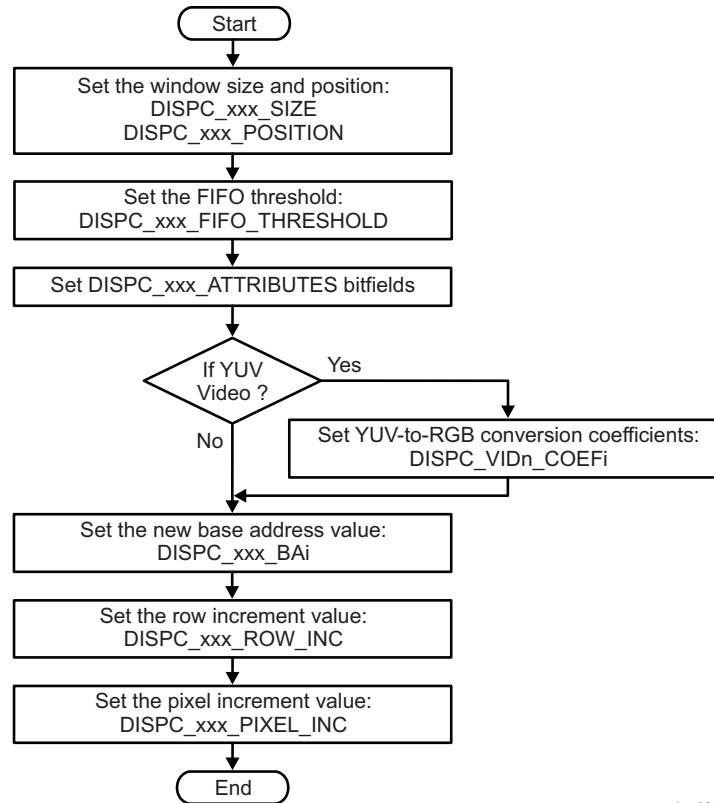

- DSS.DISPC_xxx_ATTRIBUTES: These registers contain the main settings for the pipeline, such as the image data format, the rotation value, and the enable bit for the pipeline. The bit fields of these registers play a role in the rotation and in the image data format setup.
 - The following bit fields are used by the graphics pipeline to set up the image format:
 - GFXENABLE: Set this field to activate the hardware path in use.
 - GFXFORMAT: Use this field to specify the format of the graphic frame.
 - GFXROTATION: Set this field to the value corresponding to the rotation angle desired only if the frame contains RGB24 pixel data; otherwise, set it to 0x0 regardless of the degree of rotation.
 - GFXREPLICATIONENABLE: Use this bit to determine whether the encoded pixel data in RGB formats (RGB12 and RGB16) is extended to 24-bit format with or without replication of the most significant bit (MSB) to fill the least significant bits (LSBs) of each color component. If the replication logic is turned off, the LSB parts are filled with 0s. It is recommended to always enable this feature.
 - GFXCHANNELOUT: Set this field based on whether the frame is to be rendered on the LCD or on the TV set.
 - The following bit fields for the two video pipelines:
 - VIDENABLE: Set this field to activate the hardware path in use.
 - VIDFORMAT: Use this field to specify the format of the video frame (RGB16 or YUV422).
 - VIDCOLORCONVENABLE: If the video is in YUV422 format, set this field to enabled.
 - VIDROTATION: Set this field to the value corresponding to the rotation angle desired only if the frame contains non-RGB pixel data; otherwise, set it to 0x0 regardless of the degree of rotation. See [Section 15.5.3.4.4](#) for more information.
 - VIDROWREPEATENABLE: Set this field to enabled only if the frame contains YUV pixel data and the rotation is 90-degree or 270-degree so that the row pixel data are fetched twice to extract both Y components. See [Section 15.5.3.4.4](#) for more information.
 - VIDCHANNELOUT: Set this field based on whether the frame is to be rendered on the LCD or on the TV set.
- DSS.DISPC_xxx_POSITION: Use this register to configure the position of the window.
- DSS.DISPC_xxx_SIZE: Use this register to configure the size of the window.
- DSS.DISPC_VIDn_CONV_COEF0, DSS.DISPC_VIDn_CONV_COEF1, DSS.DISPC_VIDn_CONV_COEF2, DSS.DISPC_VIDn_CONV_COEF3, and DSS.DISPC_VIDn_CONV_COEF4: These registers contain the conversion coefficients required for YUV-to-RGB color conversion.

- DSS.DISPC_xxx_FIFO_THRESHOLD: Set the low threshold (DSS.DISPC_GFX_FIFO_THRESHOLD[11:0] GFXFIFOLOWTHRESHOLD) and the high threshold (DSS.DISPC_GFX_FIFO_THRESHOLD[27:16] GFXFIFOHIGHTHRESHOLD) values to define the FIFO DMA behavior. When the low level is reached, one or more requests are issued to the L3-based interconnect to fill up the FIFO to reach the high threshold. The DMA engine then waits until the low level is reached to restart the requests.

15.5.3.4.2.2 DMA Register Settings

To configure the display controller for rotation and/or mirroring you should follow the underneath settings:

Figure 15-121. Rotation/Mirroring Settings

dss-098

Note: These registers are shadow registers. To take into account the new values, the software user has to set the DSS.DISPC_CONTROL[5] GOLCD bit to 1.

Table 15-44 details the base address, the row and pixel increment values to access the buffer in memory (contiguous pixels) except for the RGB24 packet format. Table 15-45 lists the rotation register settings for RGB24 packet format (only for the two video pipelines).

Table 15-44. DMA Rotation Register Settings

Rotation	Registers	GFX/VIDx ⁽¹⁾
0 degree	DSS.DISPC_xxx_BAi DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba 1 1
90 degrees	DSS.DISPC_xxx_BAi DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	$ba + (iw \times (ih-1) \times ps)$ $-(iw \times ps) - 1$ $(iw \times (ih-1)) \times ps + 1$
180 degrees	DSS.DISPC_xxx_BAi DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	$ba + (iw \times ih-1) \times ps$ $-2 \times ps$ $-2 \times ps$
270 degrees	DSS.DISPC_xxx_BAi DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	$ba + (iw - 1) \times ps$ $(iw - 1) \times ps + 1$ $-(iw \times (ih-1)) \times ps - ps + 1$

⁽¹⁾

- ba = start address of image buffer in memory
- iw = image width in pixels per row - 1 (for YUV: pixels per row divided by 2)
- ih = image height - 1 (number of rows)
- ps = pixel size in bytes (RGB: 2 bytes per pixel, YUV: 4 bytes per pixel)

See Table 15-43 for more information of these parameters.

Note: In case of RGB16 format and optimization enabled, the base address is aligned on a 32-bit boundary and the number of bytes to skip is a multiple of 4 bytes.

Table 15-45. Video Rotation Register Settings (With RGB24 Packet Format)

Rotation	Registers (with n = 1 or 2)	SDRAM Direct Access ⁽¹⁾
0 degree	DSS.DISPC_VIDn_BAj DSS.DISPC_VIDn_PIXEL_INC DSS.DISPC_VIDn_ROW_INC	ba 1 1
180 degrees	DSS.DISPC_VIDn_BAj DSS.DISPC_VIDn_PIXEL_INC DSS.DISPC_VIDn_ROW_INC	$ba + (iw \times ih \times 3) - 4$ -7 -7

⁽¹⁾

- ba = physical base address of the buffer in the system memory (top-left corner of the picture)
- iw = number of pixels per row - 1 (original picture in system memory) for BITMAP and RGB formats and number of pixels per row divided by 2 for YUB422 formats
- h = number of lines - 1 (original picture in system memory)
- ps = pixel size in bytes (BITMAP8: 1 byte; RGB16: 2 bytes; YUV422: 4 bytes)

See Table 15-43 for more information of these parameters.

The DMA rotation described above can be also combined with an optional mirroring on the vertical axis (see Figure 15-122). The only settings that must be changed to achieve this mirroring are the registers described above: DISPC_xxx_BAi, DISPC_xxx_PIXEL_INC, and DISPC_xxx_ROW_INC. Table 15-46 provides the DMA setup formulas for rotation with mirroring to access the buffer in memory (contiguous pixels) except for the RGB24 packet format.

Figure 15-122. 90° Rotation With Mirroring

Table 15-46. Register Settings for DMA Rotation With Mirroring

Rotation	Registers	GFX/VIDx ⁽¹⁾
0 degree	DSS.DISPC_xxx_BAi DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba + (iw-1) x ps -2 x ps + 1 2 x (iw-1) x ps + 1
90 degrees	DSS.DISPC_xxx_BAi DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba (iw-1) x ps (-iw x (ih-1)) x ps
180 degrees	DSS.DISPC_xxx_BAi DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba + iw x (ih-1) x ps 1 -2 x iw x ps
270 degrees	DSS.DISPC_xxx_BAi DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba + (iw x ih - 1) x ps (iw -1) x ps + 1 - (iw x (ih-1)) x ps - ps + 1

(1)

- ba = start address of image buffer in memory
 - iw = image width in pixels per row - 1 (for YUV: pixels per row divided by 2)
 - ih = image height - 1 (number of rows)
 - ps = pixel size in bytes (RGB: 2 bytes per pixel, YUV: 4 bytes per pixel)
- See [Table 15-43](#) for more information of these parameters.

15.5.3.4.3 Image Data from External SRAM

The device offers a rotation engine in the SMS called the VRFB. This rotation method must be used for maximum efficiency when the image data is located in SDRAM. In order to use the VRFB rotation, both the SMS module and the DSS DMA must be configured.

In the DSS, the same registers must be set up as described for DMA rotation (see [Section 15.5.3.4.2, Image Data from On-Chip SRAM](#)). The differences are in the setup of the following registers:

- DISPC_xxx_ROW_INC: This field contains the DMA addressing increment after each row (line) of pixels. This field is used to add the remaining delta at the end of each line, in order to reach the 2048-pixel line size of the VRFB (see [Table 15-47](#) for the formula).
- DISPC_xxx_PIXEL_INC: This field contains the DMA addressing increment after each pixel. For VRFB rotation, this value is set always to 1 (see [Table 15-47](#)).

Table 15-47. VRFB Rotation - DMA Settings

Rotation	Registers	GFX/VIDx ⁽¹⁾
0 degree	DSS.DISPC_xxx_BAi DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA0 1 (2048 - iw) x ps + 1
90 degrees	DSS.DISPC_xxx_BAi DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA90 + offset 1 (2048 - ih) x ps + 1
180 degrees	DSS.DISPC_xxx_BAi DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA180 + offset 1 (2048 - iw) x ps + 1
270 degrees	DSS.DISPC_xxx_BAi DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA270 + offset 1 (2048 - ih) x ps + 1

⁽¹⁾

- VBAx = virtual address of the chosen VRFB context and orientation
- iw = image width (width in pixels for RGB, width in pixels divided by 2 for YUV)
- ih = image height
- ps = pixel size in bytes (2 bytes per pixel for RGB, 4 bytes per pixel for YUV)
- Offset = see below

Figure 15-123 provides the offset values that must be added to the virtual base addresses for 90-degree, 180-degree, and 270-degree rotation. This offset is applicable only when the defined image size in the VRFB module is greater than the actual image size, because it must be a multiple of the page width and height. In the example discussed above, the image height was set to 256 lines, instead of 240, because the page height was 32 lines. This offset must be added to the virtual base addresses, because the VRFB module is not aware of the actual image size. Figure 15-123 illustrates why this occurs and how the offset is calculated.

Figure 15-123. Offset for VRFB Rotation

dss-099

Δiw = Image width delta between the actual image width and the programmed image width because of the page width

Δih = Image height delta between the actual image height and the programmed image height because of the page height:

- Offset 90-degree: Δih pixels = $\Delta ih \times ps$ bytes
- Offset 180-degree: $2048 \times \Delta ih + \Delta iw$ pixels = $2048 \times \Delta ih \times ps + \Delta iw \times ps$ bytes
- Offset 270-degree: $2048 \times \Delta iw$ pixels = $2048 \times \Delta iw \times ps$ bytes

In the example given above, the delta in the image height is $256 - 240 = 16$ lines ($\Delta ih = 16$), whereas the exact value of the width can be programmed ($\Delta iw = 0$). In that case, the resulting offset values are:

- YUV:
 - Offset 90-degree: 16×4 bytes
 - Offset 180-degree: $2048 \times 16 \times 4$ bytes
 - Offset 270-degree: 0 bytes
- RGB:
 - Offset 90-degree: 16×2 bytes
 - Offset 180-degree: $2048 \times 16 \times 2$ bytes
 - Offset 270-degree: 0 bytes

As with DMA rotation, mirroring along the vertical axis can be added on top of the rotation when using the VRFB. This mirroring is achieved by combining an appropriate VRFB rotation with a readout of the VRFB by the DSS DMA, going backwards from the last line to the first line of the rotated image. [Table 15-48](#) provides the DMA settings for VRFB rotation with mirroring.

Table 15-48. VRFB Rotation With Mirroring - DMA Settings

Rotation	Registers	GFX/VIDx ⁽¹⁾
0 degree	DSS.DISPC_xxx_BAi	VBA180 + 2048 x (ih - 1) x ps + offset
	DSS.DISPC_xxx_PIXEL_INC	1
	DSS.DISPC_xxx_ROW_INC	-(2048 + iw) x ps + 1
90 degrees	DSS.DISPC_xxx_BAi	VBA270 + 2048 x (iw - 1) x ps + offset
	DSS.DISPC_xxx_PIXEL_INC	1
	DSS.DISPC_xxx_ROW_INC	-(2048 + ih) x ps + 1
180 degrees	DSS.DISPC_xxx_BAi	VBA0 + 2048 x (ih - 1) x ps
	DSS.DISPC_xxx_PIXEL_INC	1
	DSS.DISPC_xxx_ROW_INC	-(2048 + iw) x ps + 1
270 degrees	DSS.DISPC_xxx_BAi	VBA90 + 2048 x (iw - 1) x ps + offset
	DSS.DISPC_xxx_PIXEL_INC	1
	DSS.DISPC_xxx_ROW_INC	-(2048 + ih) x ps + 1

⁽¹⁾

- VBAx = virtual address of the chosen VRFB context and orientation
- iw = image width (width in pixels for RGB, width in pixels divided by 2 for YUV)
- ih = image height
- ps = pixel size in bytes (2 bytes per pixel for RGB, 4 bytes per pixel for YUV)
- Offset = see below

Some offsets are required if there is a delta between the programmed image size in the VRFB and the actual image size. As shown in [Figure 15-124](#), this applies to 0-degree rotation with mirroring (using VBA 180°), 90° rotation with mirroring (VBA 270-degree), and 270-degree rotation with mirroring (VBA 90-degree). The offsets are calculated in this manner:

- Offset 0-degree (mirroring): 2048 x Δih + Δiw pixels = 2048 x Δih x ps + Δiw x ps bytes
- Offset 90-degree (mirroring): 2048 x Δiw pixels = 2048 x Δiw x ps bytes
- Offset 270-degree (mirroring): Δih pixels = Δih x ps bytes

Figure 15-124. Offset for VRFB Rotation With Mirroring

dss-101

15.5.3.4.4 Additional Configuration when using YUV Format

The rotation flag (DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION bit , with n = 1 or 2) and the repeat flag (DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE) indicate the rotation to apply to the video-encoded pixels from the SDRAM and SRAM. The 2D addressing mode is used, but even when accessing the SDRAM buffer, some post-processing must be performed on the YUV 4:2:2 data depending on the rotation. These bits are set only when the video format is not RGB; otherwise, the bit field is reset to 0. Table 15-49 and Table 15-50 describe the configuration of these registers.

Table 15-49. Video Rotation Register Settings (YUV Only)

Rotation	Registers (with n = 1 or 2)	SDRAM + Rotation engine
0 degree	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x0
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
90 degrees	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x1
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1

Table 15-49. Video Rotation Register Settings (YUV Only) (continued)

Rotation	Registers (with n = 1 or 2)	SDRAM + Rotation engine
180 degrees	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x2
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
270 degree	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x3
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1

Table 15-50. Video Rotation With Mirroring Register Settings (YUV Only)

Rotation	Registers (with n = 1 or 2)	SDRAM + Rotation engine
0 degree	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x2
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
90 degrees	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x1
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1
180 degrees	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x0
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
270 degree	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x3
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1

Note: For YUV 4:2:2 video-encoded pixels, the hardware must always fetch a 32-bit value from the system memory to generate a YUV 4:4:4 value before YUV-to-RGB conversion.

- For 90- and 270-degree rotation, the missing chrominance samples for the odd pixels are generated by duplicating the chrominance samples of the previous even pixels.
- For 0- and 180-degree rotation, the missing chrominance samples for the odd pixels are generated by averaging the contiguous chrominance samples.

15.5.3.5 LCD-Specific Control Registers

The following registers define the LCD output configuration:

- DSS.DISPC_CONTROL
- DSS.DISPC_CONFIG
- DSS.DISPC_DEFAULT_COLOR_m (m=0)
- DSS.DISPC_TRANS_COLOR_m (m=0)
- DSS.DISPC_TIMING_H
- DSS.DISPC_TIMING_V
- DSS.DISPC_POL_FREQ
- DSS.DISPC_DIVISOR
- DSS.DISPC_SIZE_LCD
- DSS.DISPC_DATA_CYCLEk
- DSS.DISPC_CPR_COEF_R, DSS.DISPC_CPR_COEF_G, DSS.DISPC_CPR_COEF_B

Setting/resetting the DSS.DISPC_CONTROL[0] LCDENABLE bit enables/disables the LCD output. A valid configuration must be set before enabling the LCD output.

15.5.3.5.1 LCD Attributes

The following fields define the attributes of the panel connected to the display controller:

- Monochrome or color panel (the DSS.DISPC_CONTROL[2] MONOCOLOR bit)
- Passive Matrix or active Matrix panel (the DSS.DISPC_CONTROL[3] STNTFT bit)

- Color depth (the DSS.DISPC_CONTROL[9:8] TFTDATALINES field)
- Number of lines per panel (the DSS.DISPC_SIZE_LCD[26:16] LPP field)
- Number of pixels per line (the DSS.DISPC_SIZE_LCD[10:0] PPL field)
- 4- or 8-bit interface for Passive Matrix monochrome panel (the DSS.DISPC_CONTROL[4] M8B bit)

15.5.3.5.2 LCD Timings

The following fields define the timing generation of HSYNC/VSNC:

- Horizontal front porch (the DSS.DISPC_TIMING_H[15:8] HFP field)
- Horizontal back porch (the DSS.DISPC_TIMING_H[27:20] HBP field)
- Horizontal synchronization pulse width (the DSS.DISPC_TIMING_H[5:0] HSW field)
- Vertical front porch (the DSS.DISPC_TIMING_V[15:8] VFP field)
- Vertical back porch (the DSS.DISPC_TIMING_V[27:20] VBP field)
- Vertical synchronization pulse width (the DSS.DISPC_TIMING_V[5:0] VSW field)
- On/Off control of HSYNC/VSNC pixel clock (the DSS.DISPC_POL_FREQ[17] ONOFF bit)
- Program HSYNC/VSNC rise or fall (the DSS.DISPC_POL_FREQ[16] RF bit)
- Invert HSYNC (the DSS.DISPC_POL_FREQ[13] IHS bit)
- Invert VSNC (the DSS.DISPC_POL_FREQ[12] IVS bit)
- HSYNC gated (the DSS.DISPC_CONFIG[6] HSYNCGATED bit)
- VSNC gated (the DSS.DISPC_CONFIG[7] VSYNCGATED bit)

Table 15-51 describes the programming rules for LCD timing.

Table 15-51. Programming Rules

	No Downsampling	Downsampling H or V	Downsampling H + V
$(HBP + HSW + HFP) * PCD$	> 8	> 10	> 20

Figure 15-125 shows the timing values description in the case of an active matrix display.

Figure 15-125. Timing Values Description (Active Matrix Display)

dss-102

The following fields define the timing generation of ac-bias (output enable in active matrix mode):

- Invert output enable (DSS.DISPC_POL_FREQ[15] IEO bit)
- ac-bias pin frequency (DSS.DISPC_POL_FREQ[7:0] ACB field)
- ac-bias pin transitions per interrupt (DSS.DISPC_POL_FREQ[11:8] ACBI field)
- ac-bias gated (DSS.DISPC_CONFIG[8] ACBIASGATED)

The following fields define the timing generation of the pixel clock:

- Pixel clock divisor (DSS.DISPC_DIVISOR[7:0] PCD field)
- Invert pixel clock (DSS.DISPC_POL_FREQ[14] IPC bit)
- Pixel clock gated (DSS.DISPC_CONFIG[5] PIXELCLOCKGATED bit)

The 8-bit pixel clock divider (the DSS.DISPC_DIVISOR[7:0] PCD field) selects the pixel clock frequency. This field generates a range of pixel clock frequencies from LC/1 to LC/255, where LC is the logic clock from the divided functional clock of the display controller by the DSS.DISPC_DIVISOR[23:16] LCD field.

The pixel clock is defined by the following equation:

$$\text{Pixel Clock} = (\text{FunctionalClock} / \text{LCD}[7:0]) / \text{PCD}[7:0]$$

Table 15-52 through Table 15-55 show the pixel clock frequency limitations depending the panel type (active or passive matrix) and the mode (color or monochrome).

Table 15-52. Pixel Clock Frequency Limitations - RGB16 and YUV422 Active Matrix Display

Min PCD Values		Horizontal Resampling				
		Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off	2 (1) ⁽¹⁾	2 (1) ⁽¹⁾	2	3	4
	Up	2 (1) ⁽¹⁾	2 (1) ⁽¹⁾	2	3	4
	1:1 - 1:2	3-tap	2	2	4	6
		5-tap	PCDmin	PCDmin	PCDmin	PCDmin
	1:2 - 1:4	PCDmin	PCDmin	PCDmin	PCDmin	PCDmin

⁽¹⁾ The PCD value can be 1 in case all the data and synchronization signals are asserted and deasserted on rising edge of the pixel clock.

Table 15-53. Pixel Clock Frequency Limitations - RGB16 and YUV422 Passive Matrix Display - Mono4

Min PCD Values		Horizontal Resampling				
		Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off	4	4	8	12	16
	Up	4	4	8	12	16
	1:1 - 1:2	3-tap	8	8	16	24
		5-tap	4xPCDmin	4xPCDmin	4xPCDmin	4xPCDmin
	1:2 - 1:4	4xPCDmin	4xPCDmin	4xPCDmin	4xPCDmin	4xPCDmin

Table 15-54. Pixel Clock Frequency Limitations - RGB16 and YUV422 Passive Matrix Display - Mono8

Min PCD Values		Horizontal Resampling				
		Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off	8	8	16	24	32
	Up	8	8	16	24	32
	1:1 - 1:2	3-tap	16	16	32	48
		5-tap	8xPCDmin	8xPCDmin	4xPCDmin	8xPCDmin
	1:2 - 1:4	8xPCDmin	8xPCDmin	4xPCDmin	8xPCDmin	8xPCDmin

Table 15-55. Pixel Clock Frequency Limitations - RGB16 and YUV422 Passive Matrix Display - Color

Min PCD Values		Horizontal Resampling				
		Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off	3	3	6	9	12
	Up	3	3	6	9	12
	1:1 - 1:2	3-tap	6	6	12	18
		5-tap	3xPCDmin	3xPCDmin	3xPCDmin	3xPCDmin
	1:2 - 1:4		3xPCDmin	3xPCDmin	3xPCDmin	3xPCDmin

Note: In case of RGB24 format, [Figure 15-126](#) is still valid, except the PCDmin values which must be multiplied by two.

The PCDmin for vertical downsampling only is defined by the following equations:

Figure 15-126. PCDmin Formulas (V Down-Sampling Only)

$$h_ratio = \frac{DISPC_PPL_SIZE_LCD[10:0]PLL}{DISPC_VIDn_SIZE[10:0]VIDZSIZE}$$

$$v_ratio = \frac{DISPC_VIDn_PICTURE_SIZE[10:0]VIDORGZSIZE}{DISPC_VIDn_SIZE[10:0]VIDSIZE}$$

$$PCDmin = \frac{v_ratio}{2 \times h_ratio} \quad 1 < v_ratio \leq 2$$

$$PCDmin = \max\left(\frac{v_ratio}{2 \times h_ratio}, \frac{v_ratio - 2}{2 \times (h_ratio - 1)}\right) \quad 2 < v_ratio \leq 4$$

dss-E103

The PCDmin for horizontal downsampling only is defined by the following formula:

While downsampling by n , $PCDmin = n$

For H+V downsampling, the formula is the following:

$PCDmin = \max(PCDmin \text{ H only}, PCDmin \text{ V only})$ as defined above

The refresh rate depends on the following parameters:

- Horizontal front porch (the DSS.DISPC_TIMING_H[15:8] HFP field)
- Horizontal back porch (the DSS.DISPC_TIMING_H[27:20] HBP field)
- Horizontal synchronization pulse width (the DSS.DISPC_TIMING_H[5:0] HSW field)
- Vertical front porch (the DSS.DISPC_TIMING_V[15:8] VFP field)
- Vertical back porch (the DSS.DISPC_TIMING_V[27:20] VBP field)
- Vertical synchronization pulse width (the DSS.DISPC_TIMING_V[5:0] VSW field)
- Number of lines per panel (the DSS.DISPC_SIZE[26:16] LPP field)
- Number of pixels per line (the DSS.DISPC_SIZE[10:0] PPL field)
- 4- or 8-bit interface for the passive matrix monochrome panel (the DSS.DISPC_CONTROL[4] M8B bit)

The following field defines the behavior of the internal blocks:

- Spatial/temporal dithering logic enabled (DSS.DISPC_CONTROL[7] SPATIALTEMPORALDITHERENABLE bit)
- Spatial/temporal dithering logic number of frames (DSS.DISPC_CONTROL[31:30] SPATIALTEMPORALDITHERFRAMES field). The default value of this field at reset time is 0x0, which is 1 frame only (spatial processing without temporal dithering). The possible values are 0x0 (one frame), 0x1 (two frames), and 0x2 (four frames). The number of frames is initialized before enabling the spatial/temporal dithering unit. The software must not change this field value while the spatial/temporal unit is enabled.

The following field defines the security aspect:

- Security (the DSS.DISPC_CONTROL[10] SECURE bit). The default value of this bit at reset time is 0x0 (non-secure OCP requests). When changing, it takes effect on the L3 interconnect interface only for the following OCP request. The current OCP request secure signal is maintain stable.

The following field defines the clock gating strategy:

- In active matrix mode, the pixel clock is always gated or only when valid data are present (the DSS.DISPC_CONFIG[0] PIXELGATED bit).

15.5.3.5.3 LCD Overlay

The following fields define the overlay attributes of the LCD output:

- Transparency color key (the DSS.DISPC_TRANS_COLOR0i register (i=0))
- Transparency color key enable (the DSS.DISPC_CONFIG[10] TCKLCDENABLE bit)
- Transparency color key selection between the destination graphics transparency color key and the source video transparency color key (the DSS.DISPC_CONFIG[11] TCKLCDSELECTION bit)
- The default solid background color is defined in the DSS.DISPC_DEFAULT_COLORm[23:0] DEFAULTCOLOR field (m=0).
- Alpha blender Enable (DSS.DISPC_CONFIG[18] LCDALPHABLENDERENABLE)
- Global alpha blending values (DSS.DISPC_GLOBAL_ALPHA[23:16] VID2GLOBALALPHA and DSS.DISPC_GLOBAL_ALPHA[7:0] GFXGLOBALALPHA). The value 0xFF corresponds to 100% opaque and 0 to 100% transparent

Note: The destination graphics transparency color key is available only to the overlay with which the graphics pipeline is connected. The software must set the correct configuration of the LCD and digital overlays.

Note: When the alpha blender is enabled, the destination transparency color key is not available and the source transparency color key applies to the graphics pixels and not the video pixels.

When all of these fields are set to the appropriate values, set the DSS.DISPC_CONTROL[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC_CONTROL[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC_CONTROL[0] LCDENABLE bit will be set to 1.

15.5.3.5.4 LCD TDM

The following fields define the multiple cycle output configuration:

- First cycle (the DSS.DISPC_DATA_CYCLEk (k=1) register)
- Second cycle (the DSS.DISPC_DATA_CYCLEk (k=2) register)
- Third cycle (the DSS.DISPC_DATA_CYCLEk (k=3) register)
- Enable (the DSS.DISPC_CONTROL[20] TDMENABLE bit)
- Parallel mode (the DSS.DISPC_CONTROL[22:21] TDMPARALLEMODE field)
- Cycle format (the DSS.DISPC_CONTROL[24:23] TDMCYCLEFORMAT field)
- Unused bits (the DSS.DISPC_CONTROL[26:25] TDMUNUSEDBITS field)

When all of these fields are set to the appropriate values, set the DSS.DISPC_CONTROL[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC_CONTROL[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC_CONTROL[0] LCDENABLE bit will be set to 1.

15.5.3.5.5 LCD Spatial/Temporal Dithering

The following fields define the LCD spatial/temporal dithering configuration:

- Number of frames (the DSS.DISPC_CONTROL[31:30] SPATIALTEMPORALDITHERINGFRAMES field) with:
 - 0x0 Spatial only (default value)
 - 0x1 Spatial + Temporal over two frames
 - 0x2 Spatial + Temporal over four frames
 - 0x3 Reserved
- Enable (the DSS.DISPC_CONTROL[7] SPATIALTEMPORALDITHERENABLE bit)
 - 0x0 Disabled (default value)
 - 0x1 Enabled

When all of these fields are set to the appropriate values, set the DSS.DISPC_CONTROL[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC_CONTROL[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC_CONTROL[0] LCDENABLE bit will be set to 1.

15.5.3.5.6 LCD Color Phase Rotation

The following fields define the color phase rotation configuration:

- Enable (the DSS.DISPC_CONFIG[15] CPR bit)
 - 0x0 Disabled (default value)
 - 0x1 Enabled
- Red 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC_CPR_COEF_R register)
- Green 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC_CPR_COEF_G register)
- Blue 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC_CPR_COEF_B register)

The programmable color phase rotation block for the LCD output has nine 10-bit coefficients defined in the DSS.DISPC_CPR_COEF_R, DSS.DISPC_CPR_COEF_G, and DSS.DISPC_CPR_COEF_B, as described in Figure 15-127 through Figure 15-130.

Figure 15-127. Color Phase Rotation Matrix

$$B_{out} = \frac{1}{256} * (BR * R_{in} + BG * G_{in} + BB * B_{in})$$

dss-E104

Figure 15-128. Color Phase Rotation Matrix (R Component Only)

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RR & RG & RB \\ GR & GG & GB \\ BR & BG & BB \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

dss-E105

Figure 15-129. Color Phase Rotation Matrix (G Component Only)

$$R_{iout} = \frac{1}{256} * (RR * R_{in} + RG * G_{in} + RB * B_{in})$$

dss-E106

Figure 15-130. Color Phase Rotation Matrix (B Component Only)

$$G_{out} = \frac{1}{256} * (GR * R_{in} + GG * G_{in} + GB * B_{in})$$

dss-E107

When all of these fields are set to the appropriate values, set the DSS.DISPC_CONTROL[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC_CONTROL[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC_CONTROL[0] LCDENABLE bit will be set to 1.

15.5.3.6 TV Set-Specific Control Registers

The following registers define the digital output configuration:

- DSS.DISPC_CONTROL
- DSS.DISPC_CONFIG
- DSS.DISPC_DEFAULT_COLOR_m (m=1)
- DSS.DISPC_TRANS_COLOR_m (m=1)
- DSS.DISPC_SIZE_DIG

The digital output is enabled/disabled by setting/resetting the DSS.DISPC_CONTROL[1] DIGITALENABLE field. A valid configuration must be set before the digital output can be enabled.

Perform the initialization sequence as follows:

1. Initialize the video encoder and the display controller configuration registers.
2. Set the DSS.DISPC_CONTROL[6] GODIGITAL bit and the DSS.DISPC_CONTROL[1] DIGITALENABLE bit to 1.
3. Wait for the first VSYNC pulse signal.
4. Clear the SYNCLOSTDIGITAL interrupt by setting the DSS.DISPC_IRQSTATUS[15] SYNCLOSTDIGITAL bit to 1.
5. Enable the SYNCLOSTDIGITAL interrupt by setting the DSS.DISPC_IRQENABLE[15] SYNCLOSTDIGITAL bit to 1.

15.5.3.6.1 Digital Timings

The following fields define the timing information:

- Data hold time (the DSS.DISPC_CONTROL[19:17] HT field)
- Logic clock divisor (the DSS.DISPC_DIVISOR[23:16] LCD field)

The 8-bit pixel clock divider (DSS.DISPC_DIVISOR[23:16]) field is used to select the logic clock frequency. The LCD generates a range of pixel clock frequencies from FCK/1 to FCK/255, where FCK is the input functional clock of the display controller.

15.5.3.6.2 Digital Frame/Field Size

The following fields define the field size (frame if progressive mode):

- Number of lines per panel (the DSS.DISPC_SIZE_DIG[26:16] LPP field)
- Number of pixels per line (the DSS.DISPC_SIZE_DIG[10:0] PPL field)

15.5.3.6.3 Digital Overlay

The following fields define the overlay attributes of the digital output:

- Transparency color key (the DSS.DISPC_TRANS_COLOR_m register (m=1))
- Transparency color key enable (the DSS.DISPC_CONFIG[12] TCKDIGENABLE bit)
- Transparency color key selection between the destination graphics transparency color key and the source video transparency color key (the DSS.DISPC_CONFIG[13] TCKDIGSELECTION bit)
- The default solid background color is defined in the DSS.DISPC_DEFAULT_COLOR_m[23:0] DEFAULTCOLOR field (m=1).
- Alpha blender Enable (DSS.DISPC_CONFIG[19] TVALPHABLENDERENABLE)
- Global alpha blending values (DSS.DISPC_GLOBAL_ALPHA[23:16] VID2GLOBALALPHA and DSS.DISPC_GLOBAL_ALPHA[7:0] GFXGLOBALALPHA). The value 0xFF corresponds to 100%

opaque and 0 to 100% transparent

Note: The destination graphics transparency color key is available only to the overlay with which the graphics pipeline is connected. The software must set the correct configuration of the LCD and digital overlays.

Note: When the alpha blender is enabled, the destination transparency color key is not available and the source transparency color key applies to the graphics pixels and not the video pixels.

The Security (the DSS.DISPC_CONTROL[10] SECURE bit) field defines the security aspect. The default value of this bit at reset time is 0x0 (non-secure mode). By setting the secure bit field, all the requests sent by the display controller DMA engine are secure. If not all of the requests (single or burst) have been accepted by the interconnect, the current uncompleted request sent to the interconnect, is not affected by the change to the interconnect and is not affected by the change from secure/nonsecure to nonsecure/secure mode.

When this field is set to the appropriate values, set the DSS.DISPC_CONTROL[6] GODIGITAL bit to indicate that all shadow registers of the pipelines connected to the digital output are latched by the hardware (only if the DSS.DISPC_CONTROL[1] DIGITALENABLE bit is already set to 1). If the digital output is disabled, the new values will be updated when the DSS.DISPC_CONTROL[1] DIGITALENABLE bit will be set to 1.

15.5.4 DSI Protocol Engine Basic Programming Model

This section describes the programming model of the DSI protocol engine.

15.5.4.1 Software Reset

The DSI protocol engine can be reset by software. This reset can be done for debug purposes or after a protocol error and has the same effect as the hardware reset. The DSI protocol engine can be reset by setting the DSS.DSI_SYSCONFIG[1] SOFT_RESET bit to 1. The software can monitor the DSS.DSI_SYSSTATUS[0] RESET_DONE status bit to wait for the completion of the reset procedure. If after 5 reads, the DSS.DSI_SYSSTATUS[0] RESET_DONE status bit still returns 0, it can be assumed that an error occurred during the reset stage.

Note: This software reset is optional as a hardware reset is always performed on the DSI protocol engine at device reset.

15.5.4.2 Power Management

The power management behavior of the DSI protocol engine is controlled by the DSS.DSI_SYSCONFIG register. This register completely controls the way the module interferes with the PRCM module. The DSS.DSI_SYSCONFIG[0] AUTO_IDLE bit should be set to 1 (default value) to enable automatic clock gating in the module.

15.5.4.3 Interrupts

There is a single interrupt request: DSI_IRQ. This interrupt line is merged with another interrupt line from the DISPC_IRQ in a single interrupt request DSS_IRQ. The DSI_IRQ events are generated only for the enabled virtual channel(s). Two registers are used to enable and monitor the DSI interrupt events:

- DSS.DSI_IRQENABLE register: This register indicates the enabled/disabled event for the virtual channels. Each event for the virtual channel is configured in the DSS.DSI_VCh_IRQENABLE register dedicated to the virtual channel number. In addition, it includes one bit for the enable of error reporting for the complex I/O: Error signaling from the complex I/O: The interrupt is triggered when any error is received from the complex I/O (ErrSyncEsc[4:0], ErrEsc[4:0] (edge trigger interrupt), ErrControl[4:0] and ErrContentionLP0[4:0], ErrContentionLP1[4:0] from the complex I/O).

- DSS.DSI_IRQSTATUS register : The register DSI_IRQSTATUS flags which virtual channel(s) is/have generated an interrupt. Based on the virtual channel number, the register DSI_VCn_IRQSTATUS indicates the event generating the interrupt. In addition, it includes one bit for the status of error reporting for the complex I/O.

15.5.4.4 Global Register Controls

Prior to receive data from the DSI complex I/O, the DSIPHY_SCP registers in the DSI complex I/O must be configured. Refer to Section 15.5.6 for more details. Table 15-56 details the register access width limitations for all the DSI modules.

Table 15-56. Register Access Width Limitations

Register Name	Register Access Width
All DSI complex I/O register (DSIPHY_SCP)	32-bit only
All DSI PLL control module registers	32-bit only
DSI_VCn_LONG_PACKET_HEADER	32-bit only
DSI_VCn_SHORT_PACKET_HEADER	32-bit only
DSI_VCn_LONG_PACKET_PAYLOAD	16-bit, 32-bit
All others DSI protocol engine registers	8-bit, 16-bit and 32-bit

CAUTION

In case of different access width detailed in Table 15-56, an OCP error is generated in response to the write using SResp=ERR.

The DSI protocol engine is globally controlled by the DSS.DSI_CTRL register. The interface to the complex I/O is enabled by setting the DSS.DSI_CTRL[0] IF_EN bit. When the interface is disabled, it is possible to provide data to the TX FIFO and read pending data in the RX FIFO. When the DSS.DSI_CTRL[0] IF_EN bit is set to 1, the pending packets should be sent to the DSI complex I/O, the data transfer from the video port should be ignored only when received the next Vertical Sync Event which is received but not send to the DSI complex I/O.

When the DSS.DSI_CTRL[0] IF_EN bit is reset by software, the hardware should finish the transfer of the pending data in the TX FIFO and wait for response if BTA has been sent (Protocol engine is receive mode), then the hardware resets the DSS.DSI_CTRL[0] IF_EN bit. When using the video mode, the virtual channel (VC) associated with the video port should be enabled prior to enable the interface according to the following sequence:

- DSS.DSI_CTRL[0] IF_EN bit is equal to 0
- Enable the VC associated with video mode by setting the DSS.DSI_VCn_CTRL[0] VC_EN
- Set the DSS.DSI_CTRL[0] IF_EN bit to 1

15.5.4.5 Virtual Channels

There is one set of registers for each virtual channel. The attributes of the virtual channel define the following characteristics:

- Transfer mode (DSS.DSI_VCn_CTRL[4] MODE bit):
 - Video mode
 - Command mode
- Data type
- Source (DSS.DSI_VCn_CTRL[1] SOURCE bit)

- Video port
- L4 interconnect port
- HS or LP forward transmission
- Automatic bus turn-around generation
 - Short packets (DSS.DSI_VCn_CTRL[2] BTA_SHORT_EN bit)
 - Long packets (DSS.DSI_VCn_CTRL[3] BTA_LONG_EN bit)
- DMA request configurations for RX and TX
 - DMA request number (DSS.DSI_VCn_CTRL[29:27] DMA_RX_REQ_NB field for RX FIFO and DSS.DSI_VCn_CTRL[23:21] DMA_TX_REQ_NB field for TX FIFO)
 - DMA threshold (DSS.DSI_VCn_CTRL[26:24] DMA_RX_THRESHOLD field for RX FIFO and DSS.DSI_VCn_CTRL[19:17] DMA_TX_THRESHOLD field for TX FIFO)
- Mode speed (DSS.DSI_VCn_CTRL[9] MODE_SPEED bit)
- ECC transmission (DSS.DSI_VCn_CTRL[8] ECC_TX_EN bit)
- CS transmission (DSS.DSI_VCn_CTRL[7] CS_TX_EN bit)

The virtual channel id not calculated by the DSI module but provided while writing into the registers DSI_VCn_SHORT_PACKET_HEADER and [DSI_VCn_LONG_PACKET_HEADER](#).

15.5.4.6 Packets

The DSS.DSI_VCn_SHORT_PACKET_HEADER register is used to send only short packets (ECC can be calculated by hardware or by software user for debug purpose). The register is not used for video mode data since the short packets are generated by the hardware using the following information:

- synchronization events received on the video port (assertion/deassertion of the HSYNC and VSYNC input signals)
- DSS.DSI_CTRL[18] VP_HSYNC_END
- DSS.DSI_CTRL[17] VP_HSYNC_START
- DSS.DSI_CTRL[16] VP_VSYNC_END
- DSS.DSI_CTRL[15] VP_VSYNC_START
- DSS.DSI_CTRL[10] VP_HSYNC_POL
- DSS.DSI_CTRL[11] VP_VSYNC_POL
- DSS.DSI_VCn_CTRL[1] SOURCE

The DSS.DSI_VCn_LONG_PACKET_HEADER register is used to provide header for long packets (ECC is always calculated by hardware). The register is used for video mode and command mode. If the video mode is enabled for the virtual channel VC, it is not possible to transfer concurrently (interleaved in a frame) data using long packets received on the video port and on the L4 interconnect port since the DSS.DSI_VCn_LONG_PACKET_HEADER register is used by the video mode. The register can be unprogrammed by the user to send long packets received on the L4 interconnect port only when the software user knows that there is no expected data on the video port. It is under software responsibility to program correctly the register to send sequentially long packets in video and command modes.

The DSS.DSI_VCn_LONG_PACKET_PAYLOAD register is used to provide payload data for long packets (Check-sum is calculated by hardware when DSS.DSI_VCn_CTRL[7] CS_TX_EN is set to 1 otherwise the value 0x00 is used). The register is not used in video mode since payload data are provided by the video port. The software should ensure that the following sequence for write accesses to the header and payload registers (DSS.DSI_VCn_LONG_PACKET_HEADER and [DSS.DSI_VCn_LONG_PACKET_PAYLOAD](#) respectively) is followed:

- A long packet header value with WC=0 written in DSS.DSI_VCn_LONG_PACKET_HEADER register can be followed by any access.
- A long packet header value with WC>0 written in DSS.DSI_VCn_LONG_PACKET_HEADER register should be followed by one or more writes to the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register defined by the WC value before writing again to the same DSS.DSI_VCn_LONG_PACKET_HEADER register.

CAUTION

In case this sequence is not followed, there is no error generated. Note that the access to other DSI registers during this sequence is allowed.

15.5.4.7 DSI Complex I/O

Prior to send/receive any data from the complex I/O, the DSI complex I/O timings should be set according to the display module timings. The DSI complex I/O pads must also be configured first. Refer to [Section 15.5.6](#)

15.5.4.8 Video Mode

The DSS.[DSI_VM_TIMING1](#), DSS.[DSI_VM_TIMING2](#), DSS.[DSI_VM_TIMING3](#), DSS.[DSI_VM_TIMING4](#), DSS.[DSI_VM_TIMING5](#), DSS.[DSI_VM_TIMING6](#), and DSS.[DSI_VM_TIMING7](#) registers define the timings of the video mode.

The DSS.[DSI_CTRL](#)[20] [BLANKING_MODE](#) bit defines if the long blanking packets or LPM state are used during the blanking periods (except HFP, HBP, HSA defined by other bits) when there is no pending data in TX FIFO ready to be sent. The software should ensure that there is no data in the TX FIFO, no BTA, no RESET trigger sent, and the DSS.[DSI_VCn_CTRL](#)[9] [MODE_SPEED](#) bit is set to 1 (High-Speed mode) to keep the video mode transfer is HS mode during blanking periods (except for the last blanking period since it is required to go LPM at least once per frame).

The DSS.[DSI_CTRL](#)[21] [HFP_BLANKING_MODE](#), DSS.[DSI_CTRL](#)[22] [HBP_BLANKING_MODE](#) and DSS.[DSI_CTRL](#)[23] [HSA_BLANKING_MODE](#) define if these blanking can send packets from the TX FIFO or should be kept in HS mode using only long blanking packets.

To ensure that the writes to the register DSS.[DSI_VCn_LONG_PACKET_HEADER](#) are correctly handled as header information for video mode long packets, the following registers should be programmed:

- DSS.[DSI_VCn_CTRL](#)[0] [VC_EN](#) bit set to 0
- DSS.[DSI_VCn_CTRL](#)[4] [MODE](#) bit set to 1
- DSS.[DSI_VCn_LONG_PACKET_HEADER](#) register access
- DSS.[DSI_VCn_CTRL](#)[0] [VC_EN](#) bit set to 1

Note: The DSS.[DSI_VCn_CTRL](#)[1] [SOURCE](#) and DSS.[DSI_VCn_CTRL](#)[9] [MODE_SPEED](#) bits are ignored by hardware when the video mode is selected (DSS.[DSI_VCn_CTRL](#)[4] [MODE](#) bit set to 1)

The interrupt events [SYNC_LOST_IRQ](#) and [RESYNCHRONIZATION_IRQ](#) indicates if the DSI protocol engine has not been able to resynchronize the video port timing to its own timing base or if it has been done. The [RESYNCHRONIZATION_IRQ](#) indicates to the software user that the video port works but the configuration of the timings for the Display Controller (DISPC) and for DSI Protocol engine may need to be modified to avoid the resynchronization to occur. The [SYNC_LOST_IRQ](#) and [RESYNCHRONIZATION_IRQ](#) events can be respectively monitored in DSS.[DSI_IRQSTATUS](#)[18] [SYNC_LOST_IRQ](#) and DSS.[DSI_IRQSTATUS](#)[5] [RESYNCHRONIZATION_IRQ](#) status bits.

The DSS.[DSI_VM_TIMING2](#)[27:24] [WINDOW_SYNC](#) field defines the synchronization period. The recommended value is 0x4 based on the implementation of the resynchronization scheme.

15.5.4.9 Video Port Data Bus

The DSS.[DSI_CTRL](#)[7:6] [VP_DATA_BUS_WIDTH](#) field is used to determine the width of the data bus on the video port. The supported formats are 16-bit, 18-bit and 24-bits.

15.5.4.10 Command Mode

15.5.4.10.1 Command Mode TX FIFO

The single TX FIFO is used on the L4 interconnect port to receive the data to be sent to the peripheral. The configuration of the FIFO for a specific virtual channel should be done only when the virtual channel is disabled.

The user should not enable the virtual channel if there is still some pending data in the TX FIFO for the corresponding space allocated for the VC from previous active period. When the VC space in the TX FIFO is empty, the virtual channel can be enabled.

For each virtual channel, two dedicated DSS.DSI_VCn_LONG_PACKET_HEADER and DSS.DSI_VCn_LONG_PACKET_PAYLOAD registers are used to provide data for long packets. The register DSS.DSI_VCn_SHORT_PACKET_HEADER is used to provide data for short packets (32-bit long).

For each long packet, the DSS.DSI_VCn_LONG_PACKET_HEADER register should be written first and then the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register. The only exception is when the word count defined in the header is equal to 0. In that case, it is not required to write into the payload register. For consecutive long packets, the header should be written into the DSS.DSI_VCn_LONG_PACKET_HEADER register even if the value remains the same.

The TX FIFO stores all the pending bytes to be sent to the peripheral(s). Multiple receivers can be addressed using the virtual channel capability.

The 32-bit write requests only for each virtual channel to the TX FIFO should be kept in order while sending the data to the DSIPHY inside the virtual channel requests. The only exception is in the case of last 32-bit write for the last bytes of the payload data since it could be 1, 2, 3, or 4 bytes.

Also in case the last transfer is a 32-bit write but the number of valid bytes is 1, 2, or 3 only (calculated using the header word count and the number of bytes are received for the payload), the hardware should store the 32-bit value into the TX FIFO but the invalid bytes are not sent, and are discarded.

When the word count defined in DSS.DSI_VCn_LONG_PACKET_HEADER register is not a multiple of the request threshold value defined in DSS.DSI_VCn_CTRL[19:17] DMA_TX_THRESHOLD field, 32-bit requests and/or bytes should be discarded by the hardware to store in FIFO only the exact number of valid bytes.

The DSI protocol module should be able to determine if the bytes in the TX FIFO correspond to a short or long packet without decoder the Data Type Field. When the bytes are written into the DSS.DSI_VCn_SHORT_PACKET_HEADER, DSS.DSI_VCn_LONG_PACKET_HEADER, and DSS.DSI_VCn_LONG_PACKET_PAYLOAD registers, the hardware should store the information concerning long or short packet. A one-bit flag should be used for each entry of the TX FIFO.

When the virtual channel is disabled, the remaining bytes in the FIFO should be sent to the DSI link. The start event to send data to the DSI link one of the following events:

- all bytes have been received in the FIFO (header + payload)
- the space of the FIFO allocated for the virtual channel is full
- the space of the FIFO allocated for the virtual channel is not enough to request more data using DMA request (threshold value bigger than space left in the TX FIFO for the VC)

Note: In case the video mode is active, the blanking period should be large enough to allow the transfer of the packet(s).

When consecutive packets should be sent in HS mode, to guarantee that there is no LP transition between them at least on the following condition should be valid:

- packets from the same virtual channel
- short packets or long packets with a payload size multiple of 4 bytes

To flush the FIFO (discard of the data) for some pending bytes, the software should change the allocated size of the chunk FIFO by:

- first disabling the virtual channel resetting DSS.DSI_VCn_CTRL[0] VC_EN bit to 0
- second change the size of the space of FIFO to 0 by writing the DSS.DSI_TX_FIFO_VC_SIZE VCn_FIFO_SIZE (n is the virtual channel value between 0 and 3)

If there is an on-going packet transfer from the TX FIFO to DSI-PHY, the flush of the FIFO should stop immediately the transfer. The software is responsible since the fullness of the FIFO is accessible for the user, to ensure that there is no bytes left in the FIFO before starting the flush operation. But it can be required in dead-lock situation to flush the FIFO even if there are still bytes in the FIFO, in that case, the software should also take care of having a known state of the whole DSI protocol engine module (software reset may be required) To start of new transfer through the TX FIFO.

The user can check that there is no pending request before changing the size of the allocated FIFO for the virtual channel by reading the relevant DSS.DSI_VCn_CTRL[15] VC_BUSY bit or by using the interrupt PACKET_SENT_IRQ: All the packets have been sent by counting the transferred requests to the L4 interconnect port and the number of requests sent to the DSI complex I/O. This interrupt can be monitoring by reading the DSS.DSI_VCn_IRQSTATUS[2] PACKET_SENT_IRQ status bit.

The DSS.DSI_CTRL[3] TX_FIFO_ARBITRATION bit defines if the arbitration scheme is:

- Round-robin between enabled virtual channels with pending ready requests (pending ready request means that all bytes for the packets are in the FIFO or the space of the FIFO for the virtual channel is full) starting from the virtual channel which has the least VC ID number.
- Sequential: All the pending ready requests for one virtual channel are sent before moving to another virtual channel. The condition of "space of the FIFO is full" should be evaluated after the end of each packet.

In case the user wants to use in-order for all requests for all channels, a single virtual channel should be used. (the virtual channel id defined in the header provided to the hardware using either the DSS.DSI_VCn_LONG_PACKET_HEADER or DSS.DSI_VCn_SHORT_PACKET_HEADER register is not used and not modified by the DSI protocol engine).

The register DSS.DSI_TX_FIFO_VC_SIZE defines the allocated number of 33-bit values for each virtual channel in the TX FIFO and the start address for each virtual channel. The size of the space allocated in the TX FIFO defined by DSS.DSI_TX_FIFO_VC_SIZE VCn_FIFO_SIZE (n corresponds to the VC number n) fields should be a multiple of the threshold defined in DSS.DSI_VCn_CTRL[19:17] DMA_TX_THRESHOLD field. Only the enabled virtual channels should be taken into account. To change the size of the space of the memory allocated for a specific virtual channel, the virtual channel should be disabled by setting the DSS.DSI_VCn_CTRL[0] VC_EN bit to 0. The whole FIFO may not be used by all the virtual channels at a given time since a virtual channel can be disabled to change one or multiple parameters. Software users are responsible for correctly configuring the start address and the size for each virtual channel.

Table 15-57 indicates the corresponding values for the size of the space allocated in the FIFO.

Table 15-57. Virtual Channel TX FIFO Size Values

DSI_TX_FIFO_VC_SIZE[3:0] VCn_FIFO_SIZE	Space Size (up to the size of the FIFO)
0	0 x 33 bits
1	32 x 33 bits
2	64 x 33 bits
3	96 x 33 bits
4	128 x 33 bits

Table 15-58 indicates the start address of the space in the FIFO.

Table 15-58. Virtual Channel TX FIFO Start Address

DSI_TX_FIFO_VC_SIZE[2:0] VCx_FIFO_ADD	Start Address
0	0
1	32
2	64

Table 15-58. Virtual Channel TX FIFO Start Address (continued)

DSI_TX_FIFO_VC_SIZE [2:0]	VCx_FIFO_ADD	Start Address
3		96
4		128

CAUTION

There must be no overlap of different virtual channels spaces.

When the TX FIFO is full:

- the overflow interrupt ([FIFO_TX_OVF_IRQ](#)) is generated. To monitor this interrupt request, the user can read the [DSS.DSI_VCn_IRQSTATUS](#)[3] [FIFO_TX_OVF_IRQ](#) status bit.
- there is no L4 interconnect error generated
- the commands are accepted but the data are not written into the FIFO

To ensure that all writes are correctly stored in the TX FIFO, the FIFO should not be full. The software is responsible for reading the room in the space allocated for the virtual channel in the TX FIFO by reading the [DSS.DSI_TX_FIFO_VC_EMPTYNESS](#) register. In case there is no space allocated in the TX FIFO for the virtual channel, the [DSS.DSI_TX_FIFO_VC_EMPTYNESS](#) register indicates a value of 0 for the virtual channel space emptiness.

When waiting to receive the first VSYNC event on the video port to start the video mode on DSI link no command data from TX FIFO should be sent on the interface. It is required to ensure that when receiving the VSYNC event, there is no on-going command mode transfer that could delay the start of video mode on the DSI link.

15.5.4.10.2 Command Mode RX FIFO

The RX FIFO is used to store the data received from the DSI complex I/O. The data are always packed in the RX FIFO (single or multiple packets receiving during a single or multiple BTA periods).

The read requests access to corresponding virtual channel locations to transfer data for a specific virtual channel. The logic responsible for the management of the FIFO should be able to extract 32-bit values in-order for a specific virtual channel upon read requests. The byte enable of the read access is ignored. Each read returns one 32-bit value from the RX FIFO. If the application accesses the RX FIFO should extract always 32-bit values. Only in the case of 1, 2, or 3 bytes are remaining in the RX FIFO.

The read requests (single or burst) can be less, equal or greater than the packet size. If the packet size is smaller than the read request, the following packet(s) is also transferred. If the packet size is longer than the read request, only part of the packet is transfer. In that case, the logic should keep the virtual channel information to provide the rest of the data during the next read request(s).

The register [DSS.DSI_RX_FIFO_VC_SIZE](#) defines the allocated number of 33-bit values for each virtual channel in the RX FIFO and the start address for each virtual channel. Only the enabled virtual channels should be taken into account. to change the size of the space of the memory allocated for a specific virtual channel, the virtual channel should be disabled by resetting the [DSS.DSI_VCn_CTRL](#)[0] [VC_EN](#) bit to 0. The whole FIFO may not be used by the entire virtual channel at a given time since a virtual channel can be disabled to change one or multiple parameters. Software users are responsible for correctly configuring the start address and the size for each virtual channel.

[Table 15-59](#) indicates the corresponding values for the size of the space allocated in the FIFO:

Table 15-59. Virtual Channel RX FIFO Size Values

DSI_RX_FIFO_VC_SIZE [3:0]	VCx_FIFO_SIZE	Space Size (up to the size of the FIFO)
0		0 x 33 bits
1		32 x 33 bits

Table 15-59. Virtual Channel RX FIFO Size Values (continued)

DSI_RX_FIFO_VC_SIZE [3:0] VCx_FIFO_SIZE	Space Size (up to the size of the FIFO)
2	64 x 33 bits
3	96 x 33 bits
4	128 x 33 bits

[Table 15-60](#) indicates the start address of the space in the FIFO.

Table 15-60. Virtual Channel RX FIFO Start Address

DSI_RX_FIFO_VC_SIZE [2:0] VCx_FIFO_ADD	Start Address
0	0
1	32
2	64
3	96
4	128

CAUTION

There must be no overlap of different virtual channels spaces.

While reading the received bytes in the RX FIFO, only the [DSS.DSI_VCn_SHORT_PACKET_HEADER](#) register is used since the hardware does not keep track of the header position for long packets and start/end of each packet. The software is responsible for extraction the information from the bytes read from the RX FIFO. There is no specific hardware to track the received bytes in the RX FIFO. The [DSS.DSI_VCn_LONG_PACKET_HEADER](#) and [DSS.DSI_VCn_LONG_PACKET_PAYLOAD](#) registers are not used.

The ECC is only used by the first header when receiving multiple packets during the same LP RX transfer from the peripheral since the DSI Protocol engine does not parse the header to identify the length of the packets. In case of multiple packets, the Check-sum does not be enabled since the hardware checks the check-sum considering a single packet. The ECC in the first header is used to correct and check the header. For the following headers in the same LP RX transfer, the hardware does not detect any header and can not check or/and detect errors in the headers of the packets except for the first packet.

When the RX FIFO is empty:

- there is no OCP error generated
- the commands are accepted and the data for the responses are 0s

15.5.4.10.3 Command Mode DMA Requests

The DMA requests ([DSI_DMA_REQ](#)) are used to allow automatic transfer by the system DMA or MPU (with less efficiency and through-put capability) from the DSI RX FIFO to the system memory and from the system memory to the DSI TX FIFO. Two independent DMA requests for RX FIFO and TX FIFO for the same VC are supported. The read and write accesses can use burst structure. The DSI protocol engine should access each write request in a burst without any IDLE between. For read OCP request in a burst to RX FIFO, the acceptance is sent immediately and the response is delayed by at least four L4 interface clock ([DSS.L4_ICLK](#)) cycles. In case of register reads, the response is returned in the first clock cycle.

The thresholds used for requests for the TX FIFO and RX FIFO are programmable by software. The user program the [DSS.DSI_VCn_CTRL](#)[19:17] [DMA_TX_THRESHOLD](#) and [DSS.DSI_VCn_CTRL](#)[26:24] [DMA_RX_THRESHOLD](#) fields for TX FIFO and RX FIFO respectively. The hardware asserts the DMA request based on the threshold value. The size of the space allocated in TX FIFO for each virtual channel should be a multiple of [DSS.DSI_VCn_CTRL](#)[19:17] [DMA_TX_THRESHOLD](#) field value.

The only exception is in the case of the RX FIFO when the LP data transfer finishes and the threshold value is not reached. In that case the DMA request should be asserted. So the drain of the FIFO is supported in that configuration to empty the FIFO even if the number of data received is not a multiple of the threshold value.

In case of TX FIFO, if all the bytes defined by the word count field in the DSS.DSI_VCn_LONG_PACKET_HEADER header register have been received, the DMA request is not asserted anymore even during the last transfer less than DMA_TX_THRESHOLD number of bytes have been received because of the word count being not a multiple of the DMA_TX_THRESHOLD value.

In case of RX FIFO, while the DMA request is used to transfer the data from the RX FIFO to the system memory, the system DMA should be programmed to read the exact number of received bytes in the FIFO. In case the user does not know the size of the received bytes, the direct access of the RX FIFO through the DSS.DSI_VCn_SHORT_PACKET_HEADER register is performed until the DSS.DSI_VCn_CTRL[20] RX_FIFO_NOT_EMPTY bit goes to 0.

The use of each DMA request is programmable by software. The DSS.DSI_VCn_CTRL[23:21] DMA_TX_REQ_NB is dedicated to DMA request numbering for the TX FIFO. The DSS.DSI_VCn_CTRL[29:27] DMA_RX_REQ_NB is dedicated to DMA request numbering for the RX FIFO.

When the DMA request is used to indicate the number of 32-bit values ready in the RX FIFO or BTA has been received from peripheral indicating end of the transfer from peripheral to host for a transfer to the system memory, the DMA request corresponding to the virtual channel ID is generated.

The system DMA transfers the number of 32-bit values defined in the threshold register or the exact number of bytes received from the peripheral (user should know the number of expected received bytes to program correctly the system DMA). When the system DMA transfers a multiple number of threshold value, the DSI protocol engine should send 0s for the data when there is no more received data in the RX FIFO for the virtual channel. Software users are responsible for parsing the data and determine the valid bytes.

Software users can decide to determine the number of data received in the RX FIFO to read the information in the DSS.DSI_RX_FIFO_VC_FULLNESS register. Then the system DMA can be programmed to read the exact number of bytes from the RX FIFO. The BTA interrupt (BTA_IRQ) should be used to know when to read the number of received bytes. To monitor the BTA interrupt, the user should read the DSS.DSI_VCn_IRQSTATUS[5] BTA_IRQ status bit. The DMA request should not be selected until the system DMA is programmed with the correct number of data to read from RX FIFO.

If the RX FIFO space for the virtual channel is expected to be overflow because the number of data to be received is greater than the space allocated for the virtual channel, the previous programming model should be used. In place, the DMA request should be asserted as soon as the threshold is reached or when BTA is received.

When the DMA request is used to indicate the number of 33-bit entries empty in the TX FIFO for a transfer from the system memory, the DMA request corresponding to the virtual channel ID is generated.

Note: To obtain best efficiency of the transfer the size of the request (read or write, single or burst) should be aligned with the threshold value.

Concurrent access using interlaced requests (read/write) to the TX and RX FIFO is supported for the same virtual channel id or different virtual channel IDs.

15.5.4.11 Ultra-Low Power State

This section describes how to enter/exit to/from ultra-low power state (ULPS).

Note: The DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIGy bits (x range is 1 to 3 corresponding to lane #1 to lane #3 and y range is 1 to 2) must be read back after writing to verify that the write operations are effective before proceeding to the next step. This is for taking into account for latency at low TxClkEsc frequencies.

15.5.4.11.1 Entering ULPS State

to enter in ULPS for a clock lane, the following sequence is required:

1. Wait for DSS.DSI_COMPLEXIO_CFG2[16] HS_BUSY and DSS.DSI_COMPLEXIO_CFG2[17] LP_BUSY bits to be reset to 0 and for DSS.DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit to be reset to 0
2. TxUlpsClk state should change from inactive to active by setting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1.

to enter in ULPS for a data lane, the following sequence is required:

1. Wait for all TX_FIFOs for all VCs working in HS are empty, for video mode is not active, and for DSS.DSI_COMPLEXIO_CFG2[16] HS_BUSY bit is reset to 0 (in addition for lane #1, DSS.DSI_COMPLEXIO_CFG2[17] LP_BUSY bit is reset to 0)
2. TxRequestEsc state should change from inactive to active by setting the DSS.DSI_COMPLEXIO_CFG2.LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1.

15.5.4.11.2 Exiting ULPS State

to exit from ULPS for a clock lane, the following sequence is required:

1. Change the state of TxUlpsExit for each lane to active by setting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1
2. Wait for the ULPSACTIVENOT_ALL1_IRQ interrupt indicating that all lanes with TxUlpsExit active have acknowledged by asserting UlpsActiveNot. This is performed by monitoring the DSS.DSI_COMPLEXIO_IRQSTATUS[31] ULPSACTIVENOT_ALL1_IRQ status bit.
3. Start the wake-up timer (GPTimer)
4. Wait for the time-out
5. Change TxUlpsClk signals to in-active state for the clock lane by resetting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0
6. Reset the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0

to exit from ULPS for a clock lane in case ComplexIO is in OFF state (DSI protocol engine sends ComplexIO to OFF state by issuing PWROFF command), the sequence is:

1. Change TxUlpsClk signals to in-active state for the clock lane by resetting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0
2. Change the state of TxUlpsExit for clock lane to in-active state by resetting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0. This step is necessary only in case PWROFF command is issued while sequence for exiting is in progress (TxUlpsExit signal is already in active state)

Note: When DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 and DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 are both being written to 0, this may be combined in one write. Both bits must be read back to confirm they are effective before proceeding.

to exit from ULPS for a data lane, the following sequence is required:

1. Change the state of TxUlpsExit for each lane to active by setting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1
2. Wait for the ULPSACTIVENOT_ALL1_IRQ interrupt indicating that all lanes with TxUlpsExit active have acknowledged by asserting UlpsActiveNot. This is performed by monitoring the DSS.DSI_COMPLEXIO_IRQSTATUS[31] ULPSACTIVENOT_ALL1_IRQ status bit.
3. Start the application wake-up timer (GPTimer)
4. Wait for the time-out

5. Change TxRtequestEsc signals to in-active state for the data lane by resetting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0
6. Reset the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1(x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0

Note: When DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 and DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 are both being written to 0, this may be combined in one write. Both bits must be read back to confirm they are effective before proceeding.

to exit from ULPS for a data lane in case ComplexIO is in OFF state (DSI protocol engine sends ComplexIO to OFF state by issuing PWROFF command), the sequence is:

1. Change TxRtequestEsc signals in-active state by resetting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0
2. Change the state of TxUlpsExit to in-active state by resetting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0. This step is necessary only in case PWROFF command is issued while sequence for exiting is in progress (TxUlpsExit signal is already in active state).

When the sequence for entering/exiting to/from ULP state is started for specific lanes, the user should wait for the completion of the sequence before being able to change the state of the same or other lanes.

15.5.4.12 DSI Programming Sequence Example

This section describes distinct configurations of the DSI protocol engine to support different type of traffics.

Note: When the VC is used to send video mode data from the video port, the DSS.DSI_VCn_CTRL[9] MODE_SPEED and the DSS.DSI_VCn_CTRL[1] SOURCE bits are ignored.

15.5.4.12.1 Video Mode Transfer

Description: One channel, video mode, no DMA requests, no bus turn-around.

1. Configure the DSS.DSI_VCn_CTRL register as follows:
 - SOURCE bit is ignored by hardware
 - BTA_LONG_EN bit is set to 0: No BTA on long packet
 - BTA_SHORT_EN bit is set to 0: No BTA on short packet
 - MODE bit set to 1: The video mode is selected
 - MODE_SPEED bit is ignored by hardware
 2. Configure the DSS.DSI_VM_TIMING1 to DSS.DSI_VM_TIMING7 registers
 3. Enable the channel by setting the DSS.DSI_VCn_CTRL[0] VC_EN bit to 1
 4. Enable the module by setting the DSS.DSI_CTRL[0] IF_EN bit to 1
 5. Configure the display controller with the timing parameters
 6. Enable the LCD video output by setting the DSS.DISPC_CONTROL[0] LCDENABLE bit to 1
- to stop video mode, the DSS.DSI_CTRL[0] IF_EN bit can be reset to 0 or the Virtual Channel used for mode can be disabled by resetting the DSS.DSI_VCn_CTRL[0] VC_EN bit to 0.

CAUTION

The restriction for stopping the video mode is that no frame should be sent by the display controller (DISPC) after disabling video mode in DSI.

15.5.4.12.2 Command Mode Transfer Example 1

Description: One channel, command mode, no DMA requests, manual bus turn-around

1. Configure the DSS.DSI_VCn_CTRL register as follows:
 - SOURCE bit set to 0: The source is the L4 interconnect port
 - BTA_LONG_EN bit is set to 0: No automatic BTA on long packet
 - BTA_SHORT_EN bit is set to 0: No automatic BTA on short packet
 - MODE bit set to 0: The command mode is selected
2. Enable the packet sent interrupt by setting the DSS.DSI_VCn_IRQENABLE[2] PACKET_SENT_IRQ_EN bit to 1
3. Enable the channel by setting the DSS.DSI_VCn_CTRL[0] VC_EN bit to 1
4. Enable the module by setting the DSS.DSI_CTRL[0] IF_EN bit to 1
5. Send one or more packets through L4 interconnect:
 - Write the header value into DSS.DSI_VCn_LONG_PACKET_HEADER register
 - Write the data into DSS.DSI_VCn_LONG_PACKET_PAYLOAD register for the full payload and checksum.
 - Repeat step 5 for all the long packets
6. Send short packets through L4 interconnect:
 - Write the header value into DSS.DSI_VCn_SHORT_PACKET_HEADER register
 - Repeat step 6 for all the short packets
7. Interrupt routine: Wait for PACKET_SENT_IRQ interrupt generation by polling the DSS.DSI_VCn_IRQSTATUS[2] PACKET_SENT_IRQ status bit and notify the application software when received.
8. The applicative software forces the bus turn-around:
 - Wait until the PACKET_SENT_IRQ has happened as many times as the number of sent packets
 - Set the DSS.DSI_VCn_CTRL[6] BTA_EN bit to 1 to send manually a BTA
 - Wait until the DSS.DSI_VCn_CTRL[6] BTA_EN bit is reset to 0 by hardware
9. Receive the packets from the peripheral
 - Start polling the DSS.DSI_VCn_CTRL[20] RX_FIFO_NOT_EMPTY status bit
 - Whenever the RX_FIFO_NOT_EMPTY bit equals to 1, read one word in the RX FIFO

15.5.4.12.3 Command Mode Transfer Example 2

Description: One channel, command mode, DMA request, automatic bus turn-around

1. Configure the DSS.DSI_VCn_CTRL register as follows:
 - SOURCE bit set to 0: The source is the L4 interconnect port
 - BTA_LONG_EN bit is set to 1: Automatic BTA on long packet
 - BTA_SHORT_EN bit is set to 1: Automatic BTA on short packet
 - MODE bit set to 0: The command mode is selected
2. Enable the packet sent interrupt by setting the DSS.DSI_VCn_IRQENABLE[2] PACKET_SENT_IRQ_EN bit to 1
3. Enable the channel by setting the DSS.DSI_VCn_CTRL[0] VC_EN bit to 1
4. Configure the TX FIFO threshold and DMA requests parameters:
 - Program the DSS.DSI_VCn_CTRL[19:17] DMA_TX_THRESHOLD field
 - Program the DSS.DSI_VCn_CTRL[23:21] DMA_TX_REQ_NB field
5. Program the system DMA to be ready to send data to the L4 interconnect port
6. Enable the module by setting the DSS.DSI_CTRL[0] IF_EN bit to 1
7. Write the header value into DSS.DSI_VCn_LONG_PACKET_HEADER register
8. Interrupt routine: Wait for PACKET_SENT_IRQ interrupt generation by polling the DSS.DSI_VCn_IRQSTATUS[2] PACKET_SENT_IRQ status bit and notify the application software when received.
9. Receive the packets from the peripheral
 - Start polling the DSS.DSI_VCn_CTRL[20] RX_FIFO_NOT_EMPTY status bit
 - Whenever the RX_FIFO_NOT_EMPTY bit equals to 1, read one 32-bit word in the RX FIFO

10. Repeat the steps 7 for all long packets.

15.5.5 DSI PLL Controller Basic Programming Model

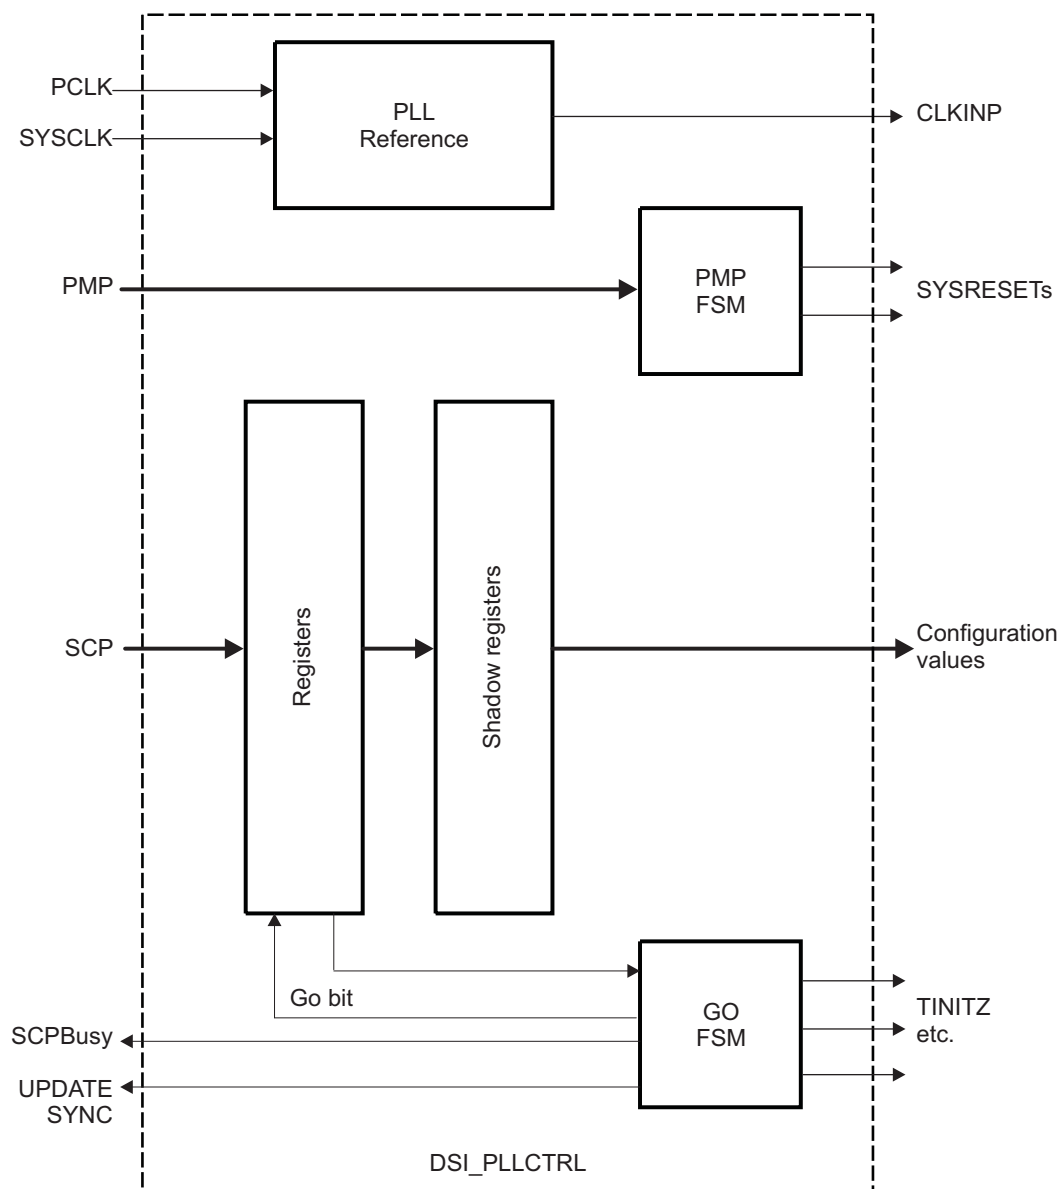

15.5.5.1 Software Reset

The DSI PLL control module does not have its own software reset. It is reset by the DSI protocol engine. Nevertheless, the software user can monitor the reset status of the DSI PLL control module by reading the `DSS.DSI_PLL_STATUS[0]` DSI_PLLCTRL_RESET_DONE status bit.

15.5.5.2 DSI PLL Programming Blocks

Figure 15-131 shows the DSI PLL programming blocks.

Figure 15-131. DSI PLL Programming Blocks

dss-181

15.5.5.3 DSI PLL Go Sequence

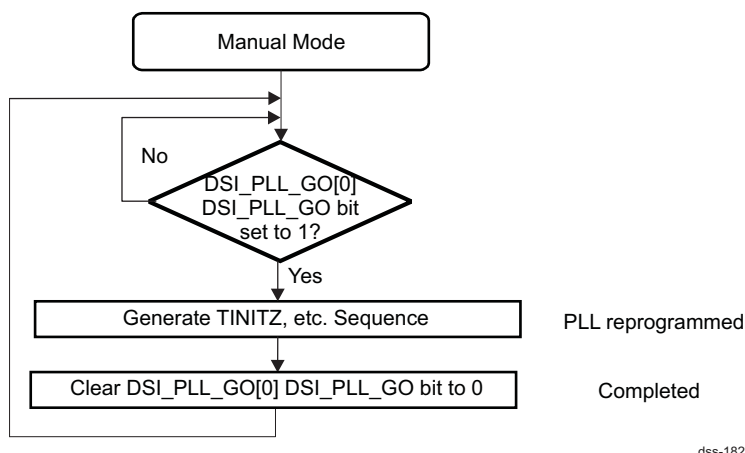

In Manual Mode (DSS.DSI_PLL_CONTROL[0] DSI_PLL_AUTOMODE bit set to 0), the DPLL requires a sequence on TINITZ, TENABLE and TENABLEDIV to update the configuration values and start the locking sequence.

Once all the configuration values have been programmed into the registers, the GO bit should be set. The appropriate sequence should then be sent on the TINITZ, TENABLE & TENABLEDIV pins, respecting the timing requirements of the ADPLLV2. The DSS.DSI_PLL_GO[0] DSI_PLL_GO bit will be cleared to 0 at the end of the sequence.

The TENABLEDIV signal is shared with the HSDIVIDER module, so that will be programmed at the same time. It is the software responsibility in this mode to deassert CLKINEN by unsetting the DSS.DSI_PLL_CONFIGURATION2[14] DSIPHY_CLKINEN to 0 and to assert HSDIVBYPASS correctly by setting the DSS.DSI_PLL_CONFIGURATION2[20] DSI_HSDIVBYPASS bit to 1 to prevent uncontrolled frequencies affecting the DSIPHY and Display Subsystem during PLL locking. In manual mode the shadow register should be updated anyway so that valid values are present when later selecting automatic mode.

Figure 15-132 shows the DSI PLL Go flowchart in manual mode (DSS.DSI_PLL_CONTROL[0] DSI_PLL_AUTOMODE bit set to 0).

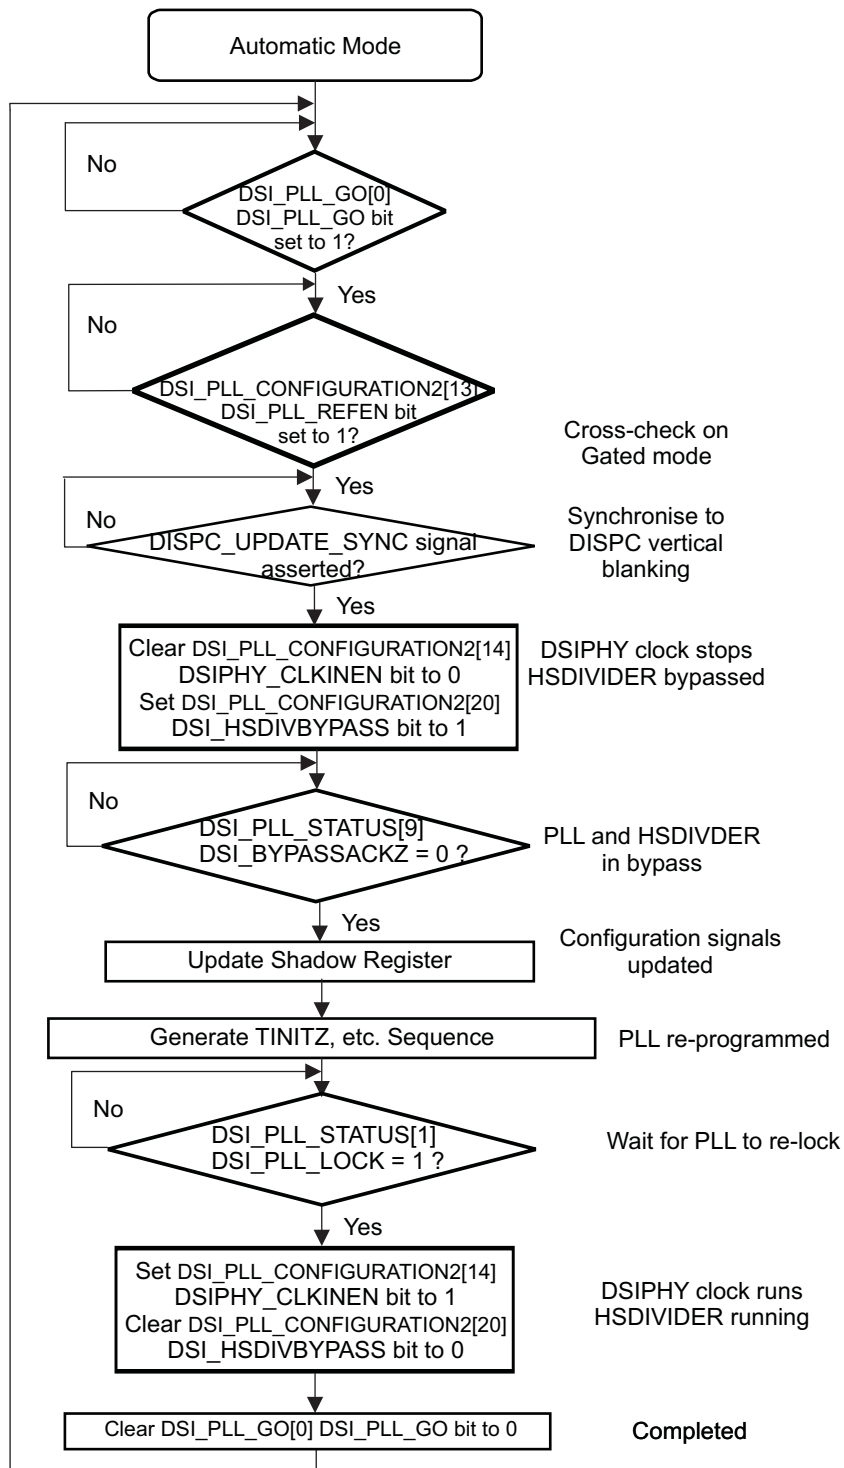

Figure 15-132. DSI PLL Go Sequence (Manual Mode)

In automatic Mode (DSS.DSI_PLL_CONTROL[0] DSI_PLL_AUTOMODE bit set to 1), the TINITZ, TENABLE and TENABLEDIV sequence and the update of the PLL configuration from the DSI_PLL_CONFIGURATION2 register will be deferred until the time of the front porch time signal sent by the DISPC module. This is intended to simplify the software to implement a configuration change (such as a frequency change to support a different link bandwidth). In this mode CLKINEN, HSDIVBYPASS and REFEN will be controlled automatically and the register value is overridden.

Figure 15-133 shows the DSI PLL Go flowchart in automatic mode (DSS.DSI_PLL_CONTROL[0] DSI_PLL_AUTOMODE bit set to 1).

Figure 15-133. DSI PLL Go Sequence (Automatic Mode)

dss-183

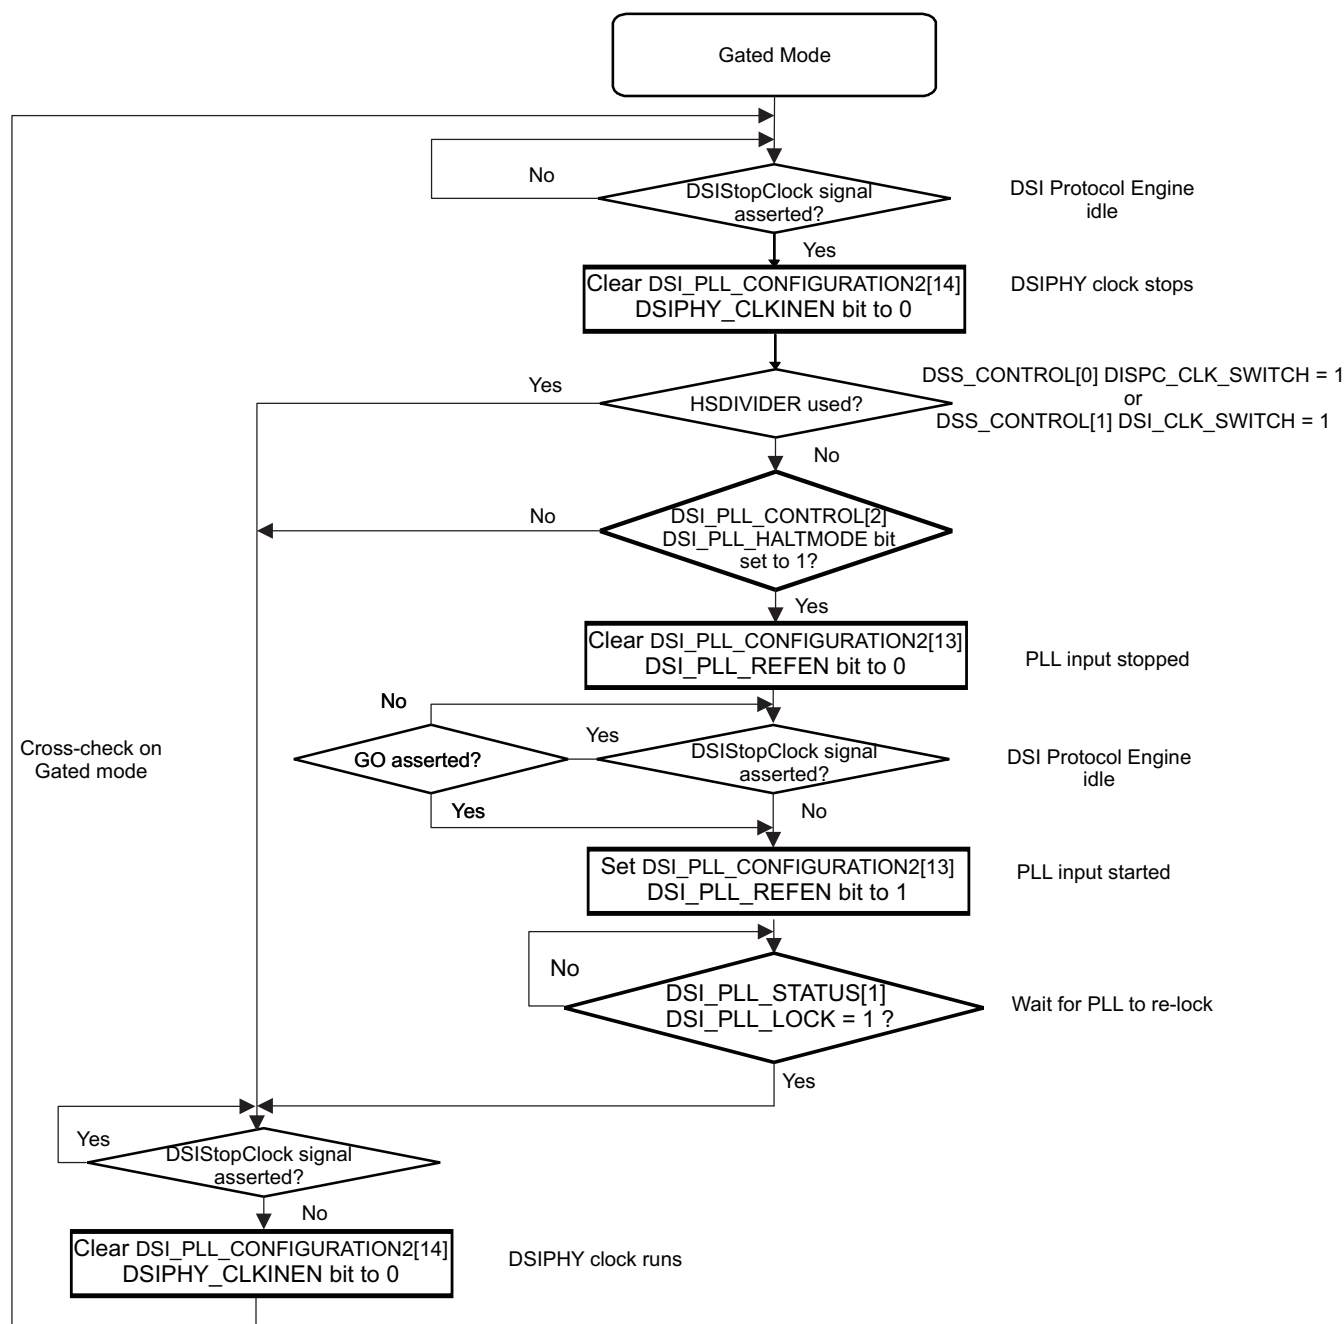

15.5.5.4 DSI PLL Clock Gating Sequence

Clock gating may be used to reduce system power consumption when the DSI protocol engine indicates that it does not need the clock. If the HSDIVIDER is not used, then the PLL can also be stopped (at the cost of additional unstarting latency).

The DSI protocol engine can verify when the PLL has unstopped by inspecting the LOCK signal (DSS.DSI_PLL_STATUS[1] DSI_PLL_LOCK status bit). Since TxByteClkHS is stopped when the DSIPHY clock is stopped, this should obviate the need for any explicit feedback that the clock has been unstopped in the other case. This flow chart should run even if the DSS.DSI_PLL_GO[0] DSI_PLL_GO bit has not been set.

Figure 15-134 shows the DSI PLL gated mode sequence.

Figure 15-134. Gated Mode Sequence

dss-184

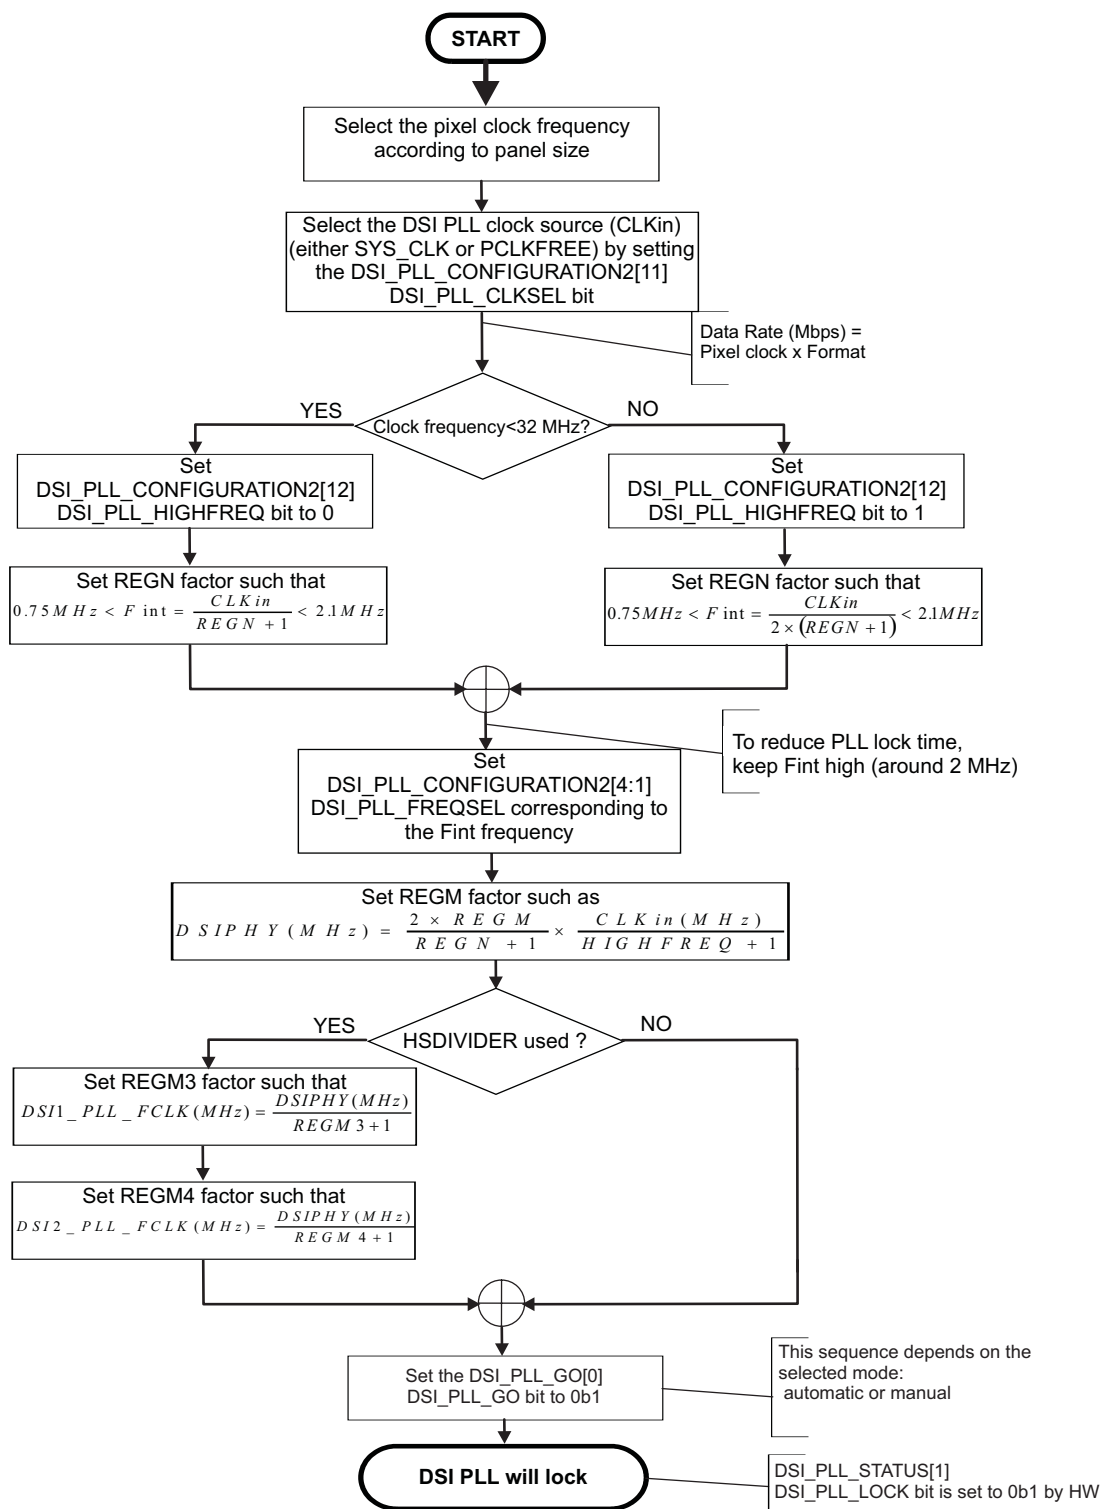

15.5.5.5 DSI PLL Lock Sequence

The DSI PLL (ADPLLv2) generates the DSIPHY clock (or DSI_PLL_HSCLK). The HSDIVIDER generates two clocks: DSI1_PLL_FCLK connected to the Display Controller (DISPC) and the DSI2_PLL_FCLK connected to the DSI protocol engine. If these two clocks are not used, the HSDIVIDER functions are not required.

The DSIPHY clock is twice the data rate, and is four times the DSI output clock frequency. The DSI PLL factors need to be calculated based on the required input and output frequencies, keeping the PLL internal reference frequency in the appropriate range:

- REGM factor is programmed by DSS.DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM field
- REGN factor is programmed by DSS.DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN field
- REGM3 factor is programmed by DSS.DSI_PLL_CONFIGURATION1[22:19] DSI_CLOCK_DIV field
- REGM4 factor is programmed by DSS.DSI_PLL_CONFIGURATION1[26:23] DSIPROTO_CLOCK_DIV field

Figure 15-135 shows the programming sequence.

Figure 15-135. DSI PLL Programming Sequence

dss-190

Notes:

- The REGM3 and REGM4 factors must be set respecting to the following conditions:
 - The DSI1_PLL_FCLK frequency must be a multiple of PCLK frequency (for proper settings of PCD and LCD factors in the DISPC)
 - The DSI1_PLL_FCLK and DSI2_PLL_FCLK frequencies must be lower than 173 MHz
- Most of the other DSI PLL programming values are available for software flexibility but it is not recommended to update the values in normal use. See [Section 15.5.5.7](#) for details on DSI PLL recommended values.

DSI PLL programming examples:

- WVGA Display on one data pair: Pixel clock (PCLK) = 30 MHz with 18-BPP pixel format

The data rate is $30 \times 18 = 540$ Mbps on one data lane. Therefore, the frequency on the data lane is twice the data rate: 1080 MHz.

The frequency on the clock lane is 270 MHz (1080 divided by 4).

The SYS_CLK at 26 MHz is selected as the clock reference by setting the DSS.DSI_PLL_CONFIGURATION2[11] DSI_PLL_CLKSEL to 0b0.

Set the DSS.DSI_PLL_CONFIGURATION2[12] DSI_PLL_HIGHFRREQ to 0b0 as PCLK is lower than 32 MHz.

Set Fint to 2 MHz as PLL internal reference frequency: Set REGN to 12 (divide by 13) by setting the DSS.DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN field to 0xC and set DSI_PLL_CONFIGURATION2[4:1] DSI_PLL_FREQSEL field to 0x7 (1.75 to 2.1 MHz range)

To get the DSIPHY clock to 1080 MHz, set the REGM factor to 270 by setting the DSS.DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM to 0x10E.

$DSIPHY = 2 \times 270 / 13 \times 26 / 1 = 1080$ MHz

Since DSI1_PLL_FCLK and DSI2_PLL_FCLK (REGM3 and REGM4 factors) must be multiple of PCLK and also lower than 173 MHz, program these frequencies to 90 MHz by setting the REGM3 and REGM4 factors to 11 (divide by 12). This is done by setting the DSS.DSI_PLL_CONFIGURATION1[22:19] DSI_CLOCK_DIV field and DSS.DSI_PLL_CONFIGURATION1[26:23] DSIPROTO_CLOCK_DIV to 0xB:

$DSI1_PLL_FCLK = DSI2_PLL_FCLK = 1080 / 12 = 90$ MHz

- XGA Display on two data pairs: Pixel clock (PCLK) = 60 MHz with 16-BPP pixel format

The data rate is $(60 \times 16) / 2 = 480$ Mbps on each data lane. Therefore, the frequency on the data lane is twice the data rate: 960 MHz.

The frequency on the clock lane is 240 MHz (960 divided by 4).

The SYS_CLK at 26 MHz is selected as the clock reference by setting the DSS.DSI_PLL_CONFIGURATION2[11] DSI_PLL_CLKSEL to 0b0.

Set the DSS.DSI_PLL_CONFIGURATION2[12] DSI_PLL_HIGHFRREQ to 0b0 as the source clock frequency (SYS_CLK in this example) is lower than 32 MHz.

Set Fint to 2 MHz as PLL internal reference frequency: Set REGN to 12 (divide by 13) by setting the DSS.DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN field to 0xC and set DSI_PLL_CONFIGURATION2[4:1] DSI_PLL_FREQSEL field to 0x7 (1.75 to 2.1 MHz range)

To get the DSIPHY clock to 960 MHz, set the REGM factor to 240 by setting the DSS.DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM to 0x0F0.

$DSIPHY = 2 \times 240 / 13 \times 26 / 1 = 960$ MHz

Since DSI1_PLL_FCLK and DSI2_PLL_FCLK (REGM3 and REGM4 factors) must be multiple of PCLK and also lower than 173 MHz, program these frequencies to 120 MHz by setting the REGM3 and REGM4 factors to 7 (divide by 8). This is done by setting the DSS.DSI_PLL_CONFIGURATION1[22:19] DSI_CLOCK_DIV field and DSS.DSI_PLL_CONFIGURATION1[26:23] DSIPROTO_CLOCK_DIV to 0x7:

$DSI1_PLL_FCLK = DSI2_PLL_FCLK = 960 / 8 = 120$ MHz

15.5.5.6 DSI PLL Error Handling

The PLL lock and recalibration signals may be monitored to detect loss of lock or requirement to recalibrate (due to large temperature change since the last lock request):

- The DSS.DSI_PLL_STATUS[1] DSI_PLL_LOCK status bit gives the DSI PLL lock state.
- The DSS.DSI_PLL_STATUS[2] DSI_PLL_RECAL status bit informs if the PLL needs to be uncalibrated

These signals can also generate interrupts at DSI protocol engine level: [9 PLL_RECAL_IRQ [8] PLL_UNLOCK_IRQ [7 PLL_LOCK_IRQ]

- The PLL_LOCK_IRQ interrupt indicates that the DSI PLL is locked. To monitor this event, read the DSS.DSI_IRQSTATUS[7] PLL_LOCK_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL_UNLOCK_IRQ interrupt indicates that the DSI PLL is unlocked. To monitor this event, read the DSS.DSI_IRQSTATUS[8] PLL_UNLOCK_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL_RECAL_IRQ interrupt indicates that the DSI PLL needs to be recalibrated. To monitor this event, read the DSS.DSI_IRQSTATUS[9] PLL_RECAL_IRQ bit. Set this bit to 1 to clear the status bit.

The PLL reference loss and limp status signals can also be monitored :

- The DSS.DSI_PLL_STATUS[3] DSI_PLL_LOSSREF status bit informs if the DSI PLL has lost the reference.
- The DSS.DSI_PLL_STATUS[4] DSI_PLL_LIMP status bit informs about the DSI PLL limp status.

15.5.5.7 DSI PLL Recommended Values

Table 15-61 shows the DSI PLL recommended values.

Table 15-61. Recommended Programming Values

Field Name	Value	Description
DSI_HSDIV_SYSRESET	0	Allow power FSM to control
DSI_PLL_SYSRESET	0	Allow power FSM to control
DSI_PLL_HALTMODE	-	See Section 15.5.5.4 for details
DSI_PLL_GATEMODE	-	See Section 15.5.5.4 for details
DSI_PLL_AUTOMODE	-	See Section 15.5.5.4 for details
DSI_PLL_GO	1->0	Write a 1 when PLL is to be (re-)locked with new parameters. This bit is cleared by hardware when the PLL request has completed
DSIPROTO_CLOCK_DIV	See ⁽¹⁾	DSI protocol engine clock divider
DSS_CLOCK_DIV	See ⁽¹⁾	DSS clock divider
DSI_PLL_REGM	See ⁽¹⁾	Feedback clock divider
DSI_PLL_REGN	See ⁽¹⁾	Reference clock divider
DSI_PLL_STOPMODE	1	Required to use GATEMODE bit
DSI_HSDIVBYPASS	0	PLL is controlling HSDIVIDER bypass
DSI_PROTO_CLOCK_PWDN	0	If PLL/HSDIVIDER is used as the DSI protocol clock source
DSI_PROTO_CLK_EN	1	If PLL/HSDIVIDER is used as the DSI protocol clock source
DSS_CLOCK_PWDN	0	If PLL/HSDIVIDER is used as the DSS clock source
DSS_CLOCK_EN	1	If PLL/HSDIVIDER is used as the DSS clock source
DSI_BYPASSEN	0	To use PLL as the clock source. For small displays it may be possible to use the DSS functional clock, in which case this bit should be set to 1

⁽¹⁾ The bit field value should be set according to the desired clock frequency.

Table 15-61. Recommended Programming Values (continued)

Field Name	Value	Description
DSIPHY_CLKINEN	1	Enable DSIPHY clock
DSI_PLL_REFEN	1	Enable PLL reference
DSI_PLL_HIGHFREQ	0/1	Set to 0 if using DSS2_ALWON_FCLK as the reference or set to 1 if using PCLKFREE as the reference and frequency is higher than 32 MHz (21 MHz if DSS.DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN = 0)
DSI_PLL_CLKSEL	0/1	Set to 0 to use DSS2_ALWON_FCLK as the PLL reference or set to 1 to use PCLKFREE as the PLL reference, in this case the DISPC must be using DSS1_ALWON_FCLK.
DSI_PLL_LOCKSEL	0x0	Phase lock criteria to lock the PLL
DSI_PLL_DRIFTGUARDEN	0x0	The RECAL status/interrupt should be used to decide when to perform a PLL uncalibration No automatic uncalibration will be performed
DSI_PLL_TIGHTPHASELOCK	0	Normal criteria
DSI_LOWCURRSTDBY	0/1	Set to 0 for fast PLL unlock, but higher standby current Set to 1 for leakage level standby current, but longer unlock time
DSI_PLLLPMODE	0	Normal operation For smaller display sizes may be possible to set to 1
DSI_PLL_FREQSEL	See ⁽¹⁾	Must be set according to the PLL internal reference frequency (after N divider) See register descriptions for values
DSI_PLL_IDLE	0	PLL active

15.5.6 DSI Complex I/O Basic Programming Model

15.5.6.1 Software Reset

The clock domain using the PPI byte clock from the DSI complex I/O has a dedicated reset done information in the DSS.DSI_COMPLEXIO_CFG1[29] RESET_DONE bit. The DSS.DSI_SYSCONFIG[1] SOFT_RESET bit is used to reset the PPI byte clock power domain. A dummy read using the SCP interface to any DSIPHY register is required after DSIPHY reset to complete the reset of the DSI complex I/O.

15.5.6.2 Reset-Done Bits

The DSI complex I/O has several clock domains. The reset status for each clock domain is provided in DSS.DSIPHY_CFG5 register:

- DSS.DSIPHY_CFG5[31] RESETDONETXBYTECLK bit : Reset done for the TXBYTECLK domain.
- DSS.DSIPHY_CFG5[28:26] RESETDONETXCLKESCi bits: Reset done for the TXCLKESC domain for lane i (i between 0 and 2).
- DSS.DSIPHY_CFG5[30] RESETDONESCPCLK bit: Reset done for the SCP clock domain. Software users must perform a dummy read on this bit to initiate the reset sequence of the SCP finite state machine. When the reset sequence is complete, the RESETDONESCPCLK signal goes high and the software user can read again the DSS.DSIPHY_CFG5[30] RESETDONESCPCLK bit to ensure that the value is now 0.

Note: The software should not write in the DSIPHY_SCP registers before the DSS.DSIPHY_CFG5[30] RESETDONESCPCCLK bit is set to 1.

- DSS.DSIPHY_CFG5[29] RESETDONEPWRCLK bit: Reset done for the PWR clock domain. The reset sequence of the PWR finite state machine is complete when the RESETDONEPWRCLK signal goes high.

15.5.6.3 Pad Configuration

The number of lanes is configurable through the DSS.DSI_COMPLEXIO_CFG1 register.

It is not allowed to change on the fly the position (by modifying the DATAi_POSITION with i=1 or 2 and CLOCK_POSITION fields), P/N order (Positive/Negative order of the differential pair by modifying the DATAi_POL with i=1 or 2 and CLOCK_POL) or number of active data lanes (by modifying the DSS.DSI_COMPLEXIO_CFG1[10:8] DATA2_POSITION bit). To add or remove the lane #2, it is required to be in OFF mode for the DSI complex I/O.

The minimum requirement for the number of lanes is one clock lane and one data lane. Note that by default, the data lane 2 is not connected (the DSS.DSI_COMPLEXIO_CFG1[10:8] DATA2_POSITION bit reset value is 0).

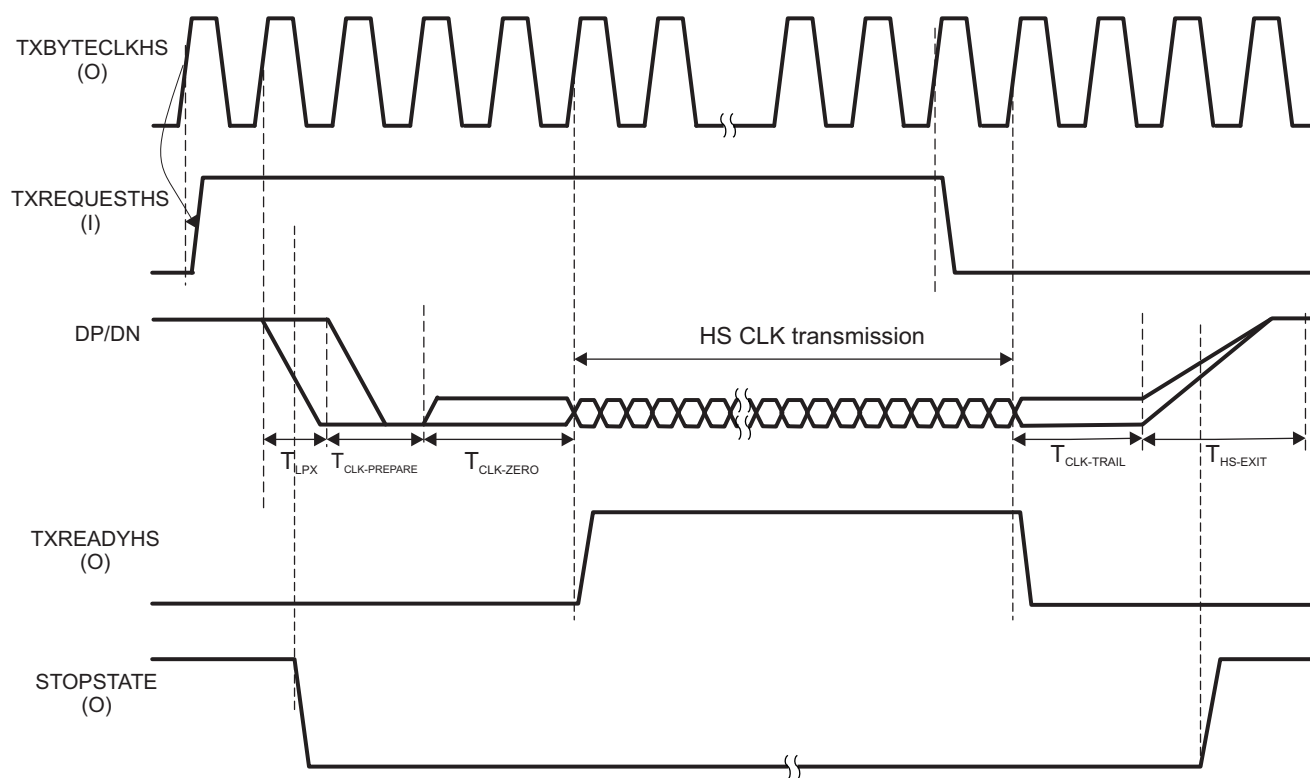

15.5.6.4 Display Timing Configuration

Depending on the DSIPHY clock frequency settings programmed with the DSI PLL control module, the software user must program accordingly the timing parameters in the DSI complex I/O registers.

15.5.6.4.1 High-Speed Clock Transmission

Figure 15-136 shows an example of High Speed Clock Transmission.

Figure 15-136. High-Speed Clock Transmission

dss-185

TXByteClkHS is an output clock which is derived by dividing CLKIN4DDR (also named DSIPHY clock) by 16.

To begin transmission, the protocol drives TXREQUESTHS high on a rising edge of TXByteClkHS. The PHY detects this signal on the next rising edge, following which it initiates the LP Start of Transmission (SoT) procedure.

TLPX, THS-PREPARE and TCLK-ZERO are timings defined by the MIPI-DPHY specification. During a High Speed Clock Transmission, these parameters are defined in multiples of CLKIN4DDR and programmed by the following register fields:

- TLPX timing is programmed by the DSS.DSIPHY_CFG1[22:16] TLPX_HALF field.
 - THS-PREPARE timing is programmed by the DSS.DSIPHY_CFG0[31:24] THS_PREPARE field.
 - TCLK-ZERO timing is programmed by the DSS.DSIPHY_CFG1[7:0] TCLK_ZERO field.
- . TCLK-ZERO is extended, if required, so that the entire LP SoT procedure lasts an integer number of TXByteClkHS cycles.

At the end of the SoT procedure, HS clock transmission begins. At the same time, TXREADYHS is made high.

To stop clock transmission, the protocol drives TXREQUESTHS low on a rising edge of TXByteClkHS. The DSIPHY detects this change in TXREQUESTHS on the next edge and stops clock transmission. TXREADYHS is made low.

The DSIPHY then goes through the LP End of Transmission (EoT) procedure. TCLK-TRAIL and THS-EXIT parameters are also multiples of CLKIN4DDR and programmed by the following register fields:

- TCLK-TRAIL timing is programmed by the DSS.DSIPHY_CFG1[15:8] TCLK_TRAIL field.
- THS-EXIT timing is programmed by the DSS.DSIPHY_CFG0[7:0] THS_EXIT field.

The DSIPHY completes the SoT and EoT procedures, once begun, irrespective of any change in PPI signals. If TXREQUESTHS goes low during the SoT procedure, the PHY start the EoT procedure immediately after finishing the SoT procedure and no clock is transmitted.

STOPSTATE is high whenever the line is in LP-11 state, as determined by the outputs of the Low Power Receivers. This signal is not synchronized with TXByteClkHS.

The D-PHY specification requires that the high speed clock be present for some time before (TCLK-PRE) and some time after (TCLK-POST) high speed data transmission. It is the responsibility of the protocol to ensure that these timings are met by asserting and deasserting TXREQUESTHS appropriately.

The PHY ensures that the clock signal has a quadrature-phase with respect to a toggling bit sequence on any Data Lane, and a rising edge in the center of the first transmitted bit of every Data byte. These relations are not described in the timing diagram.

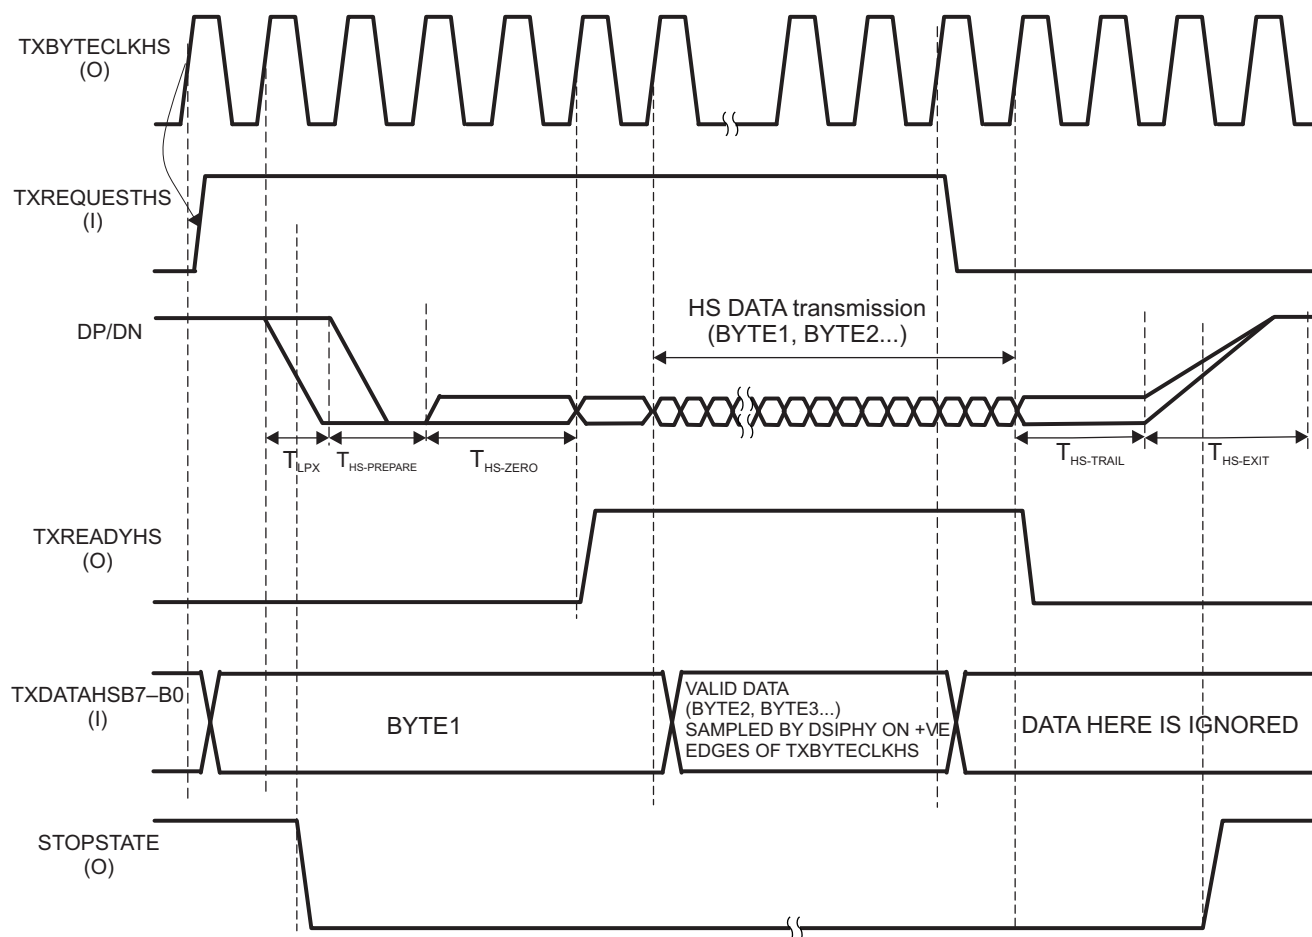

CLKIN4DDR can be shut off 300ns after the clock lane goes to STOPSTATE. Alternatively, CLKIN4DDR can be shut down after TCLK-Trail + THS-Exit + 2 Txbyteclk periods after TxRequestHS falling edge is received by DSIPHY.

The DSI protocol engine should ensure that TXREQUESTESC, TXULPSCLK and TURNREQUEST are low whenever TXREQUESTHS is asserted.

15.5.6.4.2 High-Speed Data Transmission

Figure 15-137 shows an example of High Speed Data Transmission.

Figure 15-137. High-Speed Data Transmission

dss-186

TXByteClkHS is an output clock which is derived by dividing CLKIN4DDR by 16.

To begin transmission, the protocol drives TXDATAHS with the first byte of data on a rising edge of TXByteClkHS. It also makes TXREQUESTHS high the same rising edge. The PHY detects TXREQUESTHS going high on the next rising edge of TXByteClkHS, following which it initiates the LP Start of Transmission (SoT) procedure.

TLPX, THS-PREPARE and THS-ZERO are timings defined by the MIPI-DPHY specification. During a High Speed Data Transmission, these timings are multiple of CLKIN4DDR and programmed by the following register fields:

- TLPX timing is programmed by the DSS.DSIPHY_CFG1[22:16] TLPX_HALF field.
- THS-PREPARE + THS-ZERO timing is programmed by the DSS.DSIPHY_CFG0[23:16] THS_PREPARE_THS_ZERO field.

. THS-ZERO will be extended, if required, so that the entire LP SoT procedure lasts an integer number of TXByteClkHS cycles. THS-SYNC corresponds to the length of the sync pattern which is eight High-Speed bits.

Towards the end of the SoT procedure, the PHY makes TXREADYHS high on a positive edge of TXByteClkHS and then start accepting data from TXDATAHS from the next positive edge onwards. The protocol is expected to provide (new) valid data on TXDATAHS on every positive edge of TXByteClkHS if TXREADYHS is high.

At the end of the SoT procedure, HS data transmission begins. HS Data Transmission happens LSB first.

To stop data transmission, the protocol drives TXREQUESTHS low on a rising edge of TXByteClkHS. The PHY detects this change in TXREQUESTHS on the next edge and stops data transmission. TXREADYHS is made low and data on TXDATAHS, from that point, is ignored.

The PHY then goes through the LP End of Transmission (EoT) procedure. THS-TRAIL and THS-EXIT are also multiple of CLKIN4DDR are also multiples of CLKIN4DDR and programmed by the following register fields:

- THS-TRAIL timing is programmed by the DSS.DSIPHY_CFG0[15:8] THS_TRAIL field.
- THS-EXIT timing is programmed by the DSS.DSIPHY_CFG0[7:0] THS_EXIT field.

The PHY completes the SoT and EoT procedures, once begun, irrespective of any change in PPI signals. If TXREQUESTHS goes low during the SoT procedure, the PHY start the EoT procedure immediately after finishing the SoT procedure and no data is transmitted.

STOPSTATE is high whenever the line is in LP-11 state, as determined by the outputs of the Low Power Receivers. This signal is not synchronized with TXByteClkHS.

The Protocol should ensure that TXREQUESTESC, TXULPCLK and TURNREQUEST are low whenever TXREQUESTHS is asserted.

15.5.6.4.3 Other DSI PHY Transmission and Reception

The timings of the following sequences defined in the D-PHY protocol can not be programmed by the user:

- Low-power data transmission
- Escape mode trigger command transmission
- ULP command transmission on data lanes
- ULP state transmission on clock lane
- Turn-around request in transmit mode
- Turn-around request in receive mode
- Low-power data in receive mode
- Low-power trigger in receive mode
- ULP command on clock lane in receive mode
- ULP command on data lane in receive mode.

For more details on these sequences, refer to the D-PHY specification.

15.5.6.5 Error Handling

A dedicated register for the DSI complex I/O, DSS.DSI_COMPLEXIO_IRQSTATUS, indicates the state of each error provided by the DSI complex I/O error signals. The DSIPHY reports the following errors:

- DSS.DSI_COMPLEXIO_IRQSTATUS[7:5] ERR_ESCi_IRQ: ERRESC is asserted if an unrecognized Escape entry command is received. This remains high until the next change in the line state.
- DSS.DSI_COMPLEXIO_IRQSTATUS[2:0] ERRSYNCESci_IRQ: If the number of bits received during a low-power data transmission is not a multiple of eight when the transmission ends, ERRSYNCESci is made high and remains high until the next change in line state.
- DSS.DSI_COMPLEXIO_IRQSTATUS[12:10] ERRCONTROLi_IRQ: ERRCONTROL is asserted if an incorrect line state sequence is detected. For example, if a turn-around request or escape mode request is immediately followed by a Stop state instead of the required Bridge state, this signal is asserted and remains asserted until the next change in the line state.
- DSS.DSI_COMPLEXIO_IRQSTATUS ERRCONTENTIONLP0_i_IRQ: ERRCONTENTION0LPDX and ERRCONTENTION0LPDY are asserted when the Lane module detects a contention situation on lines DX and DY respectively while trying to drive the lines low. Contention is detected only if it lasts at least 50ns
- DSS.DSI_COMPLEXIO_IRQSTATUS ERRCONTENTIONLP1_i_IRQ: ERRCONTENTION1LPDX and ERRCONTENTION1LPDY are asserted when the Lane module detects a contention situation on lines DX and DY respectively while trying to drive the lines high. Contention is detected only if it lasts at least 50ns

The ULPSACTIVENOT signal goes low which indicates to the protocol that the PHY has entered ULP state. When all the ULPSActiveNot signals are low, the DSS.DSI_COMPLEXIO_IRQSTATUS[30] ULPSACTIVENOT_ALL0_IRQ event is generated. When all the ULPSActiveNot signals are high, the DSS.DSI_COMPLEXIO_IRQSTATUS[31] ULPSACTIVENOT_ALL1_IRQ event is generated.

When any of the events defined in DSS.DSI_COMPLEXIO_IRQSTATUS register happened, the DSS.DSI_IRQSTATUS[10] COMPLEXIO_ERR_IRQ bit is set to 1 at DSI protocol engine level.

The software is responsible for taking the appropriate action when receiving the interrupt indicating the error from the complex I/O. The action can be:

- Reset of the DSI protocol engine module
- Reset of the peripheral through reset trigger or directly driving the hardware reset pin of the display module
- Ignore the error

15.5.7 RFBI Basic Programming Model

The RFBI programming model must be used for LCD display support only.

15.5.7.1 DISPC Control Registers

The following DISPC registers are used in RFBI mode:

- The RFBI mode is selected by setting the DSS.DISPC_CONTROL[11] RFBIMODE bit. The DSS.DISPC_CONTROL[5] GOLCD bit should not be set to 1 but the display controller configuration (DMA engine, pipelines associated to the LCD output,...) should be set before enabling the LCD output by setting the DSS.DISPC_CONTROL[0] LCDENABLE bit to 1.
- To enable the hardware handcheck to avoid underflow, the DSS.DISPC_CONTROL[16] FIFOHANDCHECK should be set to 1. The reset value of this bit is 0. The handcheck applies to the pipelines connected to the LCD output. It should be disabled before resetting the DSS.DISPC_CONTROL[11] RFBIMODE bit to 0. The new setting for the FIFO handcheck is used for the following frames.

Note: The LCD output is disabled at the end of the transfer of the frame. The S/W has to re-enable the LCD output to generate a new frame by setting the DSS.DISPC_CONTROL[0] LCDENABLE to 1. See [Figure 15-138](#).

15.5.7.2 RFBI Control Registers

The following registers define the RFBI control registers:

- DSS.RFBI_CONTROL
- DSS.RFBI_PIXEL_CNT
- DSS.RFBI_LINE_NUMBER

15.5.7.2.1 High Threshold

The DSS.RFBI_CONTROL[6:5] HIGHTHRESHOLD field is used to define the threshold to be used for the generation of the DMA request to receive data into the interconnect FIFO (24x31 FIFO depth) through the address of the register [RFBI_DATA](#). It should be the size of the burst. The supported values are 4x32, 8x32 and 16x32. The system DMA receives the DMA request and is in charge of providing the correct number of bytes. If the DSS.RFBI_CONTROL[7] DISABLE_DMA_REQ bit is reset, the DMA request is generated when there is enough room in the interconnect FIFO to accept the full burst. In case the RFBI receives writes L4 requests to the [RFBI_DATA](#) location when the interconnect FIFO is full, the request is not accepted. The RFBI waits for a free entry in the interconnect FIFO to accept the L4 request.

If the DSS.RFBI_CONTROL[7] DISABLE_DMA_REQ bit is set, the DMA request is not generated. The threshold value is ignored.

Note: Software users can access the [RFBI_DATA](#) location without using the DMA request and without programming the high threshold value (backward mode).

15.5.7.2.2 Bypass Mode

Setting the DSS.[RFBI_CONTROL](#)[1] BYPASSMODE bit directly outputs the LCD controller output to the LCD panel. Resetting this bit directs the MPU module to send commands/parameters and data from the input video port FIFO.

15.5.7.2.3 Enable

Setting/resetting the DSS.[RFBI_CONTROL](#)[0] ENABLE bit enables/disables the RFBI module. The hardware resets the enable bit after all of the pixels are sent to the panel. The DSS.[RFBI_PIXEL_CNT](#)[31:0] PIXELCNT field value defines the number of pixels to send to the LCD panel. When the transfer is finished, the configuration used can be modified.

Table 15-62. RFBI Behavior

RFBI_CONTROL [1] BYPASSMODE bit value	RFBI_CONTROL [0] ENABLE bit value	RFBI Behavior
0	0	L4 interconnect can write command/param/data and read data/status from the Remote Frame Buffer (RFB). L4 interconnect access can only be done to the CSx actually active
0	1	The DISPC sends pixels to the RFB.

The stall signal is asserted when the module is disabled. Through the L4 port, pixels can be sent to the LCD panel only when the pixel count has reach the value 0x0.

Note: The LCD output is disabled at the end of the transfer of the frame. The S/W has to re-enable the LCD output to generate a new frame by setting the DSS.DISPC_CONTROL[0] LCDENABLE to 1. See [Figure 15-138](#).

15.5.7.2.4 Configuration Selection

Setting the DSS.[RFBI_CONTROL](#)[3:2] CONFIGSELECT bit field selects the configuration number (1 or 0 if bits are set or reset). The registers associated with the configuration output the data to the LCD panel.

If both chip-selects are selected, the configuration for the first chip-select is used (except for the polarity of the RFBI_CS1 signal defined by the second configuration) and both devices connected to the CS signals are driven in parallel. In read mode, if both chip-selects are set, only RFBI_CS0 is asserted to read data from the device connected on RFBI_CS0. In write mode with two chip-selects selected, the RFBI can write to the two devices simultaneously.

15.5.7.2.5 ITE Bit

Set the DSS.[RFBI_CONTROL](#)[4] ITE bit to start capturing the data from the display controller. This bit has no effect if the trigger mode is set to external. The display controller must be configured in the RFBI mode to account for the RFBI_DISPC_STALL signal. Setting the trigger mode to external (DSS.[RFBI_CONFIG](#)[3:2] TRIGGERMODE field set to 0x1 or 0x2) causes the DSS.[RFBI_CONTROL](#)[4] ITE bit to be ignored. The corresponding chip-select must be selected when this bit is set by the user.

The RFBI_DISPC_STALL signal is asserted when at least one of the following cases occur:

- Default status when no data to capture from the display controller
- High FIFO threshold reached
- End of the transfer (number of data to output)

- Reset of the RFBI module
- DSS.RFBI_CONTROL[0] ENABLE bit reset to 0x0

The RFBI_DISPC_STALL signal is deasserted when the DSS.RFBI_CONTROL[0] ENABLE bit is set to 0x1 and at least one of the following cases occur:

- Low FIFO threshold reached
- External tearing effect occurs and the DSS.RFBI_CONFIGi[3:2] TRIGGERMODE field is set to 0x1 or 0x2 for automatic external trigger (start of the transfer, the FIFO pointers are reset, the FIFO is empty).
- DSS.RFBI_CONTROL[4] ITE bit set to 0x1 by the user (start of the transfer, the FIFO pointers are reset, the FIFO is empty).

15.5.7.2.6 Number of Pixels to Transfer

Setting the DSS.RFBI_PIXEL_CNT[31:0] PIXELCNT field value directs the application to indicate the number of pixels to be transferred to the LCD panel. The value can be changed only when the DSS.RFBI_CONTROL[0] ENABLE is reset.

During the transfer, the hardware decrements the register when a pixel is sent to the remote frame buffer. When the DSS.RFBI_CONTROL[0] ENABLE bit is set and a new value is written in the DSS.RFBI_PIXEL_CNT register when the current value in the register is a non-zero (the remaining number of pixels to transfer), the ongoing transfer is aborted.

From the L4 interconnect side, if DSS.RFBI_CONFIGi[10:9] CYCLEFORMAT field is equal to 0x3 and DSS.RFBI_CONFIGi[8:7] L4FORMAT is equal to 0x0, an even number of write accesses to the data register should be performed before accessing any other register (CMD/PARAM/STATUS/READ).

When DSS.RFBI_CONFIGi[10:9] CYCLEFORMAT field is 0x3 - meaning that 2 pixels are sent over 3 cycles -, the number of pixels to be programmed in the DSS.RFBI_PIXEL_CNT[31:0] PIXELCNT field should be a multiple of 2. If another CYCLEFORMAT is used, the value for PIXELCNT can be odd or even. This constraint is valid for data provided on the L4 interconnect port and from the display controller.

If the DSS.RFBI_CONFIGi[10:9] CYCLEFORMAT field is equal to 0x3, DSS.RFBI_CONFIGi[8:7] L4FORMAT is equal to 0, and back to back register write is processed, the following registers should be written after the first data: RFBI_CMD, RFBI_PARAM, RFBI_READ, and RFBI_STATUS. The whole data transfer should first be performed before being able to write to any other registers (RFBI_CMD, RFBI_PARAM, RFBI_READ, and RFBI_STATUS).

15.5.7.2.7 Programmable Line Number

When the trigger mode is set to external trigger mode with HSYNC and VSYNC or the TE, the hardware resets the line counter when the VSYNC occurs and, after a programmable number of lines (the HSYNC pulse occurs for every line), the transfer to the LCD panel begins. When the programmable line number is 0, only the VSYNC pulse indicates the beginning of the transfer in both modes: HSYNC/VSYNC and TE (logical OR operation between HSYNC and VSYNC).

15.5.7.3 RFBI Configuration

The following registers define the RFBI configuration:

- DSS.RFBI_SYSCONFIG
- DSS.RFBI_SYSSTATUS
- DSS.RFBI_CONFIG0 (configuration 0) and DSS.RFBI_CONFIG1 (configuration 1)
- DSS.RFBI_VSYNC_WIDTH
- DSS.RFBI_HSYNC_WIDTH

The configuration register for one configuration can be accessed only when the configuration is not in use (based on the value of the RFBI_CONTROL[3:2] CONFIGSELECT field).

15.5.7.3.1 Parallel Mode

The DSS.RFBI_CONFIG_i[1:0]PARALLELMODE field (with $i = 0, 1$) defines the width of the interface (8-, 9-, 12-, or 16-bit parallel).

15.5.7.3.2 Trigger Mode

Setting the DSS.RFBI_CONFIG[3:2]TRIGGERMODE field configures the trigger on the external TE signal (RFBI_TE_VSYNC), or external with VSYNC/HSYNC with the programmable number of HSYNCs to begin the transfer in both cases or the internal programmable DSS.RFBI_CONTROL[4] ITE bit.

15.5.7.3.3 VSYNC Pulse Width (Minimum Value)

The DSS.RFBI_VSYNC_WIDTH[15:0] MINVSYNCPULSEWIDTH field defines the minimum number of L4 clock cycles of the VSYNC pulse for detection on VSYNC. It allows differentiation between VSYNC and HSYNC, which are ORed on the same signal and is also used in the VSYNC/HSYNC mode on the two separate input lines.

- The VSYNC pulse width must be at least equal to two L4 cycles when HSYNC is not present.
- The VSYNC pulse width must be at least equal to four L4 cycles when HSYNC is present.

15.5.7.3.4 HSYNC Pulse Width (Minimum Value)

The DSS.RFBI_HSYNC_WIDTH[15:0] MINHSYNCPULSEWIDTH field defines the minimum number of L4 clock cycles of the HSYNC pulse for detection on HSYNC. It allows differentiation between VSYNC and HSYNC, which are ORed on the same signal, and is also used in the VSYNC/HSYNC mode on the separate two input lines. The HSYNC pulse width must always be at least equal to two L4 cycles to be detected.

15.5.7.3.5 Cycle Format

Setting the DSS.RFBI_CONFIG_i[10:9] CYCLEFORMAT field (with $i = 0, 1$) defines which registers are used to format the data in the interconnect FIFO with the appropriate number of bits (starting from the LSB) and with the alignment on the interface as follows:

- DSS.RFBI_CYCLE1 (if DSS.RFBI_CONFIG[10:9] CYCLEFORMAT field = 00) only
or
- DSS.RFBI_CYCLE1 and DSS.RFBI_CYCLE2 (if DSS.RFBI_CONFIG[10:9] CYCLEFORMAT field = 01)
or
- DSS.RFBI_CYCLE1, DSS.RFBI_CYCLE2, and DSS.RFBI_CYCLE3 (if DSS.RFBI_CONFIG[10:9] CYCLEFORMAT field = 10)

The data from the display controller and from the L4 interconnect are formatted based on the configuration of the DSS.RFBI_CYCLE_i registers (with $i = 0, 1, 2$).

15.5.7.3.6 Unused Bits

Based on the configuration, the undefined bits for each cycle are defined with the previous values of the bits at the same position in the previous cycle, 0s, or 1s (the unused bits can be at any position). The DSS.RFBI_CONFIG_i[12:11] UNUSEDBITS field (with $i = 0, 1$) is used.

15.5.7.3.7 RFBI Timings

The timing registers for one configuration can be accessed only when the configuration is not in use (based on the value of the DSS.RFBI_CONTROL[3:2] CONFIGSELECT field). Granularity is defined using the DSS.RFBI_CONFIG_i[4] TIMEGRANULARITY bit. This feature allows the extension of programmable ranges of timing parameters for the RFBI interface. Refer to [Table 15-63](#) for the bits configuration values.

- Chip-select assertion/deassertion time

RFBI_A0 setup time to chip-select assertion is assured by the programmable chip-select assertion time from the start access time:

DSS.RFBI_ONOFF_TIMEi[3:0] CSONTIME field (with i = 0, 1).

The chip-select deassertion time from the start access time is programmable:

DSS.RFBI_ONOFF_TIMEi[9:4] CSOFFTIME field (with i = 0, 1)

CAUTION

Configuring DSS.RFBI_ONOFF_TIMEi[3:0] CSONTIME = DSS.RFBI_ONOFF_TIMEi[9:4] CSOFFTIME = 0 (with i = 0, 1) is not supported and must be avoided. This configuration creates contention on the bus and progressively damages the LCD panel.

- Chip-select pulse width

The total chip-select pulse width is the time when write cycle time or read cycle time has completed and is programmable:

DSS.RFBI_CYCLE_TIMEi[17:12] CSPULSEWIDTH field (with i = 0, 1)

It applies on the read-to-write, write-to-read, read-to-read, and write-to-write access based on:

- The DSS.RFBI_CYCLE_TIMEi [19] RRENABLE bit: Read-to-read access
- The DSS.RFBI_CYCLE_TIMEi [20] WWENABLE bit: Write-to-write access
- The DSS.RFBI_CYCLE_TIMEi [18] RWENABLE bit: Read-to-write access
- The DSS.RFBI_CYCLE_TIMEi [21] WRENABLE bit: Write-to-read access

By default, it applies to any access (read-to-read, read-to-write, write-to-read, write-to-write) when the chip-select changes.

- Access time

The total access time is the time from when A0 becomes valid until data are sampled before deasserting the RE signal; access time is programmable:

DSS.RFBI_CYCLE_TIMEi[27:22] ACESSTIME field (with i = 0, 1)

When reading the data on the bus, the data are sampled at the end of the access time, which occurs before the end of the read off time (DSS.RFBI_ONOFF_TIMEi[29:24] REOFFTIME, with i = 0, 1).

- Write enable cycle time

The total write enable cycle time is the time from when A0 becomes valid until write cycle completion; the write enable cycle time is programmable:

The DSS.RFBI_CYCLE_TIMEi[5:0] WECYCLETIME field (with i = 0, 1)

- Write enable assertion/deassertion time

The WE assertion delay time from start access time is programmable:

DSS.RFBI_ONOFF_TIMEi[13:10] WEONTIME field (with i = 0, 1)

The WE deassertion delay time from the start access time is programmable:

DSS.RFBI_ONOFF_TIMEi[19:14] WEOFFTIME field (with i = 0, 1)

- Read enable cycle

The total read enable cycle time is the time when A0 becomes valid until read cycle completion; the read enable cycle time is programmable:

The DSS.RFBI_CYCLE_TIMEi[11:6] RECYCLETIME field (with i = 0, 1)

- Read enable assertion/deassertion time

The RE assertion delay time from the start access time is programmable:

DSS.RFBI_ONOFF_TIMEi[23:20] REONTIME field (with i = 0, 1)

The RE deassertion delay time from the start access time is programmable:

DSS.RFBI_ONOFF_TIMEi[29:24] REOFFTIME field (with i = 0, 1)

At cycle time completion (read access or write access) all control signals (RFBI_CSi, RFBI_WE, and RFBI_RE, with i = 0, 1) are deasserted regardless of their deassertion time parameter values, if they are not deasserted already.

However, an exception to this forced deassertion exists when a pipelined request to the same chip-select or to a different chip-select is pending. Also, a control signal with deassertion time parameters equal to the cycle time parameter is not necessarily deasserted when a pipelined request to the same chip-select or different chip-select is pending. This prevents any unnecessary glitch transitions.

If no inactive cycles are required between successive accesses to the same chip-select (the DSS.RFBI_CYCLE_TIME_i[17:12] CSPULSEWIDTH field = 0, with $i = 0, 1$), and if assertion time parameters associated with the following access equal 0, the asserted control signals (RFBI_CS_i, RFBI_WE, and RFBI_RE, with $i = 0, 1$) stay asserted. This is applicable to any read/write-to-read/write access combination.

Table 15-63 resumes the configurations values for each timing bit.

Table 15-63. RFBI Timings Configuration

Configuration bits ⁽¹⁾	Granularity ⁽²⁾	
	one	two
DSS.RFBI_ONOFF_TIME _i [3:0] CSONTIME	0 to 15	0 to 30
DSS.RFBI_ONOFF_TIME _i [9:4] CSOFFTIME	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIME _i [17:12] CSPULSEWIDTH	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIME _i [27:22] ACESSTIME	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIME _i [5:0] WECYCLETIME	0 to 63	0 to 126
DSS.RFBI_ONOFF_TIME _i [13:10] WEONTIME	0 to 15	0 to 30
DSS.RFBI_ONOFF_TIME _i [19:14] WEOFFTIME	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIME _i [11:6] RECYCLETIME	0 to 63	0 to 126
DSS.RFBI_ONOFF_TIME _i [23:20] REONTIME	0 to 15	0 to 30
DSS.RFBI_ONOFF_TIME _i [29:24] REOFFTIME	0 to 63	0 to 126

(1) Where $i = 0$ or 1 .

(2) Number of L4Clk cycles. The granularity can be configured using the DSS.RFBI_CONFIG_i[4] TIMEGRANULARITY bit.

15.5.7.3.8 RFBI State-Machine

Referring to Table 15-32, the signals RFBI_A0, RFBI_RE, and RFBI_WE are asserted/deasserted based on the register accessed (DSS.RFBI_CMD, DSS.RFBI_PARAM, DSS.RFBI_DATA, DSS.RFBI_READ, and DSS.RFBI_STATUS). When the DSS.RFBI_SYSSTATUS[8] BUSY bit is set by hardware, any access to the registers is stalled, except for the RFBI_DATA register.

The DSS.RFBI_SYSSTATUS[9] BUSYRFBIDATA bit indicates whether there are still pending data in the interconnect FIFO associated with the register RFBI_DATA only.

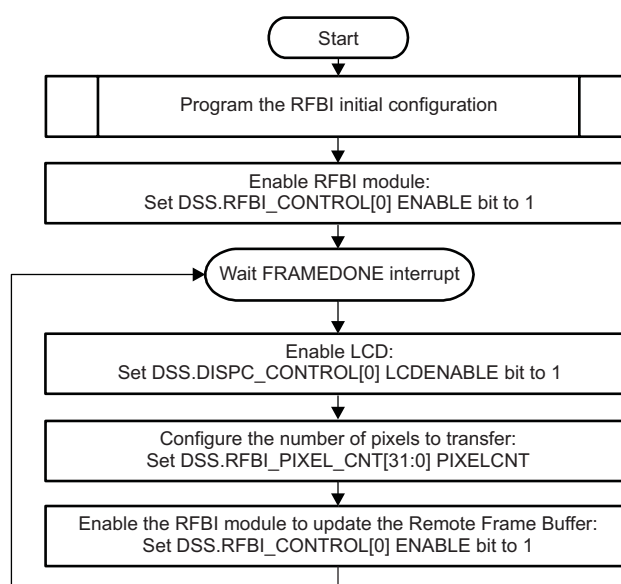

- **Command register**
Write a command at a time by writing in the DSS.RFBI_CMD register. If the previous command is not processed, the DSS.RFBI_SYSSTATUS[8] BUSY bit is set by hardware and the access to writing a new command is stalled.
- **Parameter register**
Write a parameter at a time by writing in the DSS.RFBI_PARAM register.
If the previous parameter is not processed, the DSS.RFBI_SYSSTATUS[8] BUSY bit field is set by hardware and the access to writing a new parameter is stalled.
- **Data register**
Write one or two pixels at a time by writing in the RFBI_DATA register (when DSS.RFBI_CONFIG_i[10:9] CYCLEFORMAT = 0x3 with $i = 0, 1$, two pixels must be written contiguously, no other access to RFBI registers except DSS.RFBI_DATA is allowed).
The pixels are formatted based on the specified cycle format. If two pixels are written into the 32-data register, the DSS.RFBI_CONFIG_i[8:7] L4FORMAT field indicates the number of pixels for each L4 access to the register and the order of the pixels
If the previous data are not processed, the DSS.RFBI_SYSSTATUS[8] BUSY bit is set by hardware and any access for writing new data is stalled. When the DSS.RFBI_SYSSTATUS[8] BUSY bit is reset by hardware, the access is not stalled.

- Read/status register
Send through the command and parameter registers the correct information to receive data in the data or status register. The read data from the LCD panel is initiated by writing into the DSS.RFBI_READ or DSS.RFBI_STATUS registers. In this case, the DSS.RFBI_SYSSTATUS[8] BUSY bit is set until the data are available in the register.
When the DSS.RFBI_SYSSTATUS[8] BUSY bit is set by hardware, the read or write access is stalled until the register is updated with a new value from the LCD panel. To avoid the stall, the software can poll the DSS.RFBI_SYSSTATUS[8] BUSY bit until it is reset by hardware. To receive the data, send the appropriate command/parameters.

15.5.7.3.9 RFBI Configuration Flowcharts

Figure 15-138 gives an example of how to program and use the RFBI module:

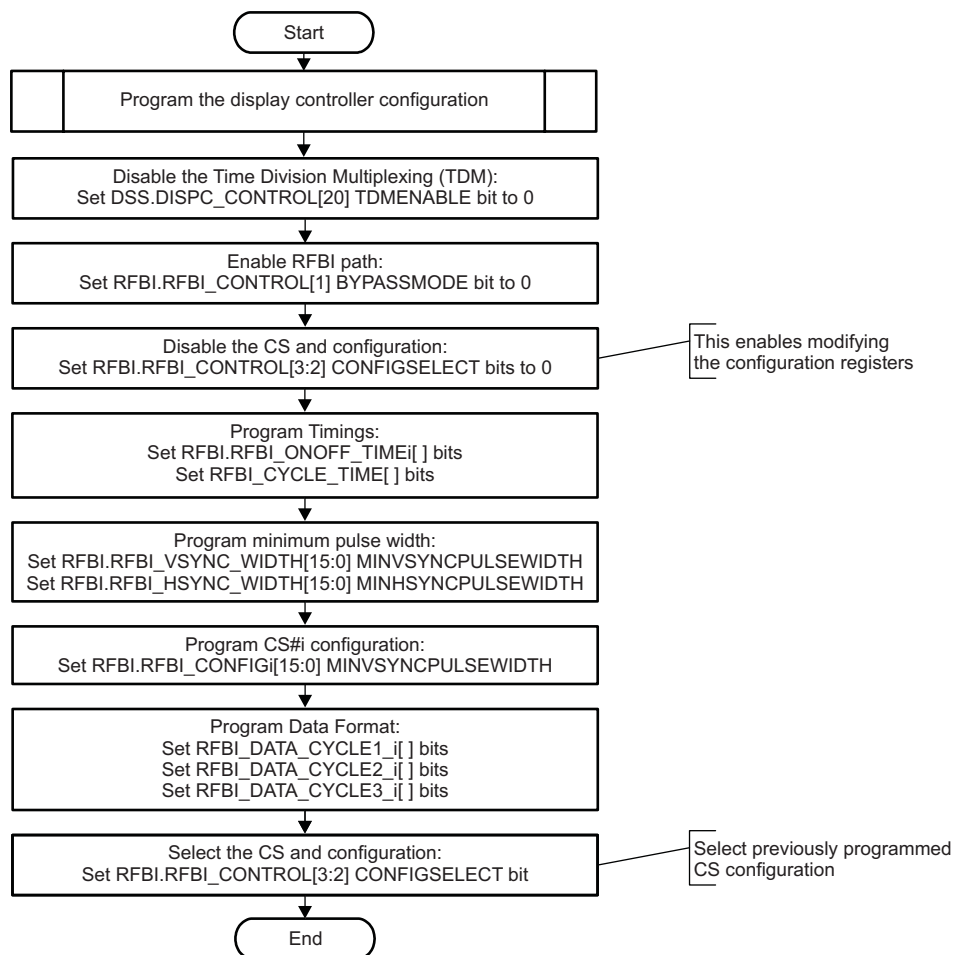

Figure 15-138. How to use RFBI

dss-192

Figure 15-139 details how to configure the RFBI registers:

Figure 15-139. RFBI Initial Configuration

dss-193

15.5.8 Video Encoder Basic Programming Model

This section describes TV OUT Encoder module.

15.5.8.1 Video Encoder Software Reset

By setting the DSS.VENC_F_CONTROL[8] RESET bit to 1, the video encoder is reset. This bit is automatically cleared by hardware when the reset is done.

Note: Before changing the standard (NTSC or PAL) and all the related registers, a software reset is required to properly initialize the VENC module.

15.5.8.2 Video DAC Settings

The video output format can be either:

- one composite video (CVBS) output signal with video DAC1 or
- two separated luma/chroma output signals with both video DAC1(luma analog signal) and DAC2 (chroma analog signal)

Selection is performed with DSS.DSS_CONTROL[6] VENC_OUT_SEL bit:

- When VENC_OUT_SEL bit is set to 0 (reset value), video DAC1 is selected for composite video (CVBS) signal
- When VENC_OUT_SEL bit is set to 1, video DAC1 is selected for luma signal

One of the first VENC settings is to enable the output of the video DACs. This setting depends on the video output format:

- CVBS video output format: Enable video DAC1 composite output by setting the DSS.VENC_OUTPUT_CONTROL[1] COMPOSITE_ENABLE bit to 1
- Separated luma/chroma output format: Enable video DAC1 luma output by setting the DSS.VENC_OUTPUT_CONTROL[0] LUMA_ENABLE bit to 1 and enable video DAC2 chroma output by setting the DSS.VENC_OUTPUT_CONTROL[2] CHROMA_ENABLE bit to 1

15.5.8.3 Video Encoder Programming Sequence

1. Set the DSS.VENC_F_CONTROL[8] RESET bit to 1 to perform a software reset of the VENC module.
2. Before any configuration change, save the DSS.DISPC_IRQENABLE register value (DSS interrupts context), and then disable the display subsystem interrupts by setting the DSS.DISPC_IRQENABLE register to 0x0000.
3. Configure the video encoder registers as described in Table 15-64, depending on the video standard used (PAL or NTSC). The DSS.VENC_F_CONTROL and DSS.VENC_SYNC_CTRL registers must be the last ones to be changed by software.
4. Set the DSS.DISPC_CONTROL[6] GODIGITAL bit and the DSS.DISPC_CONTROL[1] DIGITALENABLE bit to 1.
5. Wait for the first VSYNC pulse signal.
6. Clear the SYNCLOSTDIGITAL interrupt by setting the DSS.DISPC_IRQSTATUS[15] SYNCLOSTDIGITAL bit to 1.
7. Set the DSS.DISPC_IRQENABLE register to the value saved in step 2 (restore the DSS interrupts context).

15.5.8.4 Video Encoder Register Settings

For video encoder programming, see Table 15-64. This table lists the register values to use in standard applications. These values are validated programming values only for the TV display support (NTSC 601 and PAL 601 standards).

Table 15-64. Video Encoder Register Programming Values

Register Name	NTSC 601	PAL 601
VENC_F_CONTROL	0x00000000	0x00000000
VENC_VIDOUT_CTRL	0x00000001	0x00000001

VENC_GEN_CTRL	0x00F90000	0x00FF0000
VENC_OUTPUT_CONTROL	0x0000000A (composite video CVBS) 0x0000000D (split video S-video)	0x0000000A (composite video CVBS) 0x0000000D (split video S-video)
VENC_OUTPUT_TEST	0x00000000	0x00000000

Note: The following display controller registers must be programmed to the NTSC 601 video standard:

DSS.DISPC_SIZE_DIG[10:0] PPL = $720 - 1 = 719 = 0x2CF$

DSS.DISPC_SIZE_DIG[26:16] LPP = $(482/2) - 1 = 240 = 0xF0$

DSS.DISPC_GFX_BA0 or DSS.DISPC_VIDn_BA0 = Base address of even field data

DSS.DISPC_GFX_BA1 or DSS.DISPC_VIDn_BA1 = Base address of odd field data

15.5.9 SDI Basic Programming Model

This section describes SDI module. This module is not available on all devices. See Chapter 1, the *OMAP35x Family* section, to check availability of this module.

This section describes how to configure the SDI module for FlatLink3G-compliant LCD panel support.

Configure the SDI, and then configure the display controller.

15.5.9.1 SDI Configuration

Note: To use the SDI with the TI FlatLink3G display panel:

- Set the DSS.DISPC_CONTROL[3] STNTFT bit to 1 (active matrix display operation mode)
- Set the DSS.DISPC_CONTROL[9:8] TFTDATALINES field to 0x3 (24-bit data output)
- Set the DSS.DSS_SDI_CONTROL[1:0] SDI_BWSEL field to 0x2 (color depth is 24 bits)

15.5.9.1.1 SDI PLL Configuration

The programming of the PLL divisor must be consistent with the choice of the number of data pairs. The PLL divisor determines the multiplication factor from the pixel clock frequency to data rate.

Table 15-65 lists some example values of the PLL settings for TI FlatLink3G.

Table 15-65. PLL Divisor Example Values for TI FlatLink3G

		24-BPP data		
		1 data pair	2 data pairs	3 data pairs
Recommended values	Pixel clock frequency (MHz)	15	30	65
	DSS.DSS_PLL_CONTROL[16:11]			
	SDI_PLL_REGN field (N factor = SDI_PLL_REGN field value + 1)	0x7	0xE	0xF
	DSS.DSS_PLL_CONTROL[10:1]			
	SDI_PLL_REGM field (M factor)	0xF0	0xE1	0x140
	DDS.DSS_PLL_CONTROL[19]			
	SDI_PLL_HIGHFREQ	0	0	1
	Effective PLL divisor value (M/N)	30	15	10

For more details on SDI PLL programming settings, see .

15.5.9.1.2 Signal Features Configuration

For proper SDI operation, configure the following features in the display controller:

- Set the DSS.DISPC_POL_FREQ[16] RF bit to drive HSYNC and VSYNC on the rising edge of PCLK.
- Set the DSS.DISPC_POL_FREQ[17] ONOFF bit.
- Clear the DSS.DISPC_POL_FREQ[14] IPC bit to drive the pixel data on the rising edge of PCLK.
- Set the DSS.DISPC_CONTROL[29] LCDENABLEPOL bit to set the LCD-enable signal active high.

The following settings are not required by the SDI2 interface, but these polarities settings are the common polarities used by FlatLink3G displays:

- Clear the DSS.DISPC_POL_FREQ[13] IHS bit to set HSYNC active high.
- Clear the DSS.DISPC_POL_FREQ[12] IVS bit to set VSYNC active high.
- Clear the DSS.DISPC_POL_FREQ[15] IEO bit to set the data enable active high.

Note: HSYNC and VSYNC signals are inverted in the SDI module, so the output polarity will be active low.

15.5.9.1.3 Number of Data Pairs

To select the number of data pairs used to transmit display data between the device and the display panel, set the DSS.DSS_SDI_CONTROL[3:2] SDI_PRSEL field.

Table 15-66 lists the different values for these bits based on the number of data pairs.

Table 15-66. SDI Pixel Data Format

	DSS.DSS_SD_CONTROL[3:2] SDI_PRSEL
1 data pair (DATA1 pair)	00
2 data pairs (DATA1 and DATA2 pair)	01
3 data pairs (DATA1, DATA2, and DATA3 pair)	10

15.5.9.2 SDI Power-Management Programming Sequence

This section describes the software sequence for powering on and powering down the SDI module.

15.5.9.2.1 SDI Reset State

After DSS power domain reset or power-on reset, the SDI module is in low-power mode by default with the following configuration:

- Display SS pads multiplexing is in parallel mode and not in SDI mode:
 - CONTROL.CONTROL_PADCONF_DSS_DATA10[2:0]MUXMODE0 and CONTROL.CONTROL_PADCONF_DSS_DATA10[18:16]MUXMODE1 field values is 0x0: SDI_DATA1N/SDI_DATA1P signals are not mapped on dss_data10/dss_data11 pins.
 - CONTROL.CONTROL_PADCONF_DSS_DATA12[2:0]MUXMODE0 and CONTROL.CONTROL_PADCONF_DSS_DATA12[18:16]MUXMODE1 field values is 0x0: SDI_DATA2N/SDI_DATA2P signals are not mapped on dss_data12/dss_data13 pins.
 - CONTROL.CONTROL_PADCONF_DSS_DATA14[2:0]MUXMODE0 and CONTROL.CONTROL_PADCONF_DSS_DATA14[18:16]MUXMODE1 field values is 0x0: SDI_DATA3N/SDI_DATA3P signals are not mapped on dss_data14/dss_data15 pins.
 - CONTROL.CONTROL_PADCONF_DSS_DATA18[2:0]MUXMODE0 and CONTROL.CONTROL_PADCONF_DSS_DATA18[18:16]MUXMODE1 field values is 0x0: SDI_VSYNC/SDI_HSYNC signals are not mapped on dss_data18/dss_data19 pins.
 - CONTROL.CONTROL_PADCONF_DSS_DATA20[2:0]MUXMODE0 and CONTROL.CONTROL_PADCONF_DSS_DATA20[18:16]MUXMODE1 field values is 0x0: SDI_DEN/SDI_STP signals are not mapped on dss_data20/dss_data21 pins.
 - CONTROL.CONTROL_PADCONF_DSS_DATA22[2:0]MUXMODE0 and CONTROL.CONTROL_PADCONF_DSS_DATA22[18:16]MUXMODE1 field values is 0x0: SDI_CLKP/SDI_CLKN signals are not mapped on dss_data22/dss_data23 pins.
- SDI PLL is in reset mode: the DSS.DSS_PLL_CONTROL[18]SDI_PLL_SYSRESET bit value is 0x0.

15.5.9.2.2 SDI Power_On Sequence

When exiting OFF mode, to power-on the SDI module, the software user must program the following sequence:

1. Program the SDI pads multiplexing configuration:
 - a. Set the CONTROL.CONTROL_PADCONF_DSS_DATA10[2:0]MUXMODE0 field to 0x1 to select SDI_DATA1N signal on dss_data10 pin and CONTROL.CONTROL_PADCONF_DSS_DATA10[18:16]MUXMODE1 field to 0x1 to select SDI_DATA1P signal on dss_data11 pin.
 - b. For 2-data and 3-data pair mode: set the CONTROL.CONTROL_PADCONF_DSS_DATA12[2:0]MUXMODE0 field to 0x1 to select SDI_DATA2N on dss_data12 pin and CONTROL.CONTROL_PADCONF_DSS_DATA12[18:16]MUXMODE1 field to 0x1 to select SDI_DATA2P signal on dss_data13 pin.
 - c. For 3-data pair mode: set the CONTROL.CONTROL_PADCONF_DSS_DATA14[2:0]MUXMODE0 field to 0x1 to select SDI_DATA3N on dss_data14 pin and CONTROL.CONTROL_PADCONF_DSS_DATA14[18:16]MUXMODE1 field to 0x1 to select SDI_DATA3P signal on dss_data15 pin.

- d. Set the CONTROL.CONTROL_PADCONF_DSS_DATA18[2:0]MUXMODE0 field to 0x1 to select SDI_VSYNC signal on dss_data18 pin and CONTROL.CONTROL_PADCONF_DSS_DATA18[18:16]MUXMODE1 field to 0x1 to select SDI_HSYNC signal on dss_data19 pin.
 - e. Set the CONTROL.CONTROL_PADCONF_DSS_DATA20[2:0]MUXMODE0 field to 0x1 to select SDI_DEN signal on dss_data20 pin and CONTROL.CONTROL_PADCONF_DSS_DATA20[18:16]MUXMODE1 field to 0x1 to select SDI_STP signal on dss_data21 pin.
 - f. Set the CONTROL.CONTROL_PADCONF_DSS_DATA22[2:0]MUXMODE0 field to 0x1 to select SDI_CLKP signal on dss_data22 pin and CONTROL.CONTROL_PADCONF_DSS_DATA22[18:16]MUXMODE1 field to 0x1 to select SDI_CLKN signal on dss_data23 pin.
2. Wait 1 ms.
 3. Release the SDI PLL reset signal by setting the DSS.DSS_PLL_CONTROL[18]SDI_PLL_SYSRESET bit to 0x1.

Note: The same software sequence is needed when the DSS power domain is set to ON.

15.5.9.2.3 SDI Power-Down Sequence

To power down the SDI module, the software user must program the following sequence:

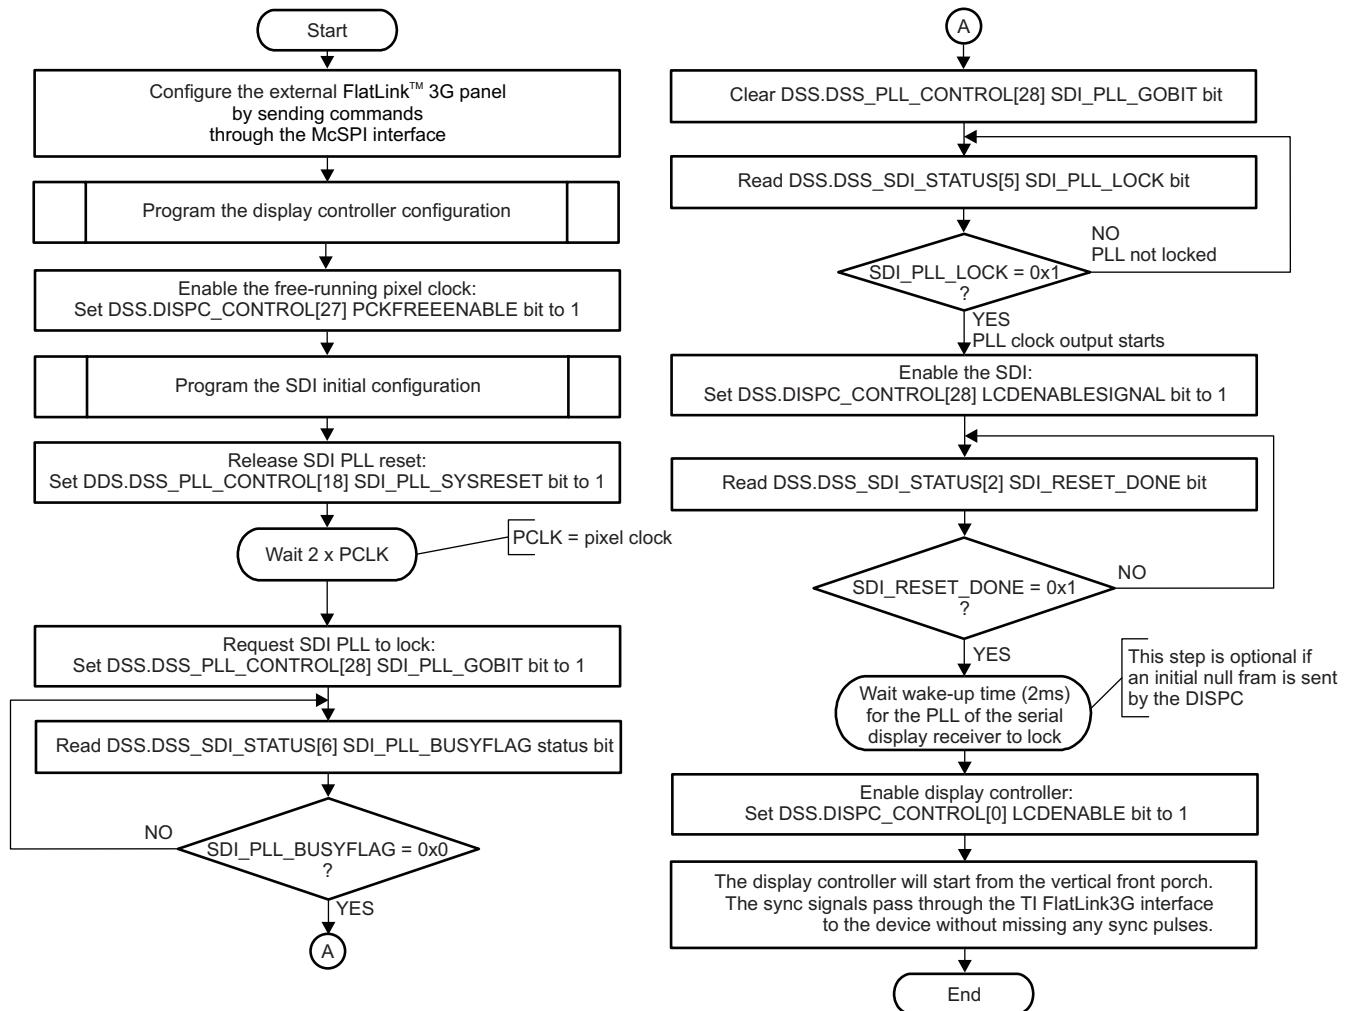

1. Power down the SDI PLL by setting the DSS.DSS_PLL_CONTROL[18]SDI_PLL_SYSRESET bit to 0x0.
2. Power-down the SDI pads:
 - a. Set the CONTROL.CONTROL_PADCONF_DSS_DATA10[2:0]MUXMODE0 field to 0x0 to un-select SDI_DATA1N signal on dss_data10 pin and CONTROL.CONTROL_PADCONF_DSS_DATA10[18:16]MUXMODE1 field to 0x0 to un-select SDI_DATA1P signal on dss_data11 pin.
 - b. For 2-data and 3-data pair mode: set the CONTROL.CONTROL_PADCONF_DSS_DATA12[2:0]MUXMODE0 field to 0x0 to un-select SDI_DATA2N on dss_data12 pin and CONTROL.CONTROL_PADCONF_DSS_DATA12[18:16]MUXMODE1 field to 0x0 to un-select SDI_DATA2P signal on dss_data13 pin.
 - c. For 3-data pair mode: set the CONTROL.CONTROL_PADCONF_DSS_DATA14[2:0]MUXMODE0 field to 0x0 to un-select SDI_DATA3N on dss_data14 pin and CONTROL.CONTROL_PADCONF_DSS_DATA14[18:16]MUXMODE1 field to 0x0 to un-select SDI_DATA3P signal on dss_data15 pin.
 - d. Set the CONTROL.CONTROL_PADCONF_DSS_DATA18[2:0]MUXMODE0 field to 0x0 to un-select SDI_VSYNC signal on dss_data18 pin and CONTROL.CONTROL_PADCONF_DSS_DATA18[18:16]MUXMODE1 field to 0x0 to un-select SDI_HSYNC signal on dss_data19 pin.
 - e. Set the CONTROL.CONTROL_PADCONF_DSS_DATA20[2:0]MUXMODE0 field to 0x0 to un-select SDI_DEN signal on dss_data20 pin and CONTROL.CONTROL_PADCONF_DSS_DATA20[18:16]MUXMODE1 field to 0x0 to un-select SDI_STP signal on dss_data21 pin.
 - f. Set the CONTROL.CONTROL_PADCONF_DSS_DATA22[2:0]MUXMODE0 field to 0x0 to un-select SDI_CLKP signal on dss_data22 pin and CONTROL.CONTROL_PADCONF_DSS_DATA22[18:16]MUXMODE1 field to 0x0 to un-select SDI_CLKN signal on dss_data23 pin.

Note: The same software sequence is needed to shut-down the DSS power domain.

15.5.9.3 SDI Start Sequence

Figure 15-140 describes the SDI start sequence.

Figure 15-140. SDI Start Sequence

dss-108

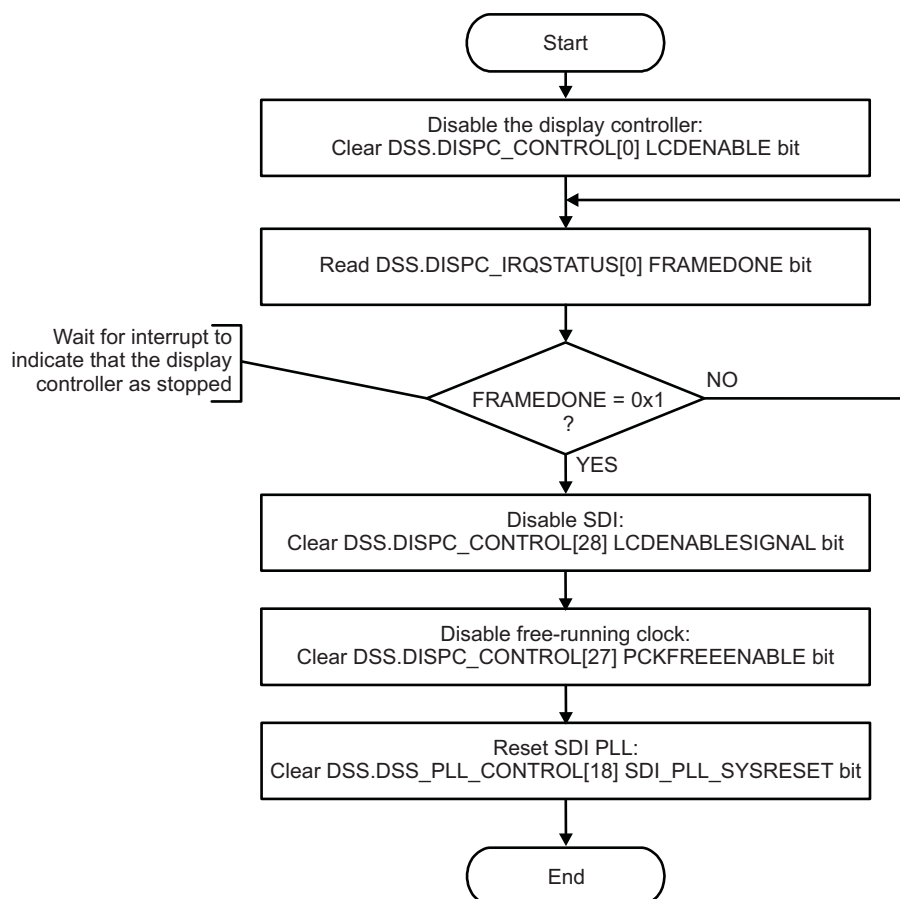

Note: The lock status of the SDI PLL is connected to the GPIO_81 signal of the GPIO3 module. To avoid polling, configure the GPIO3 module to generate an interrupt when the SDI PLL is locked (lock status is 1). For more information, see the *General-Purpose Interface* chapter.

Note: TI provides a global solution with OMAP device associated to a programmable 27-bit serial display interface receiver, the SN65LVDS302 receiver. For more details on SN65LVDS302 device, see the TI public web at www.ti.com.

15.5.9.4 SDI Stop Sequence

Figure 15-141 describes the SDI stop sequence.

Figure 15-141. SDI Stop Sequence

dss-110

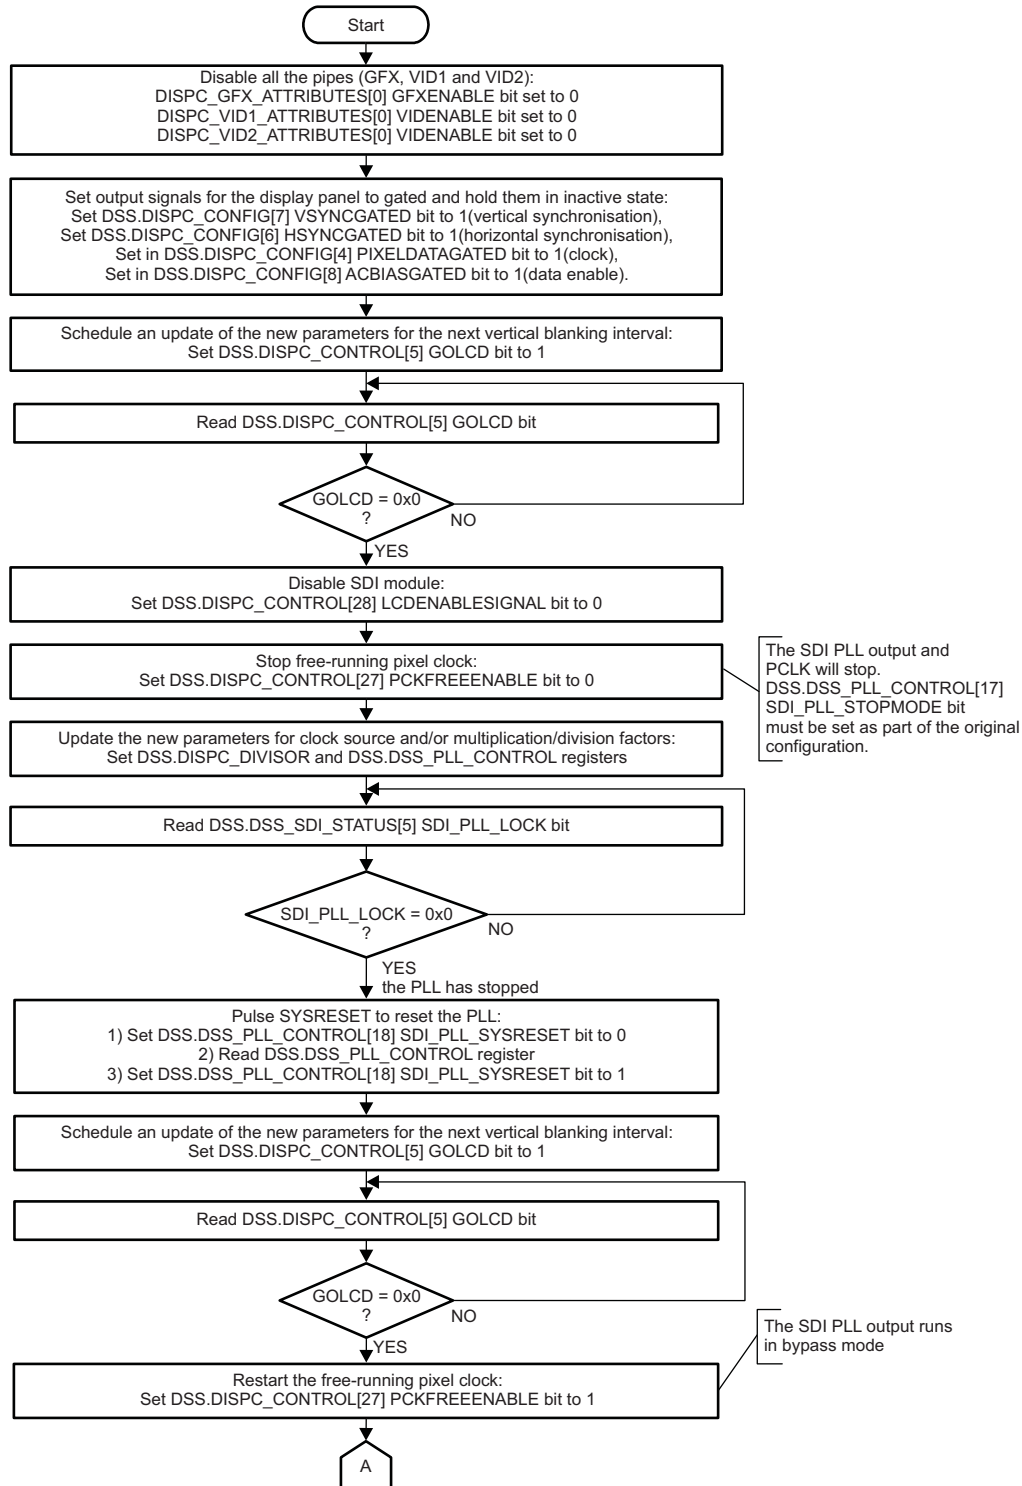

15.5.9.5 Clock Source/Frequency Change Sequence

To change clock source or frequency, the simplest procedure is to follow the stop and start sequences documented above. If it is desired to change these without stopping the display a more rigorous procedure must be used as follows. The intent of this procedure is to perform the changes as quickly as possible during the vertical blanking interval and hence to minimize any visible display effect due to the increased blanking time.

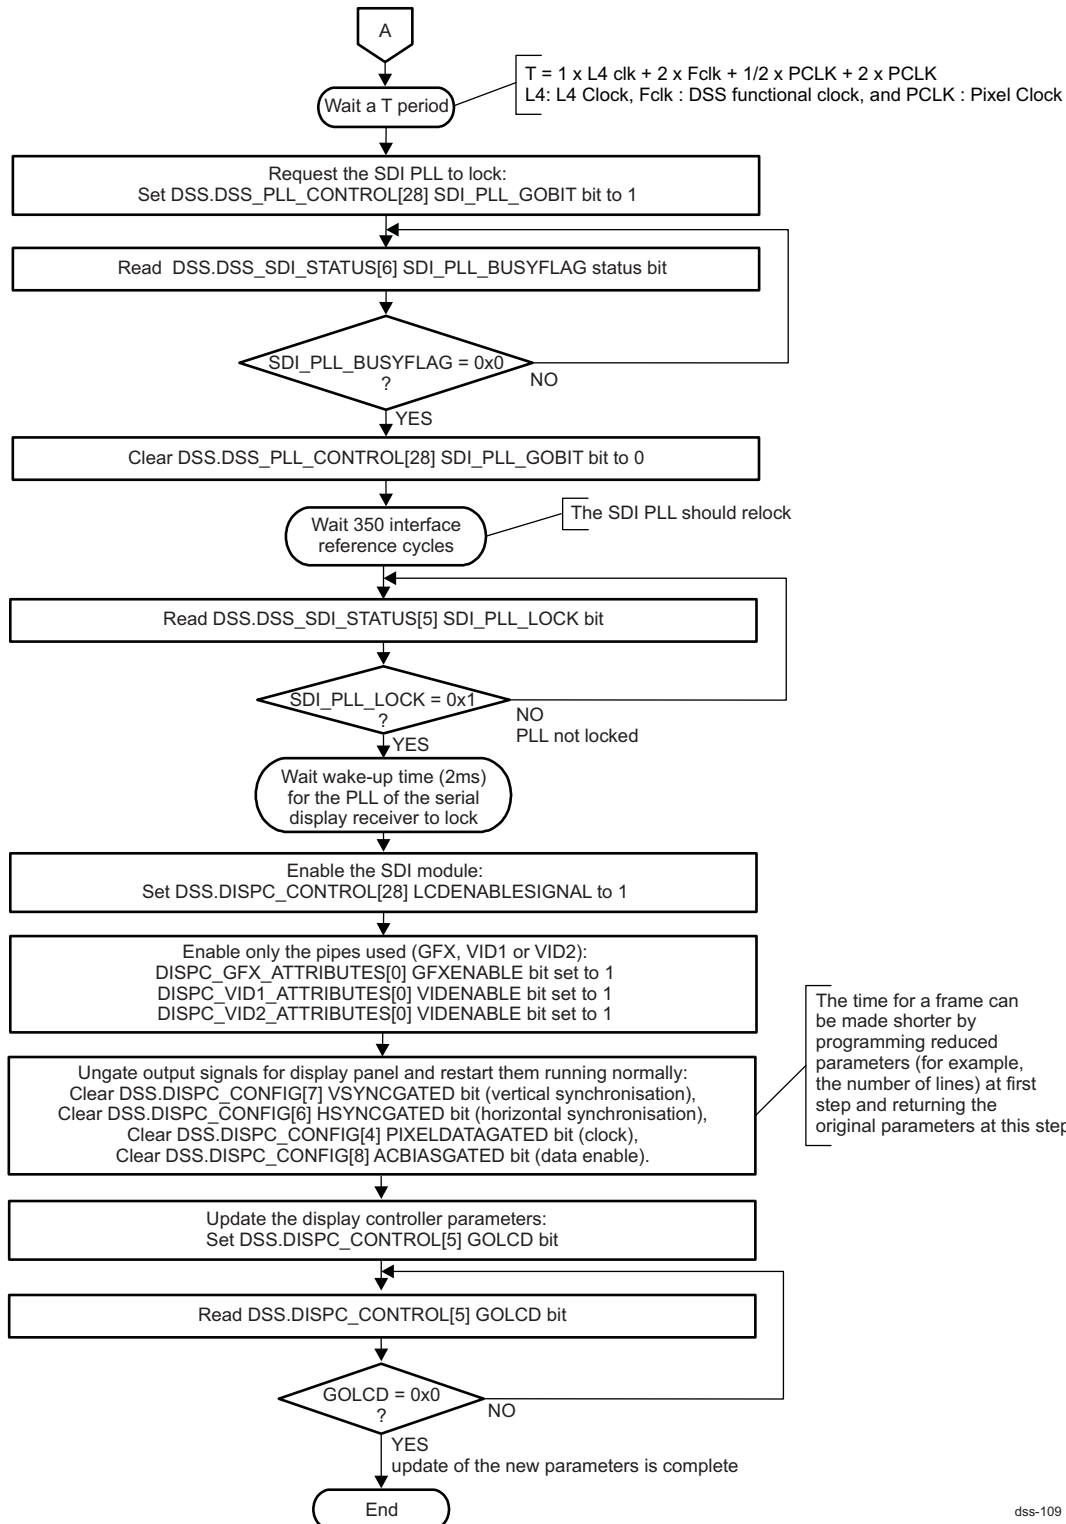

15.5.9.5.1 Complete Sequence

Figure 15-142 and Figure 15-143 describe the clock source and frequency change sequence of the SDI.

Figure 15-142. SDI Clock Source/Frequency Change Sequence Part A

dss-111

Figure 15-143. SDI Clock Source/Frequency Change Sequence Part B

dss-109

Note: One interface reference cycle is defined as follows:

Pixel Clock Frequency (PCLK)/SDI_PLL_REGN[5:0]/SDI_PLL_HIGHFREQ

Assuming the DSS.DSS_PLL_CONTROL[25:22] SDI_PLL_FREQSEL field value is between 0xB and 0xF and the DSS.DSS_PLL_CONTROL[27:26] SDI_PLL_LOCKSEL field is set to 0x0.

Note: The lock status of the SDI PLL is connected to the GPIO_81 signal of the GPIO3 module. To avoid polling, configure the GPIO3 module to generate an interrupt when the SDI PLL is locked (lock status is 1). For more information, see the *General-Purpose Interface* chapter.

Note: TI provides a global solution with OMAP device associated to a programmable 27-bit serial display interface receiver, the SN65LVDS302 receiver. For more details on SN65LVDS302 device, see the TI public web at www.ti.com.

15.5.9.5.2 Simplified Sequence When LCD and PCD Are Swapped

If the values in the DSS.DISPC_DIVISOR[23:16] LCD and DSS.DISPC_DIVISOR[7:0] PCD are exchanged (for example to reduce the internal display controller functional clock frequency while keeping the pixel clock frequency unchanged) with no other changes in the clock path, then there will be no discontinuity in the pixel clock. As a consequence the change will be transparent to the SDI module.

15.5.9.6 SDI Error Management

The DSS.DSS_SDI_STATUS[3] SDI_ERROR status bit indicates an internal buffer underflow/overflow. If such an error occurs, the SDI module must be disabled and enabled again to realign the buffer. This is done by setting the DSS.DISPC_CONTROL[28] LCDENABLESIGNAL bit to 0 (disabling) and to 1 (enabling). Ensure that the DSS.DSS_SDI_STATUS[2] SDI_RESET_DONE bit is set to 1. If this SDI error occurs during the debug phase, it is often due to programming incompatible values for MDIV, NDIV, and PDIV parameters for SDI PLL settings.

The SDI_ERROR internal signal is connected to the GPIO_82 internal signal of the GPIO3 module. Using the GPIO_82 signal, the GPIO3 bank generates two interrupts (GPIO3_MPU_IRQ and GPIO3_IVA2_IRQ) to alert the MPU or IVA2.2 subsystems, respectively, about any SDI error. For additional information, see the *General-Purpose Interface* chapter.

15.6 Display Subsystem Use Cases and Tips

This section gives some generic use cases and tips for setting the modules of the Display Subsystem.

15.6.1 How to Configure the Scaling Unit in the DISPC Module

This section describes the scaling capability of the Display Controller (DISPC). The scaling unit is a part of the video pipeline is used when transferring pixels from the system memory (SDRAM or on-chip SRAM) to the LCD panel or the TV set. The scaling unit consists of two scaling blocks: The vertical scaling block followed by the horizontal scaling block. The input pixel format is RGB24. In case the pixel format in system memory is not RGB, the color space conversion unit in front of the scaling unit converts the YUV pixels into RGB pixels. The two scaling units are independent: Neither of them, only one, or both can be used simultaneously

15.6.1.1 Filtering

The scaling is used to down-scale, up-scale, or process the image while keeping the same size. It is applied independently horizontally and vertically. The same filtering applies for each color component (R, G, or B).

15.6.1.1.1 Vertical Filtering

The vertical filtering unit is based on a poly-phase rotation architecture with eight phases and three taps. That means that 24 coefficients are programmable

The vertical 3-tap filtering macro architecture is shown in [Figure 15-144](#).

Figure 15-144. Vertical Filtering Macro Architecture (Three Taps)

dss-112

For the 3-tap vertical up-/downsampling the equation is (with the example of R component):

$$R_{out}(n) = \left(\sum_{i=-1}^{i=1} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7 \quad (15-8)$$

dss-E067

Legend:

Rout: R component output

C_i(Φ): Vertical FIR coefficients

Rin: R component input

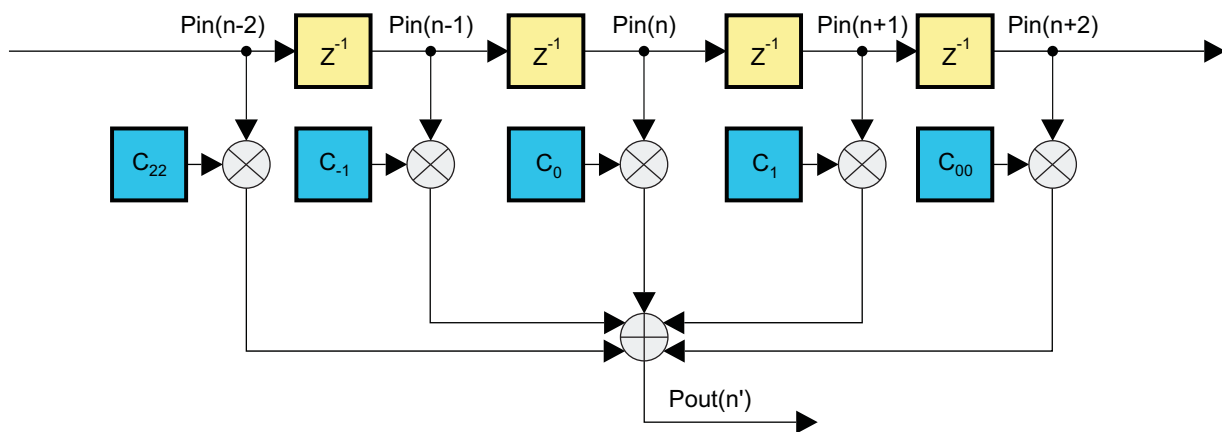

The line (n+1) is older than line (n).

The programmable three coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient C₀(Φ), which is unsigned).

The vertical filtering unit can be configured to support five taps.

The vertical 5-tap filtering macro architecture is shown in [Figure 15-145](#).

Figure 15-145. Vertical Filtering Macro Architecture (Five Taps)

dss-113

For the 5-tap vertical up/downsampling the equation is (with the example of R component):

$$Rout(n) = \left(\sum_{i=-2}^{i=2} C_i(\Phi) \times Rin(n+i) \right) \gg 7$$

dss-E066

(15-9)

Legend:

Rout: R component output

C_i(Φ): Vertical FIR coefficients with C₊₂(Φ)=C₀₀(Φ) and C₋₂(Φ)=C₂₂(Φ)

Rin: R component input

The line (n+1) is older than line (n).

The programmable five coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient C₀(Φ), which is unsigned).

In case of three taps, the memory lines are merged into three lines instead of six lines (one line is used as a cache line).

The first line is duplicated to fill up the two first lines (3-tap configuration) and the three first lines (5-tap configuration).

The last line is duplicated if the scaling logic requires loading of more lines and the last line has been reached

15.6.1.1.2 Horizontal Filtering

The horizontal filtering unit is based on a poly-phase rotation architecture with eight phases and five taps. That means that 40 coefficients are programmable.

The horizontal filtering macro architecture is shown in [Figure 15-146](#).

Figure 15-146. Horizontal Filtering Macro Architecture (Five Taps)

dss-114

For the 5-tap horizontal up-/downsampling, the equation is (with the example of R component):

$$\text{Rout}(n) = \left(\sum_{i=-3}^{i=3} C_i(\Phi) \times \text{Rin}(n+i) \right) \gg 7$$

dss-E115

(15-10)

Legend:

Rout: R component output

$C_i()$: Vertical FIR coefficients

Rin: R component input

The line (n+1) is older than line (n).

To horizontally and vertically filter the video layer, the phase is calculated separately. The programmable coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient $C_0()$, which is unsigned).

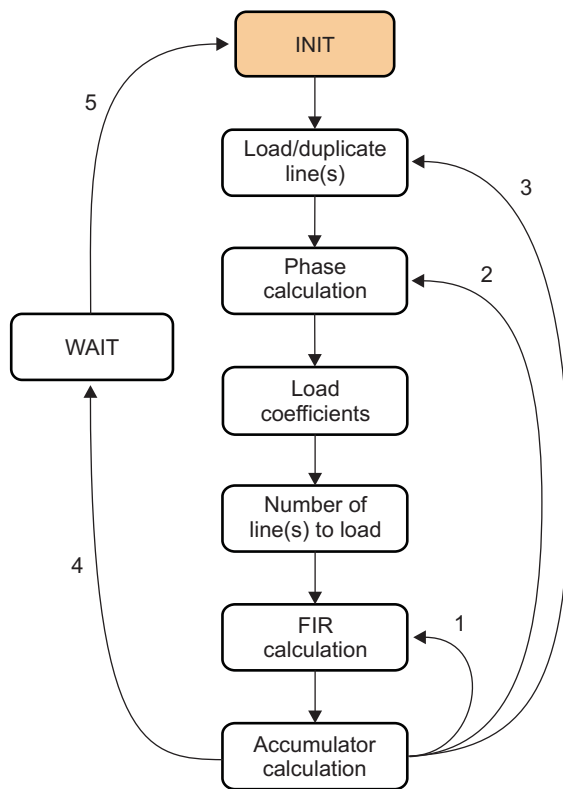

The first pixel is duplicated to fill up the three first pixel-buffers (5-tap configuration). The last pixel is duplicated if the scaling logic requires loading of more pixels and the last pixel has been reached

15.6.1.2 Scaling Algorithms

The up-/downsampling finite state machines (FSM) below are detailed in this section.

[Figure 15-147](#) presents the vertical up-/downsampling FSM.

Figure 15-147. Vertical Up-/Down-Sampling Algorithm

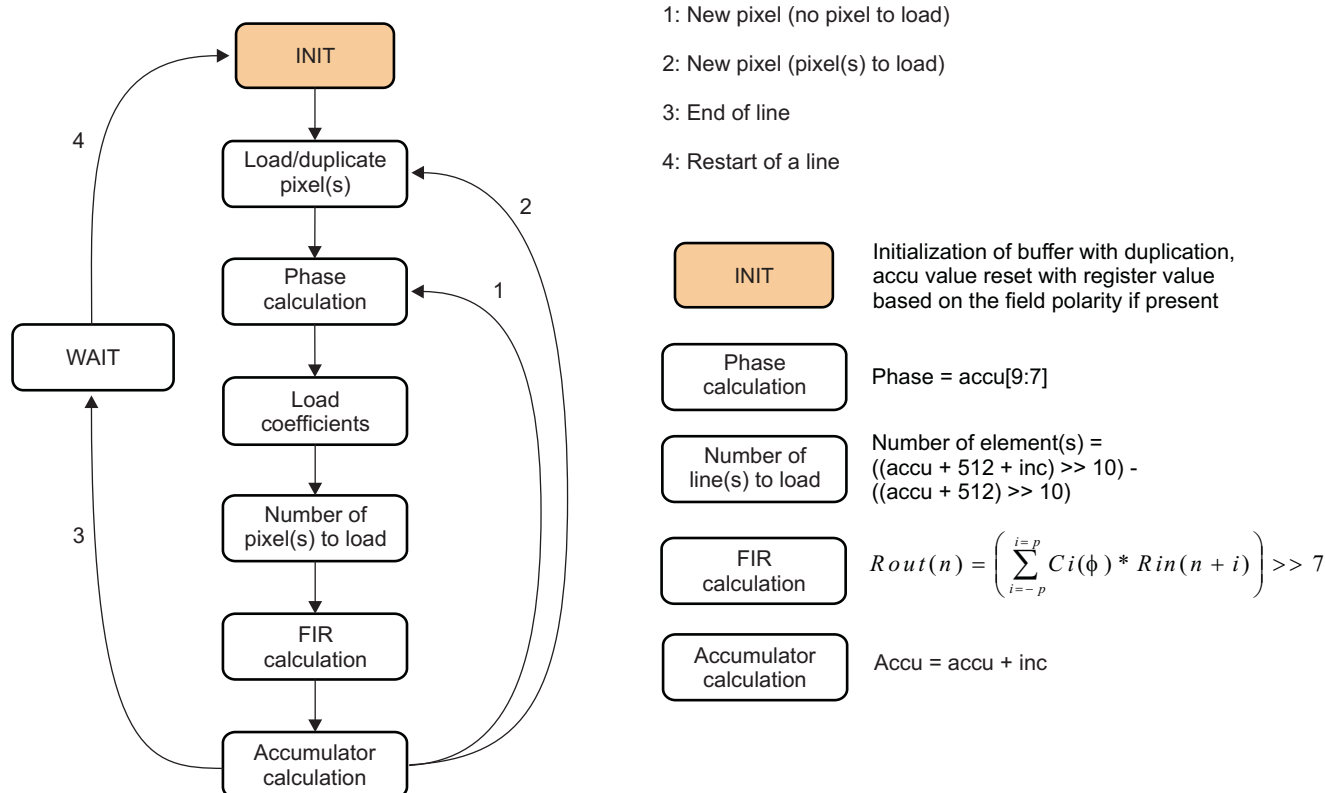

- 1: New pixel on the same line
- 2: New pixel on following line (no line to load)
- 3: New pixel on following line (line[s] to load)
- 4: End of frame
- 5: Restart of a new frame

INIT	Initialisation of buffer with duplication, accu value reset with register value based on the field polarity if present
Phase calculation	Phase = accu[9:7]
Number of line(s) to load	Number of element(s) = ((accu + 512 + inc) >> 10) - ((accu + 512) >> 10)
FIR calculation	$Rout(n) = \left(\sum_{i=-p}^{i=p} Ci(\phi) * Rin(n+i) \right) >> 7$
Accumulator calculation	Accu = accu + inc

dss-116

Figure 15-148 presents the horizontal up-/downsampling FSM.

Figure 15-148. Horizontal Up-/Down-Sampling Algorithm

dss-117

15.6.1.3 Scaling Limitations

- For upsampling, 3-tap or 5-tap vertical rescaling can be used.
- For downsampling between 1:1 to 1/2, 3-tap is used, and for downsampling between 1/2 and 1/4 5-tap is used. The consequence is the maximum input line size which is 1024 pixels with five taps and 2048 with three taps. The resampler is capable of decimation of 1/4 horizontally and vertically using poly-phase filtering. The purpose of the downsampling is to resize a SDTV (720 x 576) picture into a QCIF (177 x 144) size.

The maximum functional clock frequency after liquid crystal display (LCD) divisor logic is 173 MHz at nominal voltage and 96 MHz at low voltage.

While downsampling by 1/4, the picture size is SDTV resolution (708 x 576). The resampled picture resolution is QCIF (177 x 144) while downsampling by 1/4 and CIF (354 x 288) while downsampling by 1/2.

Table 15-67 indicates the required functional clock frequencies for several LCD panel resolutions.

Table 15-67. Functional Clock Requirement Active Matrix LCD Output SDTV Input Size VESA Timings

LCD Resolution	Pixel clock frequency (MHz)	Minimum Functional Clock frequency (MHz)		
		Downsampling (3-tap) H+V 1:2	Downsampling (5-tap) H+V 1:4	
		RGB16 YUV422 RGB24	RGB16 YUV422	RGB24
QCIF (177 x 144)	2	8	Not supported	Not supported
CIF (354 x 288)	8	32	32	64

Table 15-67. Functional Clock Requirement Active Matrix LCD Output SDTV Input Size VESA Timings (continued)

LCD Resolution	Pixel clock frequency (MHz)	Minimum Functional Clock frequency (MHz)

15.6.1.4 Scaling Settings

Notes:

- In this section, the screen word refers to LCD panel or TV set.
- n indicates pipeline 0 or 1 because there are two video pipelines in the DISPC.

15.6.1.4.1 Register List

The following registers define the scaling registers for the video layer n configuration:

- [DSS.DISPC_VIDn_BA](#)
- [DSS.DISPC_VIDn_ATTRIBUTES](#)
- [DSS.DISPC_VIDn_FIR](#)
- [DSS.DISPC_VIDn_ACCUI](#)

- [DSS.DISPC_VIDn_FIR_COEF_Hi](#)
- [DSS.DISPC_VIDn_FIR_COEF_HVi](#)
- [DSS.DISPC_VIDn_FIR_COEF_Vi](#)

[Table 15-69](#) lists the registers for programming the vertical FIR coefficients (3-tap configuration).

Table 15-69. Vertical FIR Coefficients Corresponding Table (3-Tap Configuration)

$C_x()$	$VidFIRVC_x()$
$C_{-1}()$	$VidFIRVC_2()$
$C_0()$	$VidFIRVC_1()$
$C_1()$	$VidFIRVC_0()$

The corresponding registers for programming the vertical FIR coefficients (3-tap configuration) are:

- $VidFIRVC_2() = DSS.DISPC_VIDn_FIR_COEF_HVi[31:24] \text{ VIDFIRVC2}$
- $VidFIRVC_1() = DSS.DISPC_VIDn_FIR_COEF_HVi[23:16] \text{ VIDFIRVC1}$
- $VidFIRVC_0() = DSS.DISPC_VIDn_FIR_COEF_HVi[15:8] \text{ VIDFIRVC0}$

[Table 15-70](#) lists the registers for programming the vertical FIR coefficients (5-tap configuration).

Table 15-70. Vertical FIR Coefficients Corresponding Table (5-Tap Configuration)

$C_x()$	$VidFIRVC_x()$
$C_{22}()$	$VidFIRVC_{22}()$
$C_{-1}()$	$VidFIRVC_2()$
$C_0()$	$VidFIRVC_1()$
$C_1()$	$VidFIRVC_0()$
$C_{00}()$	$VidFIRVC_{00}()$

The corresponding registers for programming the vertical FIR coefficients (5-tap configuration) are:

- $VidFIRVC_{22}() = DSS.DISPC_VIDn_FIR_COEF_Vi[15:8] \text{ VIDFIRVC22}$
- $VidFIRVC_2() = DSS.DISPC_VIDn_FIR_COEF_HVi[31:24] \text{ VIDFIRVC2}$
- $VidFIRVC_1() = DSS.DISPC_VIDn_FIR_COEF_HVi[23:16] \text{ VIDFIRVC1}$
- $VidFIRVC_0() = DSS.DISPC_VIDn_FIR_COEF_HVi[15:8] \text{ VIDFIRVC0}$
- $VidFIRVC_{00}() = DSS.DISPC_VIDn_FIR_COEF_Vi[7:0] \text{ VIDFIRVC00}$

[Table 15-71](#) lists the registers for programming the horizontal FIR coefficients (5-tap configuration).

Table 15-71. Horizontal FIR Coefficients Corresponding Table (5-Tap Configuration)

$C_x()$	$VidFIRHC_x()$
$C_{-2}()$	$VidFIRHC_4()$
$C_{-1}()$	$VidFIRHC_3()$
$C_0()$	$VidFIRHC_2()$
$C_1()$	$VidFIRHC_1()$
$C_2()$	$VidFIRHC_0()$

The corresponding registers for programming the vertical FIR coefficients (3-tap configuration) are:

- $VidFIRHC_4() = DSS.DISPC_VIDn_FIR_COEF_HVi[7:0] \text{ VIDFIRHC4}$
- $VidFIRHC_3() = DSS.DISPC_VIDn_FIR_COEF_Hi[31:24] \text{ VIDFIRHC3}$
- $VidFIRHC_2() = DSS.DISPC_VIDn_FIR_COEF_Hi[23:16] \text{ VIDFIRHC2}$
- $VidFIRHC_1() = DSS.DISPC_VIDn_FIR_COEF_Hi[15:8] \text{ VIDFIRHC1}$

- $\text{VidFIRHC}_0() = \text{DSS.DISPC_VIDn_FIR_COEF_Hi}[7:0] \text{ VIDFIRHC}_0$

15.6.1.4.2 Enabling

The video pipeline #n is enabled/disabled by setting/resetting the `DSS.DISPC_VIDn_ATTRIBUTES[0].VIDENABLE` bit. While the video pipeline is enabled/disabled, the video layer is visible/not visible on the screen (LCD panel or TV set).

The video up-/downsampling block for the video pipeline #n is programmed by setting the `DSS.DISPC_VIDn_ATTRIBUTES[6:5] VIDRESIZEENABLE` field:

- When the `VIDRESIZEENABLE[1]` bit is set to 1, the video vertical up-/downsampling block is enabled. When set to 0, the vertical resize processing is disabled.
- When the `VIDRESIZEENABLE[0]` bit is set to 1, the video horizontal up-/downsampling block is enabled. When set to 0, the horizontal resize processing is disabled.
- When the `VIDRESIZEENABLE[1:0]` is set to 0x3, both horizontal and vertical resize processing are enabled.

Notes:

- Set a valid configuration before enabling the video up-/downsampling block.
- Vertical and horizontal downsampling are limited to a 0.25 resize factor. When processing a down-scaling with a vertical factor between 0.5 and 0.25, a 5-tap filter configuration must be used. See [Section 15.6.1.4.5](#) for more information concerning the filter coefficients.

15.6.1.4.3 Factor

The following register fields define the increment value of the video up-/downsampling block for video pipeline n:

- Vertical up-/downsampling increment value (`DSS.DISPC_VIDn_FIR[27:16] VIDFIRVINC` field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$\text{VIDFIRVINC}[11:0] = 1024 \times \frac{\text{VIDORGSIZEY}[10:0]}{\text{VIDSIZEY}[10:0]} \quad \text{dss-E118} \quad (15-11)$$

Notes:

- If the `VIDFIRVINC[11:0]` field value is greater than 4096, it is clipped to 4096. If `VIDSIZEY[10:0]` equals 0x1, `VIDSIZEY[10:0]` is replaced by 0x2 in the previous equation.
- The `VIDORGSIZEY[10:0]` and `VIDSIZEY[10:0]` field values must be programmed with the value desired minus 1.
- Horizontal up-/downsampling increment value (the `DSS.DISPC_VIDn_FIR[11:0] VIDFIRHINC` field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$\text{VIDFIRHINC}[11:0] = 1024 \times \frac{\text{VIDORGSIZEX}[10:0]}{\text{VIDSIZEEX}[10:0]} \quad \text{dss-E119} \quad (15-12)$$

Notes:

- If the `VIDFIRHINC[11:0]` field value is greater than 4096, it is clipped to 4096. If `VIDSIZEEX[10:0]` equals 1, `VIDSIZEEX[10:0]` is replaced by 2 in the previous equation.
- The `VIDORGSIZEX[10:0]` and `VIDSIZEEX[10:0]` field values must be programmed with the value desired minus 1.

15.6.1.4.4 Initial Phase

- Vertical up-/downsampling accumulator value DSS.DISPC_VIDn_ACCU[25:16] VIDVERTICALACCU fields
The unsigned integer value range is [0:1023]. The accumulator value indicates on which phase the vertical filtering starts. The value 0 indicates that the phase 0 is the first phase used by the hardware to generate the first data.
- Vertical up-/downsampling accumulator value DSS.DISPC_VIDn_ACCU[9:0] VIDHORIZONTALACCU fields
The unsigned integer value range is [0:1023]. The accumulator value indicates on which phase the horizontal filtering starts. The value 0 indicates that the phase 0 is the first phase used by the hardware to generate the first data

Table 15-72 lists the vertical/horizontal accumulator values and phases

Table 15-72. Vertical/Horizontal Accumulator Phase

Accumulator Value	Phases
0	0
128	1
256	2
384	3
512	4
640	5
768	6
896	7

Note: For LCD output, the initial phase is always 0 (horizontal and vertical.) For TV output, the vertical phases (odd and even) can be nonzero values.

15.6.1.4.5 Coefficients

- Vertical up-/downsampling coefficients (DSS.DISPC_VIDn_FIR_COEF_HVi and DSS.DISPC_VIDn_FIR_COEF_V)**
The 3-tap vertical up-/downsampling coefficients are defined in DSS.DISPC_VIDn_FIR_COEF_HVi registers. There are eight registers for the eight phases with three coefficients for each of them so a total of 24 programmable coefficients for the vertical up-/downsampling block. Each register contains two 8-bit signed coefficients and one 8-bit unsigned coefficient (central one).
In addition, there are 2-tap vertical up-/downsampling coefficients defined in DSS.DISPC_VIDn_FIR_COEF_Vi registers. There are eight registers for the eight phases with two coefficients for each of them so a total of 16 programmable coefficients for the vertical up-/downsampling block used in addition of the 3-tap registers defined above. Each register contains two 8-bit signed coefficients ($C_{22}()$ and $C_{00}()$).
In case of 5-tap configuration, both sets of registers, DSS.DISPC_VIDn_FIR_COEF_HVi and DSS.DISPC_VIDn_FIR_COEF_V, are used. In case of 3-tap configuration, only one set of registers, DSS.DISPC_VIDn_FIR_COEF_HV, is used.
- Horizontal up-/downsampling coefficients (DSS.DISPC_VIDn_FIR_COEF_Hi and DSS.DISPC_VIDn_FIR_COEF_HV)**
The 5-tap horizontal up-/downsampling coefficients are defined in DSS.DISPC_VIDn_FIR_COEF_Hi and DSS.DISPC_VIDn_FIR_COEF_HVi registers. There are eight registers for the eight phases with five coefficients for each register, for a total of 40 programmable coefficients for the horizontal up-/downsampling block.
Each DSS.DISPC_VIDn_FIR_COEF_Hi register contains three 8-bit signed coefficients and one 8-bit unsigned coefficient (central one), and each DSS.DISPC_VIDn_FIR_COEF_HVi contains one 8-bit signed coefficient.

Table 15-73 through Table 15-78 give the programmable coefficients for the FIR up/downsampling filters (Max-Fauque-Berthier method).

15.6.1.4.5.1 Up-Sampling

Table 15-73 gives the 24 coefficients to program the vertical upsampling (3-tap configuration).

Table 15-73. Up-Sampling Vertical Filter Coefficients (Three Taps)

Phases	VidFIRVC ₂ ()	VidFIRVC ₁ ()	VidFIRVC ₀ ()
0	0	128	0
1	3	123	2

5	-2	-11	95	51	-5
6	-1	-11	112	30	-2
7	0	-8	124	13	-1

Table 15-75 gives the 40 coefficients to program the horizontal upsampling (5-tap configuration).

Table 15-75. Up-Sampling Horizontal Filter Coefficients (Five Taps)

Phases	VidFIRHC ₄ ()	VidFIRHC ₃ ()	VidFIRHC ₂ ()	VidFIRHC ₁ ()	VidFIRHC ₀ ()
0	0	0	128	0	0
1	-1	13	124	-8	0
2	-2	30	112	-11	-1
3	-5	51	95	-11	-2
4	0	-9	73	73	-9
5	-2	-11	95	51	-5
6	-1	-11	112	30	-2
7	0	-8	124	13	-1

The upsampling coefficients register configuration (vertical three taps and horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_HV0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_H1 = 0x0D7CF800
- DSS.DISPC_VIDn_FIR_COEF_HV1 = 0x037B02FF

- DSS.DISPC_VIDn_FIR_COEF_H2 = 0x1E70F5FF
- DSS.DISPC_VIDn_FIR_COEF_HV2 = 0x0C6F05FE
- DSS.DISPC_VIDn_FIR_COEF_H3 = 0x335FF5FE
- DSS.DISPC_VIDn_FIR_COEF_HV3 = 0x205907FB
- DSS.DISPC_VIDn_FIR_COEF_H4 = 0xF74949F7
- DSS.DISPC_VIDn_FIR_COEF_HV4 = 0x00404000
- DSS.DISPC_VIDn_FIR_COEF_H5 = 0xF55F33FB
- DSS.DISPC_VIDn_FIR_COEF_HV5 = 0x075920FE
- DSS.DISPC_VIDn_FIR_COEF_H6 = 0xF5701EFE
- DSS.DISPC_VIDn_FIR_COEF_HV6 = 0x056F0CFF
- DSS.DISPC_VIDn_FIR_COEF_H7 = 0xF87C0DFF
- DSS.DISPC_VIDn_FIR_COEF_HV7 = 0x027B0300

Note: In this case, the DSS.DISPC_VIDn_FIR_COEF_Vi registers are not used.

The upsampling coefficients register configuration (both vertical and horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_HV0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_V0 = 0x00000000
- DSS.DISPC_VIDn_FIR_COEF_H1 = 0x0D7CF800
- DSS.DISPC_VIDn_FIR_COEF_HV1 = 0x0D7CF8FF
- DSS.DISPC_VIDn_FIR_COEF_V1 = 0x0000FF00
- DSS.DISPC_VIDn_FIR_COEF_H2 = 0x1E70F5FF
- DSS.DISPC_VIDn_FIR_COEF_HV2 = 0x1E70F5FE
- DSS.DISPC_VIDn_FIR_COEF_V2 = 0x0000FEFF
- DSS.DISPC_VIDn_FIR_COEF_H3 = 0x335FF5FE
- DSS.DISPC_VIDn_FIR_COEF_HV3 = 0x335FF5FB
- DSS.DISPC_VIDn_FIR_COEF_V3 = 0x0000FBFE
- DSS.DISPC_VIDn_FIR_COEF_H4 = 0xF74949F7
- DSS.DISPC_VIDn_FIR_COEF_HV4 = 0xF7404000
- DSS.DISPC_VIDn_FIR_COEF_V04 = 0x000000F7
- DSS.DISPC_VIDn_FIR_COEF_H5 = 0xF55F33FB
- DSS.DISPC_VIDn_FIR_COEF_HV5 = 0xF55F33FE
- DSS.DISPC_VIDn_FIR_COEF_V5 = 0x0000FEFB
- DSS.DISPC_VIDn_FIR_COEF_H6 = 0xF5701EFE
- DSS.DISPC_VIDn_FIR_COEF_HV6 = 0xF5701EFF
- DSS.DISPC_VIDn_FIR_COEF_V6 = 0x0000FFFE
- DSS.DISPC_VIDn_FIR_COEF_H7 = 0xF87C0DFF
- DSS.DISPC_VIDn_FIR_COEF_HV7 = 0xF87C0D00
- DSS.DISPC_VIDn_FIR_COEF_V7 = 0x000000FF

15.6.1.4.5.2 Down-Sampling

Table 15-76 gives the 24 coefficients to program the vertical downsampling (3-tap configuration).

Table 15-76. Down-Sampling Vertical Filter Coefficients (Three Taps)

Phases	VidFIRVC ₂ ()	VidFIRVC ₁ ()	VidFIRVC ₀ ()
0	36	56	36
1	40	57	31
2	45	56	27

6	-5	27	54	44	8
7	-2	31	55	40	4

Table 15-78 gives the 40 coefficients to program the horizontal downsampling (5-tap configuration).

Table 15-78. Down-Sampling Horizontal Filter Coefficients (Five Taps)

Phases	VidFIRHC ₄ ()	VidFIRHC ₃ ()	VidFIRHC ₂ ()	VidFIRHC ₁ ()	VidFIRHC ₀ ()
0	0	36	56	36	0
1	4	40	55	31	-2
2	8	44	54	27	-5
3	-12	48	53	22	-7
4	-9	17	52	51	17
5	-7	22	53	48	12
6	-5	27	54	44	8
7	-2	31	55	40	4

The downsampling coefficients register configuration (vertical three taps and horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H0 = 0x24382400
- DSS.DISPC_VIDn_FIR_COEF_HV0 = 0x24382400
- DSS.DISPC_VIDn_FIR_COEF_H1 = 0x28371FFE
- DSS.DISPC_VIDn_FIR_COEF_HV1 = 0x28391F04
- DSS.DISPC_VIDn_FIR_COEF_H2 = 0x2C361BFB
- DSS.DISPC_VIDn_FIR_COEF_HV2 = 0x2D381B08
- DSS.DISPC_VIDn_FIR_COEF_H3 = 0x303516F9
- DSS.DISPC_VIDn_FIR_COEF_HV3 = 0x3237170C
- DSS.DISPC_VIDn_FIR_COEF_H4 = 0x11343311
- DSS.DISPC_VIDn_FIR_COEF_HV4 = 0x123737F7
- DSS.DISPC_VIDn_FIR_COEF_H5 = 0x1635300C
- DSS.DISPC_VIDn_FIR_COEF_HV5 = 0x173732F9
- DSS.DISPC_VIDn_FIR_COEF_H6 = 0x1B362C08

- DSS.DISPC_VIDn_FIR_COEF_HV6 = 0x1B382DFB
- DSS.DISPC_VIDn_FIR_COEF_H7 = 0x1F372804
- DSS.DISPC_VIDn_FIR_COEF_HV7 = 0x1F3928FE

Notes:

- In this case, the DSS.DISPC_VIDn_FIR_COEF_Vi registers are not used.
 - In this case, the downsampling factor must be higher than 1/2.
-

The downsampling coefficients register configuration (both the vertical and the horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H0 = 0x24382400
- DSS.DISPC_VIDn_FIR_COEF_HV0 = 0x24382400
- DSS.DISPC_VIDn_FIR_COEF_V0 = 0x00000000
- DSS.DISPC_VIDn_FIR_COEF_H1 = 0x28371FFE
- DSS.DISPC_VIDn_FIR_COEF_HV1 = 0x28371F04
- DSS.DISPC_VIDn_FIR_COEF_V1 = 0x000004FE
- DSS.DISPC_VIDn_FIR_COEF_H2 = 0x2C361BFB
- DSS.DISPC_VIDn_FIR_COEF_HV2 = 0x2C361B08
- DSS.DISPC_VIDn_FIR_COEF_V2 = 0x000008FB
- DSS.DISPC_VIDn_FIR_COEF_H3 = 0x303516F9
- DSS.DISPC_VIDn_FIR_COEF_HV3 = 0x3035160C
- DSS.DISPC_VIDn_FIR_COEF_V3 = 0x00000CF9
- DSS.DISPC_VIDn_FIR_COEF_H4 = 0x11343311
- DSS.DISPC_VIDn_FIR_COEF_HV4 = 0x113433F7
- DSS.DISPC_VIDn_FIR_COEF_V4 = 0x0000F711
- DSS.DISPC_VIDn_FIR_COEF_H5 = 0x1635300C
- DSS.DISPC_VIDn_FIR_COEF_HV5 = 0x163530F9
- DSS.DISPC_VIDn_FIR_COEF_V5 = 0x0000F90C
- DSS.DISPC_VIDn_FIR_COEF_H6 = 0x1B362C08
- DSS.DISPC_VIDn_FIR_COEF_HV6 = 0x1B362CFB
- DSS.DISPC_VIDn_FIR_COEF_V6 = 0x0000FB08
- DSS.DISPC_VIDn_FIR_COEF_H7 = 0x1F372804
- DSS.DISPC_VIDn_FIR_COEF_HV7 = 0x1F3728FE
- DSS.DISPC_VIDn_FIR_COEF_V7 = 0x0000FE04

Note: This configuration must be used for vertical downsampling factors between 1/2 and 1/4

15.6.2 Display Low-Power Refresh Settings

This section describes the display low-power refresh application on the device. The display subsystem remains active while saving power by putting unused power domains and unused modules into idle mode. This process can be expanded to include the screen saver mode in which the MPU subsystem wakes up to update the frame buffer and then returns to idle mode. On an OMAP platform, where power consumption is of high importance, the display modes must be configured properly to achieve optimal power savings

The display low-power refresh mode can be used in the following scenarios:

- During the period of time when there is no application running and the backlight turns off.
- Once the backlight turns off, the LCD display can be shut off or can be refreshed showing the time and date. The screen saver mode can be used to update the time every minute.

This section discusses the methodology for finding optimal power savings. These settings are detailed for a 16-bit, 240 x 320 pixel QVGA LCD.

15.6.2.1 Display Low-Power Refresh Overview

When the device is not in idle mode, meaning all clocks are on and the power is applied to all power domains, the following activity typically occurs with respect to the display subsystem:

- The MPU subsystem is processing
- The display subsystem DMA controller is moving data from the SDRAM frame buffer location to the display subsystem internal FIFO.
- The LCD data is being sent from the internal FIFO to the display panel.

When the MPU goes into idle mode, the following activity occurs:

- The display subsystem DMA controller remains active, moving data from the SDRAM frame buffer to the internal FIFO.
- The SDRAM will go in and out of self-refresh between transfers.
- The display subsystem internal FIFO will continue to send LCD data to the display panel.

This procedure is named as the display low-power refresh scenario.

Note: In the device, the display subsystem has its own power domain (the DSS power domain).

15.6.2.2 Display Subsystem Clock

15.6.2.2.1 Display Subsystem Clock Configuration

The display subsystem contains two possible functional clock sources, DSS functional clock 1 (DSS1_ALWON_FCLK) and DSI PLL functional clock 1 (DSI1_PLL_FCLK):

- DSS1_ALWON_FCLK is sourced from DPLL4 (DPLL4_ALWON_FCLK), with several multipliers available and is configured in the PRCM.CM_CLKSEL_DSS[4:0] CLKSEL_DSS1 field.
- DSI1_PLL_FCLK is one of the two output clocks from the DSI PLL.

The pixel clock is set as either DSS1_ALWON_FCLK or DSI1_PLL_FCLK by configuring the DSS.DISPC_CONTROL[0] DISPC_CLK_SWITCH bit

Note: When the DSI PLL is in bypass mode, the DSI1_PLL_FCLK clock is the DSS2_ALWON_FCLK clock. This ensures the backward compatibility with OMAP2 devices.

The LCD logic clock is determined by the DSS.DISPC_DIVISOR[23:16] LCD bit field. This divisor is used on the DSS functional clock that is selected in the DISPC_CONTROL register (either DSS1_ALWON_FCLK or DSS2_ALWON_FCLK). This LCD divisor selects the logical clock frequency which is used to clock the logic in the display subsystem. For some applications there is a required minimum logical clock frequency. The lower the logical clock frequency then the lower the power consumption.

The pixel clock is determined by setting the DSS.DISPC_DIVISOR[7:0] PCD bit field. This divisor is used on the LCD logic clock.

In the following example, the DPLL4 clock (DPLL4_ALWON_FCLK) is enabled and running at 266 MHz:

The PRCM.CM_CLKSEL2_PLL[18:8] PERIPH_DPLL_MULT field is set to 0x4 and the PRCM.CM_CLKSEL2_PLL[6:0] PERIPH_DPLL_DIV field is set to 0x1 (DPLL4 x 4/(1+1)):

$$DPLL4_ALWON_FCLKOUTX2 = DPLL4_ALWON_FCLK(266MHz) \times 4/2 = 532 \text{ MHz}$$

Note: The DPLL4_ALWON_FCLKOUTX2 clock is an internal clock in DPLL4 module after the DPLL_MULT and DPLL_DIV stages. The DPLL4_M4X2_CLK clock is one of the DPLL4 output clocks and is the clock source for DSS1_ALWON_FCLK.

The DSS.DSS_CONTROL[0] DSS_CLK_SWITCH bit is set to 0x0 to select DSS1_ALWON_FCLK as the display subsystem functional clock:

$$DSS1_ALWON_FCLK = DPLL4_M4X2_CLK$$

The PRCM.CM_CLKSEL_DSS[4:0] CLKSEL_DSS1 field is set to 0x08:

$$DSS1_ALWON_FCLK = \frac{DPLL4_ALWON_FCLKOUTX2(532\text{MHz})}{8} = 66.5\text{ MHz}$$

(15-13)

The DSS.DISPC_DIVISOR[23:16] LCD field is set to 0x01:

$$\text{LogicClock} = \frac{DSS1_ALWON_FCLK(66.5\text{MHz})}{1} = 66.5\text{ Mhz}$$

(15-14)

The DSS.DISPC_DIVISOR[6:0] PCD field is set to 0x0C:

$$\text{PixelClock} = \frac{\text{LogicClock}(66.5\text{MHz})}{12} = 5.54\text{ Mhz}$$

(15-15)

15.6.2.2.1.1 Pixel Clock Frequency Settings to Reduce Power Consumption

Power consumption is reduced when a low pixel clock frequency is used. If the clock frequency is set too low, however, the frames-per-second (FPS) are reduced. This can result in visible flickering on the screen each time the screen is refreshed. To avoid electrical polarization problems, refer to the appropriate LCD panel datasheet to determine the maximum range of pixel clock frequency variation. To save power, therefore, the pixel clock frequency during low-power mode must be set as low as possible, but high enough to eliminate visible flickering

15.6.2.2.1.2 Display Subsystem Divider Settings to Reduce Power Consumption

The pixel clock is determined by the DSS.DISPC_DIVISOR[7:0] PCD and DSS.DISPC_DIVISOR[23:16] LCD settings. In most cases, the LCD[7:0] field is set to 0x1 and the PCD[7:0] field is used as the main divider. To reduce power consumption, the software user should investigate if the DSS.DISPC_DIVISOR[23:16] LCD field can be set to a value other than 0x1 and then decrease DSS.DISPC_DIVISOR[7:0] PCD field value. For example, if the desired pixel clock is 1.625 MHz with a 13-MHz functional clock, then this pixel clock can be achieved by setting DSS.DISPC_DIVISOR[23:16] LCD to 0x1 and DSS.DISPC_DIVISOR[7:0] PCD to 0x8. The same pixel clock can be achieved by setting DSS.DISPC_DIVISOR[23:16] LCD to 0x2 and DSS.DISPC_DIVISOR[7:0] PCD to 0x4.

15.6.2.2.2 Display Subsystem Clock Enable

To take the DSS out of reset, all DSS-related clocks must be enabled, and the DPLL4 clock must be enabled. After taking the DSS out of reset, these clocks can be disabled if they are not used. The following clocks must be enabled before the DSS can come out of reset:

- PRCM.CM_FCLKEN_DSS[0] EN_DSS1 = 0x1
- PRCM.CM_FCLKEN_DSS[1] EN_DSS2 = 0x1
- PRCM.CM_FCLKEN_DSS[2] EN_TV = 0x1
- PRCM.CM_ICLKEN_DSS[0] EN_DSS = 0x1
- PRCM.CM_CLKEN_PLL[18:16] EN_PERIPH_DPLL = 0x7

Once these clocks are enabled, the display subsystem can be taken out of reset.

The following sections explain the display low-power mode configuration options, which are determined by product requirements (LCD panel type).

15.6.2.3 DPLL4 in Low-Power Mode

For optimal power savings in low-power mode, DPLL4 can be put into low-power stop mode. Thus the DSS1_ALWON_FCLK clock cut when DPLL4 is in low-power stop mode. Software users must switch from DSS1_ALWON_FCLK to DSI1_PLL_FCLK by setting the DSS.DSS_CONTROL[0] DISPC_CLK_SWITCH bit to 0x1.

Note: Before switching to DSI1_PLL_FCLK, the DSI PLL and the HS divider must be programmed and the DSI PLL must be locked.

DPLL4 can be put in low-power stop mode in either of the following methods:

- Manually: When setting the PRCM.CM_CLKEN_PLL[18:16] EN_PERIPH_DPLL bit to 0x1.
- Automatically: When setting the PRCM.CM_AUTOIDLE_PLL[5:3] AUTO_PERIPH_DPLL field to 0x1. DPLL4 is automatically put in low-power stop mode when none of the 96- MHz and 54- MHz clocks are required anymore. DPLL4 is also restarted automatically.

Software users must remember to change the clock configuration after enabling DPLL4 when leaving low-power mode by setting the DSS.DSS_CONTROL[0] DISPC_CLK_SWITCH bit to 0x0. The DSS1_ALWON_FCLK clock will be selected.

Lock time must be considered before disabling the DSS1_ALWON_FCLK clock.

15.6.2.4 Autoidle and Smart Idle

15.6.2.4.1 Autoidle

To further save power consumption, the autoidle feature at the module can be enabled for the active modules. For example, the PRCM and the system control modules are active during this mode. By enabling the autoidle feature, the clocks at the module level are gated when they are not needed.

The RFBI, display controller, and L4 interfaces can internally gate their clocks to decrease power consumption if no transaction is present on the related bus. The following bits must be set to enable this functionality:

- DSS.DSS_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display subsystem
- DSS.RFBI_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the RFBI
- DSS.DISPC_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display controller
- DSS.DISPC_CONFIG[9] FUNCGATED bit (1: Functional clocks gated enabled, 0: Functional clocks gated disabled) for the display controller

15.6.2.4.2 Smart-Idle

The smart-idle feature can be enabled to allow the module to enter idle when the clocks are not needed. The smart-idle feature can be enabled for the display subsystem submodules to further save power consumption:

- Display subsystem: DSS.DSS_SYSCONFIG[4:3] SIDLEMODE
- Display controller: DSS.DISPC_SYSCONFIG[4:3] SIDLEMODE
- RFBI: DSS.RFBI_SYSCONFIG[4:3] SIDLEMODE

15.6.2.5 FIFO Thresholds

The display subsystem internal FIFO is used to move data to the LCD panel. This FIFO is filled by the display subsystem DMA controller. The DMA controller is triggered to start and stop based on two thresholds:

- DSS.DISPC_GFX_FIFO_THRESHOLD[11:0] GFXFIFOLOWTHRESHOLD
- DSS.DISPC_GFX_FIFO_THRESHOLD[27:16] GFXFIFOHIGHTHRESHOLD

When the level of the FIFO reaches the low threshold, the internal DMA controller begins to fill the FIFO with the data in the frame buffer. Once the amount of pixel data reaches the high threshold, the internal DMA controller stops.

15.6.2.5.1 FIFO Threshold Settings to Reduce Power Consumption

Power consumption is reduced by increasing the difference between the high and low FIFO threshold levels, thereby leaving the SDRAM in self-refresh for a longer period of time. To perform this reduction, consider the following:

- The low FIFO threshold level must be as low as possible, but not low enough to cause any underflow.
- The high FIFO threshold level must not exceed the FIFO size minus one burst. A value above this limit results in the DMA controller trying to fill the FIFO to a level that cannot be reached, which will increase power consumption.
- The difference between high and low FIFO threshold levels must not be less than one burst size. These settings do not reduce power consumption because the SDRAM never goes into self-refresh, but they will avoid underflow.

15.6.2.6 Vertical and Horizontal Timings

The vertical and horizontal timings and the pixel clock speed determine the number of frames updated per second. [Figure 15-149](#) shows the timings for a 240 x 320 pixel QVGA LCD panel. If the pulse width (also called blanking) and the front porch parameters are increased, more setup time is added before the data is transferred. This additional time is beneficial for delaying the data transfer if the data is not ready because of bandwidth limitations. Care must be taken to determine the fps when modifying these parameters.

Use the following formula to determine the fps for a 240 x 320 QVGA LCD:

$$f_{ps} = \frac{1}{[(Hsw + 1) + (Hrp + 1) + 240 + (Hbp + 1)] \times [(Vsw + 1) + Vrp + 320 + Vbp]} \times (PCLK)$$

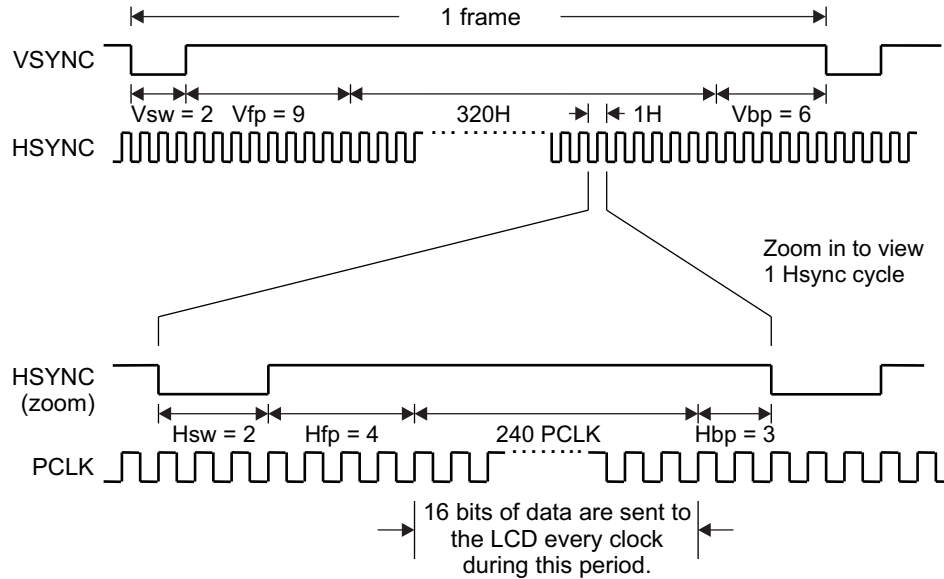

(15-16)

With:

- Hsw: DSS.DISPC_TIMING_H[5:0] HSW field value
- Hp: DSS.DISPC_TIMING_H[15:8] HFP field value
- Hbp: DSS.DISPC_TIMING_H[27:20] HBP field value
- Vsw: DSS.DISPC_TIMING_V[5:0] VSW field value
- Vp: DSS.DISPC_TIMING_V[15:8] VFP field value
- Vpb: DSS.DISPC_TIMING_V[27:20] VBP field value
- PCLK: Pixel clock period

The horizontal (Hsw) and vertical (Vsw) pulse widths and the horizontal front (Hp) and back (Hbp) porches are increased by 1 because the value is programmed as the desired value minus 1.

Figure 15-149. QVGA LCD Timings

dss-124

The fps for the example of 6-MHz pixel clock with the setting shown in [Figure 15-149](#) is as follows:

$$fps = \frac{1}{[(2 + 1) + 4 + 240 + 3] \times [(2 + 1) + 9 + 320 + 6] \times 166.67 \times 10^{-9}}$$

dss-E125

(15-17)

$$fps = 71 Hz$$

15.6.2.6.1 Horizontal and Vertical Timing Settings to Reduce Power Consumption

The number of fps that the screen is refreshed is also determined by the vertical and horizontal timings. Consequently, longer timings between frames (blanking periods) reduce the fps and reduce average power consumption. Shorter blanking periods increase fps and increases power consumption. If the blanking between frames is too small, a FIFO underflow may occur.

15.7 Display Subsystem Registers

CAUTION

- The DISS, DISPC, RFBI, and VENC registers have no register data width access restriction and can be accessed in 8-bit, 16-bit and 32-bit access..
- The DSI complex I/O and DSI PLL control module registers are limited to 32-bit data access; 16-bit and 8-bit data accesses are not allowed and can corrupt register content.
- The DSI protocol engine DSS.DSI_VCn_LONG_PACKET_HEADER and DSS.DSI_VCn_SHORT_PACKET_HEADER registers are limited to 32-bit data access; 16-bit and 8-bit data accesses are not allowed and can corrupt register content.
- The DSI protocol engine DSS.DSI_VCn_LONG_PACKET_PAYLOAD register is limited to 32-bit and 16-bit data access; 8-bit data accesses are not allowed and can corrupt register content.
- All other DSI protocol engine registers have no register data width access restriction and can be accessed in 8-bit, 16-bit and 32-bit access.

Table 15-79 summarizes the display subsystem instance.

Table 15-79. Instance Summary

Module Name	Base Address	Size
DSI Protocol Engine	0x4804 FC00	512 bytes
DSI PHY	0x4804 FE00	64 bytes
DSI PLL Controller	0x4804 FF00	32 bytes
Display Subsystem	0x4805 0000	512 bytes
Display Controller	0x4805 0400	1K byte
Display Controller VID1	0x4805 0400	1K byte
Display Controller VID2	0x4805 0400	1K byte
RFBI	0x4805 0800	256 bytes
Video Encoder	0x4805 0C00	256 bytes

15.7.1 Display Subsystem Register Mapping Summary

This section describes SDI module. This module is not available on all devices. See Chapter 1, the *OMAP35x Family* section, to check availability of this module. DSS_SDI_CONTROL , DSS_PLL_CONTROL registers and some bits of DSS_SDI_STATUS register are dedicated to SDI module.

Table 15-80 through Table 15-83 summarize the display subsystem register mapping.

Table 15-80. Display Subsystem Register Mapping Summary

Bits	Field Name	Description	Type	Reset
31:30	SPATIALTEMPORAL DITHERINGFRAMES	Spatial/Temporal dithering number of frames wr: VFP 0x0: Spatial only 0x1: Spatial and temporal over two frames 0x2: Spatial and temporal over four frames 0x3: Reserved	RW	0x0
29	LCDENABLEPOL	LCD Enable Signal Polarity 0x0: Active low 0x1: Active high	RW	0
28	LCDENABLESIGNAL	LCD Enable Signal: LCD interface active/inactive 0x0: Signal disabled 0x1: Signal enabled	RW	0
27	PCKFREEENABLE	Pixel clock free-running enabled/disabled 0x0: Clock disabled 0x1: Clock enabled	RW	0
26:25	TDMUNUSEDDBITS	State of unused bits (TDM mode only) WR: VFP 0x0: Low level (0) 0x1: High level (1) 0x2: Unchanged from previous state 0x3: Reserved	RW	0x0
24:23	TDMCYCLEFORMAT	Cycle format (TDM mode only) WR: VFP 0x0: 1 cycle for 1 pixel 0x1: 2 cycles for 1 pixel 0x2: 3 cycles for 1 pixel 0x3: 3 cycles for 2 pixels	RW	0x0
22:21	TDMPARALLELMODE	Output Interface width (TDM mode only) WR: VFP 0x0: 8-bit parallel output interface selected	RW	0x0

Display Subsystem Registers

www.ti.com

Bits	Field Name	Description	Type	Reset
		0x1: 9-bit parallel output interface selected 0x2: 12-bit parallel output interface selected 0x3: 16-bit parallel output interface selected		
20	TDMENABLE	Enable the multiple cycle format (TDM mode used only for Active Matrix mode with the RFBI enable bit off). WR: VFP 0x0: TDM disabled 0x1: TDM enabled	RW	0
19:17	HT	Hold Time for digital output WR: EVSYNC Encoded value (from 0 to 7) holds time for digital output. The data will be held for (HT + 1) external digital clock periods.	RW	0x0
16	GPOUT1	General Purpose Output Signal 0x0: The GPout1 is reset. 0x1: The GPout1 is set.	RW	0
15	GPOUT0	General Purpose Output Signal 0x0: The GPout0 is reset. 0x1: The GPout0 is set.	RW	0
14	GPIN1	General Purpose Input Signal WR: VFP Read 0x0: The GPin1 has been reset. Read 0x1: The GPin1 has been set.	R	0
13	GPIN0	General Purpose Input Signal WR: VFP Read 0x0: The GPin0 has been reset. Read 0x1: The GPin0 has been set.	R	0
12	OVERLAYOPTIMIZATION	Overlay Optimization (available when graphics format is NOT is 1-, 2, and 4-BPP) WR: VFP or EVSYNC 0x0: Graphics data below video1 window fetched from memory or no overlap between graphics and video1 windows. 0x1: Graphics data below video1 window not fetched from memory.	RW	0
11	RFBI MODE	RFBI Mode for the LCD output wr: VFP 0x0: Normal mode selected 0x1: RFBI mode selected. The Display Controller sends the data without considering the VSYNC/HSYNC. The LCD output is disabled at the end of the transfer of the frame. The S/W has to re-enable the LCD output to generate a new frame.	RW	0
10	SECURE	Secure bit set/reset by secure request only 0x0: Non-secure mode 0x1: Secure mode	RW	0
9:8	TFTDATALINES	Number of lines of the LCD interface WR: VFP 0x0: 12-bit output aligned on the LSB of the pixel data interface 0x1: 16-bit output aligned on the LSB of the pixel data interface 0x2: 18-bit output aligned on the LSB of the pixel data interface 0x3: 24-bit output aligned on the LSB of the pixel data interface	RW	0x0

Bits	Field Name	Description	Type	Reset
7	STDITHERENABLE	Spatial temporal dithering enable WR: VFP 0x0: Spatial/temporal dithering logic disabled 0x1: Spatial/temporal dithering logic enabled	RW	0
6	GODIGITAL	Digital GO Command 0x0: The hardware has finished updating the internal shadow registers of the pipeline(s) associated with the digital output using the user values. The hardware resets the bit when the update is completed. 0x1: The user has finished programming the shadow registers of the pipeline(s) associated with the digital output and the hardware can update the internal registers at the external VSYNC.	RW	0
5	GOLCD	LCD GO Command 0x0: The hardware has finished updating the internal shadow registers of the pipeline(s) connected to the LCD output using the user values. The hardware resets the bit when the update is completed. 0x1: The user has finished programming the shadow registers of the pipeline(s) associated with the LCD output and the hardware can update the internal registers at the VFP start period.	RW	0
4	M8B	Mono 8-bit mode WR: VFP 0x0: Pixel data [3:0] is used to output four pixel values to the panel at each pixel clock transition (only in Passive Mono 8-bit mode). 0x1: Pixel data [7:0] is used to output eight pixel values to the panel each pixel clock transition (only in Passive Mono 8-bit mode).	RW	0
3	STNTFT	LCD display type WR: VFP 0x0: Passive or Passive Matrix display operation enabled. Passive Matrix dither logic enabled. 0x1: Active Matrix display operation enabled. Passive Matrix Dither logic and output FIFO bypassed.	RW	0
2	MONOCOLOR	Monochrome/Color WR: VFP 0x0: Color operation enabled (Passive Matrix mode only) 0x1: Monochrome operation enabled (Passive Matrix mode only)	RW	0
1	DIGITALENABLE	Digital enable 0x0: Digital output disabled (at the end of the current field if interlace output when the bit is reset) 0x1: Digital output enabled	RW	0
0	LCDENABLE	LCD enable 0x0: LCD output disabled (at the end of the frame when the bit is reset) 0x1: LCD output enabled	RW	0

Bits	Field Name	Description	Type	Reset
31:20	Reserved	Write 0s for future compatibility. Read returns 0	RW	0x000000
19	TVALPHABLENDERENABLE	Selects the alpha blender overlay manager instead of the color key alpha blender (TV output) 0x0: Alpha blender is disabled. The color key alpha blending is used. 0x1: The alpha blender is enabled.	RW	0
18	LCDALPHABLENDERENABLE	Selects the alpha blender overlay manager instead of the color key alpha blender (LCD output)	RW	0

Bits	Field Name	Description	Type	Reset
		0x0: Alpha blender is disabled. The color key alpha blending is used.		
		0x1: The alpha blender is enabled.		
17	FIFOFILLING	Controls if the FIFO are re-filled only when the LOW threshold is reached or if all FIFO are re-filled when at least one of them reaches the LOW threshold. 0x0: Each FIFO is re-filled when it reaches LOW threshold. 0x1: All FIFO are re-filled up to high threshold when at least one of them reaches the LOW threshold. (only active FIFOs shall be considered and when reaching the end of the frame the FIFO goes to empty condition so no need to fill it again).	RW	0
16	FIFOHANDCHECK	Controls the handcheck between FIFO and RFBI STALL in order to prevent from underflow. The bit shall be set to 0 when the module is not in RFBI mode. 0x0: Only the STALL signal from RFBI is used regardless of the FIFO fullness information in order to provide data to the RFBI module. 0x1: The STALL signal from RFBI is used in combination with the FIFO fullness information in order to provide data to the RFBI module only when it does not generated FIFO underflow.	RW	0
15	CPR	Color phase rotation control wr: VFP 0x0: Color phase rotation disabled 0x1: Color phase rotation enabled	RW	0
14	FIFOMERGE	FIFO merge control wr: EVSYNC or VFP 0x0: FIFO merge disabled Each FIFO is dedicated to one pipeline. 0x1: FIFO merge enabled All the FIFOS are merged into a single one to be used by the single active pipeline.	RW	0
13	TCKDIGSELECTION	Transparency color key selection (digital output) wr: EVSYNC 0x0: Graphics destination transparency color key selected 0x1: Video source transparency color key selected	RW	0
12	TCKDIGENABLE	Transparency color key enabled (digital output) wr: EVSYNC 0x0: Disable the transparency color key for digital output 0x1: Enable the transparency color key for digital output	RW	0
11	TCKLCDSELECTION	Transparency color key selection (LCD output) WR: VFP 0x0: Graphics destination transparency color key selected 0x1: Video source transparency color key selected	RW	0
10	TCKLCDENABLE	Transparency color key enabled (LCD output) WR: VFP * 0x0: Disable the transparency color key for the LCD 0x1: Enable the transparency color key for the LCD	RW	0
9	FUNCGATED	Functional clocks gated enabled WR: immediate 0x0: Functional clocks gated disabled 0x1: Functional clocks gated enabled	RW	0
8	ACBIASGATED	ACBias Gated Enabled WR: VFP 0x0: ACBias Gated Disabled 0x1: ACBias Gated Enabled	RW	0

Bits	Field Name	Description	Type	Reset
7	VSYNCGATED	VSYNC Gated Enabled WR: VFP 0x0: VSYNC Gated Disabled 0x1: VSYNC Gated Enabled	RW	0
6	HSYNCGATED	HSYNC Gated Enabled WR: VFP 0x0: HSYNC Gated Disabled 0x1: HSYNC Gated Enabled	RW	0
5	PIXELCLOCKGATED	Pixel Clock Gated Enabled WR: VFP 0x0: Pixel Clock Gated Disabled 0x1: Pixel Clock Gated Enabled	RW	0
4	PIXELDATAGATED	Pixel Data Gated Enabled WR: VFP 0x0: Pixel Data Gated Disabled 0x1: Pixel Data Gated Enabled	RW	0
3	PALETTEGAMMATABL E	Palette/Gamma Table selection WR: EVSYNC or VFP 0x0: LUT used as palette (only if graphics format is BITMAP1, 2, 4, and 8) 0x1: LUT used as gamma table (only if graphics format is NOT BITMAP1, 2, 4, and 8 or no graphics window present)	RW	0
2:1	LOADMODE	Loading Mode for the Palette/Gamma Table WR: EVSYNC or VFP 0x0: Palette/Gamma Table and data are loaded every frame. 0x1: Palette/Gamma Table to be loaded. The user sets the bit when the palette/gamma table has to be loaded. H/W resets the bit when table has been loaded. (DISPC_GFX_ATTRIBUTES . GFXEnable has to be set to 1). 0x2: Frame data only loaded every frame 0x3: Palette/Gamma Table and frame data loaded on first frame then switch to 10 (H/W).	RW	0x0
0	PIXELGATED	Pixel Gated Enable (only for Active Matrix Display) WR: VFP 0x0: Pixel clock always toggles (only in Active Matrix mode) 0x1: Pixel clock only toggles when there is valid data to display. (only in Active Matrix mode)	RW	0

Description	The register configures the timing logic for the VSYNC signal. Shadow register, updated on VFP start period		
Type	RW		

Bits	Field Name	Description	Type	Reset
31:28	Reserved	Write 0s for future compatibility. Read returns 0	RW	0x0
27:20	VBP	Vertical back porch Encoded value (from 0 to 255) to specify the number of line clock periods to add to the beginning of a frame before the first set of pixels is output to the display.	RW	0x00
19:16	Reserved	Write 0s for future compatibility. Read returns 0	RW	0x0
15:8	VFP	Vertical front porch Encoded value (from 0 to 255) to specify the number of line clock periods to add to the end of each frame.	RW	0x00
7:6	Reserved	Write 0s for future compatibility. Read returns 0	RW	0x0
5:0	VSW	Vertical synchronization pulse width In active mode, encoded value (from 1 to 64) to specify the number of line clock periods (program to value minus one) to pulse the frame clock (VSYNC) pin at the end of each frame after the end of frame wait (VFP) period elapses. Frame clock uses as VSYNC signal in active mode. In passive mode, encoded value (from 1 to 64) to specify the number of extra line clock periods to insert after the vertical front porch (VFP) period has elapsed.	RW	0x00

Bits	Field Name	Description		Type	Reset																																																												
31: 25	Reserved	Write 0s for future compatibility. Read returns 0.		RW	0x0000																																																												
24	VIDSELFREFRESH	Enables the self refresh of the video window from its own FIFO only. 0x0: The video pipeline accesses the interconnect to fetch data from the system memory 0x1: The video pipeline does not need anymore to fetch data from memory. Only the video FIFO is used. It takes effect after the frame has been loaded in the FIFO		RW	0																																																												
23	VIDARBITRATION	Determines the priority of the video pipeline. The video pipeline is one of the high priority pipeline. The arbitration wheel gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. 0x0: The video pipeline is one of the normal priority pipeline. 0x1: The video pipeline is one of the high priority pipeline.		RW	0																																																												
22	VIDLINEBUFFERSPLIT	Video vertical line buffer split 0x0: Vertical line buffers are not split. 0x1: Vertical line buffers are split into two.		RW	0																																																												
21	VIDVERTICALTAPS	Video vertical resize tap number 0x0: Three taps are used for the vertical filtering logic. The other two taps are not used. 0x1: Five taps are used for the vertical filtering logic.		RW	0																																																												
20	VIDDMAOPTIMIZATION	Video optimization in case of 0x0: The DMA engine fetches one pixel for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation (accessing on-chip memory and off-chip memory). 0x1: The DMA engine fetches two pixels for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation (accessing on-chip memory and off-chip memory).		RW	0																																																												
19	VIDFIFOPRELOAD	Video preload value 0x0: H/W prefetches pixels up to the preload value defined in the preload register. 0x1: H/W prefetches pixels up to the high threshold value.		RW	0																																																												

Bits	Field Name	Description	Type	Reset
18	VIDROWREPEATENABLE	Video Row Repeat (YUV case only when rotating 90 or 270-degree) 0x0: Row of VIDn won't be read twice. 0x1: The Row data are fetched twice to extract both the Y components	RW	0
17	VIDENDIANNESS	Video endianness 0x0 Little endian operation is selected 0x1 Big endian operation is selected	RW	0
16	VIDCHANNELOUT	Video Channel Out configuration wr: Immediate 0x0: LCD output selected 0x1: 24 bit output selected	RW	0
15:14	VIDBURSTSIZE	Video DMA Burst Size 0x0: 4x32bit bursts 0x1: 8x32bit bursts 0x2: 16x32bit bursts 0x3: Reserved	RW	0x0
13:12	VIDROTATION	Video Rotation Flag 0x0: No rotation or VidFormat is RGB 0x1: Rotation by 90 degrees 0x2: Rotation by 180 degrees 0x3: Rotation by 270 degrees	RW	0x0
11	VIDFULLRANGE	VidFullRange 0x0: Limited range selected: 16 subtracted from Y before color space conversion 0x1: Full range selected: Y is not modified before the color space conversion	RW	0
10	VIDREPLICATIONENABLE	VidReplicationEnable 0x0: Disable Video replication logic 0x1: Enable Video replication logic	RW	0
9	VIDCOLORCONVENABLE	VidColorConvEnable 0x0: Disable Color Space Conversion CbYCr to RGB 0x1: Enable Color Space Conversion CbYCr to RGB	RW	0
8	VIDVRESIZECONF	Video Vertical Resize Configuration 0x0: Up-sampling selected 0x1: Down-sampling selected	RW	0
7	VIDHRESIZECONF	Video Horizontal Resize Configuration 0x0: Up-sampling selected 0x1: Down-sampling selected	RW	0
6:5	VIDRESIZEENABLE	Video Resize Enable 0x0: Disable the resize processing 0x1: Enable the horizontal resize processing 0x2: Enable the vertical resize processing 0x3: Enable both horizontal and vertical resize processing	RW	0x0

15.7.4 RFBI Register Descriptions

15.7.4.1 RFBI_SYSCONFIG

Table 15-205. RFBI_SYSCONFIG

Address Offset	0x10																															
Physical address	0x4805 0810								Instance								RFBI															
Description	This register allows control of various parameters of the interconnect interface.																															
Type	RW																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reserved																								Reserved	Reserved	SIDLEMODE	Reserved	SOFTRESET	AUTOIDLE			
Bits	Field Name		Description																			Type		Reset								
31:7	Reserved		Write 0s for future compatibility. Read returns 0.																			RW		0x0000000								
6	Reserved		Write 0s for future compatibility. Read returns 0.																			RW		0								
5	Reserved		Write 0s for future compatibility. Read returns 0.																			RW		0								
4:3	SIDLEMODE		Slave interface power management, Idle req/ack control 00: Force-idle: Idle request is acknowledged unconditionally. 01: No idle: An idle request is never acknowledged 10: Smart idle: Idle request is acknowledged based on the internal activity of the module. 11: Reserved																			RW		0x0								
2	Reserved		Write 0s for future compatibility Read returns 0																			RW		0								
1	SOFTRESET		Software reset Sets this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0. 0: Normal mode 1: The module is reset																			RW		0								
0	AUTOIDLE		Internal clock gating strategy (interconnectL4 and display controller clock) 0: Interconnect L4 clock and display controller clock are free-running. 1: Automatic clock gating strategy is applied for the interconnect L4 clock and display controller clock, based on the interconnect interface and internal activity.																			RW		1

15.7.4.3 RFBI_CONTROL

Table 15-209. RFBI_CONTROL

Address Offset	0x40	Instance	RFBI
Physical address	0x4805 0840		
Description	The control register allows configuration of the RFBI module.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																SMART_DMA_REQ		DISABLE_DMA_REQ		HIGHTHRESHOLD		ITE		CONFIGSELECT		BYPASSMODE		ENABLE			

Bits	Field Name	Description	Type	Reset
31: 9	Reserved	Write 0s for future compatibility Read returns 0	RW	0x00000000
8	SMART_DMA_REQ	Smart DMA request 0x0: The dmareq is asserted and de-asserted depending on interconnect FIFO space even if Mldlreq is high in smart idle/no-idle mode and the entire burst gets error responses from the module. 0x1: The dmareq is de-asserted after 2 clk cycles if it has been asserted for more than or equal to 2 clk cycles and Mldlreq is high in smart idle or no idle mode. No more burst requests will be given even if the space is available in the interconnect FIFO.	RW	0x0
7	DISABLE_DMA_REQ	Disable DMA request 0x0: The dmareq is enabled and the signal is generated based on the space available and the request coming into the data register 0x1: The dmareq is disabled and the signal is not generated at all based on space in interconnect FIFO. It stays high until the DISABLE DMAREQ is high even if there is space in interconnect FIFO to take requests	RW	0x0
6:5	HIGHTHRESHOLD	Defines the interconnect FIFO high threshold used by HW to assert DMA request. Used only if data written to RFBI_DATA are sent using system DMA. 0x0: Size of the transfer of 4 words of 32-bit wide 0x1: Size of the transfer of 8 words of 32-bit wide 0x2: Size of the transfer of 16 words of 32-bit wide	RW	0x0
4	ITE	Internal Trigger 0: H/W waits for ITE bit to be set if in internal trigger mode for the configuration in use. 1: User sets the ITE bit to start the transfer, when H/W takes into account the bit, the H/W resets it.	RW	0
3:2	CONFIGSELECT	Select the CS and configuration 00: No CS selected 01: CS0 selected and configuration #0 10: CS1 selected and configuration #1 11: CS0 and CS1 both selected (only the configuration for CS0 is used)	RW	0x0
1	BYPASSMODE	Bypass Mode 0: The bypass mode not selected 1: The bypass mode is selected	RW	1
0	ENABLE	Enable/Disable flag 0: Disable the RFBI module 1: Enable the RFBI module	RW	0

This section describes TV OUT Encoder module.

15.7.5.1 VENC_STATUS

Table 15-241. VENC_STATUS

Address Offset	0x04	Instance	VENC
Physical address	0x4805 0C04		
Description	VENC_STATUS		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																								CCE		CCO		FSQ			

Bits	Field Name	Description	Type	Reset
31:5	Reserved	Reserved. Read returns 0s.	R	0x0000000
4	CCE	Closed Caption Status for Even Field. This bit is set immediately after the data in registers LINE21_E0 and LINE21_E1 have been encoded to closed caption. This bit is reset when both of these registers are written.	R	0
3	CCO	Closed Caption Status for Odd Field. This bit is set immediately after the data in registers LINE21_O0 and LINE21_O1 have been encoded to closed caption. This bit is reset when both of these registers are written.	R	0
2:0	FSQ	Field Sequence ID. For PAL, all three FSQ[2:0] are used whereas for NTSC only FSQ[1:0] is meaningful. Furthermore, FSQ[0] represents ODD field when it is '0' and EVEN field when it is '1'. Read 0x0: ODD field Read 0x1: EVEN field	R	0x0

RESERVED								LUMA_TEST								RESERVED								CHROMA_SOURCE	COMPOSITE_SOURCE	LUMA_SOURCE	TEST_MODE	VIDEO_INVERT	CHROMA_ENABLE	COMPOSITE_ENABLE	LUMA_ENABLE

Bits	Field Name	Description	Type	Reset
31:26	RESERVED	Reserved. Read returns 0s.	RW	0x00
25:16	LUMA_TEST	In test mode, DAC 1 input value (if s-video video mode is selected)	RW	0x000
15:8	RESERVED	Reserved. Read returns 0s.	RW	0x00
7	CHROMA_SOURCE	Source of chroma video data in test mode 0x0: Chroma test data comes from internal register OUTPUT_TEST[25:16] 0x1: Chroma test data comes from display controller video port G[1:0], B[7:0]	RW	0x0
6	COMPOSITE_SOURCE	Source of composite video data in test mode 0x0: Composite test data comes from internal register OUTPUT_TEST[9:0] 0x1: Composite test data comes from display controller video port G[1:0], B[7:0]	RW	0x0
5	LUMA_SOURCE	Source of luminance video data in test mode 0x0: Luma test data comes from internal register OUTPUT_CONTROL[25:16] 0x1: Luma test data comes from display controller video port G[1:0], B[7:0]	RW	0x0

Bits	Field Name	Description	Type	Reset
4	TEST_MODE	This enables the video DACs to be tested. The values sent to the DACs comes from a register for each output channel (Luma, Composite or Chroma) or from the display controller video port bits G[1:0], B[7:0], depending on the setting of the Source bits 0x0: Video outputs are in normal operation 0x1: Test mode. Video outputs are directly connected to either internal registers or the display controller video port.	RW	0x0
3	VIDEO_INVERT	Controls the video output polarity. This may be used to correct for inversion in an external video amplifier. 0x0: Video outputs are inverted 0x1: Video outputs are normal polarity	RW	0x1
2	CHROMA_ENABLE	Enable the Chrominance output channel 0x0: Chroma output is disabled 0x1: Chroma output is enabled	RW	0x0
1	COMPOSITE_ENABLE	Enable the Composite output channel 0x0: Composite output is disabled 0x1: Composite output is enabled	RW	0x0
0	LUMA_ENABLE	Enable the Luminance output channel 0x0: Luma output is disabled 0x1: Luma output is enabled	RW	0x0

Bits	Field Name	Description	Type	Reset
2	ENWAKEUP	Force-idle. An idle request is acknowledged unconditionally 0x0: Wakeup is disabled 0x1: Wakeup is enabled	RW	0x0
1	SOFT_RESET	Software reset. Set the bit to 1 to trigger a module reset. The bit is automatically reset by the hw. During reads return 0. 0x0: Normal mode. 0x1: The module is reset	RW	0x0
0	AUTO_IDLE	Internal intrface clock gating strategy 0x0: Interface clock is free-running. 0x1: Automatic Interface clock gating strategy is applied based on the module interface activity.	RW	0x1

15.7.6.5 DSI_CTRL

Table 15-333. DSI_CTRL

Address Offset	0x0000 0040	Instance	DSI_PROTOCOL_ENGINE
Physical Address	0x4804 FC40		
Description	GLOBAL CONTROL REGISTER This register controls the DSI Protocol Engine module. This register shall not be modified dynamically (except IF_EN bit field).		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								HSA_BLANKING_MODE	HBP_BLANKING_MODE	HFP_BLANKING_MODE	BLANKING_MODE	RESERVED	VP_HSYNC_END	VP_HSYNC_START	VP_VSYNC_END	VP_VSYNC_START	TRIGGER_RESET_MODE	LINE_BUFFER	VP_VSYNC_POL	VP_HSYNC_POL	VP_DE_POL	VP_CLK_POL	VP_DATA_BUS_WIDTH	TRIGGER_RESET	VP_CLK_RATIO	TX_FIFO_ARBITRATION	ECC_RX_EN	CS_RX_EN	IF_EN		

Bits	Field Name	Description	Type	Reset
31:24	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x00
23	HSA_BLANKING_MODE	Blanking mode 0x0: Packets in TX FIFO are sent during HSA blanking period of video mode or LPM is used. 0x1: LONG BLANKING PACKETS only are used during HSA blanking period of video mode.	RW	0x0
22	HBP_BLANKING_MODE	Blanking mode 0x0: Packets in TX FIFO are sent during HBP blanking period of video mode or LPM is used. 0x1: LONG BLANKING PACKETS only are used during HBP blanking period of video mode.	RW	0x0
21	HFP_BLANKING_MODE	Blanking mode 0x0: Packets in TX FIFO are sent during HFP blanking period of video mode or LPM is used. 0x1: LONG BLANKING PACKETS only are used during HFP blanking period of video mode.	RW	0x0

Bits	Field Name	Description	Type	Reset
20	BLANKING_MODE	Blanking mode 0x0: ULPS is used during blanking periods of video mode (except HSA, HBP, HFP defined in HSA_BLANKING_MODE, HBP_BLANKING_MODE and HFP_BLANKING_MODE fields respectively) when there is no command mode data in TX FIFO ready to be sent. So blanking periods can be different during the frame depending on the TX FIFO. 0x1: LONG BLANKING PACKETS are used during blanking periods of video mode (except HSA, HBP, HFP defined in HSA_BLANKING_MODE, HBP_BLANKING_MODE and HFP_BLANKING_MODE fields respectively) regardless of the packets present in the TX FIFO ready to be sent	RW	0x0
19	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x0
18	VP_HSYNC_END	HSYNC end pulse. 0x0: Disabled. No HSYNC END short packet is generated. 0x1: Enabled. While the HSYNC END pulse is detected, the associated short packet HSYNC END is generated.	RW	0x0
17	VP_HSYNC_START	HSYNC start pulse. 0x0: Disabled. No HSYNC START short packet is generated. 0x1: Enabled. While the HSYNC start pulse is detected, the associated short packet HSYNC START is generated.	RW	0x0
16	VP_VSYNC_END	VSYNC end pulse. 0x0: Disabled. No VSYNC END short packet is generated. 0x1: Enabled. While the VSYNC END pulse is detected, the associated short packet VSYNC END is generated.	RW	0x0
15	VP_VSYNC_START	VSYNC start pulse. 0x0: Disabled. No VSYNC START short packet is generated. 0x1: Enabled. While the VSYNC START pulse is detected, the associated short packet VSYNC START is generated.	RW	0x0
14	TRIGGER_RESET_MODE	Selection of the trigger reset mode 0x0: Synchronized: the mode is only valid if there is virtual channel using the video mode and it is active. The principle is to wait for the current video frame to be transferred on the link. Any data received after the VSYNC are ignored. 0x1: Immediate: all pending requests in TX FIFO are taken into account for transfer scheduling, the RX FIFO is ignored, and the data from video port are ignored as soon as possible. Only the current transfer on DSI link and already scheduled ones are transmitted. All the other transfers are discarded.	RW	0x0
13:12	LINE_BUFFER	Number of line buffers to be used while receiving data on the video port. 0x0: No line buffer 0x1: 1 line buffer 0x2: 2 line buffers	RW	0x0
11	VP_VSYNC_POL	VP vertical synchronization signal polarity 0x0: VSYNC signal on the video port is active low. 0x1: VSYNC signal on the video port is active high.	RW	0x0

Bits	Field Name	Description	Type	Reset
10	VP_HSYNC_POL	VP horizontal synchronization signal polarity 0x0: HSYNC signal on the video port is active low. 0x1: HSYNC signal on the video port is active high.	RW	0x0
9	VP_DE_POL	VP data enable signal polarity 0x0: DE signal on the video port is active low. 0x1: DE signal on the video port is active high.	RW	0x0
8	VP_CLK_POL	VP clock polarity 0x0: The DSI Protocol Engine module captures the data on the VP on the pixel clock falling edge. The module connected to the VP shall drive the data on the pixel clock rising edge. 0x1: The DSI Protocol Engine module captures the data on the VP on the pixel clock raising edge. The module connected to the VP shall drive the data on the pixel clock falling edge.	RW	0x1
7:6	VP_DATA_BUS_WIDTH	Defines the size of the video port data bus 0x0: 16-bits data width (LSB of the 24-bit video port data bus) 0x1: 18-bits data width (LSB of the 24-bit video port data bus) 0x2: 24-bits data width (LSB of the 24-bit video port data bus)	RW	0x0
5	TRIGGER_RESET	Send the reset trigger to the peripheral. 0x0: READS: Reset trigger generation is completed. It is reset by HW when it is completed. WRITES: Cancellation of the request for Reset trigger generation (maybe too late since it is already on going) 0x1: READS: Generation of the reset trigger has been requested by user (could be on going but not completed yet). WRITES: Request for Reset trigger to be sent to the peripheral.	RW	0x0
4	VP_CLK_RATIO	The field indicates the clock ratio between VP_CLK and VP_PCLK. The clock VP_PCLK is generated from VP_CLK. It is divided down. The information is only used when the video port is used to provide data in command mode. In the case of video mode, it is not used. 0x0: The clock VP_PCLK is the clock VP_CLK divided by 2. The duty cycle of VP_PCLK is 50/50. 0x1: The clock VP_PCLK is the clock VP_CLK divided by 3 or more. The duty cycle of VP_PCLK is not 50/50 for odd ratio numbers (3,5,7,...).	RW	0x0
3	TX_FIFO_ARBITRATION	Defines the arbitration scheme for granting the virtual channel pending ready requests in the TX FIFO 0x0: Round-Robin Scheme is used 0x1: Sequential Scheme is used	RW	0x0
2	ECC_RX_EN	Enables the Error Correction Code check for the received header (short and long packets for all virtual channel ids). 0x0: Disabled 0x1: Enabled	RW	0x0
1	CS_RX_EN	Enables the checksum check for the received payload (long packet only for all virtual channel ids). 0x0: Disabled 0x1: Enabled	RW	0x0

Bits	Field Name	Description	Type	Reset
0	IF_EN	<p>Enables the module. When the module is disabled the signals from the complex I/O are gated (no updates of the interrupt status register).</p> <p>It is not possible to change the bit-fields in the register DSI_CTRL register except IF_EN when it is enabled. All the other registers can be changed except the ones that require DSI_VCN_CTRL[0] VC_EN to be equal to 0 to be modified.</p> <p>0x0: The interface is disabled. If one of the virtual channel uses the video mode with the video port to receive the data, the DSI protocol engines is disabled when the next VSYNC is received and all the data in the FIFO for the other virtual channels in command mode are sent to the peripherals (if BTA_EN bit is enabled, the DSI protocol engine needs to wait for the response and BTA from the peripheral before disabling all the internal logic since an acknowledge is requested).</p> <p>0x1: The interface is enabled immediately, the data acquisition on the video port starts on the next VSYNC (video mode) or first data received in the Slave port FIFO (command mode).</p>	RW	0x0

Bits	Field Name	Description	Type	Reset
31	SHADOWING	Shadowing configuration. 0x0: Disabled. The writes to the first 2 registers of the complex I/O address map is done like the other SCP registers. 0x1: Enabled. The writes to the first 2 registers of the complex I/O address map is done only when the GObit is set and when the signal DISPC_UPDATE_SYNC from the display controller module is active.	RW	0x0
30	GOBIT	Allows the synchronized update of the shadow registers when the signal DISPC_UPDATE_SYNC is active. 0x0: Resets the Gobit. The hardware has finished the update of the shadow SCP registers. The bit is reset by Hardware. The software can reset the bit in case the user decides to abort it. There is no guarantee that the software reset is done before the transfer of the values to the complex I/O. 0x1: Set the Gobit. Only when the transfer of the new values for the two first registers is completed (2, 1, or 0 transfers are performed based on the number of registers to update), the GOBIT bit is reset. The DISPC_UPDATE_SYNC signal is used to synchronize the update. The bit shall be set only when it is in reset state.	RW	0
29	RESET_DONE	Internal reset monitoring of the power domain using the PPI byte clock from the complex I/O 0x0: Internal module reset is on going. 0x1: Reset completed.	R	1
28:27	PWR_CMD	Command for power control of the complex I/O 0x0: Command to change to OFF state 0x1: Command to change to ON state 0x2: Command to change to Ultra Low Power state	RW	0x0
26:25	PWR_STATUS	Status of the power control of the complex I/O 0x0: complex I/O in OFF state 0x1: complex I/O in ON state 0x2: complex I/O in Ultra Low Power state	R	0x0
24:22	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x0
21	LDO_POWER_GOOD_STATE	Indicates the state of the signal LDOPWRGOOD. The interrupt LDO_POWER_GOOD_IRQ is generated when a transition is detected on the signal LDOPWRGOOD from the DSIPHY. 0x0: VDDALDODSIPLL power supply is down 0x1: VDDALDODSIPLL power supply is up	R	0x0

Bits	Field Name	Description	Type	Reset
20	USE_LDO_EXTERNAL	Select the external LDO for the DSIPHY. 0x0: DSIPHY internal LDO is used. 0x1: External LDO is used. DSIPHY LDO is tri-stated.	RW	0x0
19	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x0
18:16	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x0
15	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x0
14:12	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x0
11	DATA2_POL	+/- differential pin order of DATA lane 2. 0x0: +/- pin order (dsi_dx=+ and dsi_dy=-) 0x1: -/+ pin order (dsi_dx=- and dsi_dy=+)	RW	0x0
10:8	DATA2_POSITION	Position and order of the DATA lane 2. 0x0: Not used/connected 0x1: Data lane 2 is at the position 1. 0x2: Data lane 2 is at the position 2. 0x3: Data lane 2 is at position 3. Other values: reserved	RW	0x0
7	DATA1_POL	+/- pin orderHS_MANUAL_STOP_CTRL 0x0: +/- pin order (dsi_dx=+ and dsi_dy=-) 0x1: -/+ pin order (dsi_dx=- and dsi_dy=+)	RW	0x0
6:4	DATA1_POSITION	Position and order of the DATA lane 1. The data lane 1 is always present. 0x1: Data lane 1 is at the position 1. 0x2: Data lane 1 is at the position 2. 0x3: Data lane 1 is at position 3. Other values: reserved	RW	0x0
3	CLOCK_POL	+/- differential pin order of CLOCK lane. 0x0: +/- pin order (dsi_dx=+ and dsi_dy=-) 0x1: -/+ pin order (dsi_dx=- and dsi_dy=+)	RW	0x0
2:0	CLOCK_POSITION	Position and order of the CLOCK lane. The clock lane is always present. 0x1: Clock lane is at the position 1. 0x2: Clock lane is at the position 2. 0x3: Clock lane is at position 3. Other values: reserved	RW	0x0

Bits	Field Name	Description	Type	Reset
31	ULPSACTIVENOT_ALL1_IRQ	All the ULPSActiveNOT signals corresponding to the lanes with TXULPSExit being high are high. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
30	ULPSACTIVENOT_ALL0_IRQ	All signals ULPSActiveNOT are 0 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
29	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x0
28	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x0
27	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x0
26	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x0
25	ERRCONTENTIONLP1_3_IRQ	Contention LP1 error for lane #3 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
24	ERRCONTENTIONLP0_3_IRQ	Contention LP0 error for lane #3 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0

Bits	Field Name	Description	Type	Reset
23	ERRCONTENTIONLP1_2_IRQ	Contention LP1 error for lane #2 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
22	ERRCONTENTIONLP0_2_IRQ	Contention LP0 error for lane #2 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
21	ERRCONTENTIONLP1_1_IRQ	Contention LP1 error for lane #1 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
20	ERRCONTENTIONLP0_1_IRQ	Contention LP0 error for lane #1 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
19	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x0
18	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x0
17	STATEULPS3_IRQ	Lane #3 in Ultra Low Power State 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
16	STATEULPS2_IRQ	Lane #2 in Ultra Low Power State 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
15	STATEULPS1_IRQ	Lane #1 in Ultra Low Power State 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
14	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x0
13	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x0
12	ERRCONTROL3_IRQ	Control error for lane #3 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
11	ERRCONTROL2_IRQ	Control error for lane #2 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0

Bits	Field Name	Description	Type	Reset
10	ERRCONTROL1_IRQ	Control error for lane #1 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
9	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x0
8	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x0
7	ERRESC3_IRQ	Escape entry error for lane #3 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
6	ERRESC2_IRQ	Escape entry error for lane #2 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
5	ERRESC1_IRQ	Escape entry error for lane #1 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
4	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x0
3	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x0
2	ERRSYNCESC3_IRQ	Low power Data transmission synchronization error for lane #3 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
1	ERRSYNCESC2_IRQ	Low power Data transmission synchronization error for lane #2 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
0	ERRSYNCESC1_IRQ	Low power Data transmission synchronization error for lane #1 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0

15.7.6.9 DSI_CLK_CTRL

Table 15-341. DSI_CLK_CTRL

Address Offset	0x0000 0054	Instance	DSI_PROTOCOL_ENGINE
Physical Address	0x4804 FC54		
Description	CLOCK CONTROL This register controls the CLOCK GENERATION. The register can be modified only when IF_EN is reset.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
PLL_PWR_CMD		PLL_PWR_STATUS		RESERVED				LP_RX_SYNCHRO_ENABLE		LP_CLK_ENABLE		HS_MANUEL_STOP_CTRL		HS_AUTO_STOP_ENABLE		LP_CLK_NULL_PACKET_SIZE		LP_CLK_NULL_PACKET_ENABLE		CIO_CLK_ICG		DDR_CLK_ALWAYS_ON		LP_CLK_DIVISOR											

Bits	Field Name	Description	Type	Reset
31:30	PLL_PWR_CMD	<p>Command for power control of the DSI PLL Control module</p> <p>PLL Power CTRL signal to go to PLL OFF state</p> <p>PLL Power CTRL signal to go to on state for PLL only</p> <p>PLL Power CTRL signal to go to on state for both PLL and HSDIVIDER (DSI clock is not output from PLL to complex I/O)</p> <p>PLL Power CTRL signal to go to on state for both PLL and HSDIVIDER</p> <p>0x0: Command to change to OFF state</p> <p>0x1: Command to change to ON state for PLL only (HSDIVISER is OFF)</p> <p>0x2: Command to change to ON state for both PLL and HSDIVISER</p> <p>0x3: Command to change to ON state for both PLL and HSDIVISER (no clock output to the DSI complex I/O)</p>	RW	0x0
29:28	PLL_PWR_STATUS	<p>Status of the power control of the DSI PLL Control module</p> <p>0x0: DSI PLL Control module in OFF state</p> <p>0x1: DSI PLL Control module in ON state for PLL only (HSDIVISER is OFF)</p> <p>0x2: DSI PLL Control module in ON state for both PLL and HSDIVISER</p> <p>0x3: DSI PLL Control module in ON state for both PLL and HSDIVISER (no clock output to the DSI complex I/O)</p>	R	0x0
27:22	RESERVED	<p>Write 0's for future compatibility.</p> <p>Reads returns 0.</p>	RW	0x00
21	LP_RX_SYNCHRO_ENABLE	<p>Defines if the DSI functional clock is higher or lower than 30 MHz. The information is used to define synchronization to be used for RxValidEsc.</p> <p>0x0: The DSI functional clock is equal or slower than 30 MHz. The synchronization is falling/rising.</p> <p>0x1: The DSI functional clock is higher than 30 MHz. The synchronization is rising/rising.</p>	RW	0x0
20	LP_CLK_ENABLE	<p>Controls the gating of the TXCLKESC clock.</p> <p>0x0: Disabled. The clock is not generated. The value of LP_CLK_DIVISOR[12:0] field is not used and does not need to be programmed.</p> <p>0x1: Disabled. The clock is generated. The value of LP_CLK_DIVISOR[12:0] field is used and needs to be programmed.</p>	RW	0x0
19	HS_MANUEL_STOP_CTRL	<p>In case HS_AUTO_STOP_ENABLE bit is set to 0 (reset value), the bit-field allows manual control of the assertion/de-assertion of the signal DSISStopClk by the user.</p> <p>0x0: DSISStopClk de-assertion unconditionally.</p> <p>0x1: DSISStopClk assertion unconditionally.</p>	RW	0x0
18	HS_AUTO_STOP_ENABLE	<p>Enables the automatic assertion/de-assertion of DSISStopClk signal.</p> <p>0x0: Auto mode disabled.</p> <p>0x1: Auto mode enabled.</p>	RW	0x0
17:16	LP_CLK_NULL_PACKET_SIZE	<p>Indicates the size of LS NULL Packets to be sent automatically when after the last LP packet transfer. It is used by the receiver to drain its internal pipeline. The valid values are from 0 to 3 bytes for the payload size.</p>	RW	0x0

Bits	Field Name	Description	Type	Reset
15	LP_CLK_NULL_PACKET_ENABLE	Enables the generation of NULL packet in low speed. 0x0: Disabled. The NULL packet is not sent in LP mode after the last LP packet. 0x1: Enabled. The NULL packet is sent in LP mode after the last LP packet.	RW	0x0
14	CIO_CLK_ICG	Controls the signal for gating the L3_ICLK clock provided to the complex I/O 0x0: Disabled. The L3_ICLK clock to the DSI complex I/O is gated. 0x1: Enabled. The L3_ICLK clock to the DSI complex I/O is not gated.	RW	0x0
13	DDR_CLK_ALWAYS_ON	Defines if the DDR clock is also sent when there is no HS packets sent to the peripheral (low power mode). So TXRequest for the clock lane is not de-asserted. 0x0: Disabled. The DDR clock is only provided when HS packets are sent. 0x1: Enabled. The DDR clock is always sent to the peripheral regardless of the state of the data lanes (HS or LS mode).	RW	0x0
12:0	LP_CLK_DIVISOR	Defines the ratio to be used for the generation of the Low Power mode clock from DSI functional clock. The supported values are from 1 to 8191(the value 0 is invalid). The output frequency shall be in the range between 20 MHz and 32 kHz.	RW	0x0001

15.7.6.10 DSI_TIMING1

Table 15-343. DSI_TIMING1

Address Offset	0x0000 0058		
Physical Address	0x4804 FC58	Instance	DSI_PROTOCOL_ENGINE
Description	TIMING1 REGISTER This register controls the DSI Protocol Engine module timers. Any bit-field can be modified while DSI_CTRL.IF_EN is set to '1'. It is used to indicate the number of DSI_CLK functional clock cycles for the timers FORCE_TX_STOP_TIMER and TA_TO_TIMER		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TA_TO	TA_TO_X16	TA_TO_X8	TA_TO_COUNTER													FORCE_TX_STOP_MODE_IO	STOP_STATE_X16_IO	STOP_STATE_X4_IO	STOP_STATE_COUNTER_IO												

Bits	Field Name	Description	Type	Reset
31	TA_TO	Enables the turn-around timer 0x0: Turn-around counter is disabled. 0x1: Turn-around counter is enabled (required to receive TA interrupt in case the turn-around procedure is not successful).	RW	0x0
30	TA_TO_X16	Multiplication factor for the number of DSI_FCLK clock cycles defined in TA_TO_COUNTER bit-field 0x0: The number of DSI_FCLK clock cycles defined in TA_TO_COUNTER is multiplied by 1x 0x1: The number of DSI_CLK functional clock cycles defined in TA_TO_COUNTER is multiplied by 16x	RW	0x1
29	TA_TO_X8	Multiplication factor for the number of DSI_FCLK functional clock cycles defined in TA_TO_COUNTER bit-field 0x0: The number of DSI_FCLK clock cycles defined in TA_TO_COUNTER is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in TA_TO_COUNTER is multiplied by 8x	RW	0x1
28:16	TA_TO_COUNTER	Turn around counter. It indicates the number of DSI_FCLK clock cycles to wait for the change of the Direction PPI signal according to the TurnRequest signal. The value is from 0 to 8191.	RW	0x1FFF
15	FORCE_TX_STOP_MODE_IO	Control of ForceTxStopMode signal 0x0: De-assertion of ForceTxStopMode. The hardware reset the bit at the end of the ForceTXStopMode assertion. The SW can reset the bit in order to stop the assertion of the ForceTXStopMode signal prior to the completion of the period. 0x1: Assertion of ForceTxStopMode	RW	0x0
14	STOP_STATE_X16_IO	Multiplication factor for the number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER bit-field 0x0: The number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER is multiplied by 16x	RW	0x1
13	STOP_STATE_X4_IO	Multiplication factor for the number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER bit-field 0x0: The number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER is multiplied by 4x	RW	0x1
12:0	STOP_STATE_COUNTER_IO	Stop state counter. It indicates the number of DSI_FCLK clock cycles to assert ForceTXStopMode signal. The value is from 0 to 8191.	RW	0x1FFF

Table 15-345. DSI_TIMING2

Address Offset	0x0000 005C	Instance	DSI_PROTOCOL_ENGINE
Physical Address	0x4804 FC5C		
Description	TIMING2 REGISTER This register controls the DSI Protocol Engine module timers. Any bit-field can be modified while DSI_CTRL.IF_EN is set to '1'. It is used to indicate the number of DSI_CLK functional clock cycles for the timers HS_TX_TIMER and LP_RX_TIMER		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HS_TX_TO	HS_TX_TO_X16	HS_TX_TO_X8	HS_TX_TO_COUNTER												LP_RX_TO	LP_RX_TO_X16	LP_RX_TO_X4	LP_RX_TO_COUNTER													

Bits	Field Name	Description	Type	Reset
31	HS_TX_TO	Enables the HS TX timer. 0x0: Turn-around counter is disabled. 0x1: Turn-around counter is enabled (required to receive TA interrupt in case the turn-around procedure is not successful).	RW	0x0
30	HS_TX_TO_X16	Multiplication factor for the number of TxByteClkHS functional clock cycles defined in HS_TX_COUNTER bit-field 0x0: The number of TxByteClkHS functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 1x 0x1: The number of TxByteClkHS functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 16x	RW	0x1
29	HS_TX_TO_X8	Multiplication factor for the number of TxByteClkHS functional clock cycles defined in HS_TX_COUNTER bit 0x0: The number of TxByteClkHS functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 1x 0x1: The number of TxByteClkHS functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 8x	RW	0x1
28:16	HS_TX_TO_COUNTER	HS_TX_TIMER counter. It indicates the number of TxByteClkHS function clock for the HS TX timer. The value is from 0 to 8191.	RW	0x1FFF
15	LP_RX_TO	Enables the LP RX timer. 0x0: Turn-around counter is disabled. 0x1: Turn-around counter is enabled (required to receive TA interrupt in case the turn-around procedure is not successful).	RW	0x0

Bits	Field Name	Description	Type	Reset
14	LP_RX_TO_X16	Multiplication factor for the number of DSI_FCLK clock cycles defined in LP_RX_COUNTER bit-field 0x0: The number of DSI_FCLK clock cycles defined in LP_RX_TO_COUNTER is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in LP_RX_TO_COUNTER is multiplied by 16x	RW	0x1
13	LP_RX_TO_X4	Multiplication factor for the number of DSI_FCLK clock cycles defined in LP_RX_COUNTER bit 0x0: The number of DSI_FCLK clock cycles defined in LP_RX_TO_COUNTER is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in LP_RX_TO_COUNTER is multiplied by 4x	RW	0x1
12:0	LP_RX_TO_COUNTER	LP_RX_TIMER counter. It indicates the number of DSI_FCLK clock cycles for the LP RX timer. The value is from 0 to 8191.	RW	0x1FFF

16.3.2.1 DSI_VM_TIMING1

Table 15-347. DSI_VM_TIMING1

Address Offset	0x0000 0060		
Physical Address	0x4804 FC60	Instance	DSI_PROTOCOL_ENGINE
Description	VIDEO MODE TIMING REGISTER This register defines the video mode timing.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HSA								HFP								HBP															

Bits	Field Name	Description	Type	Reset
31:24	HSA	Defines the horizontal Sync active period used in video mode in number of byte clock cycles (PPI clock) The supported values are from 0 to 255.	RW	0x00
23:12	HFP	Defines the horizontal front porch used in video mode in number of byte clock cycles (PPI clock) The supported values are from 0 to 255	RW	0x000
11:0	HBP	Defines the horizontal back porch used in video mode in number of byte clock cycles (PPI clock) The supported values are from 0 to 255	RW	0x000

Table 15-349. DSI_VM_TIMING2

Address Offset	0x0000 0064	Instance	DSI_PROTOCOL_ENGINE
Physical Address	0x4804 FC64		
Description	VIDEO MODE TIMING REGISTER This register defines the video mode timing.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								VSA								VFP								VBP							

Bits	Field Name	Description	Type	Reset
31:28	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x0
27:24	WINDOW_SYNC	Number of TxByteClkHS clock cycles for the synchronization window. An interrupt for synchronization lost is generated when the received synchronzation on video port is not inside the window. The DSI protocol engine does not change its own timings if the synch is inside the window. The valid values are from 0 to 15.	RW	0x0
23:16	VSA	Defines the vertical Sync active period used in video mode in number of lines. The supported values are from 0 to 255 It is used to generate the short packet for End of Vertical synchronization.	RW	0x00
15:8	VFP	Defines the vertical front porch used in video mode in number of lines. The supported values are from 0 to 255	RW	0x00
7:0	VBP	Defines the vertical back porch used in video mode in number of lines. The supported values are from 0 to 255	RW	0x00

Table 15-353. DSI_CLK_TIMING

Address Offset	0x0000 006C	Instance	DSI_PROTOCOL_ENGINE
Physical Address	0x4804 FC6C		
Description	CLOCK TIMING REGISTER This register controls the DSI Protocol Engine module timers. This register shall not be modified while DSI_CTRL .IF_EN is set to '1'.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																DDR_CLK_PRE								DDR_CLK_POST							
Bits	Field Name							Description															Type				Reset				
31:16	RESERVED							Write 0's for future compatibility. Reads returns 0.															RW				0x0000				
15:8	DDR_CLK_PRE							Indicates the number of PPI Byte clock cycles between the start of the DDR clock and the assertion of the data request signal. The values from 1 to 255 are valid. The value 0 is reserved. The value is not used if DSI_CLK_CTRL [13] DDR_CLK_ALWAYS_ON is set to '1' since the DDR clock is always present.															RW				0x01				
7:0	DDR_CLK_POST							Indicates the number of PPI Byte clock cycles after the de-assertion of the data request signal and the stop of the DDR clock. The values from 1 to 255 are valid. The value 0 is reserved. The value is not used if DSI_CLK_CTRL [13] DDR_CLK_ALWAYS_ON is set to '1' since the DDR clock is always present.															RW				0x01

Table 15-369. DSI_VM_TIMING6

Address Offset	0x0000 008C	Instance	DSI_PROTOCOL_ENGINE
Physical Address	0x4804 FC8C		
Description	VIDEO MODE TIMING REGISTER This register defines the video mode timing.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
BL_HS_INTERLEAVING																BL_LP_INTERLEAVING																
Bits	Field Name															Description															Type	Reset
31:16	BL_HS_INTERLEAVING															Defines the number of TxByteClkHS clock cycles that can be used for interleaving High Speed command mode packet into Video Mode stream during blanking periods during VSA, VBP, VFP periods inside one video frame on PPI link. The supported values are from 0 to 65535 .															RW	0x0000
15:0	BL_LP_INTERLEAVING															Defines the maximum number of bytes for Low Power command mode packets that can be sent on PPI link during blanking periods during VSA, VBP or VFP periods inside one video frame on PPI link. The supported values are from 0 to 65535															RW	0x0000

Table 15-371. DSI_VM_TIMING7

Address Offset	0x0000 0090	Instance	DSI_PROTOCOL_ENGINE
Physical Address	0x4804 FC90		
Description	Defines the maximum number of bytes of Low Power command mode packets that can be sent on PPI link during blanking periods during VSA, VBP or VFP periods inside one video frame on PPI link. The supported values are from 0 to 65535		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ENTER_HS_MODE_LATENCY																EXIT_HS_MODE_LATENCY															

Bits	Field Name	Description	Type	Reset
31:16	ENTER_HS_MODE_LATENCY	Defines the number of TxByteClkHS clock cycles necessary for entering to HS mode. It corresponds to the delay in number of HS clock cycles from assertion of TxRequestHS signal to 1 until assertion of TxReadyHS signal to 1. The supported values are from 0 to 65535 .	RW	0x0000
15:0	EXIT_HS_MODE_LATENCY	Defines the number of TxByteClkHS clock cycles necessary for exiting from HS mode. It corresponds to the maximum delay in number of HS byte clock from de-assertion of TxRequestHS signal until PPI link is in LP-11 state from which a new entrance to HS mode can be initiated which does not take more than ENTER_HS_MODE_LATENCY clock cycles. The supported values are from 0 to 65535	RW	0x0000

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x0
29:27	DMA_RX_REQ_NB	Selection of the use of the DMA request (associated to the RX FIFO) 0x0: DSI_DMA_REQ0 is selected 0x1: DSI_DMA_REQ1 is selected 0x2: DSI_DMA_REQ2 is selected 0x3: DSI_DMA_REQ3 is selected 0x4: No DMA req selected	RW	0x0
26:24	DMA_RX_THRESHOLD	Defines the threshold value for the DMA request (associated to the RX FIFO) 0x0: 1x 32 bits 0x1: 2 x 32 bits 0x2: 4 x 32 bits 0x3: 8 x 32 bits 0x4: 16 x 32 bits 0x5: 32 x 32 bits	RW	0x0
23:21	DMA_TX_REQ_NB	Selection of the use of the DMA request (associated to the TX FIFO) 0x0: DSI_DMA_REQ0 is selected 0x1: DSI_DMA_REQ1 is selected 0x2: DSI_DMA_REQ2 is selected 0x3: DSI_DMA_REQ3 is selected 0x4: No DMA req selected	RW	0x0
20	RX_FIFO_NOT_EMPTY	FIFO status 0x0: The RX FIFO is empty (the FIFO does not contain any data for the virtual channel) 0x1: The RX FIFO is not empty (the FIFO contains at least one byte for the virtual channel)	R	0x0

Bits	Field Name	Description	Type	Reset
19:17	DMA_TX_THRESHOLD	Defines the threshold value for the DMA request (associated to the TX FIFO) 0x0: 1x 32 bits 0x1: 2 x 32 bits 0x2: 4 x 32 bits 0x3: 8 x 32 bits 0x4: 16 x 32 bits 0x5: 32 x 32 bits	RW	0x0
16	TX_FIFO_FULL	FIFO status 0x0: The TX FIFO is not full (the FIFO can accept at least one more 32-bit value) 0x1: The TX FIFO is full	R	0x0
15	VC_BUSY	Indicates if previously scheduled activities (packets, BTA) are still being processed. Forced to 1 by hardware if VC is enabled. Software should check this bit is 0 before changing channel configuration. 0x0: No pending operations for this VC 0x1: Pending operations for this VC	R	0x0
14:10	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x00
9	MODE_SPEED	Selection of the mode 0x0: Low power mode (CMOS) is used to send short and long packets to the peripheral. 0x1: High Speed mode (SLVS) is used to send short and long packets to the peripheral.	RW	0x0
8	ECC_TX_EN	Enables the Error Correction Code generation for the transmit header (short and long packets). 0x0: Disabled 0x1: Enabled	RW	0x0
7	CS_TX_EN	Enables the checksum generation for the transmit payload (long packet only). 0x0: Disabled. The value 0x00 is used. 0x1: Enabled. The Check-sum value is calculated by HW.	RW	0x0
6	BTA_EN	Send the bus turn around to the peripheral. It can be used when the automatic mode is enabled (BTA_SHORT_EN=1 or/and BTA_LONG_EN=1). In that case only one BTA is sent to the peripheral. The manual mode is used to allow the user to define for which packets, the turn around is required for example getting acknowledge from the peripheral. 0x0: READS: BTA generation is completed. It is reset by HW when it is completed. WRITES: Cancellation of the BTA generation (not guarantee since it could already on going, shall not be used). 0x1: READS: BTA generation has been requested by user (it could be on going but not completed). WRITES: Request for BTA generation.	RW	0x0
5	TX_FIFO_NOT_EMPTY	FIFO status 0x0: The TX FIFO is empty (the FIFO does not contain any data for the virtual channel) 0x1: The TX FIFO is not empty (the FIFO contains at least one byte for the virtual channel)	R	0x0
4	MODE	Selection of the mode 0x0: Command mode. 0x1: Video mode.	RW	0x0

Bits	Field Name	Description	Type	Reset
3	BTA_LONG_EN	Enables the automatic bus turn-around after completion of each long packet transmission. 0x0: Disabled 0x1: Enabled	RW	0x0
2	BTA_SHORT_EN	Enables the automatic bus turn-around after completion of each short packet transmission. 0x0: Disabled 0x1: Enabled	RW	0x0
1	SOURCE	Selection of the source between slave port and Video port. 0x0: All the data are provided by the slave port. Any transfer on the video port is ignored for this virtual channel. 0x1: If MODE=VIDEO_MODE, any data received on the video port (pixels and enabled synchronization events using DSI_CTRL[17] VP_HSYNC_START, DSI_CTRL[18] VP_HSYNC_END, DSI_CTRL[15] VP_VSYNC_START, DSI_CTRL[16] VP_VSYNC_END,) are sent on the virtual channel (only one virtual channel can be associated with the video port, it is the software responsibility to ensure that no more than one virtual channel is enabled with the video port as the main source for data). If MODE=COMMAND_MODE, the VP_STALL signal is used by the protocol engine to indicate when new data are required. The synchronization signals are not generated by the display controller. Regardless of the MODE, no data can be provided on the slave port.	RW	0x0
0	VC_EN	Enables the virtual channel. 0x0: Disabled. The virtual channel shall be disabled for any register change in the DSI_VCn_XXX registers the corresponding virtual channel id (except for setting the bit-fields/registers: DSI_VCn_CTRL[6] BTA_EN, DSI_VCn_TE[15:0] TE_SIZE, DSI_VCn_TE[17] TE_START, DSI_VCn_LONG_XXX , DSI_VCn_SHORT_XXX , DSI_VCn_IRQXXX registers). 0x1: Enabled. No change is allowed to the virtual channel registers expect resetting the VC_EN.	RW	0x0

15.7.6.27 DSI_VCn_TE

Table 15-376. DSI_VCn_TE

Address Offset	0x0000 0104+ (n* 0x20)	Index	n = 0 to 3	
Physical Address	0x4804 FD04+ (n* 0x20)	Instance	DSI_PROTOCOL_ENGINE	
Description	CONTROL REGISTER - Virtual channel This register controls the tearing effect logic. It defines the size of the transfer when TE occurs and enables the automatic TE mode.			
Type	RW			

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED														TE_START	TE_EN	TE_SIZE															

Bits	Field Name	Description	Type	Reset
31:18	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x0000
17	TE_START	Manual control of the start of the transfer. The user can use the TE interrupt in order to know that the TE trigger has been received prior to set the TE_START bit-field. It is not mandatory to use the TE interrupt. 0x0: Indicates the end of the transfer. The bit can be used by user to cancel the transfer. The FIFO shall be flushed by SW to ensure there is no data remaining in it. 0x1: Starts the transfer of the data. The size is defined in TE_SIZE. The bit-field is set until the transfer is completed. It is reset by HW when the transfer is completed.	RW	0x0
16	TE_EN	Tearing Effect Control 0x0: Disables the automatic transfer of the data using the TE trigger as a synchronization event. The user shall use the interruption in order to know when TE trigger is received. The HW reset the bit-field when the transfer is completed (TE_SIZE=0). 0x1: Enables the automatic transfer of the data using the TE trigger as a synchronization event.	RW	0x0
15:0	TE_SIZE	Defines the number of byte (payload data excluding the check -sum) to be sent. The write into the DSI_VCn_LONG_PACKET_HEADER register shall be performed by the user before sending data from the DSI_VCn_LONG_PACKET_PAYLOAD register. The register value is decremented for every byte sent of the DSI link. At the end of the transfer (TE_SIZE=0), the bit-field TE_EN is reset by HW. The DMA_request shall be asserted when the trigger is received in order to receive data in the TX FIFO. It shall not be used until all data (TE_SIZE) have been received in the FIFO.	RW	0x0000

15.7.6.31 DSI_VCn_IRQSTATUS

Table 15-384. DSI_VCn_IRQSTATUS

Address Offset	0x0000 0118+ (n* 0x20)	Index	n = 0 to 3
Physical Address	0x4804 FD18+ (n* 0x20)	Instance	DSI_PROTOCOL_ENGINE
Description	INTERRUPT STATUS REGISTER - Virtual channel This register regroups all the events related to the virtual channel.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																FIFO_TX_UDF_IRQ		ECC_NO_CORRECTION_IRQ		BTA_IRQ		FIFO_RX_OVF_IRQ		FIFO_TX_OVF_IRQ		PACKET_SENT_IRQ		ECC_CORRECTION_IRQ		CS_IRQ	

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x000000
7	FIFO_TX_UDF_IRQ	FIFO underflow status. The FIFO used on the slave port for buffering the data received on the OCP slave port for the virtual channel has underflowed which means that the data for the current packet have not been received in time since the transfer of the packet are already started (transfer started since the packet size is bigger than space allocated in the FIFO). 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
6	ECC_NO_CORRECTION_IRQ	ECC error status (short and long packets). No correction of the header because of more than 1-bit error. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
5	BTA_IRQ	Virtual channel - BTA status. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0

Bits	Field Name	Description	Type	Reset
4	FIFO_RX_OVF_IRQ	FIFO overflow error status. The FIFO used on the slave port for buffering the data received on the DSI link for the virtual channel has overflowed. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
3	FIFO_TX_OVF_IRQ	FIFO overflow error status. The FIFO used on the slave port for buffering the data received on the OCP slave port for the virtual channel has overflowed. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
2	PACKET_SENT_IRQ	Indicates that a packet has been sent. It is used when BTA manual mode is used. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
1	ECC_CORRECTION_IRQ	Virtual channel - ECC has been used to do the correction of the only 1-bit error status (short and long packet only). 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
0	CS_IRQ	Virtual channel - Check-Sum mismatch status. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0

15.7.6.32 DSI_VCn_IRQENABLE

Table 15-386. DSI_VCn_IRQENABLE

Address Offset	0x0000 011C+ (n* 0x20)	Index	n = 0 to 3
Physical Address	0x4804 FD1C + (n* 0x20)	Instance	DSI_PROTOCOL_ENGINE
Description	INTERRUPT ENABLE REGISTER - Virtual channel This register regroups all the events related to virtual channel.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																FIFO_TX_UDF_IRQ_EN		ECC_NO_CORRECTION_IRQ_EN		BTA_IRQ_EN		FIFO_RX_OVF_IRQ_EN		FIFO_TX_OVF_IRQ_EN		PACKET_SENT_IRQ_EN		ECC_CORRECTION_IRQ_EN		CS_IRQ_EN	

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x000000
7	FIFO_TX_UDF_IRQ_EN	FIFO underflow enable. The FIFO used on the slave port for buffering the data received on the OCP slave port for the virtual channel has underflowed which means that the data for the current packet have not been received in time since the transfer of the packet are already started (transfer started since the packet size is bigger than space allocated in the FIFO). 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
6	ECC_NO_CORRECTION_IRQ_EN	ECC error (short and long packets). No correction of the header because of more than 1-bit error. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
5	BTA_IRQ_EN	Virtual channel -Bus turn around reception 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
4	FIFO_RX_OVF_IRQ_EN	FIFO overflow enable. The FIFO used on the slave port for buffering the data received on the DSI link for the virtual channel has overflowed. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
3	FIFO_TX_OVF_IRQ_EN	FIFO overflow enable. The FIFO used on the slave port for buffering the data received on the OCP slave port for the virtual channel has overflowed. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
2	PACKET_SENT_IRQ_EN	Indicates that a packet has been sent. It is used when BTA manual mode is used. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
1	ECC_CORRECTION_IRQ_EN	Virtual channel - ECC has been used to correct the only 1-bit error (short and long packet only). 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
0	CS_IRQ_EN	Virtual channel - Check-Sum of the payload mismatch detection 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0

15.8 Revision History

Table 15-406 lists the changes made since the previous version of this document.

Table 15-406. Document Revision History

Reference	Additions/Modifications/Deletions
Global	Changed TWL4030 to TPS65950.
Global	Changed register name DSI_VCn_SHORT_PACKET to DSI_VCn_SHORT_PACKET_HEADER.
Global	Changed register DISPC_DEFAULT_COLORi to DISPC_DEFAULT_COLORm
Global	Changed register DISPC_TRANS_COLORi to DISPC_TRANS_COLORm
Global	Changed register DISPC_GFX_BAi to DISPC_GFX_BAj
Global	Changed register DISPC_VIDn_BAi to DISPC_VIDn_BAj
Global	Changed register DISPC_DATA_CYCLEi to DISPC_DATA_CYCLEk
Global	Changed register DISPC_VIDn_ACCUi to DISPC_VIDn_ACCUI
Section 15.1	Changed bullets.
Section 15.2.1.1.4	Changed 2nd bullet.
Section 15.2.4	Changed 2nd bullet in Caution.

16.1 Timers Overview

The device includes several types of timers used by the system software, including 12 general-purpose timers (GP timers), three watchdog timers (WDTs), a 32-kHz synchronized timer. Figure 16-1 shows the counters in the device in a high-level block diagram.

Figure 16-1. Timers

PU108-027

The three WDTs are divided into a single secure WDT and two general-purpose WDTs. The WDTs are clocked with 32-kHz clocks. The 32-kHz synchronized timer, which is reset only at power up, provides the operating system with a stable timing source that stores the relative time since the last power cycle of the product. Finally, 12 GP timers, which are useful simply as basic timers, are included to generate time-stamp-based interrupts to the system software or to use as a source of pulse-width modulation (PWM) signals.

16.2 General-Purpose Timers

16.2.1 GP Timers Overview

The device has 12 GP timers: GPTIMER1 through GPTIMER12.

Each timer can be clocked from either the system clock (12, 13, 16.8, 19.2, 26, or 38.4 MHz) or the 32-kHz clock. The selection of the clock source is made at the power, reset, clock management (PRCM) module level. For more information, see [Section 16.2.3.1, Clocking, Reset, and Power-Management Scheme](#).

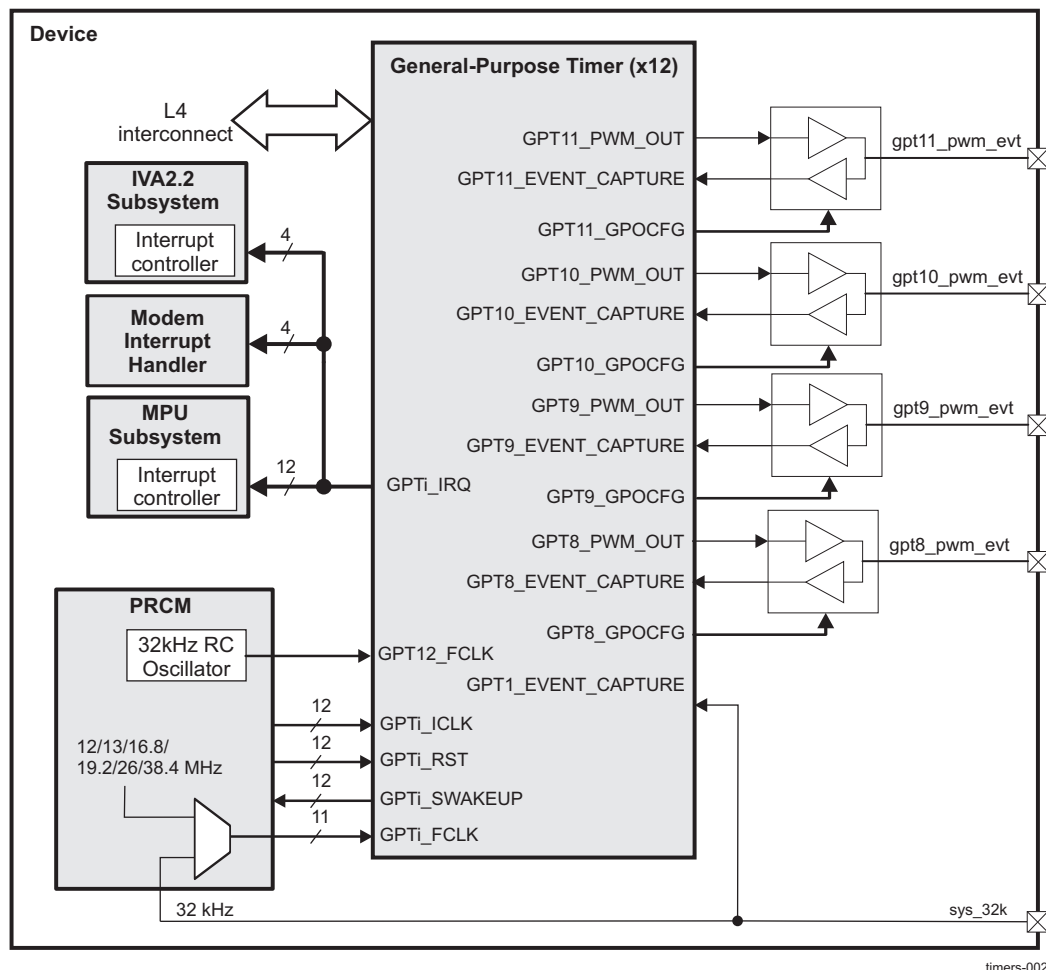

GPTIMER1 has its GPT1_EVENT_CAPTURE pin tied to the 32-kHz clock and can be used to gauge the system clock input; it detects its frequency among 12, 13, 16.38, 19.2, 26, or 38.4 MHz.

Each timer can provide an interrupt to the microprocessor unit (MPU) subsystem. In addition, GPTIMER5 through GPTIMER8 also have interrupts connected to the IVA2.2 subsystem.

GPTIMER1, GPTIMER2, and GPTIMER10 include specific functions to generate accurate tick interrupts to the operating system. GPTIMER8 through GPTIMER11 are connected to external pins by their PWM output or their event capture input pin (for external timer triggering). [Figure 16-2](#) shows an overview of the GP timers.

Note: GPTIMER12 is part of the security domain and is referred to as the security timer. Its reference clock input is issued from an internal 32-kHz oscillator.

Figure 16-2. GP Timers Overview

16.2.1.1 GP Timers Features

The following are the main features of the GP timers controllers:

- L4 slave interface support:
 - 32-bit data bus width
 - 32-/16-bit access supported
 - 8-bit access not supported
 - 10-bit address bus width
 - Burst mode not supported
 - Write nonposted transaction mode supported
- Interrupts generated on overflow, compare, and capture
- Free-running 32-bit upward counter
- Compare and capture modes
- Autoreload mode
- Start/stop mode
- Programmable divider clock source (2^n with $n = [0:8]$)
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- Dedicated output signal for general-purpose using GPTi_GPOCFG signal
- On-the-fly read/write register (while counting)
- 1-ms tick with 32,768 Hz functional clock generated (only GPTIMER1, GPTIMER2, and GPTIMER10)

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

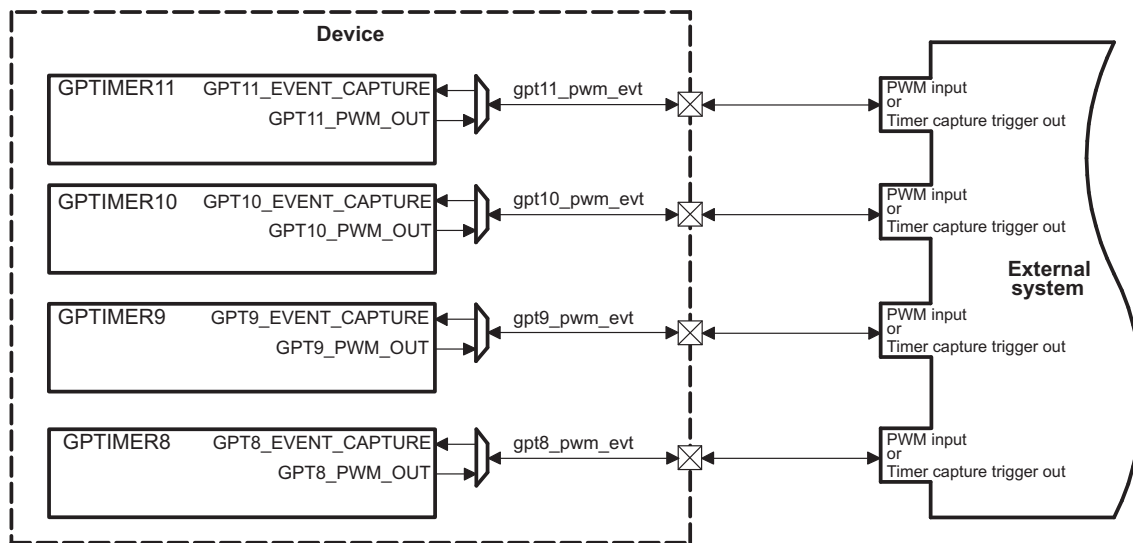

16.2.2 GP Timers Environment

16.2.2.1 GP Timers External System Interface

Four of the 12 GP timers can send or receive stimulus to/from the external (off-chip) system. In the device, however, only GPTIMER8 through GPTIMER11 are configured to output a PWM pulse or receive an external event signal used as a trigger to capture the current timer count. GPTIMER1 is also configured to receive an event trigger input (GPT1_EVENT_CAPTURE) tied to the internal 32-kHz clock. This event signal gauges the system clock input; it detects its frequency among 12, 13, 16.8, 19.2, 26, or 38.4 MHz.

[Figure 16-3](#) shows the external system interface for the GP timers, and [Table 16-1](#) describes the GP timer inputs and outputs.

Figure 16-3. GP Timers External System Interface

PU108-003

Table 16-1. Input/Output Description

Pin Name	Type ⁽¹⁾	Reset Value	Signal Name	Description
gpt8_pwm_evt	I/O	0	GPT8_EVENT_CAPTURE GPT8_PWM_OUT	GPTIMER8 trigger input/ PWM output
gpt9_pwm_evt	I/O	0	GPT9_EVENT_CAPTURE GPT9_PWM_OUT	GPTIMER9 trigger input/ PWM output
gpt10_pwm_evt	I/O	0	GPT10_EVENT_CAPTURE GPT10_PWM_OUT	GPTIMER10 trigger input/ PWM output
gpt11_pwm_evt	I/O	0	GPT11_EVENT_CAPTURE GPT11_PWM_OUT	GPTIMER11 trigger input/ PWM output

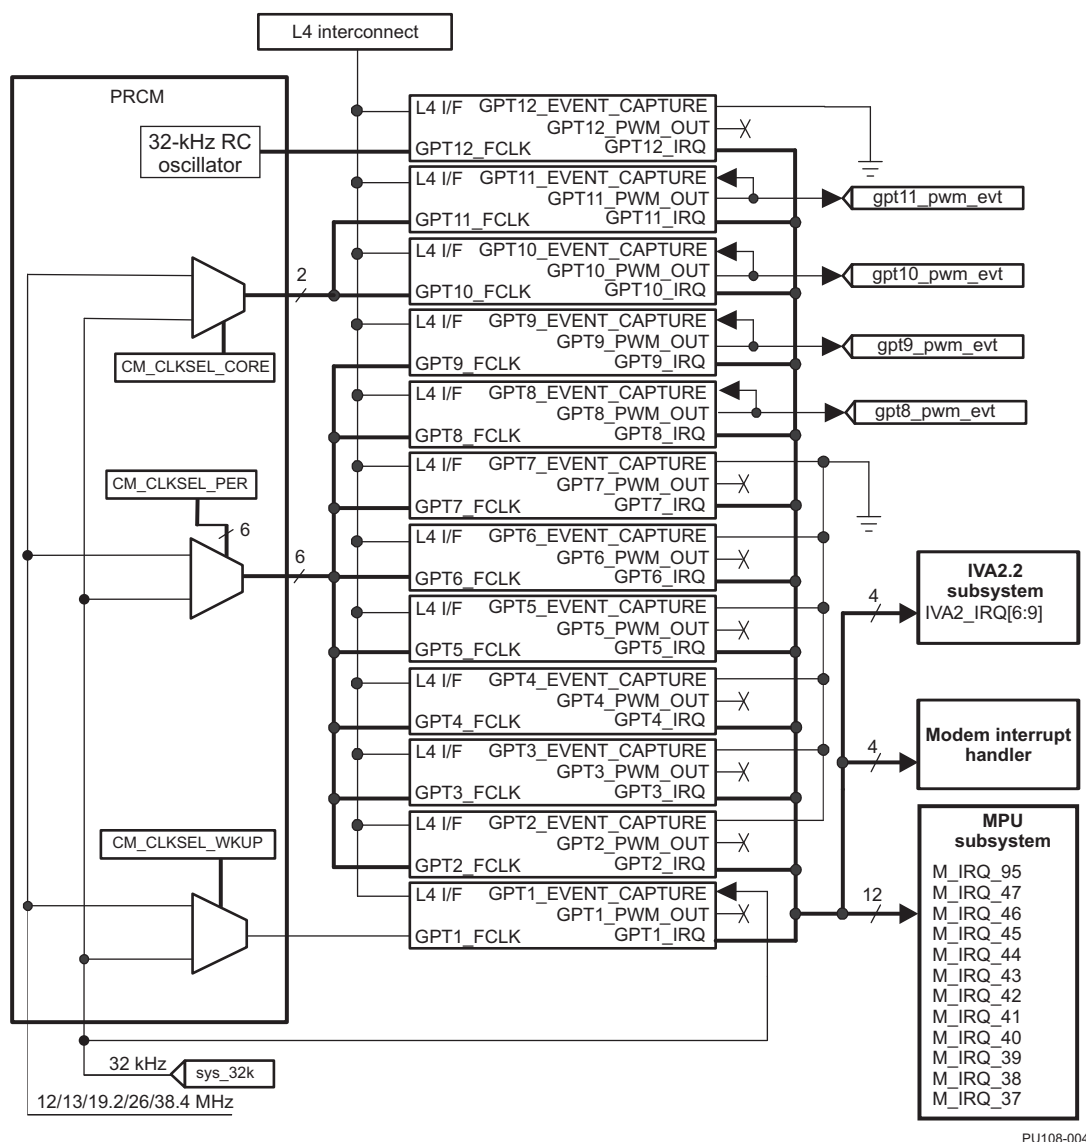

⁽¹⁾ When configured for that function; I = input, O = output

Note: The event trigger input (GPTi_EVENT_CAPTURE) for GPTIMER2 through GPTIMER7 and GPTIMER12 is internally tied low, and the PWM output (GPTi_PWM_OUT) is not connected.

16.2.3 GP Timers Integration

Figure 16-4 shows the GP timer integration in the device.

Figure 16-4. GP Timer Integration

16.2.3.1 Clocking, Reset, and Power-Management Scheme

16.2.3.1.1 Clock Management

There are two clock domains in the GP timers:

- Functional clock domain: GPTi_FCLK is the GP timer functional clock. It is used to clock the GP timer internal logic.
- Interface clock domain: GPTi_ICLK is the GP timer interface clock. It is used to synchronize the GP timer L4 port to the L4 interconnect. All accesses from the interconnect are synchronous to GPTi_ICLK.

Table 16-2 lists the source clocks for each GP timer in the device. For more information on clock control and domains, see the *Power, Reset, and Clock Management* chapter.

Table 16-2. Clock, Power, and Reset Domains for GP Timers

Timer	Interface Clock	Functional Clock	Power Domain
GPTIMER1	WKUP_L4_ICLK	GPT1_FCLK	WKUP
GPTIMER2 through GPTIMER9	PER_L4_ICLK	GPTx_ALWON_FCLK (x = 2 through 9)	PER
GPTIMER10 and 11	CORE_L4_ICLK	GPTx_FCLK (x = 10 or 11)	CORE
GPTIMER12	WKUP_L4_ICLK	SECURE_32K_FCLK	WKUP

GP timers can be selected as the source of GPTi_FCLK (32-kHz clock or 12, 13, 16.8, 19.2, 26, or 38.4 MHz) at the PRCM level in the corresponding registers. For more information, see the *Power, Reset, and Clock Management* chapter. [Table 16-3](#) lists the GP timer PRCM clock selection bits.

Table 16-3. GP Timer PRCM Clock Selection Bits

Name	Associated PRCM Clock Output	Selection Bit
GPT1_FCLK	GPT1_FCLK	PRCM.CM_CLKSEL_WKUP[0] CLKSEL_GPT1
GPT[2:9]_FCLK	GPT[2:9]_ALWON_FCLK	PRCM.CM_CLKSEL_PER [0:7] CLKSEL_GPT[2:9]
GPT10_FCLK	GPT10_FCLK	PRCM.CM_CLKSEL_CORE [6] CLKSEL_GPT10
GPT11_FCLK	GPT11_FCLK	PRCM.CM_CLKSEL_CORE [7] CLKSEL_GPT11
GPT12_FCLK	SECURE_32K_FCLK	None

From a global system power-management perspective, when one or both of the GP timer clocks is no longer required, the GP timers can be deactivated at the PRCM level in the corresponding registers.

[Table 16-4](#) lists the GP timer PRCM clock control bits.

Table 16-4. GP Timer PRCM Clock Control Bits

Name	Associated PRCM Clock Output	Enable Bit	Autoidle Bit
GPT1_FCLK	GPT1_FCLK	PRCM.CM_FCLKEN_WKUP[0] EN_GPT1 bit	N/A
GPT[2:9]_FCLK	GPT[2:9]_ALWON_FCLK	PRCM.CM_FCLKEN_PER [3:10] EN_GPT[2:9] bit	N/A
GPT10_FCLK	GPT10_FCLK	PRCM.CM_FCLKEN1_CORE [11] EN_GPT10 bit	N/A
GPT11_FCLK	GPT11_FCLK	PRCM.CM_FCLKEN1_CORE [12] EN_GPT11 bit	N/A
GPT12_FCLK	SECURE_32K_FCLK	None	N/A
GPT1_ICLK	WKUP_L4_ICLK	PRCM.CM_ICLKEN_WKUP[0] EN_GPT1 bit	PRCM.CM_AUTOIDLE_WKUP[0] AUTO_GPT1 bit
GPT12_ICLK		PRCM.CM_ICLKEN_WKUP[1] EN_GPT12 bit	PRCM.CM_AUTOIDLE_WKUP[1] AUTO_GPT12 bit
GPT[2:9]_ICLK	PER_L4_ICLK	PRCM.CM_ICLKEN_PER[3:10] EN_GPT[2:9] bit	PRCM.CM_AUTOIDLE_PER[3:10] AUTO_GPT[2:9] bit
GPT10_ICLK	CORE_L4_ICLK	PRCM.CM_ICLKEN1_CORE[11] EN_GPT10 bit	PRCM.CM_AUTOIDLE1_CORE[11] AUTO_GPT10 bit
GPT11_ICLK		PRCM.CM_ICLKEN1_CORE[12] EN_GPT11 bit	PRCM.CM_AUTOIDLE1_CORE[12] AUTO_GPT11 bit

Notes:

- The PRCM function clock outputs are gated at the PRCM level, assuming all the modules that share it are disabled in the corresponding register. Disabling GP timers is a necessary but not sufficient action. The clock is effectively out when all PRCM conditions are fulfilled. For the other actions to be taken, see the *Power, Reset, and Clock Management* chapter.
- The PRCM interface clock outputs are gated at the PRCM level, assuming all the modules that share it are disabled in the corresponding register. Disabling GP timers is a necessary but not sufficient action. The clock is effectively out when all PRCM conditions are fulfilled. For the other actions to be taken, see the *Power, Reset, and Clock Management* chapter.
- The PRCM AUTOIDLE bits are used to link/unlink the GP timers from the clock domain transitions related to the GPTi_ICLK clocks.
- For further details about source clock gating and domain transitions, see the *Power, Reset, and Clock Management* chapter.

GP timer modules also have an internal bit, GPTi.TIOCP_CFG[0] AUTOIDLE. The GP timer AUTOIDLE bit is used to apply an internal interface clock gating strategy.

At the PRCM level, when all conditions to shut off the PRCM functional or interface output clocks are met (see the *Power, Reset, and Clock Management* chapter for details), the PRCM automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the GPTi.TIOCP_CFG[4:3] IDLEMODE bit. [Table 16-5](#) lists the IDLEMODE settings and the related acknowledgement modes.

Table 16-5. IDLEMODE Settings

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The GP timer acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.
01	No-idle	The GP timer never acknowledges an IDLE request from the PRCM module. This mode is secure from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, however, because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
10	Smart-idle	The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach for efficient system power management.
11	Reserved	

When configured in smart-idle mode, the GP timer also offers an additional granularity on GPTi_FCLK and GPTi_ICLK gating. The GPTi.TIOCP_CFG[9:8] CLOCKACTIVITY bit field is used to determine which clock will be shut down (GPTi_FCLK, GPTi_ICLK, neither of them, or both of them).

The CLOCKACTIVITY setting is used internally to the GP timer to determine the part of the module on which the conditions to acknowledge the PRCM IDLE request will be tested. For example, if GPTi_FCLK is not to be shut down on a PRCM IDLE request, the GP timer considers only GPTi_ICLK and the associated pending activities before acknowledging the request.

Some GP timer features are associated with GPTi_ICLK and others are associated with GPTi_FCLK. Using the CLOCKACTIVITY setting along with the smart-idle mode ensures that the features associated with the clock that will remain active are always enabled, even if the GP timer acknowledges an IDLE request.

Table 16-6 lists the CLOCKACTIVITY settings and the associated features.

Table 16-6. CLOCKACTIVITY Settings

CLOCKACTIVITY Value	GPTi_ICLK Effects	GPTi_FCLK Effects	Description	Associated Features
00	OFF	OFF	Both GPTi_ICLK and GPTi_FCLK are considered for generating the acknowledge. This setting also means both GPTi_FCLK and GPTi_ICLK are likely to be shut down on PRCM IDLE request.	The idle acknowledge signal is asserted when there are no pending activities on the functional clock domain (improved latency in assertion of idle acknowledge). The wake-up capability of the GP timer is disabled.
01	OFF	ON	GPTi_FCLK is not shut down on PRCM IDLE request; only GPTi_ICLK is affected.	
10	ON	OFF	GPTi_ICLK is not shut down on PRCM IDLE request; only GPTi_FCLK is affected.	The idle acknowledge signal is asserted when there are no pending activities on the interface clock domain, without evaluating the pending activities on the functional clock domain (the GP timer enters into sleep mode, and if a pending interrupt event is finished during idle mode, the wake-up signal is asserted). The wake-up signal is enabled.
11	ON	ON	None of the clocks are shut down. Therefore, the GP timer can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clocks.	

CAUTION

The PRCM module does *not* have any hardware means to read the CLOCKACTIVITY settings. The software must ensure consistent programming between the GP timer CLOCKACTIVITY and the PRCM functional clock and interface clock control bits. If the GP timer is disabled in both CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated with the GP timer clocks. This can lead to unpredictable behavior.

16.2.3.1.2 Wake-Up Capability

If the GPTi.TIOCP_CFG[4:3] IDLEMODE field sets the smart-idle mode, the timer module evaluates its internal capability to have the interface clock switched off. When there is no more internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters into sleep mode, ready to issue a wake-up request. This wake-up request is sent only if the GPTi.TIOCP_CFG[2] ENAWAKEUP bit enables the timer wake-up capability.

Figure 16-5 shows the wake-up request generation. For more information on the GP timer clock control, see Section 16.2.3.1.1, *Clock Management*.

Figure 16-5. Wake-Up Request Generation

PU108-005

The timer wake-up enable register (GPTi.TWER) allows masking the expected source of the wake-up event that generates a wake-up request. The GPTi.TWER register is programmed synchronously with the interface clock before the PRCM module sends an idle mode request. The expected source of the wake-up event is an overflow (GPTi.TCRR), a timer match (the compare result of GPTi.TCRR and GPTi.TMAR matches the counter value), and a timer capture (an external pulse transition of the correct polarity is detected on the GPTi_EVENT_CAPTURE).

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (GPTi.TISR). The pending wake-up event is reset when the set status bit is overwritten by 1.

Note: The status bit must be reset to re-enter idle mode.

16.2.3.1.3 Reset and Power Management

GPTIMER1 and GPTIMER12 belong to the WKUP power domain. As part of that domain, these GP timers are sensitive to a WKUP_RST signal issued by the PRCM module. For further details about the WKUP power domain implementation and the WKUP_RST signal, see the *Power, Reset, and Clock Management* chapter.

GPTIMER2 through GPTIMER9 belong to the PER power domain. As part of that domain, these GP timers are sensitive to a PER_RST signal issued by the PRCM module. For further details about the PER power domain implementation and the PER_RST signal, see the *Power, Reset, and Clock Management* chapter.

GPTIMER10 and GPTIMER11 belong to the CORE power domain. As part of that domain, these GP timers are sensitive to a CORE_RST signal issued by the PRCM module. For further details about the CORE power domain implementation and the CORE_RST signal, see the *Power, Reset, and Clock Management* chapter.

Note: The secure GP timer (GPTIMER12) is reset only on power-on reset, and then it starts counting.

16.2.3.2 Software Reset

Two bit fields (GPTi.TIOCP_CFG[1] SOFTRESET and GPTi.TSICR[1] SFT) can generate a software reset of the GP timer. For both of these bits, all read accesses return 0.

The GPTi.TIOCP_CFG[1] SOFTRESET bit allows resetting the functional and interface domains. The GPTi.TSICR[1] SFT bit allows resetting the functional part of the GP timer.

Before accessing or using the GP timer, the local host must ensure that both internal resets are released by reading the GPTi.TISTAT[0] RESETDONE bit. This bit field monitors the internal reset status.

16.2.3.3 GP Timer Interrupts

Table 16-7 lists the interrupt mapping from the 12 GP timers to the three internal processors.

Table 16-7. Timer Interrupt Names and Processor IRQ Mapping

Timer	Interrupt Name	Mapping	Comments
GPTIMER1	GPT1_IRQ	M_IRQ_37	GPTIMER1 interrupt to MPU
GPTIMER2	GPT2_IRQ	M_IRQ_38	GPTIMER2 interrupt to MPU
GPTIMER3	GPT3_IRQ	M_IRQ_39	GPTIMER3 interrupt to MPU
GPTIMER4	GPT4_IRQ	M_IRQ_40	GPTIMER4 interrupt to MPU
GPTIMER5	GPT5_IRQ	M_IRQ_41	GPTIMER5 interrupt to MPU
		IVA2_IRQ[6]	GPTIMER5 interrupt to IVA2.2
GPTIMER6	GPT6_IRQ	M_IRQ_42	GPTIMER6 interrupt to MPU
		IVA2_IRQ[7]	GPTIMER6 interrupt to IVA2.2
GPTIMER7	GPT7_IRQ	M_IRQ_43	GPTIMER7 interrupt to MPU
		IVA2_IRQ[8]	GPTIMER7 interrupt to IVA2.2
GPTIMER8	GPT8_IRQ	M_IRQ_44	GPTIMER8 interrupt to MPU
		IVA2_IRQ[9]	GPTIMER8 interrupt to IVA2.2
GPTIMER9	GPT9_IRQ	M_IRQ_45	GPTIMER9 interrupt to MPU
GPTIMER10	GPT10_IRQ	M_IRQ_46	GPTIMER10 interrupt to MPU
GPTIMER11	GPT11_IRQ	M_IRQ_47	GPTIMER11 interrupt to MPU
GPTIMER12	GPT12_IRQ	M_IRQ_95	GPTIMER12 interrupt to MPU

The timer can issue an overflow interrupt, a timer match interrupt, and a timer capture interrupt. Each internal interrupt source can be independently enabled/disabled in the interrupt enable register (GPTi.TIER). When the interrupt event is issued, the associated interrupt status bit is set in the timer status register (GPTi.TISR). The pending interrupt event is reset when the set status bit is overwritten by a1.

16.2.4 GP Timers Functional Description

Each GP timer contains a free-running upward counter with autoreload capability on overflow. The timer counter can be read and written on-the-fly (while counting). Each GP timer includes compare logic to allow an interrupt event on a programmable counter matching value. A dedicated output signal can be pulsed or toggled on either an overflow or a match event. This offers time-stamp trigger signaling or PWM signal sources. A dedicated input signal can be used to trigger an automatic timer counter capture or an interrupt event on a programmable input signal transition type. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged into one module interrupt line and one wake-up line. Each internal interrupt source can be independently enabled/disabled with a dedicated bit of the GPTi.TIER register for the interrupt features and a dedicated bit of the GPTi.TWER register for the wakeup. In addition, GPTIMER1, GPTIMER2, and GPTIMER10 have implemented a mechanism to generate an accurate tick interrupt.

For each GP timer implemented in the device, there are two possible clock sources:

- 32-kHz clock
- System clock

Selection of the input clock source is done in the registers in the PRCM configuration (see [Section 16.2.1, GP Timer Overview](#)).

Each GP timer supports three functional modes:

- Timer mode
- Capture mode
- Compare mode

By default, after core reset, the capture and compare modes are disabled.

16.2.4.1 GP Timers Block Diagram

Figure 16-6 shows the block diagram of common GP timers, and Figure 16-7 shows the block diagram of GP timers with 1-ms tick generation module.

Figure 16-6. Block Diagram of GPTIMER3 through GPTIMER9, GPTIMER11, and GPTIMER12

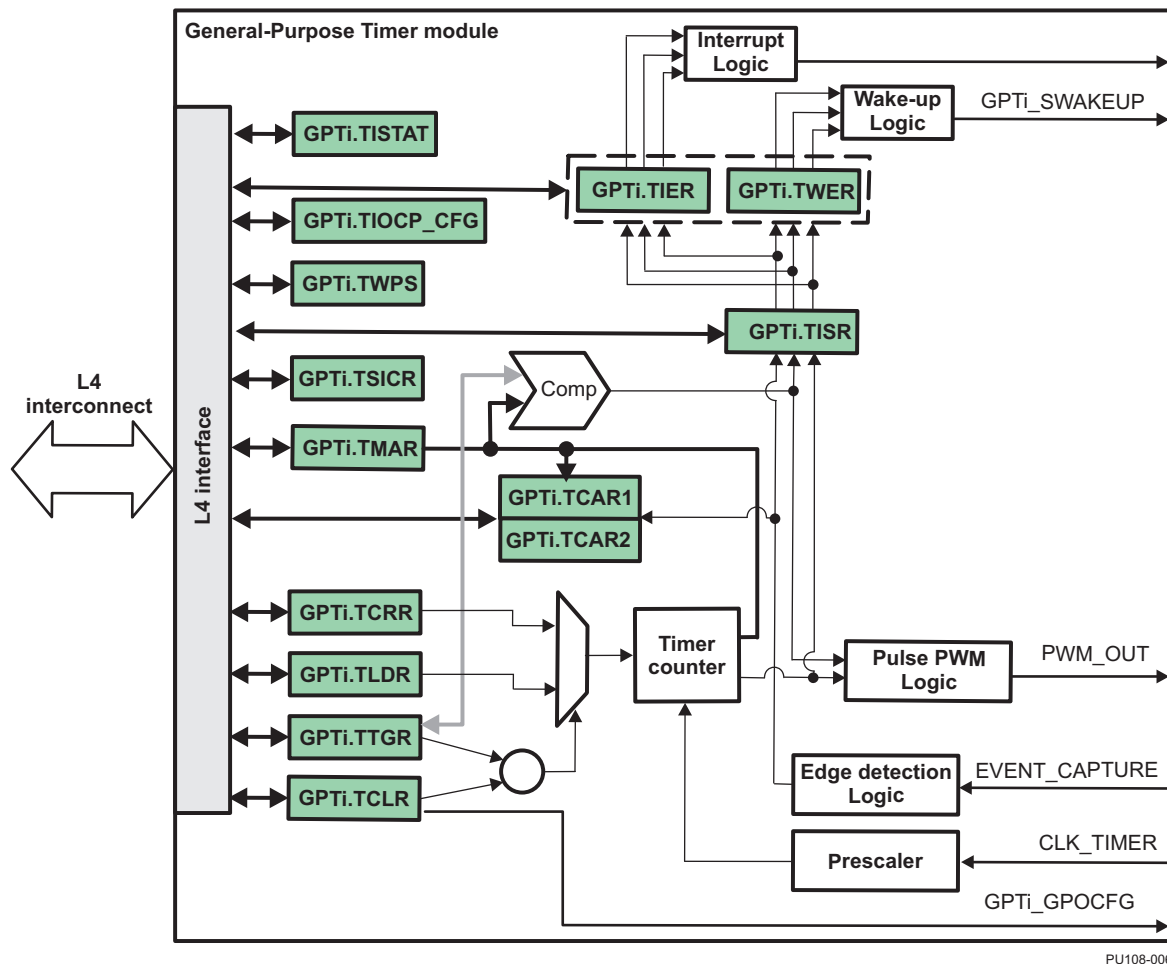

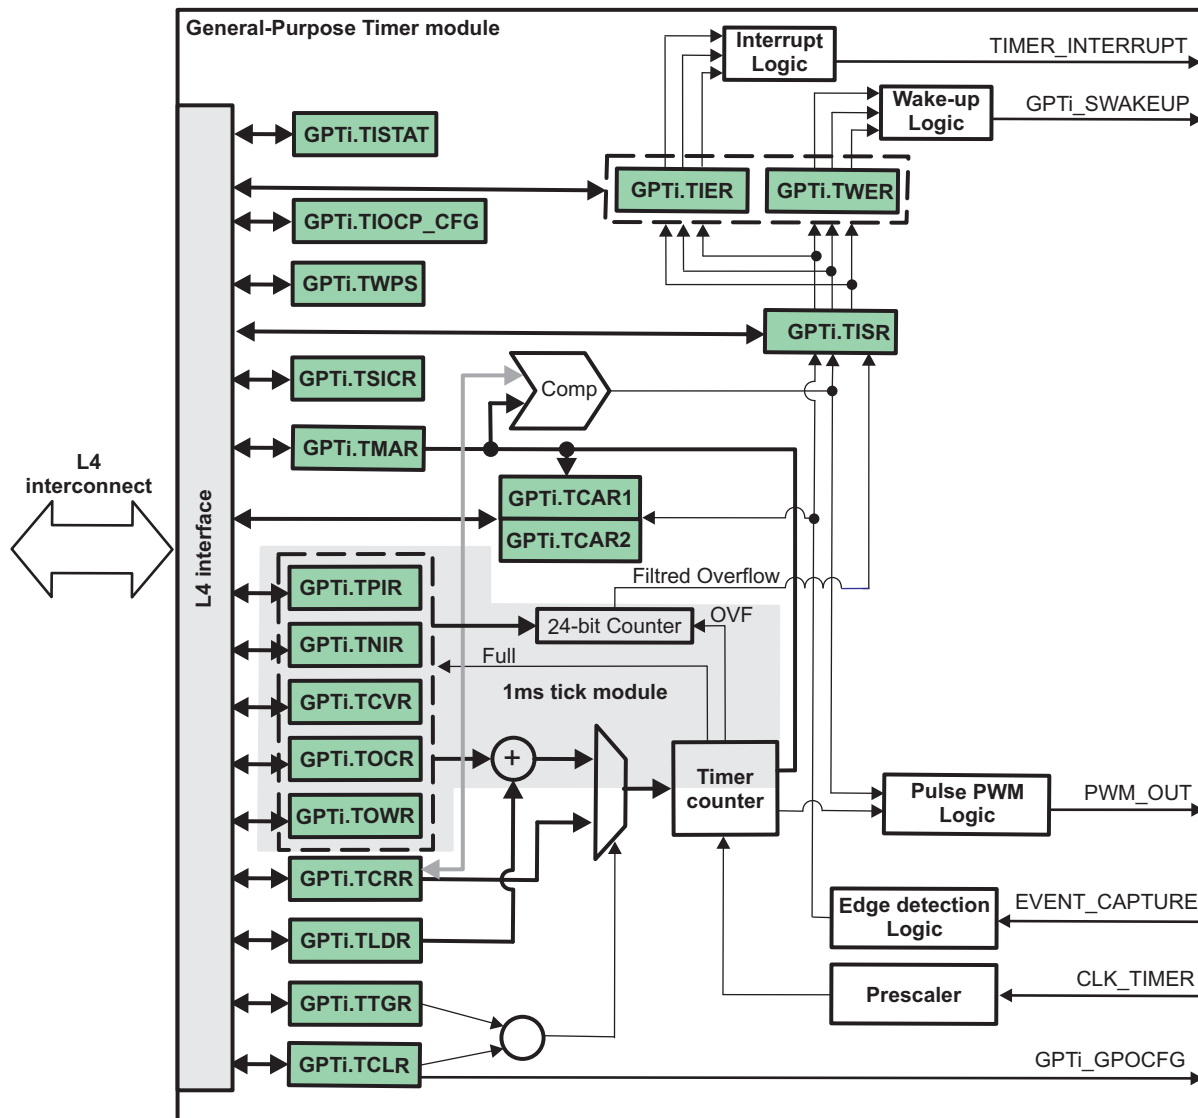

Figure 16-7. Block Diagram of GPTIMER1, GPTIMER2, and GPTIMER10

PU108-007

16.2.4.2 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the timer control register (GPTi.TCLR[0] ST bit). The timer counter register (GPTi.TCRR) can be loaded when stopped or on-the-fly (while counting). GPTi.TCRR can be loaded directly by a GPTi.TCRR write access with a new timer value. The GPTi.TCRR register can also be loaded with the value held in the timer load register GPTi.TLDR by a trigger register (GPTi.TTGR) write access. The GPTi.TCRR loading is done regardless of the GPTi.TTGR written value. The timer counter register GPTi.TCRR value can be read when stopped or captured on-the-fly by a GPTi.TCRR read access. The timer is stopped and the counter value is set to 0 when the module reset is asserted. The timer is maintained at stop after the reset is released.

In one-shot mode (the GPTi.TCLR[1] AR bit set to 0), the counter is stopped after counting overflow occurs (the counter value remains at 0).

When the autoreload mode is enabled (the GPTi.TCLR[1] AR bit set to 1), the GPTi.TCRR register is reloaded with the timer load register (GPTi.TLDR) value after a counting overflow occurs.

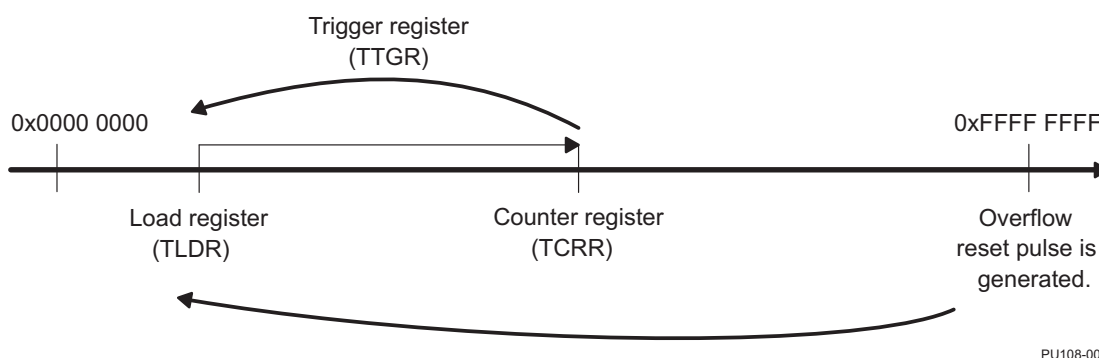

CAUTION

Do not put the overflow value (0xFFFFFFFF) in the GPTi.TLDR register because it can lead to undesired results.

An interrupt can be issued on overflow if the overflow interrupt enable bit is set in the timer interrupt enable register (GPTi.TIER[1] OVF_IT_ENA bit set to 1), the interrupt is enabled after $10 * \text{GPTi.ICLK}$ clock cycles. A dedicated output pin (timer PWM) can be programmed in GPTi.TCLR[12] through GPTi.TCLR[11:10] (PT and TRG bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs. The GPTi.TCLR[12] PT bit selects pulse/toggle modulation (GPTi.TCLR[11:10] TRG bit field select trigger mode).

Figure 16-8 shows the GPTi.TCRR timing value.

Figure 16-8. GPTi.TCRR Timing Value

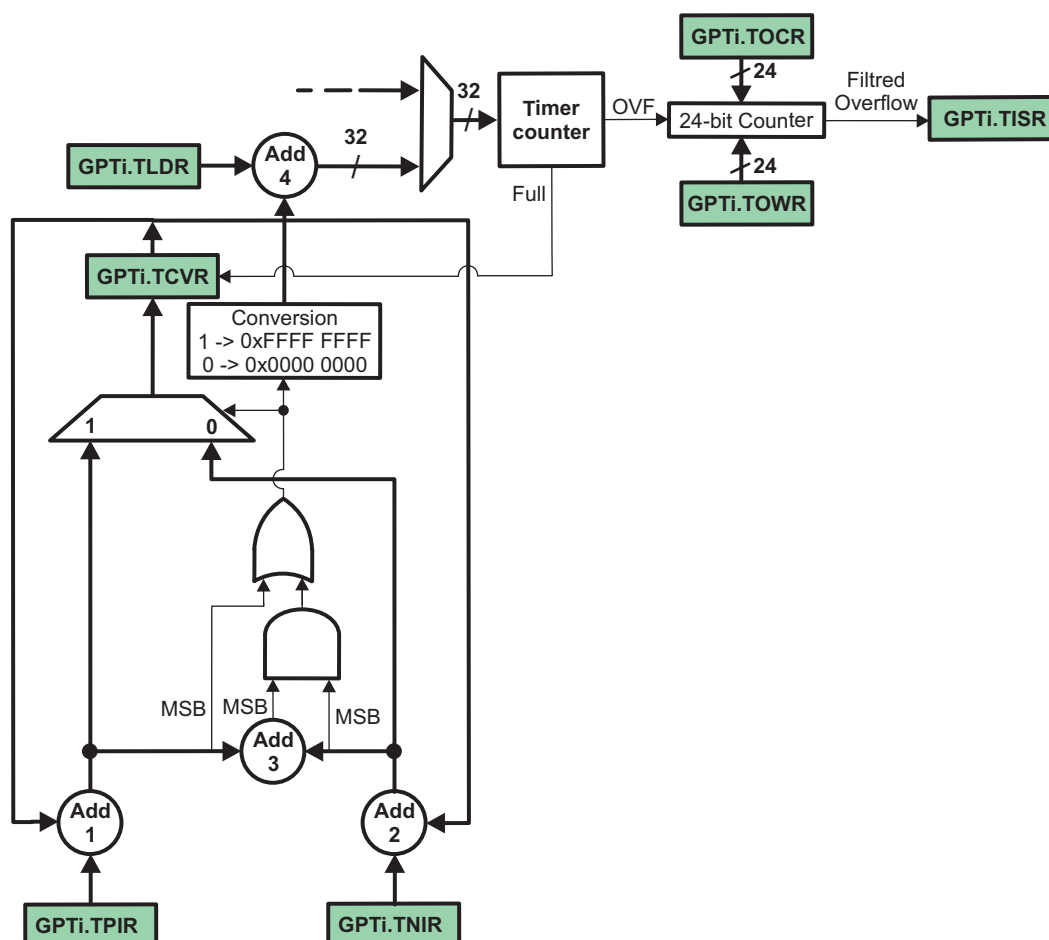

16.2.4.2.1 1-ms Tick Generation (Only GPTIMER1, GPTIMER2, and GPTIMER10)

Because the timer input clock is 32,768 Hz, the interrupt period is not exactly 1 ms. If the clock counts up to 32, it obtains a 0.977-ms period; if it counts up to 33, it obtains a 1.007-ms period. For large granularity, the error is cumulative and can generate important deviations to the standard value.

To minimize the error between a true 1-ms tick and the tick generated by the 32,768 Hz timer, the sequencing of periods less than 1 ms and periods greater than 1 ms must be shuffled. An additional 1-ms block is used to correct this error. Refer to Figure 16-9.

In this implementation, the increment sequencing is automatically managed by the timer to minimize the error. The user must define only the value of the timer positive increment register (GPTi.TPIR[31:0] POSITIVE_INC_VALUE bit field) and the timer negative increment register (GPTi.TNIR[31:0] NEGATIVE_INC_VALUE bit field). An automatic adaptation mechanism is used to simplify the programming model.

Figure 16-9. Block Diagram of the 1-ms Tick Module

PU108-009

The GPTi.TPIR, GPTi.TNIR, and GPTi.TCVR registers and adders Add1, Add2, and Add3 are used to define whether the next value loaded in the timer counter register (GPTi.TCRR[31:0] TIMER_COUNTER bit field) is the value of the GPTi.TLDR[31:0] LOAD_VALUE bit field (period less than 1 ms) or the value of GPTi.TLDR[31:0] LOAD_VALUE - 1 (period greater than 1 ms).

Table 16-8 lists the value loaded in the GPTi.TCRR register according to the sign of the result of Add1, Add2, and Add3.

MSB = 0: Positive value, MSB = 1: Negative value

Table 16-8. Value Loaded in GPTi.TCRR to Generate 1-ms Tick

Add1 MSB	Add2 MSB	Add3 MSB	Value of GPTi.TCRR Register
0	0	0	GPTi.TLDR[31:0] LOAD_VALUE bit field
0	0	1	GPTi.TLDR[31:0] LOAD_VALUE bit field
0	1	0	GPTi.TLDR[31:0] LOAD_VALUE bit field
0	1	1	GPTi.TLDR[31:0] LOAD_VALUE - 1
1	0	0	N/A
1	0	1	N/A
1	1	0	GPTi.TLDR[31:0] LOAD_VALUE - 1
1	1	1	GPTi.TLDR[31:0] LOAD_VALUE - 1

The values of the GPTi.TPIR and GPTi.TNIR registers are calculated using the following formula:

- Positive increment value = $(\text{INTEGER}[\text{Fclk} * \text{Ttick}] + 1) * 1\text{e}6 - (\text{Fclk} * \text{Ttick} * 1\text{e}6)$
- Negative increment value = $(\text{INTEGER}[\text{Fclk} * \text{Ttick}] * 1\text{e}6) - (\text{Fclk} * \text{Ttick} * 1\text{e}6)$

Note: Fclk clock frequency (kHz)

Ttick tick period (ms)

The timer overflow counter register (GPTi.TOCR) and the timer overflow wrapping register (GPTi.TOWR) are used to filter interrupts. When the timer overflows, it increments the 24-bit TOCR register. When the 24-bit TOCR register values match the value in the 24-bit TOWR register and the timer overflow is asserted, the TOCR register is reset and an interrupt is generated to the TISR register.

With the conversion block in reset state (the positive increment register, negative increment register, and counter value register are zeroed), the programming model and the behavior of GPTIMER1, GPTIMER2, and GPTIMER10 remain unchanged.

For 1-ms tick with a 32,768-Hz clock:

- GPTi.TPIR[31:0] POSITIVE_INC_VALUE = 232000
- GPTi.TNIR[31:0] NEGATIVE_INC_VALUE = -768000
- GPTi.TLDR[31:0] LOAD_VALUE = 0xFFFFFEE0

Note: Any value of the tick period can be generated with the appropriate value of the GPTi.TPIR, GPTi.TNIR, and GPTi.TLDR registers.

By default, the GPTi.TPIR, GPTi.TNIR, GPTi.TCVR, GPTi.TOCR, and GPTi.TOWR registers and the associated logic are in reset mode (all 0s) and have no action on the programming model.

16.2.4.3 Capture Mode Functionality

When a transition is detected on the module input pin (EVENT_CAPTURE), the timer value in the GPTi.TCRR register can be captured and saved in the GPTi.TCAR1 or GPTi.TCAR2 register function of the mode selected in the GPTi.TCLR[13] CAPT_MODE bit. The edge detection circuitry monitors transitions on the input pin (EVENT_CAPTURE).

The rising edge, falling edge, or both, can be selected in the GPTi.TCLR[9:8] TCM field to trigger the timer counter capture. The module sets the GPTi.TISR[2] TCAR_IT_FLAG bit when an active edge is detected, and at the same time, the counter value GPTi.TCRR is stored in timer capture register GPTi.TCAR1 or GPTi.TCAR2, as follows:

- If the GPTi.TCLR[13] CAPT_MODE bit is 0, then on the first enabled capture event the value of the counter register is saved in the GPTi.TCAR1 register, and all the next events are ignored (no update on the GPTi.TCAR1 register and no interrupt triggering) until the detection logic is reset or the GPTi.TISR[2] TCAR_IT_FLAG bit is cleared by writing 1 in it.
- If the GPTi.TCLR[13] CAPT_MODE bit is 1, then on the first enabled capture event the value of the counter register is saved in the GPTi.TCAR1 register, and on the second enabled capture event, the value of the counter register is saved in the GPTi.TCAR2 register. If a capture interrupt is enabled, the interrupt triggers on the second event capture. All other events are ignored (no update on GPTi.TCAR1/GPTi.TCAR2 and no interrupt triggering) until the detection logic is reset or GPTi.TISR[2] TCAR_IT_FLAG bit is cleared by writing 1 in it. This mechanism is useful for period calculation of a clock, if that clock is connected to the EVENT_CAPTURE input pin.

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served the GPTi.TISR[2] TCAR_IT_FLAG bit (previously 1) is cleared by writing 1 to it or when the edge detection mode bits (the GPTi.TCLR[9:8] TCM field) are changed from no-capture mode detection to any other mode. The timer functional clock (input to prescaler) is used to sample the input pin (EVENT_CAPTURE). An input negative or positive pulse can be detected when the pulse time is greater than the functional clock period. An interrupt is issued on edge detection if the capture interrupt enable bit is set in the GPTi.TIER[2] TCAR_IT_ENA bit. See the examples in Figure 16-10 and Figure 16-11.

In Figure 16-10, the GPTi.TCLR[9:8] TCM value is 0b01, and GPTi.TCLR[13] CAPT_MODE is 0. Only the rising edge of EVENT_CAPTURE triggers a capture in the GPTi.TCAR1 and GPTi.TCAR2 registers, and only the GPTi.TCAR1 register updates.

Figure 16-10. Capture Wave Example for GPTi.TCLR[13] CAPT_MODE = 0

PU108-010

In Figure 16-11, the GPTi.TCLR[9:8] TCM value is 0b01, and GPTi.TCLR[13] CAPT_MODE is 1. Only the rising edge of EVENT_CAPTURE triggers a capture in the GPTi.TCAR1 register on the first enabled event, and the GPTi.TCAR2 register updates on the second enabled event.

Figure 16-11. Capture Wave Example for GPTi.TCLR[13] CAPT_MODE = 1

PU108-011

16.2.4.4 Compare Mode Functionality

When the compare enable register GPTi.TCLR[6] CE bit is set to 1, the timer value (GPTi.TCRR[31:0] TIMER_COUNTER field) is continuously compared to the value held in the timer match register (GPTi.TMAR). The GPTi.TMAR[31:0] COMPARE_VALUE value can be loaded at any time (timer counting or stopped). When the GPTi.TCRR and the GPTi.TMAR values match, an interrupt is issued, if the GPTi.TIER[0] MAT_IT_ENA bit is set.

The dedicated output pin (timer PWM) can be programmed in the GPTi.TCLR[12] PT bit through the GPTi.TCLR[11:10] TRG field to generate one positive pulse (timer clock duration) or to invert the current value (toggle mode) when an overflow or a match occurs.

16.2.4.5 Prescaler Functionality

A prescaler can be used to divide the timer counter input clock frequency. The prescaler is enabled when the GPTi.TCLR[5] PRE bit is set. The GPTi.TCLR[4:2] PTV field sets the second prescaler ratio. The prescaler counter is reset when the timer counter is stopped or reloaded on-the-fly.

Table 16-9 lists the prescaler/timer reload values versus contexts.

Table 16-9. Prescaler/Timer Reload Values Versus Contexts

Context	Prescaler	Timer Counter
Overflow (when autoreload is on)	Reset	GPTi.TLDR[31:0]
TCCR write	Reset	GPTi.TCCR[31:0]
TTGR write	Reset	GPTi.TLDR[31:0]
Stop	Reset	Frozen

16.2.4.6 Pulse-Width Modulation

The timer can be configured to provide a programmable PWM output. The timer PWM output pin can be configured to toggle on an event. The GPTi.TCLR[11:10] TRG field determines on which register value the PWM pin toggles. Either overflow alone or both overflow and match can be selected to toggle the timer PWM pin when a compare condition occurs.

CAUTION

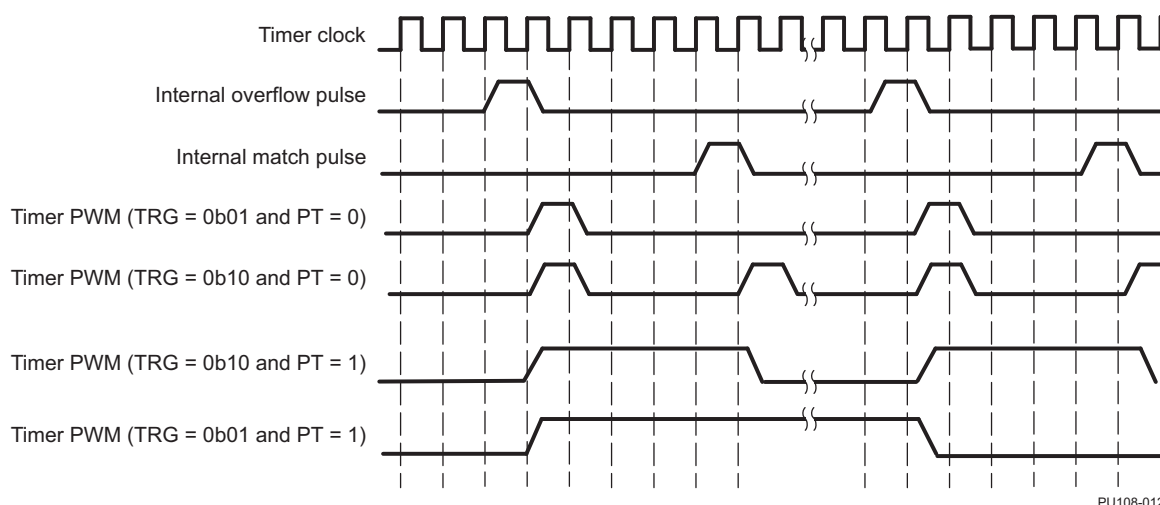

In toggle mode when GPTi.TCLR[11:10] TRG = 0x2 (overflow and match), the first event that will toggle the PWM line is an overflow event. If a match event occurs first, it will not toggle the PWM line. Figure 16-13 illustrates those.

The GPTi.TCLR[7] SCPWM bit can be programmed to set or clear the timer PWM output signal only while the counter is stopped or the trigger is off. This allows setting the output pin to a known state before modulation starts. Modulation synchronously stops when the GPTi.TCLR[11:10] TRG field is cleared and overflow occurs. This allows fixing a deterministic state of the output pin when modulation stops.

In Figure 16-12, the internal overflow pulse is set each time (0xFFFF FFFF - GPTi.TLDR[31:0] LOAD_VALUE + 1) the value is reached, and the internal match pulse is set when the counter reaches the GPTi.TMAR register value. According to the value of the GPTi.TCLR[12] PT and GPTi.TCLR[11:10] TRG bits, the timer provides pulse or PWM event on the output pin (timer PWM).

The GPTi.TLDR and GPTi.TMAR registers must keep values smaller than the overflow value (0xFFFF FFFF) by at least two units. In case the PWM trigger events are both overflow and match, the difference between the values kept in the GPTi.TMAR register and the value in the GPTi.TLDR register must be at least two units. When match event is used, the compare mode GPTi.TCLR[6] CE bit must be set.

In Figure 16-12, the GPTi.TCLR[7] SCPWM bit is set to 0. In Figure 16-13, the GPTi.TCLR[7] SCPWM bit is set to 1. To obtain the desired wave form, start the counter at 0xFFFF FFFE value (to ensure an overflow first) or adjust the line polarity (GPTi.TCLR[7] SCPWM bit).

Figure 16-12. Timing Diagram of PWM with GPTi.TCLR[7] SCPWM Bit = 0

Figure 16-13. Timing Diagram of PWM with GPTi.TCLR[7] SCPWM Bit = 1

16.2.4.7 Timer Counting Rate

The timer rate is defined by the following values:

- Value of the prescaler fields (GPTi.TCLR[5] PRE bit and GPTi.TCLR[4:2] PTV field)
- Value loaded into the timer load register (GPTi.TLDR)

Table 16-10 lists prescaler clock ratio values.

Table 16-10. Prescaler Clock Ratio Values

GPTi.TCLR[5] PRE	GPTi.TCLR[4:2] PTV	Divisor (PS)
0	X	1
1	0	2
1	1	4
1	2	8
1	3	16
1	4	32

Table 16-10. Prescaler Clock Ratio Values (continued)

GPTi.TCLR[5] PRE	GPTi.TCLR[4:2] PTV	Divisor (PS)
1	5	64
1	6	128
1	7	256

Thus, the timer overflow-rate is expressed as:

$$\text{OVF_Rate} = (\text{0xFFFF FFFF} - \text{GPTn.TLDR} + 1) * (\text{timer-functional clock period}) * \text{PS}$$

With (timer-functional clock period) = 1 / (timer-functional clock frequency) and PS = $2^{(\text{PTV} + 1)}$ if prescaler is enabled, or PS = 1 if prescaler is disabled.

CAUTION

Internal resynchronization causes any write to the GPTn.TCLR[1] ST bit to have some latency before the register is updated:

2.5 * functional clock cycles write_GPTn.TCLR_latency 3.5 * functional clock cycles

Remember to take this latency into account whenever the timer must be started or stopped by a software change to the GPTn.TCLR[1] ST bit.

CAUTION

- In the non-PWM mode, GTPi.TLDR must be maintained at less than or equal to 0xFFFF FFFE.
- In the PWM mode, GTPi.TLDR must be maintained at less than or equal to 0xFFFF FFED.

For example, with a timer clock input of 32 kHz and a GPTn.TCLR[5] PRE field equal to 0, the timer output period is as listed in [Table 16-11](#).

Table 16-11. Value and Corresponding Interrupt Period

GPTi.TLDR[31:0] LOAD_VALUE	Interrupt Period
0x0000 0000	39 h
0xFFFF 0000	2.1 s
0xFFFF FFF0	524 μs
0xFFFF FFFE	65.5 μs

16.2.5 Timer Under Emulation

During emulation mode, the timer continues to run according to the value of the GPTi.TIOCP_CFG[5] EMUFREE bit.

If the GPTi.TIOCP_CFG[5] EMUFREE bit is set to 1, timer execution is not stopped in emulation mode and the interrupt is still generated when overflow or match is reached.

If the GPTi.TIOCP_CFG[5] EMUFREE bit is set to 0, the prescaler and timer are frozen and both resume on exit from emulation mode. The asynchronous external input pin (gpti_pwm_evt, with i=[9:12]) is internally synchronized on two timer-clock rising edges.

16.2.6 Accessing GP Timer Registers

All accesses are nonposted until software reconfiguration.

All registers are 32 bits wide, accessible through the L4 interface with 16-bit or 32-bit access (read/write).

Any 16-bit write access must be least-significant bit (LSB) first, and the second write access must be most-significant bit (MSB). Write operations to the GP timer registers (GPTi.TIOCP_CFG, GPTi.TISR, GPTi.TIER, GPTi.TWER, and GPTi.TSICR) can skip the MSB access if it is not necessary to update the 16 MSBs of the register.

Write operations to any functional register (GPTi.TCLR, GPTi.TCRR, GPTi.TLDR, GPTi.TTGR, and GPTi.TMAR, and GPTi.TPIR, GPTi.TNIR, GPTi.TCVR, GPTi.TOCR, and GPTi.TOWR for GPTIMER1, GPTIMER2, and GPTIMER10) must be complete (the MSB must be written even if the MSB data is not used).

16.2.6.1 Writing to Timer Registers

The host uses the L4 interface to write the following registers synchronously with the timer interface clock:

- GPTi.TLDR
- GPTi.TCRR
- GPTi.TIER
- GPTi.TISR
- GPTi.TCLR
- GPTi.TIOCP_CFG
- GPTi.TWER
- GPTi.TTGR
- GPTi.TSICR
- GPTi.TMAR

GPTIMER1, GPTIMER2, and GPTIMER10 also have the following registers:

- GPTi.TPIR
- GPTi.TNIR
- GPTi.TCVR
- GPTi.TOCR
- GPTi.TOWR

In 16-bit access mode, the 16 LSBs must be written before writing to the 16 MSBs.

16.2.6.1.1 Write Posting Synchronization Mode

This mode is used if the GPTi.TSICR[2] POSTED bit is set to 1.

This mode uses a posted write scheme to update any internal register (GPTi.TCLR, GPTi.TCRR, GPTi.TLDR, GPTi.TTGR, GPTi.TMAR, and GPTi.TPIR, GPTi.TNIR, GPTi.TCVR, GPTi.TOCR, and GPTi.TOWR for GPTIMER1, GPTIMER2, and GPTIMER10). Therefore, the write transaction is immediately acknowledged on the L4 interface, although the effective write operation occurs later, because of a resynchronization in the timer clock domain. The advantage is that neither the interconnect nor the device that requested the write transaction is stalled.

For each register, a status bit is provided in the timer write-posted status register GPTi.TWPS. In this mode, it is mandatory that the software checks this status bit prior to any write access. In case a write is attempted to a register with a previous access pending, the previous access is discarded without notice.

The timer module updates the timer counter register value synchronously with the L4 clock. Consequently, any read access to the timer counter register GPTi.TCRR does not add any resynchronization latency; the current value is always available.

If a write access is pending for a register, reading from this register does not yield a correct result. Software synchronization must be used to avoid incorrect results.

The drawback of this automatic update mechanism is that it assumes a given relationship between the timer interface frequency and the timer clock frequency.

Functional frequency range: $\text{freq}(\text{timer clock}) < \text{freq}(\text{L4 interface clock})/4$

16.2.6.1.2 Write Nonposting Synchronization Mode

This mode is used if the GPTi.TSICR[2] POSTED bit is set to 0.

This mode uses a nonposted write scheme to update any internal register. Therefore, the write transaction is not acknowledged on the L4 interface until the effective write operation occurs after the resynchronization in the timer functional clock domain. The drawback is that both the interconnect and the device that requested the write transaction are stalled during this period.

The same full resynchronization scheme is used for a read transaction, and the same stall period applies. A register read following a write to the same register is always coherent.

This mode is functional regardless of the ratio between the L4 interface frequency and the timer clock frequency.

16.2.6.2 Reading from Timer Counter Registers

In 16-bit access mode, reading the 16 LSBs from the timer counter registers (GPTi.TCRR, GPTi.TCAR1, and GPTi.TCAR2) captures the current timer counter value. This must be followed by reading the 16MSBs.

IVA2.2 subsystem 16-bit accesses can be interleaved with MPU subsystem 32-bit accesses.

Note: LSB/MSB accesses cannot be interleaved (that is, the sequence LSB register 1, LSB register 2, MSB register 1, MSB register 2 is not supported).

16.3 General-Purpose (GP) Timer Registers

Table 16-12 lists the base address and block size for the GP timer module instances. All timers are memory mapped to the L4 peripheral bus memory space.

Table 16-12. GP Timer Instance Summary

Module Name	Base Address	Size
GPTIMER1	0x4831 8000	4K bytes
GPTIMER2	0x4903 2000	4K bytes
GPTIMER3	0x4903 4000	4K bytes
GPTIMER4	0x4903 6000	4K bytes
GPTIMER5	0x4903 8000	4K bytes
GPTIMER6	0x4903 A000	4K bytes
GPTIMER7	0x4903 C000	4K bytes
GPTIMER8	0x4903 E000	4K bytes
GPTIMER9	0x4904 0000	4K bytes
GPTIMER10	0x4808 6000	4K bytes
GPTIMER11	0x4808 8000	4K bytes
GPTIMER12	0x4830 4000	4K bytes

16.3.1 GP Timer Register Mapping Summary

CAUTION

The GP timer registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

Table 16-13 through Table 16-15 provide the register summary and associated offset addresses for the 12 GP timer internal registers. (Example: The physical address for the **TCLR** register of GPTIMER8 is 0x4903 E024.)

Table 16-13. GPTIMER1 to GPTIMER4 Register Summary

16.3.2 GP Timer Register Descriptions

Table 16-16 through Table 16-52 describe the GP timer register bits.

16.3.2.1 TIOCP_CFG

Address Offset	0x010		
Physical Address	0x4831 8010	Instance	GPT1
	0x4903 2010		GPT2
	0x4903 4010		GPT3
	0x4903 6010		GPT4
	0x4903 8010		GPT5
	0x4903 A010		GPT6
	0x4903 C010		GPT7
	0x4903 E010		GPT8
	0x4904 0010		GPT9
	0x4808 6010		GPT10
	0x4808 8010		GPT11
	0x4830 4010		GPT12
Description	This register controls the various parameters of the GP timer L4 interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
Reserved																						CLOCKACTIVITY	Reserved								EMUFREE	IDLEMODE	ENAWAKEUP	SOFTRESET	AUTOIDLE

Bits	Field Name	DESCRIPTION	Type	Reset
31:10	Reserved	Write 0s for future compatibility. Reads return 0.	R	0x0000000
9:8	CLOCKACTIVITY	Clock activity during wakeup mode period: 0x0: L4 interface and Functional clocks can be switched off. 0x1: L4 interface clock is maintained during wake-up period; Functional clock can be switched off. 0x2: L4 interface clock can be switched off; Functional clock is maintained during wake-up period. 0x3: L4 interface and Functional clocks are maintained during wake-up period.	RW	0x0
7:6	Reserved	Write 0s for future compatibility. Reads return 0.	R	0x0
5	EMUFREE	Emulation mode 0x0: Timer counter frozen in emulation 0x1: Timer counter free-running in emulation	RW	0
4:3	IDLEMODE	Power management, req/ack control 0x0: Force-idle. An idle request is acknowledged unconditionally. 0x1: No-idle. An idle request is never acknowledged. 0x2: Smart-idle. Acknowledgement to an idle request is given based on the internal activity of the module. 0x3: Reserved. Do not use.	RW	0x0
2	ENAWAKEUP	Wake-up feature global control 0x0: No wake-up line assertion in idle mode 0x1: Wake-up line assertion enabled in smart-idle mode	RW	0
1	SOFTRESET	Software reset. This bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: Normal mode	RW	0

Bits	Field Name	DESCRIPTION	Type	Reset
		0x1: The module is reset.		
0	AUTOIDLE	Internal L4 interface clock gating strategy		0
		0x0: L4 interface clock is free-running.		
		0x1: Automatic L4 interface clock gating strategy is applied, based on the L4 interface activity.

	0x4808 6024																GPT10															
	0x4808 8024																GPT11															
	0x4830 4024																GPT12															
Description	This register controls optional features specific to the timer functionality.																															
Type	RW																															
<div><div><div>313029282726252423222120191817161514131211109876543210</div><div><div>Reserved</div><div>GPO_CFG</div><div>CAPT_MODE</div><div>PT</div><div>TRG</div><div>TCM</div><div>SCPWM</div><div>CE</div><div>PRE</div><div>PTV</div><div>AR</div><div>ST</div></div></div></div>																																
Bits	Field Name		Description																Type				Reset									
31:15	Reserved		Reads return 0.																R				0x00000									
14	GPO_CFG		PWM output/event detection input pin direction control: 0x0: Configures the pin as an output (needed when PWM mode is required) 0x1: Configures the pin as an input (needed when capture mode is required)																RW				0									
13	CAPT_MODE		Capture mode select bit (first/second) 0x0: Capture the first enabled capture event in TCAR1 . 0x1: Capture the second enabled capture event in TCAR2 .																RW				0									
12	PT		Pulse or toggle select bit 0x0: Pulse modulation 0x1: Toggle modulation																RW				0									
11:10	TRG		Trigger output mode 0x0: No triaquer																RW				0x0									

Bits	Field Name	Description	Type	Reset
		0x1: Overflow trigger		
		0x2: Overflow and match trigger		
		0x3: Reserved		
9:8	TCM	Transition capture mode	RW	0x0
		0x0: No capture		
		0x1: Capture on rising edges of EVENT_CAPTURE pin.		
		0x2: Capture on falling edges of EVENT_CAPTURE pin.		
		0x3: Capture on both edges of EVENT_CAPTURE pin.		
7	SCPWM	Pulse-width-modulation output pin default setting when counter is stopped or trigger output mode is set to no trigger.	RW	0
		0x0: Default value of PWM_out output: 0		
		0x1: Default value of PWM_out output: 1		
6	CE	Compare enable	RW	0
		0x0: Compare disabled		
		0x1: Compare enabled		
5	PRE	Prescaler enable	RW	0
		0x0: Prescaler disabled		
		0x1: Prescaler enabled		
4:2	PTV	Trigger output mode		
		0x0: The timer counter is prescaled with the value: $2^{(PTV+1)}$. Example: PTV = 3, counter increases value (if started) after 16 functional clock periods.	RW	0x0
1	AR	Autoreload mode	RW	0
		0x0: One-shot mode overflow		
		0x1: Autoreload mode overflow		
0	ST	Start/stop timer control	RW	0
		0x0: Stop the timer		
		0x1: Start the timer

16.4 Watchdog Timers

16.4.1 WDTs Overview

The device includes three instances of the 32-bit WDT: WDT1 through WDT3. [Figure 16-14](#) shows how each timer is connected in the device.

Note: WDT_i (where *i* is the watchdog timer instance: *i* = 1, 2, or 3) stands for the following:

- WDT1: Watchdog timer 1, also called secure watchdog timer
 - WDT2: Watchdog timer 2, also called MPU watchdog timer
 - WDT3: Watchdog timer 3, also called IVA2 watchdog timer
-

Each WDT is an upward counter capable of generating both a pulse on the reset pin and an interrupt to the device system modules following an overflow condition. The secure WDT and MPU WDT serve resets to the PRCM module (their interrupt outputs are unused), and the IVA2 WDT serves watchdog interrupts to the MPU (its reset outputs are unused).

The WDTs can be accessed, loaded, and cleared by registers through the L4 interface. The MPU and IVA2 WDTs have the 32-kHz clock for their timer clock input, whereas the secure WDT uses the internal 32-kHz oscillator.

The secure WDT and MPU WDT directly generate a warm reset condition on overflow. The IVA2 WDT generates an MPU interrupt condition on overflow, which can be used by the application software via the PRCM to indirectly trigger a reset condition (that is, to the IVA2 subsystem).

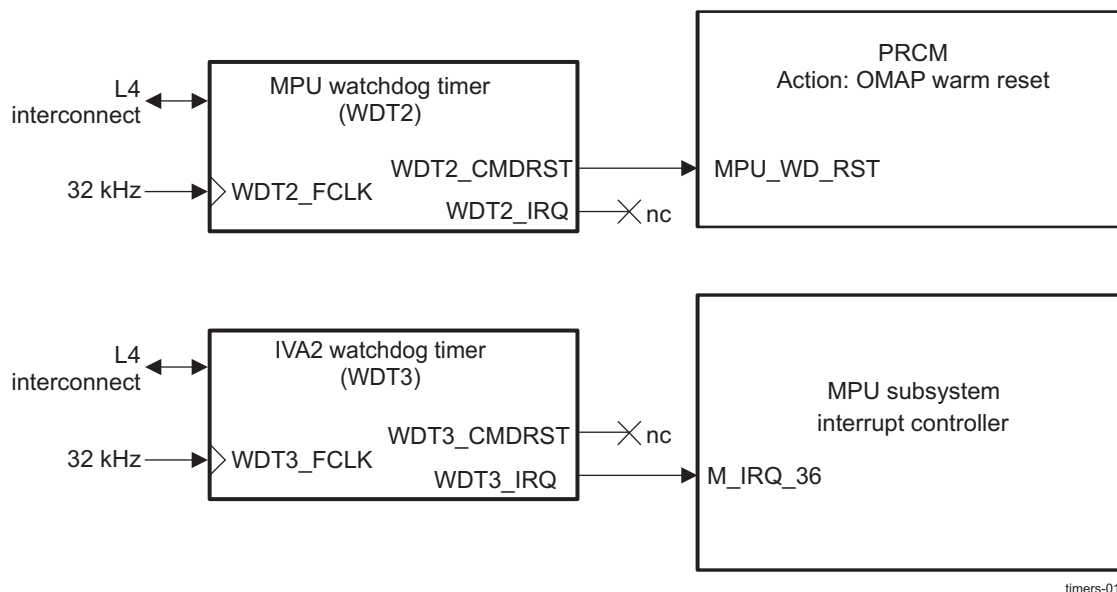

The secure WDT and MPU WDT connect to a single target agent port on the L4 interconnect.

For more information on WDT1 as it applies to high-security (HS) devices refer to your device-specific data manual. Note that a HS version of your device may not be available.

Table 16-54. WD Timers Default State for GP, EMU and HS Device

Timer	Device					
	HS		EMU		GP	
Secure WDTIMER1	Enabled	Running	Disabled		Disabled (permanently, no access)	
MPU WDTIMER2	Enabled	Running	Enabled	Running	Enabled	Running
IVA2 WDTIMER3	Enabled	NOT Running	Enabled	NOT Running	Enabled	NOT Running

Figure 16-14. WDTs Block Diagram

16.4.1.1 WDT Features

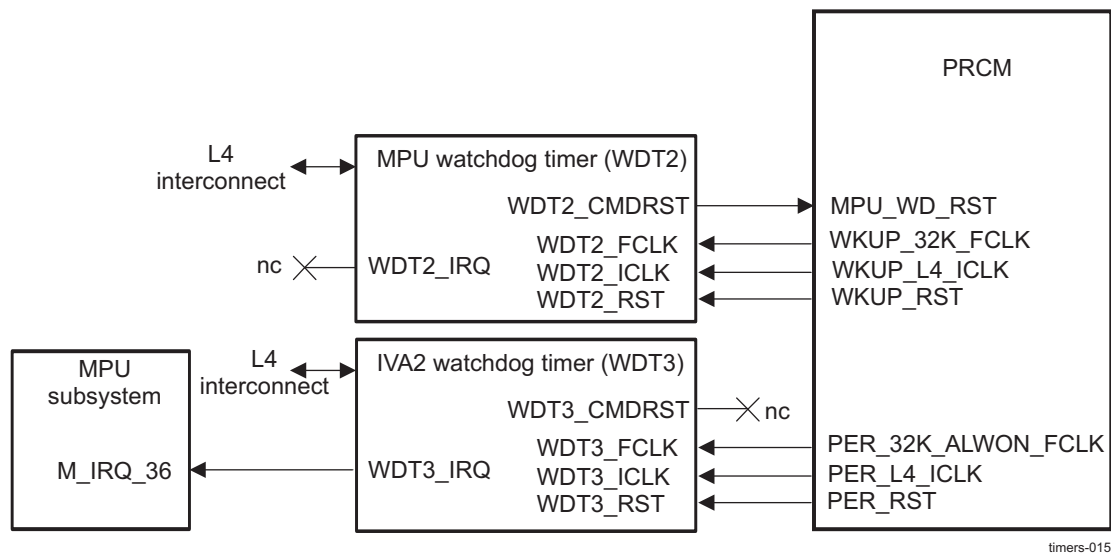

The following are the main features of the WDT controllers:

- L4 slave interface support:
 - 32-bit data bus width
 - 32-/16-bit access supported
 - 8-bit access not supported
 - 11-bit address bus width
 - Burst mode not supported
 - Write nonposted transaction mode only
- Free-running 32-bit upward counter
- Programmable divider clock source (2^n with $n=[0:7]$)
- On-the-fly read/write register (while counting)
- Subset programming model of the GP timer
- The secure watchdog timer (WDT1) is reset only on power-on reset, and then it starts counting. It is not sensitive to other reset sources.
- Other WDTs are reset either on power-on or after a warm reset.
- Reset or interrupt actions when a timer overflow condition occurs
- WDT generates either a reset or an interrupt in its hardware integration (WDT1, WDT2, or WDT3).

16.4.2 WDT Integration

Figure 16-15 shows the integration of the WDT in the device.

Figure 16-15. WDT Integration

16.4.2.1 Clocking, Reset, and Power-Management Scheme

16.4.2.1.1 Clock Management

There are two clock domains in the WDTs:

- Functional clock domain: WDTi_FCLK is the WDT functional clock. It is used to clock the WDT internal logic.
- Interface clock domain: WDTi_ICLK is the WDT interface clock. It is used to synchronize the WDT L4 port to the L4 interconnect. All accesses from the interconnect are synchronous to WDTi_ICLK.

Table 16-55 lists the the source clocks for each WDT in the device. For more information on clock control and domains, see the *Power, Reset, and Clock Management* chapter.

Table 16-55. Clock, Power, and Reset Domains for WDTs

Timer	Interface Clock	Functional Clock	Power Domain
Secure WDT	WKUP_L4_ICLK	SECURE_32K_FCLK	WKUP
MPU WDT	WKUP_L4_ICLK	WKUP_32K_FCLK	WKUP
IVA2 WDT	PER_L4_ICLK	PER_32K_ALWON_FCLK	PER

From a global system power-management perspective, when one or both of the WDT clocks is no longer required, the WDTs can be deactivated at the PRCM level in the corresponding registers. Table 16-56 lists the WDT PRCM clock control bits.

Table 16-56. WDT PRCM Clock Control Bits

Name	Associated PRCM Clock Output	Enable Bit	Autoidle Bit
WDT1_FCLK	SECURE_32K_FCLK	None	N/A
WDT2_FCLK	WKUP_32K_FCLK	PRCM.CM_FCLKEN_WKUP[5] EN_WDT2 bit	N/A
WDT3_FCLK	PER_32K_ALWON_FCLK	PRCM.CM_FCLKEN_PER[12] EN_WDT3 bit	N/A

Table 16-56. WDT PRCM Clock Control Bits (continued)

Name	Associated PRCM Clock Output	Enable Bit	Autoidle Bit
WDT1_ICLK	WKUP_L4_ICLK	PRCM.CM_ICLKEN_WKUP[4] EN_WDT1 bit	PRCM.CM_AUTOIDLE_WKUP[4] AUTO_WDT1 bit
WDT2_ICLK		PRCM.CM_ICLKEN_WKUP[5] EN_WDT2 bit	PRCM.CM_AUTOIDLE_WKUP[5] AUTO_WDT2 bit
WDT3_ICLK	PER_L4_ICLK	PRCM.CM_ICLKEN_PER[12] EN_WDT3 bit	PRCM.CM_AUTOIDLE_PER[12] AUTO_WDT3 bit

Notes:

- The PRCM function clock outputs are gated at the PRCM level, assuming the modules that share it have been disabled in the corresponding register. Disabling the WDTs is a necessary but not sufficient action. The clock is effectively out when all PRCM conditions are fulfilled. For the other actions to be taken, see the *Power, Reset, and Clock Management* chapter.
- The PRCM interface clock outputs are gated at the PRCM level, assuming the modules that share it have been disabled in the corresponding register. Disabling the WDTs is a necessary but not sufficient condition. The clock is effectively out when all PRCM conditions are fulfilled. For the other actions to be taken, see the *Power, Reset, and Clock Management* chapter.
- The PRCM AUTOIDLE bits are used to link/unlink the WDTs from the clock domain transitions related to the GPTi_ICLK clocks.
- For further details about source clocks gating and domain transitions, see the *Power, Reset, and Clock Management* chapter.

At the PRCM level, when the conditions to shut off the PRCM functional or interface output clocks are met (see the *Power, Reset, and Clock Management* chapter for details), the PRCM automatically launches a hardware handshake protocol to ensure the WDT is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the WDT.

Although this handshake is a hardware function and out of software control, the way the WDT acknowledges the PRCM IDLE request is configurable through the WDTi.WD_SYSCONFIG[4:3] IDLEMODE bit. [Table 16-57](#) lists the IDLEMODE settings and the related acknowledgement modes.

Table 16-57. IDLEMODE Settings

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The WDT acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent loss of data when the clock is switched off.
01	No-idle	The WDT never acknowledges an IDLE request from the PRCM module. This mode is secure from a module point of view, because it ensures the clocks remain active; it is not efficient from a power-saving perspective, however, because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
10	Smart-idle	The WDT acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQs requests are treated. This is the best approach for efficient system power management.
11	Reserved	

When configured in smart-idle mode, the WDT also offers an additional granularity on WDTi_FCLK and WDTi_ICLK gating. The WDTi.WD_SYSCONFIG[9:8] CLOCKACTIVITY bit field is used to determine which clock will be shut down (WDTi_FCLK, WDTi_ICLK, neither of them, or both of them).

The CLOCKACTIVITY setting is used internally to the WDT to determine the part of the module on which the conditions to acknowledge the PRCM IDLE request will be tested. For example, if WDTi_FCLK is not to be shut down on a PRCM IDLE request, the WDT considers only WDTi_ICLK and the associated pending activities before acknowledging the request.

Some WDT features are associated with WDTi_ICLK, and others are associated with WDTi_FCLK. Using the CLOCKACTIVITY setting along with the smart-idle mode ensures that the features associated with the clock that will remain active are always enabled, even if the WDT acknowledges an IDLE request.

Table 16-58 lists the CLOCKACTIVITY settings.

Table 16-58. CLOCKACTIVITY Settings

CLOCKACTIVITY Value	WDTi_ICLK Effects	WDTi_FCLK Effects	Description
00	OFF	OFF	Both WDTi_ICLK and WDTi_FCLK are considered for generating the acknowledge. This setting also means both WDTi_FCLK and WDTi_ICLK are likely to be shut down on a PRCM IDLE request.
01	OFF	ON	WDTi_FCLK is not shut down on a PRCM IDLE request; only WDTi_ICLK is concerned.
10	ON	OFF	WDTi_ICLK is not shut down on a PRCM IDLE request; only WDTi_FCLK is concerned.
11	ON	ON	None of the clocks are shut down. Therefore, the WDT can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clocks.

CAUTION

The PRCM module does *not* have any hardware means to read the CLOCKACTIVITY settings. The software must ensure consistent programming between the WDT CLOCKACTIVITY and the PRCM functional clock and interface clock control bits. If the WDT is disabled in both the CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated with the WDT clocks. This can lead to unpredictable behavior.

16.4.2.1.2 Reset and Power Management

The secure WDT (WDT1) and MPU WDT (WDT2) belong to the WKUP power domain. As part of that domain, these WDTs are sensitive to a WKUP_RST signal issued by the PRCM module. For further details about the WKUP power domain implementation and WKUP_RST signal, see the *Power, Reset, and Clock Management* chapter.

The IVA WDT (WDT3) belongs to the PER power domain. As part of that domain, WDT3 is sensitive to the PER_RST signal issued by the PRCM module. For further details about the PER power domain implementation and PER_RST signal, see the *Power, Reset, and Clock Management* chapter.

Note: WDT1 is reset only on power-on reset, and then it starts counting.

WDT2 is reset on power-on or after a warm reset, and then it starts counting.

WDT3 is reset either on power-on or after a warm reset, and then it doesn't start counting.

16.4.2.2 Interrupts

Table 16-59 shows interrupt mapping from the three WDTs to the MPU.

Table 16-59. WDT Interrupt Names and Processor IRQ Mapping

Timer	Interrupt Name	Mapping	Comments
Secure WDT	WDT1_IRQ	Not connected	
MPU WDT	WDT2_IRQ	Not connected	
IVA2 WDT	WDT3_IRQ	M_IRQ_36	IVA2 WDT overflow

16.4.3 WDTs Functional Description

16.4.3.1 General WDT Operation

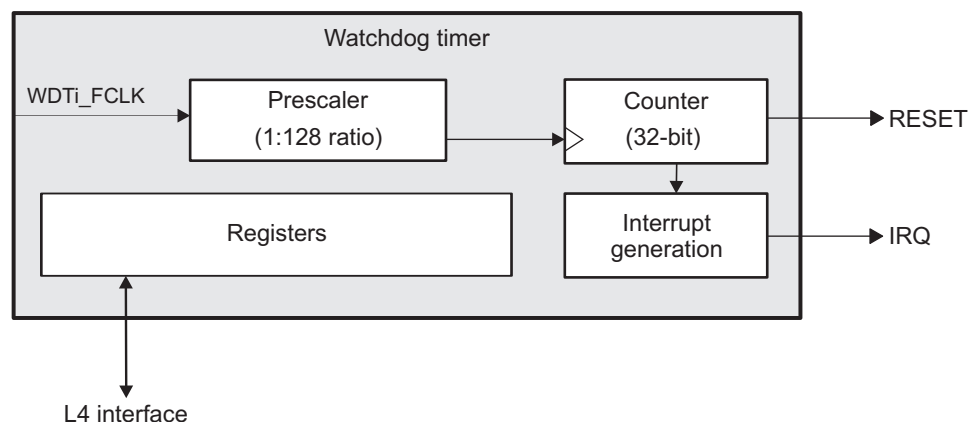

The WDTs are based on an upward 32-bit counter coupled with a prescaler. The counter overflow is signaled through two independent signals: a simple reset signal and an interrupt signal, both active low. The use of these signals depends on whether they are connected or not. For this information, see [Figure 16-14](#). The interrupt generation mechanism is controlled through the WDTi.WIER and WDTi.WISR registers.

The prescaler ratio can be set between 1 and 128 by accessing the WDTi.WCLR[4:2] PTV and WDTi.WCLR[5] PRE fields of the watchdog control register (WDTi.WCLR).

The current timer value can be accessed on-the-fly by reading the WDT counter register (WDTi.WCRR), modified by accessing the WDT load register (WDTi.WLDR) (no on-the-fly update), or reloaded by following a specific reload sequence on the WDT trigger register (WDTi.WTGR). A start/stop sequence applied to the WDT start/stop register (WDTi.WSPR) can start and stop the WDT.

For the secure watchdog (WDT1), access to registers inside the WDT is granted by a secure protocol.

Figure 16-16. 32-Bit WDT Functional Block Diagram

timers-016

16.4.3.2 Reset Context

After reset, the WDTs are enabled. [Table 16-60](#) lists the default reset values of the three WDT load registers (WDTi.WLDR) and prescaler ratios (WDTi.WCLR[4:2] PTV field). To get these values, software must read the corresponding WDTi.WCLR[4:2] PTV fields and the 32-bit register to retrieve the static configuration of the module.

Table 16-60. Count and Prescaler Default Reset Values

Timer	WLDR Reset Value	PTV Reset Value
Secure WDT (WDT1)	0xFFA6 0000	0
OMAP WDT (WDT2)	0xFFFFB 0000	0
IVA2 WDT (WDT3)	0xFFFFB 0000	0

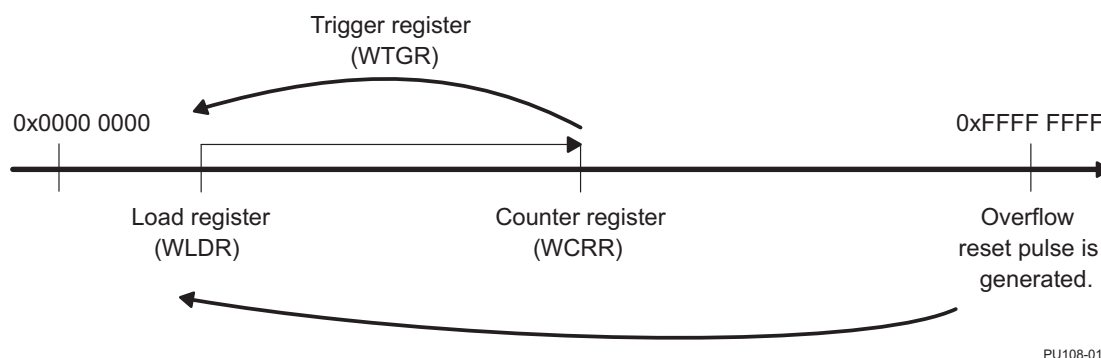

16.4.3.3 Overflow/Reset Generation

When the WDT counter register (WDTi.WCRR) overflows, an active-low reset pulse is generated to the PRCM module. This pulse is one prescaled timer clock cycle wide and occurs at the same time as the timer counter overflow.

After reset generation, the counter is automatically reloaded with the value stored in the watchdog load register (WDTi.WLDR) and the prescaler is reset (the prescaler ratio remains unchanged). Then, after the reset pulse output has been generated, the timer counter begins incrementing again.

Figure 16-17 shows a general functional view of the WDT.

Figure 16-17. WDT General Functional View

16.4.3.4 Prescaler Value/Timer Reset Frequency

Each WDT is composed of a prescaler stage and a timer counter.

The timer rate is defined by the following values:

- Value of the prescaler fields (the WDTi.WCLR[5] PRE bit and the WDTi.WCLR[4:2] PTV field)
- Value loaded into the timer load register (WDTi.WLDR)

The prescaler stage is clocked with the timer clock and acts as a clock divider for the timer counter stage. The ratio is managed by accessing the ratio definition field (the WDTi.WCLR[4:2] PTV field) and is enabled with the WDTi.WCLR[5] PRE bit.

Table 16-61 lists the prescaler clock ratio values.

Table 16-61. Prescaler Clock Ratios

PRE Bit (in WDTi.WCLR Register)	PTV Bits (in WDTi.WCLR Register)	Clock Divider (PS)
0	X	1
1	0	1
1	1	2
1	2	4
1	3	8
1	4	16
1	5	32
1	6	64
1	7	128

The watchdog timer overflow rate is expressed by: $OVF_Rate = (0xFFFF\ FFFF - WDTn.WLDR + 1) * (wd\text{-}functional\ clock\ period) * PS$

With $wd\text{-}functional\ clock\ period = 1 / (wd\text{-}functional\ clock\ frequency)$ and $PS = 2^{(PTV)}$.

CAUTION

Internal resynchronization causes any software write to GPTn.WSPR to have some latency before WSPR is updated with the programmed value:

$1.5 * functional\ clock\ cycles \leq write_WSPR_latency \leq 2.5 * functional\ clock\ cycles$

Remember to take this latency into account whenever the watchdog must be started or stopped.

For example, for a timer clock input of 32 kHz with a prescaler ratio value of 0x1 (clock divided by 2) and WDTi.WCLR[5] PRE bit = 1 (clock divider enabled), the reset period is as listed in Table 16-62.

Table 16-62. Reset Period Examples

WDTi.WLDR Value	Reset Period
0x0000 0000	74 h 56 min
0xFFFF 0000	4 s
0xFFFF FFF0	1 ms
0xFFFF FFFF	62.5 us

CAUTION

- Ensure that the reloaded value allows the correct operation of the application. When a WDT is enabled, the software must periodically trigger a reload before the counter overflows. Hence, the WDTi.WLDR[31:0] value must be chosen according to the ongoing activity preceding the watchdog reload.
- Due to design reasons, WDTi.WLDR[31:0] = 0xFFFF FFFF is a special case, although such a WDTi.WLDR value is meaningless. When WDTi.WLDR is programmed with the overflow value, a triggering event generates a reset/interrupt one functional clock cycle later, even if the WDT is stopped.

Table 16-63 lists the default reset periods for the WDTs.

Table 16-63. Default WDT Time Periods

WDTs	Clock Source	Default Reset Period
Secure WDT	32 kHz	3 mn ⁽¹⁾
OMAP/IVA2 WDTs	32 kHz	10 s

⁽¹⁾ 3 mn is the typical value (min: 98 s, max: 368 s)

16.4.3.5 Triggering a Timer Reload

To reload the timer counter and reset the prescaler before reaching overflow, a reload command is executed by accessing the WDT trigger register (WDTi.WTGR) using a specific reload sequence.

The specific reload sequence is performed whenever the written value on the WDT trigger register (WDTi.WTGR) differs from its previous value. In this case, reload is executed in the same way as an overflow autoreload, but without a reset pulse generation.

The timer counter is loaded with the WDT load register value (the WDTi.WLDR[31:0] TIMER_LOAD field), and the prescaler is reset.

16.4.3.6 Start/Stop Sequence for WDTs (Using WDTi.WSPR Register)

To start/stop a WDT, access must be made through the start/stop register (WDTi.WSPR) using a specific sequence.

To disable the timer, follow this sequence:

1. Write 0xFFFF AAAA in WDTi.WSPR.
2. Write 0xFFFF 5555 in WDTi.WSPR.

To enable the timer, follow this sequence:

1. Write 0xFFFF BBBB in WDTi.WSPR.
2. Write 0xFFFF 4444 in WDTi.WSPR.

All other write sequences on WDTi.WSPR have no effect on the start/stop feature of the module.

16.4.3.7 Modifying Timer Count/Load Values and Prescaler Setting

To modify the timer counter value (WDTi.WCRR), prescaler ratio (the WDTi.WCLR[4:2] PTV field), or load value (the WDTi.WLDR[31:0] TIMER_LOAD field), the WDT must be disabled by using the start/stop sequence (the WDTi.WSPR register).

After a write access, the load register value and prescaler ratio registers are updated immediately, but new values are considered only after the next consecutive counter overflow or after a new trigger command (WDTi.WTGR).

16.4.3.8 Watchdog Counter Register Access Restriction (WDTi.WCRR Register)

Because the WDTi.WCRR register is directly related to the timer counter value and is updated on the timer clock (WDTi_FCLK), a 32-bit shadow register is implemented to read a coherent value of the WDTi.WCRR register. The shadow register is updated by a 16-bit LSB read command.

Note: Although the L4 clock (WDTi_ICLK) is completely asynchronous with the timer clock (WDTi_FCLK), some synchronization is done to ensure that the WDTi.WCRR value is not read while it is being incremented.

When 32-bit read access is performed, the shadow register is not updated. Read access is made directly from the accessed register.

To ensure that a coherent value is read inside WDTi.WCRR, the first read access is to the lower 16 bits (offset = 0x08), followed by read access to the upper 16 bits (offset = 0x0A).

16.4.3.9 WDT Security Features (WDT1 Only)

Read/write access is granted to secure WDT registers only if the secure mode is entered. Secure mode is only available in high-security (HS) devices. To determine if a HS version of your device is available and for more information on HS devices, please refer to your device-specific data manual.

16.4.3.10 WDT Interrupt Generation

The WDT issues an overflow interrupt if this interrupt is enabled in the WDT interrupt enable register (WDTi.WIER[0] OVF_IT_ENA = 1). When the overflow occurs, the interrupt status bit (the WDTi.WISR[0] OVF_IT_FLAG bit) is set to 1. The output interrupt line (WDTi_IRQ) is asserted (active low) when both status (OVF_IT_FLAG) and enable (OVF_IT_ENA) flags are set to 1; the order is not relevant. Writing 1 in the enable bit (the status is already set at 1) also triggers the interrupt in the normal order (enable first, status after). The pending interrupt event is cleared when the set status bit is overwritten by a value of 1 by a write command in the WDTi.WISR register. Reading the WDTi.WISR register and writing the value back allows a fast acknowledge interrupt process.

Note: Writing 0 in the WDTi.WISR[0] OVF_IT_FLAG bit has no effect on it.

Because the interrupt event is generated on the functional clock domain (WDTi_FCLK), during the interrupt status register (WDTi.WISR) update, the two clock domains are resynchronized.

16.4.3.11 WDT Under Emulation

During emulation mode, the WDT can/cannot continue running, according on the value of the WDTi.WD_SYSCONFIG[5] EMUFREE bit of the system configuration register (WDTi.WD_SYSCONFIG).

- When EMUFREE is 1, WDT execution is not stopped and a reset pulse is still generated when overflow is reached.
- When EMUFREE is 0, the counters (prescaler/timer) are frozen and incrementation restarts after exiting from emulation mode.

16.5 Watchdog Timer (WDT) Registers

All registers are 32 bits wide and are accessible through the L4 interface with 16-bit or 32-bit access (read/write). For the secure WDT (WDT1), access to registers is allowed only when secure mode is active.

[Table 16-64](#) lists the base address and address space for the WDT module instances. All timers are memory mapped to the L4 peripheral bus memory space.

Table 16-64. WDT Instance Summary

Module Name	Base Address	Size
WDTIMER1	0x4830 C000	4K bytes
WDTIMER2	0x4831 4000	4K bytes
WDTIMER3	0x4903 0000	4K bytes

16.5.1 WDT Register Mapping Summary

CAUTION

The WDT registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt register content.

[Table 16-65](#) lists the WDT1 registers, [Table 16-66](#) lists the WDT2 registers, and [Table 16-67](#) lists the WDT3 registers.

16.6 32-kHz Synchronized Timer

16.6.1 32-kHz Sync Timer Functional Description

The 32-kHz sync timer is a 32-bit counter, clocked by the falling edge of the 32-kHz system clock. It is reset while the external asynchronous power-up reset (sys_nrespwron) primary I/O is active (main device reset). When sys_nrespwron is released (on the rising edge of sys_nrespwron), after three 32-kHz clock periods, the counter starts counting up from the reset value of the counter register on the falling edge of the 32-kHz system clock. After reaching its highest value, the counter wraps back to 0 and starts counting again. Figure 16-18 shows the block diagram of the 32-kHz sync timer.

Note: sys_nrespwron is an active low I/O.

Figure 16-18. 32-kHz Sync Timer Block Diagram

16.6.1.1 Reading the 32-kHz Sync Timer

The sync counter register is 32 bits wide and for correct count capture must be accessed as 16-bit LSB access first and two 16-bit MSB access last. Internal synchronization logic allows reading of the counter value while the counter is running. The time latency to read the counter is one L4 interconnect clock period.

16.6.1.2 32-kHz Sync Timer Features

The following are the main features of the 32-kHz sync timer controller:

- L4 slave interface support:
 - 32-bit data bus width
 - 32-/16-bit access supported
 - 8-bit access not supported
 - 16-bit address bus width
 - Burst mode not supported
 - Write nonposted transaction mode supported
- Only read operations are supported on the module registers; no write operation is supported (no error/no action on write).
- Free-running 32-bit upward counter
- Start and keep counting after power-on reset
- Automatic roll over to 0, highest value reached (0xFFFF FFFF)
- On-the-fly read (while counting)

16.6.2 32-kHz Sync Timer Environment

The sync timer is accessible only through the L4 interface.

16.6.3 32-kHz Sync Timer Integration

16.6.3.1 Clocking, Reset, and Power-Management Scheme

Table 16-87 lists the power and reset domain and the source clock for the 32-kHz sync timer in the device. For more information on power, reset, and clock control and domains, see the *Power, Reset, and Clock Management* chapter.

Table 16-87. Clock, Power, and Reset Domains for 32-kHz Sync Timer

Timer	Source Clock	Interface Clock	Clock and Power Domain	Reset Domain
32-kHz sync timer	sys_32k	32KSYNC_ICLK	WKUP	SYNCT_RST ⁽¹⁾

16.6.3.2 Interrupts

The 32-kHz sync timer has no interrupt outputs.

16.6.3.3 Sync Timer 32k and MSuspend Signal

By default, the Sync Timer 32k is not stopped when the MPU or DSP is in "halt". In order to activate its sensitivity to the MSuspend Signal, the CONTROL.CONTROL_MSUSPEND_2[29:27] SyncTMMsctrl bit has been added to the System Control Module.

16.7 32-kHz Sync Timer Registers

[Table 16-88](#) lists the base address and block size for the 32-kHz sync timer. It is memory mapped to the L4 peripheral bus memory space.

Table 16-88. 32-kHz Sync Timer Instance Summary

Module Name	Base Address	Size
32-kHz sync timer	0x4832 0000	4K bytes

16.7.1 32-kHz Sync Timer Register Mapping Summary

CAUTION

The 32-kHz sync timer registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

[Table 16-89](#) lists the 32-kHz sync timer registers. [Table 16-90](#) through [Table 16-92](#) describe the register bits.

UART/IrDA/CIR Module

This chapter describes the function, operation, and configuration of the universal asynchronous receiver/transmitter (UART)/infrared data association (IrDA)/consumer infrared (CIR) module on the OMAP35x Applications Processor.

Topic	Page
17.1 UART/IrDA/CIR Overview	2506

17.7 Revision History	2612

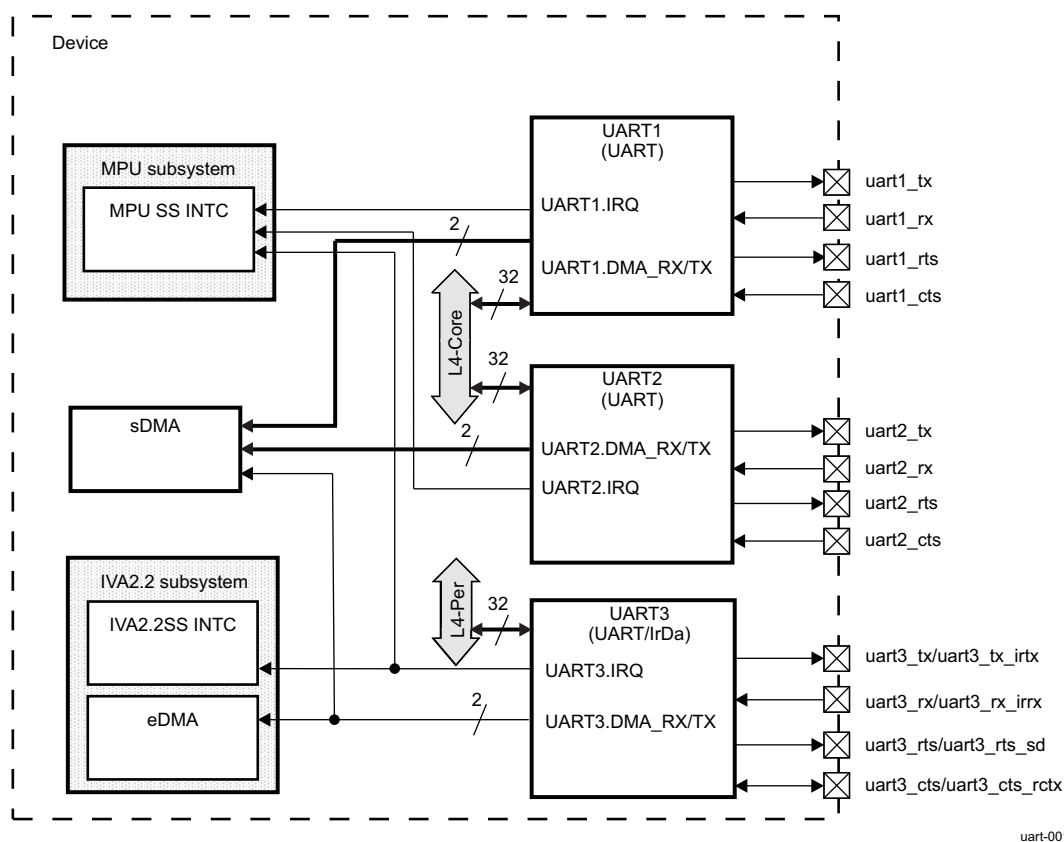

17.1 UART/IrDA/CIR Overview

The OMAP35x Applications Processor contains three universal asynchronous receiver/transmitter (UART) devices controlled by the microprocessor unit (MPU) (see [Figure 17-1](#)):

- Two UART-only modules, UART1 and UART2, are pinned out for use as UART devices only. UART1 and UART2 must be programmed by setting the UARTi.MDR1_REG[2:0] MODE_SELECT field to one of the three UART operating modes.
- UART3, which adds infrared communication support, is pinned out for use as a UART, infrared data association (IrDA), or consumer infrared (CIR) device, and can be programmed to any available operating mode.

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

Figure 17-1. UART Module

17.1.1 UART Features

The UARTs (UART1, UART2, and UART3 when in UART mode) include the following key features:

- 16C750 compatibility
- 64-byte FIFO for receiver and 64-byte FIFO for transmitter
- Programmable interrupt trigger levels for FIFOs
- Baud generation based on programmable divisors N (N = 1...16,384) operating from a fixed functional clock of 48 MHz

Oversampling is programmed by software as 16 or 13; thus, the baud rate computation is either:

- Baud rate = (functional clock/16)/N
- Baud rate = (functional clock/13)/N

This software programming mode enables higher baud rates with the same error amount without changing the clock source:

- Break character detection and generation
- Configurable data format
 - Data bit: 5, 6, 7, or 8 bits
 - Parity bit: Even, odd, none
 - Stop-bit: 1, 1.5, 2 bit(s)
- Flow control: Hardware (RTS/CTS) or software (XON/XOFF)

The UART clocks are connected to produce a baud rate of up to 3.6M bits/s. [Table 17-1](#) lists the supported baud rates, the requested divisor, and the corresponding error versus the standard baud rate.

Table 17-1. UART Mode Baud Rates, Divisor Values, and Error Rates

Baud Rate	Oversampling	Divisor	Error (%)
300	16	10000	0
600	16	5000	0
1200	16	2500	0
2400	16	1250	0
4800	16	625	0
9600	16	312	0.16
14,400	16	208	0.16
19,200	16	156	0.16
28,800	16	704	0.16
38,400	16	78	0.16
57,600	16	52	0.16
115,200	16	26	0.16
230,400	16	13	0.16
460,800	13	8	0.16
921,600	13	4	0.16
1,843,200	13	2	0.16
3,000,000	16	1	0
3,686,400	13	1	0.16

17.1.2 IrDA Features

The IrDA (UART3 only) includes the following key features:

- Support of IrDA 1.4 slow infrared (SIR), medium infrared (MIR), and fast infrared (FIR) communications
 - Frame formatting: Addition of variable beginning-of-frame (xBOF) characters and end-of-frame (EOF) characters
 - Uplink/downlink cyclic redundancy check (CRC) generation/detection
 - Asynchronous transparency (automatic insertion of break character)
 - Eight-entry status FIFO (with selectable trigger levels) to monitor frame length and frame errors
 - Framing error, CRC error, illegal symbol (FIR), and abort pattern (SIR, MIR) detection

[Table 17-2](#) lists the supported baud rates, the requested divisor, and the corresponding error versus the standard baud rate.

Table 17-2. UART IrDA Mode Baud Rates, Divisor Values, and Error Rates

Baud Rate	IR Mode	Encoding	Divisor	Error (%)
2400	SIR	3/16	1250	0
9600	SIR	3/16	312	0.16
19,200	SIR	3/16	156	0.16
38,400	SIR	3/16	78	0.16
57,600	SIR	3/16	52	0.16
115,200	SIR	3/16	26	0.16
576,000	MIR	1/4	2	0
1,152,000	MIR	1/4	1	0
4,000,000	FIR	4 PPM ⁽¹⁾	1	0

⁽¹⁾ PPM = pulse-position-modulation

17.1.3 CIR Features

The CIR mode uses a variable pulse-width modulation (PWM) technique (based on multiples of a programmable t period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on a user-definable frame structure and packet content.

The CIR (UART3 only) includes the following key features to provide CIR support for remote control applications:

- Transmit mode only (receive mode is not supported)
- Free data format (supports any remote-control private standards)
- Selectable bit rate
- Configurable carrier frequency
- 1/2, 5/12, 1/3, or 1/4 carrier duty cycle

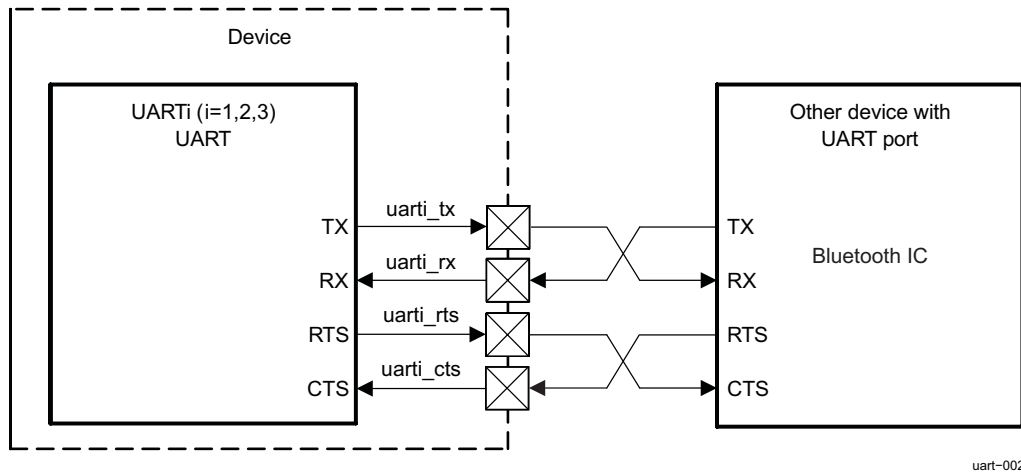

17.2 UART/IrDA/CIR Environment

This section describes the UART/IrDA/CIR connection with an external device.

17.2.1 System Using UART Communication with Hardware Handshake

UART1, UART2, or UART3 can be connected easily to the UART port of an external IC (see [Figure 17-2](#)).

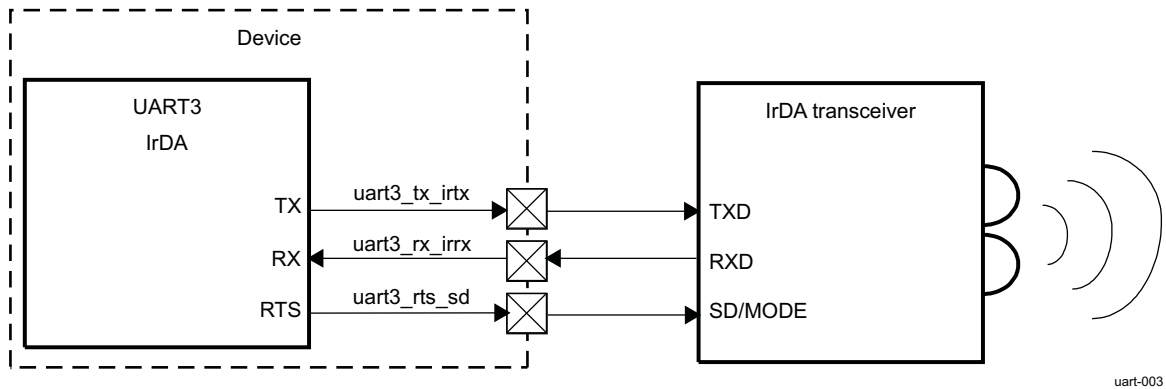

Figure 17-2. UART Mode Bus System Overview

17.2.2 System using IrDA Communication Protocol

As [Figure 17-3](#) shows, UART3 can be connected to an external infrared transceiver in the IrDA modes (FIR, SIR, and MIR).

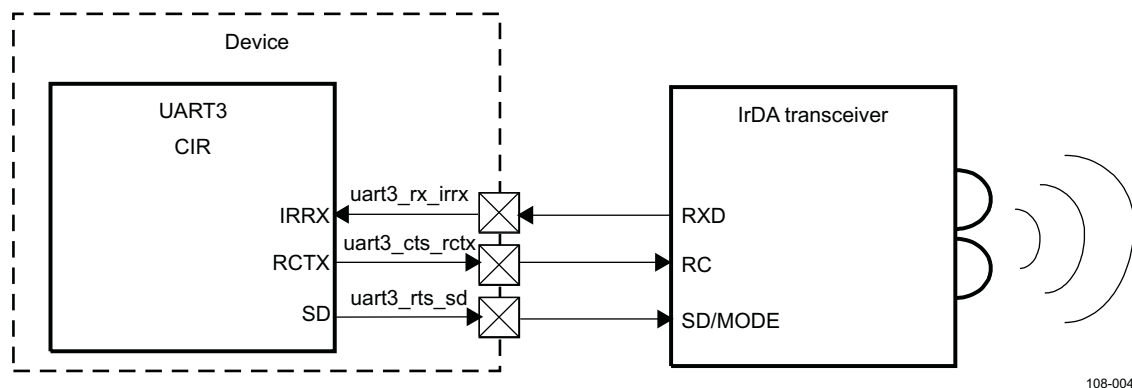

Figure 17-3. IrDA System Overview

17.2.3 System using CIR Communication Protocol with Remote Control

UART3 can be connected to an external Infrared transceiver in CIR mode (see [Figure 17-4](#)).

Figure 17-4. CIR System Overview

17.2.4 UART Interface Description

17.2.4.1 UART Interface Description

[Table 17-3](#) describes the UART interface.

Table 17-3. UART I/O Pin Description

Signal	I/O ⁽¹⁾	Description	Reset
UART Modem Signals			
uarti_rx	I	Serial data input	Unknown
uarti_tx	O	Serial data output Because this pin is active high in the IrDA mode and the output is muxed, this pin is set to low on reset (when UARTi.MDR1_REG[2:0] is set to 0x7) and takes the defined inactive level of that signal corresponding to when and how UARTi.MDR1_REG is programmed; that is, the output is 1 (inactive for UART modem modes) and 0 (inactive for IrDA modes).	0
uarti_cts	I	Clear to send Active-low modem status signal. Reading the UARTi.MSR_REG[4] NCTS_STS bit checks the condition of uarti_cts. Reading the UARTi.MSR_REG[0] CTS_STS bit checks a change of state of uarti_cts since the last read of the modem status register. The auto-nCTS mode uses uarti_cts to control the transmitter.	0
uarti_rts	O	Request to send When active (low), the module is ready to receive data. Setting the UARTi.MCR_REG[1] RTS bit activates uarti_rts, which becomes inactive as the result of a module reset, loopback mode, or clearing the UARTi.MCR_REG[1] RTS bit. In auto-RTS mode, uarti_rts becomes inactive as a result of the receiver threshold logic.	0

⁽¹⁾ I = Input, O = Output

17.2.4.2 UART Protocol and Data Format

The UART device operates in three modes:

- UART 16x mode (≤ 230.4 K bits/s)
- UART 16x mode with autobauding (≥ 1200 bits/s and ≤ 115.2 K bits/s)

- UART 13x mode (≥ 460.8 K bits/s)

CAUTION

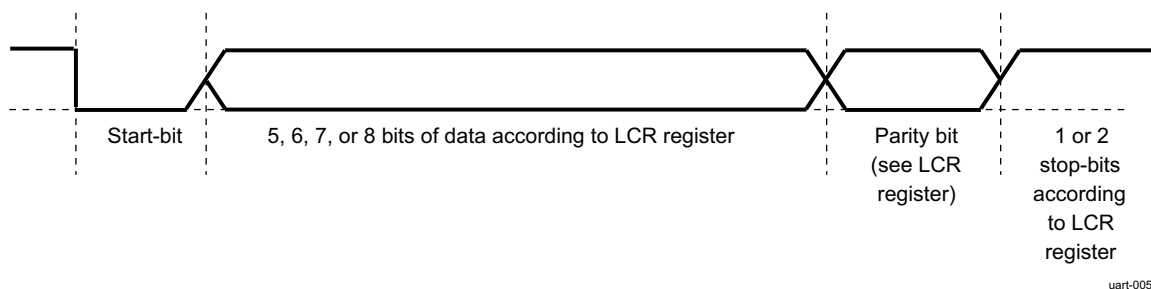

To be used as a UART, the operating mode must be programmed appropriately in the UARTi.MDR1_REG[2:0] MODE_SELECT field to select the UART, IrDA, or CIR mode.

The UART uses a wired interface for serial communication with a remote device.

The UART module is functionally compatible with the TL16C750 UART and earlier designs such as the TL16C550.

Figure 17-5 shows the UART frame data format.

Figure 17-5. UART Frame Data Format

17.2.5 IrDA Functional Interfaces

17.2.5.1 UART3 Interface Description

Table 17-4 describes the UART3 interface.

Table 17-4. UART3 I/O Description

Signal	I/O ⁽¹⁾	Description	Reset
IrDA Signals			
uart3_rx_irrx	I	Serial data input	Unknown
uart3_tx_irtx	O	Serial data output in IrDA modes (SIR, MIR, and FIR). In other modes, this pin is set to the reset value (inactive state).	0
uart3_rts_sd	O	SD mode is used to configure the transceivers. The SD pinout is an inverted value of the UART3.ACREG_REG[6] SD_MOD bit.	1

⁽¹⁾ I = Input, O = Output

17.2.5.2 IrDA Protocol and Data Format

17.2.5.2.1 SIR Mode

In SIR mode, data is transferred between the MPU and peripheral devices at speeds of up to 115,200 baud. A SIR transmit frame begins with start flags (a single 0xC0, a multiple 0xC0, or a single 0xC0 preceded by a number of 0xFF flags), is followed by frame data and a CRC-16, and ends with a stop flag (0xC1).

The bit format for a single word uses 1 start bit, 8 data bits, and 1 stop bit, and is unaffected by the use and settings of the UART3.LCR_REG register.

The UART3.BLR_REG[6] XBOF_TYPE bit selects whether the 0xC0 or 0xFF start patterns are used when multiple start flags are required.

The SIR transmit state-machine attaches start flags, CRC-16, and stop flags, and checks the outgoing data to establish whether data transparency is required.

SIR transparency is carried out if the outgoing data between the start and stop flags contains 0xC0, 0xC1, or 0x7D. If one of these start flags is about to be transmitted, the SIR state-machine first sends an escape character (0x7D), then inverts the fifth bit of the real data to be sent, and sends this data immediately after the 0x7D character.

The SIR receive state-machine recovers the receive clock, removes the start flags and any transparency from the incoming data, and determines the frame boundary with reception of the stop flag. The SIR state-machine also checks for errors, such as a frame abort (0x7D character followed immediately by a 0xC1 stop flag without transparency), a CRC error, and a frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.LSR_REG) to find possible errors of the received frame.

Note: Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. See the UART3.ACREG_REG[5] DIS_IR_RX bit description. This applies to all three modes: SIR, MIR, and FIR.

Infrared output in SIR mode can be either 1.6-us or 3/16th encoding, selected by the UART3.ACREG_REG[7] PULSE_TYPE bit. In 1.6-us encoding, the infrared pulse width is 1.6 μ s; and in 3/16th encoding, the infrared pulse width is 3/16th of a bit duration (1/ baud rate).

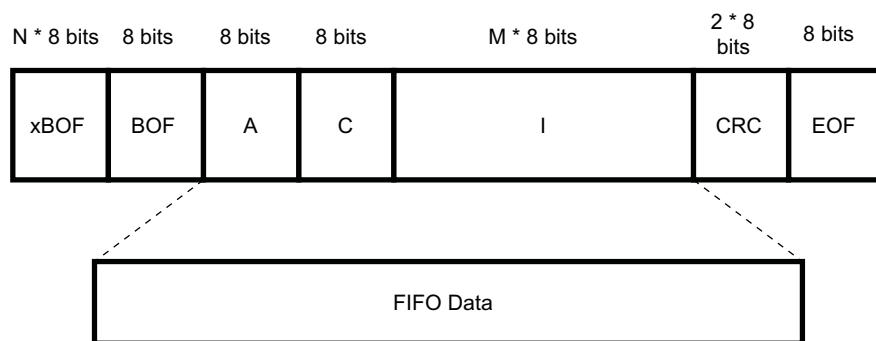

The transmitting device must send at least two start flags at the start of each frame for back-to-back frames.

Note: Reception supports variable-length stop-bits.

17.2.5.2.1.1 Frame Format

Figure 17-6 shows the IrDA SIR frame format.

Figure 17-6. IrDA SIR Frame Format

uart-006

The CRC is applied on the address (A), control (C), and information (I) bytes.

Note: The two words of CRC are written to the FIFO in reception.

17.2.5.2.1.2 Asynchronous Transparency

Before transmitting a byte, the UART IrDA controller examines each byte of the payload and the CRC field (between BOF and EOF). For each byte equal to 0xC0 (BOF), 0xC1 (EOF), or 0x7D (control escape), the controller performs certain tasks:

- In transmission:
 - Inserts a control escape (CE) byte preceding the byte
 - Complements bit 5 of the byte (that is, exclusive ORs the byte with 0x20)
 The byte sent for the CRC computation is the initial byte written in the TX FIFO (before the XOR with 0x20).
- In reception:

For the A, C, I, CRC field:

 - Compares the byte with the CE byte; if they are not equal, sends the byte to the CRC detector and stores it in the RX FIFO
 - If the byte is equal to the CE byte, discards the CE byte
 - Complements bit 5 of the byte following the CE
 - Sends the complemented byte to the CRC detector and stores it in the RX FIFO

17.2.5.2.1.3 Abort Sequence

The transmitter can decide to prematurely close a frame. The transmitter aborts by sending the following sequence: 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

The receiver treats a frame as an aborted frame when a 0x7D character followed immediately by a 0xC1 character is received without transparency.

17.2.5.2.1.4 Pulse Shaping

The SIR mode supports both the 3/16th and the 1.6- μ s pulse duration methods. The UART3.ACREG_REG[7] PULSE_TYPE bit selects the pulse width method in transmit mode.

17.2.5.2.1.5 Encoder

Serial data from the transmit state-machine is encoded to transmit data to the optoelectronics. While the TX FIFO output is high, the uart3_tx_irtx line is always low, and the counter used to form a pulse on uart3_tx_irtx is cleared continuously.

After the TX FIFO output resets to 0, uart3_tx_irtx rises on the falling edge of the 7th 16XCLK. On the falling edge of the 10th 16XCLK pulse, uart3_tx_irtx falls, creating a three-clock-wide pulse. While the TX FIFO output stays low, a pulse is transmitted during the 7th to the 10th clock of each 16-clock bit cycle.

Figure 17-7 shows the IrDA SIR encoding mechanism.

17.2.5.2.1.6 Decoder

After reset, the RX FIFO input is high and the 4-bit counter is cleared. When a rising edge is detected on RX, the RX FIFO input falls on the next rising edge of 16XCLK with sufficient setup time. The RX FIFO input stays low for 16 cycles (16XCLK) and then returns to high as required by the IrDA specification. As long as no pulses (rising edges) are detected on the RX, the RX FIFO input remains high.

Figure 17-8 shows the IrDA SIR decoding mechanism.

Figure 17-8. IrDA SIR Decoding Mechanism

Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. The operation of the `uart3_rx_irrx` input can be disabled using the `UART3.ACREG_REG[5]` `DIS_IR_RX` bit. Furthermore, the `UART3.MDR2_REG[6]` `IRRXINVERT` bit can invert the signal from the transceiver (RXD) pin to the IRRX logic inside the UART. This inversion is performed by default.

17.2.5.2.1.7 IR Address Checking

In all IR modes, when address checking is enabled by setting `EFR_REG[1:0]` (see Table 17-5), only frames intended for the device are written to the RX FIFO. This is to avoid receiving frames not meant for this device in a multipoint infrared environment. To program two frame addresses that the UART3 receives in IrDA mode, use the `UART3.XON1_ADDR1_REG[7:0]` field and the `UART3.XON2_ADDR2_REG[7:0]` field.

Table 17-5. EFR_REG[0-1] IR Address Checking Options

<code>EFR_REG[1]</code>	<code>EFR_REG[0]</code>	IR Address Checking
0	0	All address-checking operations disabled
0	1	Only address 1 checking enabled
1	0	Only address 2 checking enabled
1	1	All address-checking operations enabled

17.2.5.2.2 SIR Free Format Mode

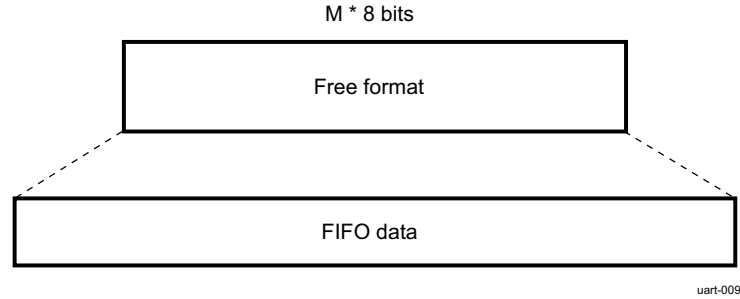

To allow complete software flexibility when transmitting and receiving infrared data packets, the SIR free format (FF) mode is a subfunction of the existing SIR mode; all frames going to and from the FIFO buffers are untouched with respect to appending and removing control characters and CRC values.

This mode corresponds to a UART mode with a pulse modulation of 3/16 of baud rate pulse width.

For example, a normal SIR packet has BOF control and CRC error-checking data appended (transmitting) or removed (receiving) from the data going to and from the FIFOs.

Figure 17-9 shows the SIR free format mode.

Figure 17-9. SIR Free Format Mode

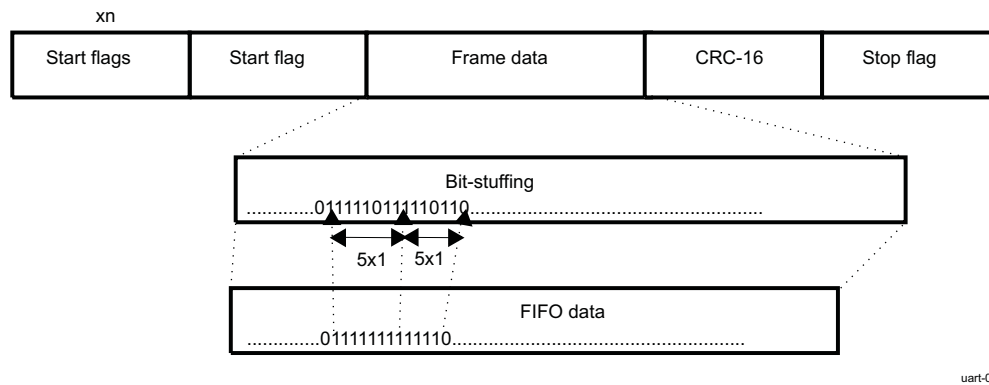

In the SIR free format mode, the MPU software must construct (that is, encode and decode) the entire FIFO data packet.

17.2.5.2.3 MIR Mode

In MIR mode, data is transferred between the MPU and the peripheral devices at 0.576 or 1.152M bits/s speed. A MIR transmit frame starts with start flags (at least two), followed by a frame data, CRC-16, and ends with a stop flag (see [Figure 17-10](#)).

Figure 17-10. MIR Transmit Frame Format

On transmit, the MIR state-machine attaches start flags, CRC-16, and stop flags, as in SIR mode. All fields are transmitted least-significant bit (LSB) of each byte first.

Contrary to SIR mode:

- The state-machine looks for consecutive 1s in the frame data and automatically inserts 0 after five consecutive 1s (this is called bit-stuffing).
- 0x7E is used for both start and stop flags (unambiguously, not data, because of bit-stuffing).
- Abort sequence requires a minimum of seven consecutive 1s (unambiguously, not data, because of bit stuffing).
- Back-to-back frames are allowed with three or more stop flags in between. If two consecutive frames are not back to back, the gap between the last stop flag of the first frame and the start flag of the second frame must be separated by at least seven bit durations.

On receive, the MIR receive state-machine recovers the receive clock, removes the start flags, destuffs the incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors, such as frame abort, CRC error, and frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.LSR_REG) to detect possible errors of the received frame.

Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

17.2.5.2.3.1 MIR Encoder/Decoder

To meet the MIR baud rate tolerance of ± 0.1 percent with a 48-MHz clock input, a 42-41-42 encoding/decoding adjustment is performed. The reference start point is the first start flag, and the 42-41-42 cyclic pattern is repeated until the stop flag is sent or detected.

The jitter created this way is within MIR tolerances. The pulse width is not exactly 1/4, but it is within the tolerances defined by the IrDA specifications.

Figure 17-11 shows the MIR baud rate adjustment mechanism.

Figure 17-11. MIR Baud Rate Adjustment Mechanism

17.2.5.2.3.2 SIP Generation

In the MIR and FIR operation modes, the transmitter must send a serial infrared interaction pulse (SIP) at least once every 500 ms. The SIP informs slow devices (operating in SIR mode) that the medium is currently occupied.

Figure 17-12 shows the SIP.

Figure 17-12. SIP

17.2.5.2.4 FIR Mode

In FIR mode, data is transferred between the MPU and the peripheral devices at 4M bits/s. A FIR transmit frame starts with a preamble that is followed by a start flag, frame data, CRC-32, and ends with a stop flag.

Table 17-6 shows the FIR transmit frame format.

Table 17-6. FIR Transmit Frame Format

Preamble (16x)	Start flag	Frame data	CRC-32	Stop flag
-------------------	------------	------------	--------	-----------

On transmit, the FIR transmit state-machine attaches the preamble, start flag, CRC-32, and stop flag. An abort sequence requires at least two transmissions of 0000. Back-to-back frames are allowed, but each frame must be complete.

The state-machine also encodes the transmit data into 4-PPM format (see [Table 17-7](#)) and generates the SIP (see [Section 17.2.5.2.3.2, SIP Generation](#)).

Table 17-7. 4-PPM Format

Data Bit Pair (Bin)	4-PPM Data Symbol (Bin)
00	1000
01	0100
10	0010
11	0001

The four symbols described in [Table 17-7](#) are the legal encoded data symbols. All other combinations are illegal for encoding data. Some of these illegal symbols are used in the definition of the preamble, start flag, and stop flag because they are unambiguously not data (see [Table 17-8](#)).

Table 17-8. FIR Preamble, Start Flag, and Stop Flag

Frame Part	Transmitted Frame (Bin)
Preamble	1000 0000 1010 1000 (16 repeated transmissions)
Start Flag	0000 1100 0000 1100 0110 0000 0110 0000
Stop Flag	0000 1100 0000 1100 0000 0110 0000 0110

All fields are transmitted the LSBs of each byte first (see [Table 17-9](#)).

Table 17-9. FIR Data Byte Transmission Order Example

Data Byte (Hex)	Data Byte Pair (Bin)	4-PPM Data Symbol (Bin)	Transmission Order
0x0B	00	1000	4
	00	1000	3
	10	0010	2
	11	0001	1

On receive, the FIR receive state-machine recovers the receive clock, removes the preamble and the start flag, decodes the 4-PPM incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors, such as illegal symbol, CRC error, and frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.LSR_REG) to detect possible errors of the received frame.

Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

17.2.6 CIR Functional Interfaces

17.2.6.1 CIR Interface Description

Table 17-10 describes the CIR interface.

Table 17-10. CIR I/O Description

Signal	I/O ⁽¹⁾	Description	Reset
CIR Signals			
uart3_rx_irrx	I	Serial data input	Unknown
uart3_cts_rctx	O	Serial data output in CIR mode. In other modes, this pin is set to the reset value (inactive state).	0
uart3_rts_sd	O	SD mode is used to configure the transceivers. The SD pinout is an inverted value of the UART3.ACREG_REG[6] SD_MOD bit.	1

⁽¹⁾ I = Input, O = Output

17.2.6.2 CIR Protocol and Data Format

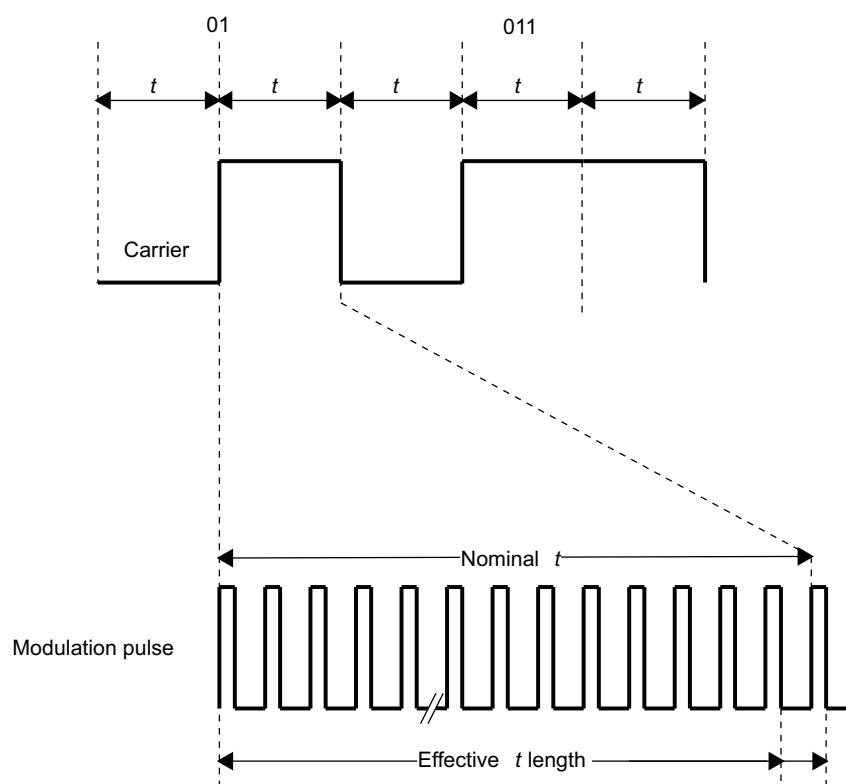

In the CIR mode, the infrared operation functions as a programmable (universal) remote control.

The CIR mode uses a variable PWM technique (based on multiples of a programmable t period) to encompass the various formats of infrared encoding for remote control applications. The CIR logic transmits data packets based on the user-defined frame structure and packet content.

17.2.6.2.1 Carrier Modulation

Each modulated pulse that constitutes a digit is a train of on/off pulses (see Figure 17-13).

Figure 17-13. CIR Pulse Modulation

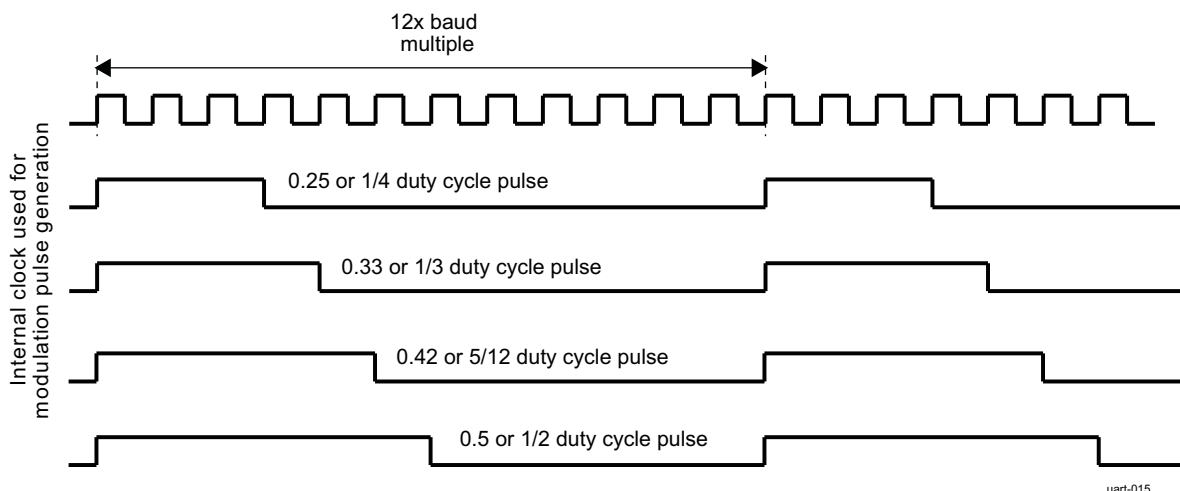

uart-014

17.2.6.2.2 Pulse Duty Cycle

The programmer can choose between four possible duty cycles for modulation pulses by setting the appropriate value in the UART3.MDR2_REG[5:4] CIR_PULSE_MODE field (1/4, 1/3, 5/12, or).

Figure 17-14 shows the CIR modulation duty cycles.

Figure 17-14. CIR Modulation Duty Cycle

The transmission logic ensures that all pulses are transmitted completely (that is, no cutoff during transmission). Furthermore, while transmitting continuous bytes back-to-back, no delay is inserted between 2 transmitted bytes. Thus, software must handle the delay between consecutively transmitted bytes if the receiving end needs it.

17.2.6.2.3 Consumer IR Encoding/Decoding

There are two methods of encoding for remote control applications. The first method uses time-extended bit forms (a variable pulse distance, or duration, in which the difference between a logic 1 and logic 0 is the length of the pulse width).

The second encoding method uses a biphase in which the encoding of the logic 0 and logic 1 is in the change of signal level from 1 to 0 or 0 to 1, respectively. Japanese manufacturers favor pulse duration encoding; European manufacturers favor biphase encoding.

The CIR mode uses a completely flexible free-format encoding in which the TX FIFO is transmitted as a modulated pulse with duration T.

Similarly, 0 is transmitted as a blank duration T. The MPU constructs and deciphers the protocol of the data. For example, the RC-5 protocol using Manchester encoding can be emulated as using a 01 pair for 1 and a 10 pair for 0 (see Figure 17-15.).

Figure 17-15. RC-5 Bit Encoding

Because the CIR mode logic does not impose a fixed format for infrared packets of data, the MPU software can define the format using simple data structures that are then modulated into an industry standard, such as RC-5 or SIRC. To send a sequence of 0101 in RC-5, the MPU software must write an 8-bit binary character of 10011001 to the data FIFO of the UART.

For SIRC, the modulation length (that is, multiples of T) is the method used to distinguish between 1 and 0. The following SIRC digits show the difference in encoding between this and, for example, RC-5. The pulse width is extended for one digit.

Figure 17-16 shows SIRC bit encoding.

Figure 17-16. SIRC Bit Encoding

To construct comprehensive packets constituting remote-control commands, the MPU software must combine a number of 8-bit data characters in a sequence that follows one of the universally accepted formats.

Figure 17-17 shows a standard RC-5 frame as detected by the UART3 in CIR mode (the SIRC format follows this). Each field in RC-5 can be considered as two T pulses (digital bits) from the TX and RX FIFOs.

Figure 17-17. RC-5 Standard Packet Format

Where:

- S1, S2: Start bits (always 1)
- T: Toggle bit
- A4..A0: Address (or system) bits
- C5..C0: Command bits

The toggle bit T changes when a new command is transmitted to detect when the same key is pressed twice (effectively receiving the same data from the host consecutively). A brief delay in the transmission of the same command is detected by the use of the toggle bit because a code is sent while the MPU transmits characters to the UART for transmission. The address bits define the machine or device for which the infrared transmission is intended, and the command defines the operation.

To accommodate an extended RC-5 format, the S2 bit is replaced by an additional command bit (C6) that allows the command range to increase to 7 bits. This format is known as the extended RC-5 format.

SIRC encoding uses the duration of modulation for mark and space; therefore, the duration of data bits inside the standard frame length varies.

Figure 17-18 shows the packet format and bit encoding. As Figure 17-19 shows, 1 start bit of 2 ms and control codes are followed by data that constitute the entire frame.

Figure 17-18. SIRC Packet Format

Note: The encoding must take a standard duration, but the contents of the data can vary. This implies that the control software for emitting and receiving data packets must exercise a scheme of interpacket delay, where the emission of successive packets can be done only after a real-time delay has expired.

Figure 17-19. SIRC Bit Transmission Example

This document does not describe all encoding methods and techniques; the preceding information shows the considerations required to employ different encoding methods for different industry-standard protocols. See industry-standard documentation for specific methods of encoding and protocol usage.

Table 17-11. UART Clocks (continued)

Clock Type	Frequency	Name	Comments
UART2			
Functional clock	CORE_48M_FCLK	UART2_FCLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_FCLKEN1_CORE[14] EN_UART2 bit.
Interface clock	CORE_L4_ICLK	UART2_ICLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_ICLKEN1_CORE[14] EN_UART2 bit. Enable/disable auto-idle for this clock with the PRCM.CM_AUTOIDLE1_CORE[14] AUTO_UART2 bit.
UART3			
Functional clock	PER_48M_FCLK	UART3_FCLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_FCLKEN_PER[11] EN_UART3 bit.
Interface clock	PER_L4_ICLK	UART3_ICLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_ICLKEN_PER[11] EN_UART3 bit. Enable/disable auto-idle for this clock with the PRCM.CM_AUTOIDLE_PER[11] AUTO_UART3 bit.

The idle and wake-up processes use a handshake protocol between the PRCM module and the UARTs (for a description of the protocol, see the *Power, Reset, and Clock Management* chapter). The UARTi.SYSC_REG[4:3] IDLEMODE field controls the UART idle mode.

17.3.1.2 Hardware Reset

Table 17-12 lists the UART reset domain.

Table 17-12. Reset Domain

Peripherals	Reset Domain
UART1	CORE_RST
UART2	CORE_RST
UART3	PER_RST

17.3.1.3 Software Reset

The UARTi.SYSC_REG[1] SOFTRESET bit controls the software reset; writing 1 to this bit triggers a software-reset functionally equivalent to hardware reset.

17.3.1.4 Power Domain

Each UART in the CORE or PER power domain can dynamically switch between available voltage levels (see Table 17-13).

Table 17-13. Power Domain

Peripherals	Power Domain
UART1	CORE
UART2	CORE
UART3	PER

17.3.2 Hardware Requests

17.3.2.1 Interrupts

Table 17-14 describes the UART interrupt mappings.

Table 17-14. Interrupt Mapping to MPU Subsystem

IRQ	Source	Description
M_IRQ_72	UART1_IRQ	UART module 1 interrupt to MPU
M_IRQ_73	UART2_IRQ	UART module 2 interrupt to MPU
M_IRQ_74	UART3_IRQ	UART module 3 interrupt to MPU

Table 17-15. Interrupt Mapping to IVA2.2 Subsystem

IRQ	SOURCE	DESCRIPTION
IVA2_IRQ[15]	UART3_IRQ	UART module 3 interrupt to IVA2.2 subsystem

17.3.2.2 DMA Requests

Table 17-16 describes the UART DMA requests.

Table 17-16. UART DMA Requests to System DMA

DMA ⁽¹⁾	Source	Description
S_DMA_48	UART1_DMA_TX	UART module 1 transmit request
S_DMA_49	UART1_DMA_RX	UART module 1 receive request
S_DMA_50	UART2_DMA_TX	UART module 2 transmit request
S_DMA_51	UART2_DMA_RX	UART module 2 receive request
S_DMA_52	UART3_DMA_TX	UART module 3 transmit request
S_DMA_53	UART3_DMA_RX	UART module 3 receive request

⁽¹⁾ This table assumes that DMA mode 1 is used.

Table 17-17. UART DMA Requests to IVA2.2 Subsystem DMA

DMA	SOURCE	DESCRIPTION
D_DMA_10	UART3_DMA_TX	UART module 3 transmit request
D_DMA_11	UART3_DMA_RX	UART module 3 receive request

17.3.2.3 Wake-up Request

The UART can wake up the system on different events (see [Section 17.6, UART/IrDA/CIR Registers](#)).

One important wake-up generation is event detection on the uarti_cts pin when the system is idle. The uarti_cts pin uses an asynchronous path to transmit the wake-up request to the system (PRCM), which enables wake-up capabilities to be active even if all module clocks are off (see [Table 17-18](#)).

Table 17-18. Wake-Up Requests from PRCM

Wake-Up Pin	PRCM Input	Description
uart1_cts	UART1_SWAKEUP	Wake UART1 (system wake-up capabilities)
uart2_cts	UART2_SWAKEUP	Wake UART2 (system wake-up capabilities)

Table 17-18. Wake-Up Requests from PRCM (continued)

Wake-Up Pin	PRCM Input	Description
uart3_cts	UART3_SWAKEUP	Wake UART3 (system wake-up capabilities)

CAUTION

UARTs are not in the WAKEUP power domain, which implies limitations on wake-up capability. If the CORE power domain is off, UART1 and UART2 cannot wake up the system, because power is not supplied. If the PER power domain is off, UART3 cannot wake up the system, because power is not supplied. In these cases, a GPIO multiplexed on the uarti_cts pin can be used to capture the event and wake up the system. Software must enable this strategy, if required. See the *General-Purpose Interface* chapter for a full description of this mechanism.

17.4 UART/IrDA/CIR Functional Description

17.4.1 UART/IrDA/CIR Block Description

The UART/IrDA/CIR module can be divided into three main blocks:

- FIFO management
- Mode selection
- Protocol formatting

FIFO management is common to all functions and enables the transmission and reception of data from the host processor point of view.

There are two mode selections:

- Function mode selection: Route the data to the chosen functionality (UART, IrDA, or CIR) and enable the mechanism corresponding to the chosen functionality.
- Register mode selection, which enables conditional access to registers

Protocol formatting has three subcategories:

- Clock generation: The 48-MHz input clock generates all necessary clocks.
- Data formatting: Each function uses its own state-machine, which assumes the transition between FIFO data and frame data.
- Interrupt management: Different interrupt types are generated depending on the chosen function.

In parallel with these functional blocks, a power-saving strategy exists for each function.

Figure 17-21 is the UART/IrDA/CIR block diagram.

Figure 17-21. UART/IrDA/CIR Block Diagram

uart-022

17.4.2 FIFO Management

The FIFO is accessed by reading/writing the UARTi.[RHR_REG](#) and UARTi.[THR_REG](#) registers. Parameters are controlled using the FIFO control register (UARTi.[FCR_REG](#)) and supplementary control register (UARTi.[SCR_REG](#)). Reading the UARTi.[SSR_REG](#)[0] TX_FIFO_FULL bit at 1 means the FIFO is full.

The UARTi.[TLR_REG](#) register controls the FIFO trigger level, which enables the DMA and interrupt generation. After reset, both transmitter and receiver FIFOs are disabled; so, in effect, the trigger level is the default value of 1 byte. [Figure 17-22](#) shows the FIFO management registers.

Note: Data in the UARTi.[RHR_REG](#) register is not overwritten when an overflow occurs.

Note: The UARTi.[SFLSR_REG](#), UARTi.[SFREGL_REG](#), and UARTi.[SFREGH_REG](#) status registers are used in IrDA mode only. For use, see [Section 17.4.4.2.3, IrDA Data Formatting](#).

Figure 17-22. FIFO Management Registers

uart-023

17.4.2.1 FIFO Trigger

17.4.2.1.1 Transmit FIFO Trigger

Table 17-19 summarizes the transmit FIFO trigger level settings.

Table 17-19. TX FIFO Trigger Level Setting Summary

SCR_REG[6]	TLR_REG[3:0]	TX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.FCR_REG[5:4] TX_FIFO_TRIG field (8,16, 32, or 56 spaces)
0	≠ 0x0	Defined by the UARTi.TLR_REG[3:0] TX_FIFO_TRIG_DMA field (from 4 to 60 spaces with a granularity of 4 spaces)
1	Value	Defined by the concatenated value of TX_FIFO_TRIG_DMA and TX_FIFO_TRIG (from 1 to 63 spaces with a granularity of 1 space) Note: The combination of TX_FIFO_TRIG_DMA = 0x0 and TX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of one space required). All zeros result in unpredictable behavior.

17.4.2.1.2 Receive FIFO Trigger

Table 17-20 summarizes the receive FIFO trigger level settings.

Table 17-20. RX FIFO Trigger Level Setting Summary

SCR_REG[7]	TLR_REG[7:4]	RX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.FCR_REG[7:6] RX_FIFO_TRIG field (8,16, 56, or 60 characters)
0	≠ 0x0	Defined by UARTi.TLR_REG[7:4] RX_FIFO_TRIG_DMA field (from 4 to 60 characters with a granularity of 4 characters)
1	Value	Defined by the concatenated value of RX_FIFO_TRIG_DMA and RX_FIFO_TRIG (from 1 to 63 characters with a granularity of 1 character). Note: The combination of RX_FIFO_TRIG_DMA = 0x0 and RX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum 1 character required). All zeros result in unpredictable behavior.

The receive threshold is programmed using the UARTi.TCR_REG[7:4] RX_FIFO_TRIG_START and UARTi.TCR_REG[3:0] RX_FIFO_TRIG_HALT fields.

- Trigger levels from 0 to 60 bytes are available with a granularity of four. (Trigger level = 4 x [4-bit register value])
- To ensure correct device operation, ensure that RX_FIFO_TRIG_HALT > RX_FIFO_TRIG when auto-RTS is enabled.
- In the FIFO interrupt mode with flow control, ensure that the trigger level to HALT transmission is greater than or equal to the receive FIFO trigger level (either the UARTi.TCR_REG[7:4] RX_FIFO_TRIG_START field or the UARTi.FCR_REG[7:6] RX_FIFO_TRIG field); otherwise, FIFO operation stalls. In the FIFO DMA mode with flow control, this concept does not exist, because a DMA request is sent when a byte is received.

17.4.2.2 FIFO Interrupt Mode

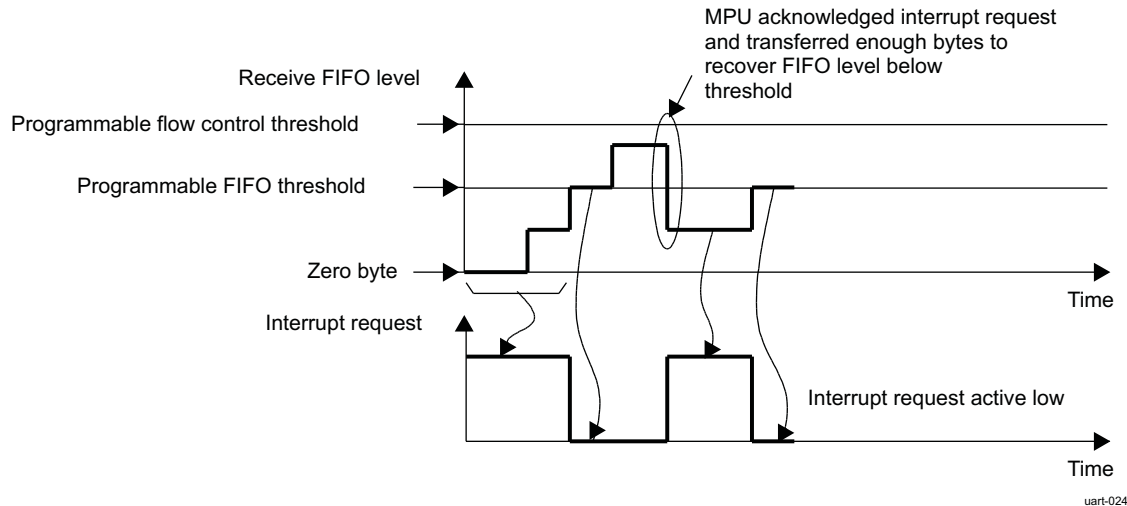

In the FIFO interrupt mode (the FIFO control register UARTi.FCR_REG[0] FIFO_EN bit is set to 1 and relevant interrupts are enabled by the UARTi.IER_REG register), an interrupt signal informs the processor of the status of the receiver and transmitter. These interrupts are raised when the receive/transmit FIFO threshold (the UARTi.TLR_REG[7:4] RX_FIFO_TRIG_DMA and UARTi.TLR_REG[3:0] TX_FIFO_TRIG_DMA fields or the UARTi.FCR_REG[7:6] RX_FIFO_TRIG and UARTi.FCR_REG[5:4] TX_FIFO_TRIG fields, respectively) is reached.

The interrupt signals instruct the MPU to transfer data to the destination (from the UART module in receive mode and/or from any source to the UART FIFO in transmit mode).

When the UART flow control is enabled with the interrupt capabilities, the UART flow control FIFO threshold (UARTi.TCR_REG[3:0] RX_FIFO_TRIG_HALT field) must be greater than or equal to the receive FIFO threshold.

Figure 17-23 shows the generation of the receive FIFO interrupt request.

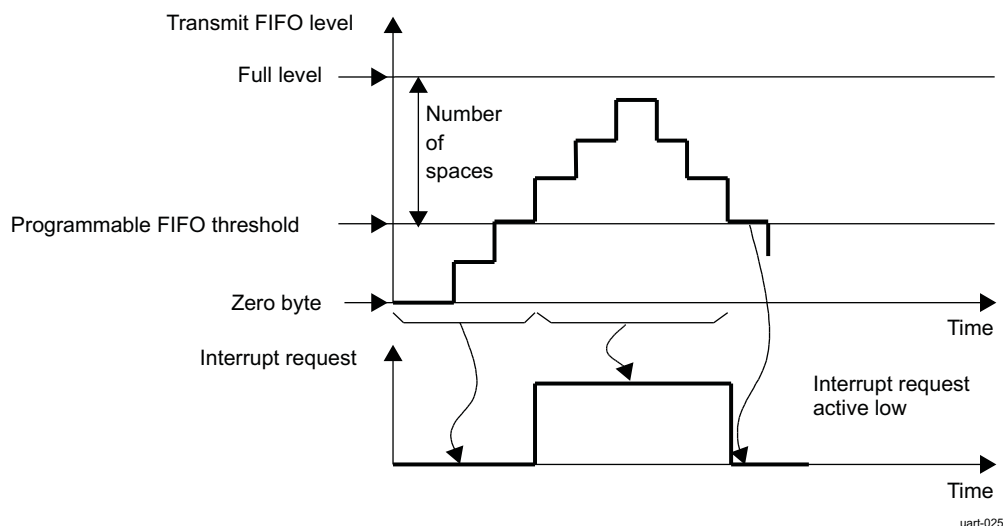

Figure 17-23. Receive FIFO Interrupt Request Generation

In receive mode, no interrupt is generated until the receive FIFO reaches its threshold. Once low, the interrupt can be deasserted only when the MPU has handled enough bytes to make the FIFO level below threshold. The flow control threshold is set at a higher value than the FIFO threshold.

Figure 17-24 shows the generation of the transmit FIFO interrupt request.

Figure 17-24. Transmit FIFO Interrupt Request Generation

In transmit mode, an interrupt request is automatically asserted when the TX FIFO is empty. This request is deasserted when the TX FIFO crosses the threshold level. The interrupt line is deasserted until a sufficient number of elements is transmitted to go below the TX FIFO threshold.

17.4.2.3 FIFO Polled Mode Operation

In the FIFO polled mode (the UARTi.FCR_REG[0] FIFO_EN bit is set to 0 and the relevant interrupts are disabled by the UARTi.IER_REG register), the status of the receiver and transmitter can be checked by polling the line status register (UARTi.LSR_REG).

This mode is an alternative to the FIFO interrupt mode of operation in which the status of the receiver and transmitter is automatically determined by sending interrupts to the MPU.

17.4.2.4 FIFO DMA Mode Operation

Although DMA operation includes four modes (DMA modes 0/1/2/3), the information in [Table 17-16](#) assumes that mode 1 is used. (Mode 2 and mode 3 are legacy modes that use only one DMA request for each module.)

In mode 2, the remaining DMA request is used for RX. In mode 3, the remaining DMA request is used for TX.

The DMA requests in mode 2 and mode 3 use S_DMA_48, S_DMA_50, and S_DMA_52/D_DMA_10. S_DMA_49, S_DMA_51, and S_DMA_53/D_DMA_11 are not used by the module in mode 2 and mode 3 and can be selected as follows:

- When the UARTi.SCR_REG[0] DMA_MODE_CTL bit is set to 0, setting the UARTi.FCR_REG[3] DMA_MODE bit to 0 enables DMA mode 0. Setting the DMA_MODE bit to 1 enables DMA mode 1.
- When the DMA_MODE_CTL bit is set to 1, the UARTi.FCR_REG[2:1] DMA_MODE_2 field determines DMA mode 0 to 3 based on the supplementary control register (SCR_REG) description.

For example:

- If no DMA operation is desired, set the DMA_MODE_CTL bit to 1 and the DMA_MODE_2 field to 0x0. (The DMA_MODE bit is discarded.)
- If DMA mode 1 is desired, set either the DMA_MODE_CTL bit to 0 and the DMA_MODE bit to 1, or set the DMA_MODE_CTL bit to 1 and the DMA_MODE_2 field to 01. (The DMA_MODE bit is discarded.)

If the FIFOs are disabled (the UARTi.FCR_REG[0] FIFO_EN bit = 0), the DMA occurs in single-character transfers.

When DMA mode 0 is programmed, the signals associated with DMA operation are not active.

17.4.2.4.1 DMA Transfers (DMA Mode 1, 2, or 3)

Figure 17-25 through Figure 17-28 show the supported DMA operations.

Figure 17-25. Receive FIFO DMA Request Generation (32 Characters)

uart-026

In receive mode, a DMA request is generated when the receive FIFO reaches its threshold level defined in the trigger level register (UARTi.TLR_REG). This request is deasserted when the number of bytes defined by the threshold level is read by the system DMA (sDMA).

In transmit mode, a DMA request is automatically asserted when the transmit FIFO is empty. This request is deasserted when the number of bytes defined by the number of spaces in the trigger level register (UARTi.TLR_REG) is written by the sDMA. If an insufficient number of characters is written, the DMA request stays active.

Figure 17-26. Transmit FIFO DMA Request Generation (56 Spaces)

uart-027

The DMA request is again asserted if the FIFO can receive the number of bytes defined by the UARTi.TLR_REG register.

The threshold can be programmed in a number of ways. Figure 17-26 shows a DMA transfer operating with a space setting of 56 that can arise from using the auto settings in the UARTi.FCR_REG[5:4] TX_FIFO_TRIG field or the UARTi.TLR_REG[3:0] TX_FIFO_TRIG_DMA field concatenated with the TX_FIFO_TRIG field.

The setting of 56 spaces in the UART/IrDA/CIR module must correlate with the settings of the sDMA so that the buffer does not overflow (program the DMA request size of the local host controller to be equal to the number of spaces value in the UART/IrDA/CIR module).

Figure 17-27 shows an example with eight spaces to show the buffer level crossing the space threshold. Again, the local host DMA controller settings must correspond to that of the UART/IrDA/CIR module.

Figure 17-27. Transmit FIFO DMA Request Generation (8 Spaces)

uart-028

The final example shows the setting of one space that uses the DMA for each transfer of one character to the transmit buffer (see [Figure 17-28](#)). The buffer is filled at a faster rate than the baud rate at which data is transmitted to the TX pin. Eventually, the buffer is completely full and the DMA operations stop transferring data to the transmit buffer.

On two occasions the buffer holds the maximum amount of data words; shortly after this, the DMA is disabled to show the slower transmission of the data words to the TX pin. Eventually, the buffer is emptied at the rate specified by the baud rate settings of the UARTi.DLL_REG and the UARTi.DLH_REG registers.

Again, the DMA settings must correspond to the system local host DMA controller settings to ensure correct operation of this logic.

Figure 17-28. Transmit FIFO DMA Request Generation (1 Space)

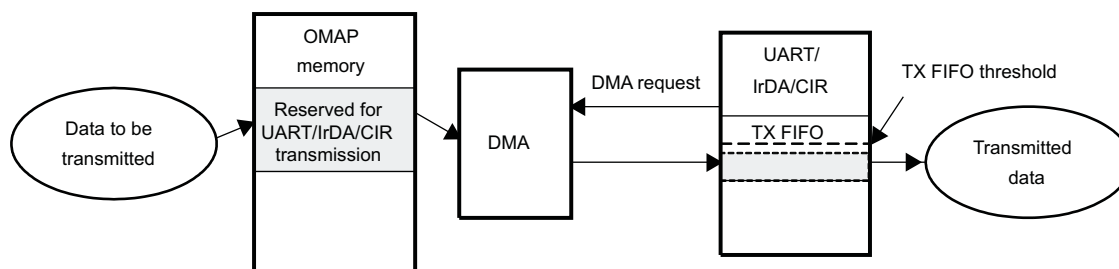

uart-029

17.4.2.4.2 DMA Transmission

Figure 17-29 shows the DMA transmission process.

Figure 17-29. Transmission Process

uart-030

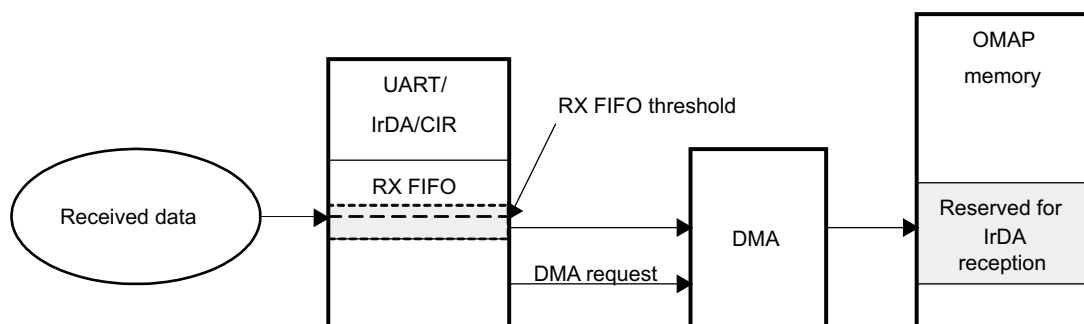

- Data to be transmitted are put in the OMAP35x memory reserved for UART/IrDA/CIR transmission by the DMA:
 - Until the TX FIFO trigger level is not reached, a DMA request is generated.
 - An element (1 byte) is transferred from the SDRAM to the TX FIFO at each DMA request (DMA element synchronization).
- Data in the TX FIFO are automatically transmitted.
- The end of the transmission is signaled by the UARTi.THR_REG empty (TX FIFO empty).

Note: In IrDA mode, the transmission is not ended immediately after the TX FIFO empties, at which point there are still the last data byte, the CRC field, and the stop flag to be transmitted; thus, the end of transmission is a few milliseconds after the UARTi.THR_REG register empties.

17.4.2.4.3 DMA Reception

Figure 17-30 shows the DMA reception process.

Figure 17-30. Reception Process

uart-031

1. Enable the reception.
2. Received data are put in the RX FIFO.
3. Data are transferred from the RX FIFO to the device memory by the DMA.
 - At each received byte, the RX FIFO trigger level (one character) is reached and a DMA request is generated.
 - An element (1 byte) is transferred from the RX FIFO to the SDRAM at each DMA request (DMA element synchronization).
4. The end of the reception is signaled by the EOF interrupt.

17.4.3 Mode Selection

17.4.3.1 Register Access Modes

17.4.3.1.1 Operational Mode and Configuration Modes

Register access depends on the register access mode, although register access modes are not correlated to functional mode selection. Three different modes are available:

- Operational mode
- Configuration mode A
- Configuration mode B

Operational mode is the selected mode when the function is active; serial data transfer can be performed in this mode.

Both configuration mode A and configuration mode B are used during module initialization steps. These modes enable access to configuration registers, which are hidden in the operational mode. The modes are used when the module is inactive (no serial data transfer processed) and only in the initialization step or reconfiguration of the module.

The value of the UARTi.LCR_REG register determines the register access mode (see [Table 17-21](#)).

Table 17-21. UART/IrDA/CIR Register Access Mode Programming (Using LCR_REG)

Mode	Condition
Configuration_mode_A	LCR_REG[7] = 0x1 and LCR_REG[7:0]! = 0xBF
Configuration_mode_B	LCR_REG[7] = 0x1 and LCR_REG[7:0] = 0xBF
Operational_mode	LCR_REG[7] = 0x0

17.4.3.1.2 Register Access Submode

In each access register mode (operational mode or configuration mode A/B), some register accesses are conditional to the programming of a submode (MSR_SPR, TCR_TLR, and XOFF). These registers are identified in [Section 17.6, UART/IrDA/CIR Registers](#).

[Table 17-22](#) through [Table 17-24](#) summarize the register access submodes.

Table 17-22. Sub-Configuration_Mode_A Mode Summary

Mode	Condition
MSR_SPR	(EFR_REG[4] = 0x0 or MCR_REG[6] = 0x0)
TCR_TLR	EFR_REG[4] = 0x1 and MCR_REG[6] = 0x1

Table 17-23. Sub-Configuration_Mode_B Mode Summary

Mode	Condition
TCR_TLR	EFR_REG[4] = 0x1 and MCR_REG[6] = 0x1
XOFF	(EFR_REG[4] = 0x0 or MCR_REG[6] = 0x0)

Table 17-24. Sub-Operational_Mode Mode Summary

Mode	Condition
MSR_SPR	EFR_REG[4] = 0x0 or MCR_REG[6] = 0x0
TCR_TLR	EFR_REG[4] = 0x1 and MCR_REG[6] = 0x1

17.4.3.1.3 Registers Available for the Register Access Modes

Table 17-25 lists the names of the register hits in each access register mode. Gray-shaded registers do not depend on the register access mode (available in all modes).

Table 17-25. UART/IrDA/CIR Register Access Mode Overview

Address Offset	Registers					
	Configuration_Mode_A		Configuration_Mode_B		Operational_Mode	
	Read	Write	Read	Write	Read	Write

⁽¹⁾ if MSR_SPR mode is active (see Section 17.4.3.1.2, Register Access Submode)

⁽²⁾ if TCR_TLR mode is active (see Section 17.4.3.1.2, Register Access Submode)

⁽³⁾ if XOFF mode is active (see Section 17.4.3.1.2, Register Access Submode)

17.4.3.2 UART/IrDA (SIR, MIR, FIR)/CIR Mode Selection

To select a mode, set the UARTi.MDR1_REG[2:0] MODE_SELECT field (see [Table 17-26](#)).

Table 17-26. UART Mode Selection

Value	Mode
0x0:	UART 16x mode
0x1:	SIR mode (UART3 only)
0x2:	UART 16x auto-baud
0x3:	UART 13x mode
0x4:	MIR mode (UART3 only)
0x5:	FIR mode (UART3 only)
0x6:	CIR mode (UART3 only)

MODE_SELECT is effective when the module is in operational mode (see [Section 17.4.3.1, Register Access Modes](#)).

17.4.3.2.1 Registers Available for the UART Function

Only the registers listed in [Table 17-27](#) are used for the UART function.

Table 17-27. UART Mode Register Overview⁽¹⁾⁽²⁾

Address Offset	Registers					
	Configuration_Mode_A		Configuration_Mode_B		Operational_Mode	
	Read	Write	Read	Write	Read	Write
0x000	DLL_REG	DLL_REG	DLL_REG	DLL_REG	RHR_REG	THR_REG

(1) REGISTER_NAME(UART) notation indicates that the register exists for other functions (IrDA or CIR), but fields have different meanings for other functions (described separately in [Section 17.6, UART/IrDA/CIR Registers](#)).

(2) REGISTER_NAME[m:n] notation indicates that only register bits numbered m to n apply to the UART function.

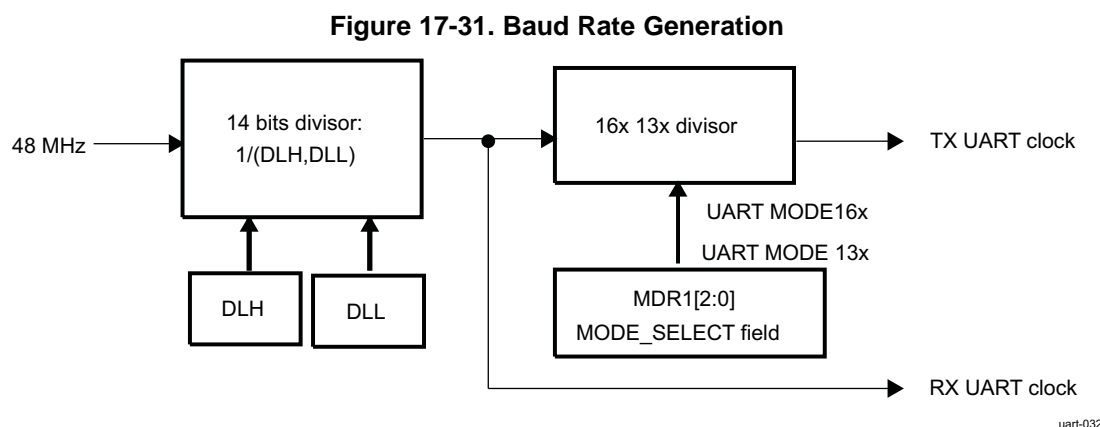

17.4.4 Protocol Formatting

17.4.4.1 UART Mode

17.4.4.1.1 UART Clock Generation: Baud Rate Generation

The UART function contains a programmable baud generator and a set of fixed divisors that divide the 48-MHz clock input down to the expected baud rate.

Figure 17-31 shows the baud rate generator and associated controls.

CAUTION

It is mandatory that `MODE_SELECT = DISABLE` (`UARTi.MDR1_REG[2:0] = 0x7`) before initializing or modifying clock parameter controls (`UARTi.DLH_REG`, `UARTi.DLL_REG`). Failure to observe this rule can result in unpredictable module behavior.

17.4.4.1.2 Choosing the Appropriate Divisor Value

Two divisor values are:

- UART 16x mode: Divisor value = Operating frequency/(16x baud rate)
- UART 13x mode: Divisor value = Operating frequency/(13x baud rate)

Table 17-30 describes the UART baud rate settings.

Table 17-30. UART Baud Rate Settings (48-MHz Clock)

Baud Rate	Baud Multiple	DLH,DLL (Decimal)	DLH,DLL (Hex)	Actual Baud Rate	Error (%)
0.3 Kbps	16x	10000	0x27, 0x10	0.3 Kbps	0
0.6 Kbps	16x	5000	0x13, 0x88	0.6 Kbps	0
1.2 Kbps	16x	2500	0x09, 0xC4	1.2 Kbps	0
2.4 Kbps	16x	1250	0x04, 0xE2	2.4 Kbps	0
4.8 Kbps	16x	625	0x02, 0x71	4.8 Kbps	0
9.6 Kbps	16x	312	0x01, 0x38	9.6153 Kbps	+0.16
14.4 Kbps	16x	208	0x00, 0xD0	14.423 Kbps	+0.16
19.2 Kbps	16x	156	0x00, 0x9C	19.231 Kbps	+0.16
28.8 Kbps	16x	104	0x00, 0x68	28.846 Kbps	+0.16

Table 17-30. UART Baud Rate Settings (48-MHz Clock) (continued)

Baud Rate	Baud Multiple	DLH,DLL (Decimal)	DLH,DLL (Hex)	Actual Baud Rate	Error (%)
38.4 Kbps	16x	78	0x00, 0x4E	38.462 Kbps	+0.16
57.6 Kbps	16x	52	0x00, 0x34	57.692 Kbps	+0.16
115.2 Kbps	16x	26	0x00, 0x1A	115.38 Kbps	+0.16
230.4 Kbps	16x	13	0x00, 0x0D	230.77 Kbps	+0.16
460.8 Kbps	13x	8	0x00, 0x08	461.54 Kbps	+0.16
921.6 Kbps	13x	4	0x00, 0x04	923.08 Kbps	+0.16
1.843 Mbps	13x	2	0x00, 0x02	1.846 Mbps	+0.16
3.6884 Mbps	13x	1	0x00, 0x01	3.6923 Mbps	+0.16

17.4.4.1.3 UART Data Formatting

The UART module can use hardware flow control to manage transmission/reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals.

The UART module is enhanced with the autobauding function. In control mode, autobauding allows the speed, the number of bits per character, and the parity selected to be set automatically.

17.4.4.1.3.1 Frame Formatting

When autobauding is not used, frame format attributes must be defined in the UARTi.LCR_REG register.

Character length is specified using the UARTi.LCR_REG[1:0] CHAR_LENGTH field.

The number of stop bits is specified using the UARTi.LCR_REG[2] NB_STOP register bit.

The parity bit is programmed using the UARTi.LCR_REG[5:3] PARITY_EN, PARITY_TYPE_1, and PARITY_TYPE_2 register bits (see Table 17-31).

Table 17-31. UART Parity Bit Encoding

PARITY_EN	PARITY_TYPE1	PARITY_TYPE2	Parity
0	N/A	N/A	No parity
1	0	0	Odd parity
1	1	0	Even parity
1	0	1	Forced 1
1	1	1	Forced 0

17.4.4.1.3.2 Hardware Flow Control

Hardware flow control is composed of auto-CTS and auto-RTS. Auto-CTS and auto-RTS can be enabled/disabled independently by programming the UARTi.EFR_REG[7:6] AUTO_CTS_EN and AUTO_RTS_EN bits, respectively.

With auto-CTS, uarti_cts must be active before the module can transmit data.

Auto-RTS activates the uarti_rts output only when there is enough room in the RX FIFO to receive data. It deactivates the uarti_rts output when the RX FIFO is sufficiently full. The HALT and RESTORE trigger levels in the UARTi.TCR_REG register determine the levels at which uarti_rts is activated/deactivated.

If both auto-CTS and auto-RTS are enabled, data transmission does not occur unless the receiver FIFO has empty space. Thus, overrun errors are eliminated during hardware flow control. If auto-CTS and auto-RTS are not enabled, overrun errors occur if the transmit data rate exceeds the receive FIFO latency.

- **Auto-RTS**

Auto-RTS data flow control originates in the receiver block. The receiver FIFO trigger levels used in auto-RTS are stored in the UARTi.TCR_REG register. uarti_rts is active if the RX FIFO level is below the HALT trigger level in the UARTi.TCR_REG[3:0] RX_FIFO_TRIG_HALT field. When the receiver FIFO HALT trigger level is reached, uarti_rts is deasserted. The sending device (for example, another UART) might send an additional byte after the trigger level is reached because it might not recognize the deassertion of RTS until it begins sending the additional byte.

uarti_rts is automatically reasserted when the receiver FIFO reaches the RESUME trigger level programmed by the UARTi.TCR_REG[7:4] RX_FIFO_TRIG_START field. This reassertion requests the sending device to resume transmission.

In this case, uarti_rts is an active-low signal.

- **Auto-CTS**

The transmitter circuitry checks uarti_cts before sending the next data byte. When uarti_cts is active, the transmitter sends the next byte. To stop the transmitter from sending the next byte, uarti_cts must be deasserted before the middle of the last stop bit currently sent.

The auto-CTS function reduces interrupts to the host system. When auto-CTS flow control is enabled, the uarti_cts state changes do not have to trigger host interrupts because the device automatically controls its own transmitter. Without auto-CTS, the transmitter sends any data present in the transmit FIFO, and a receiver overrun error can result.

In this case, uarti_cts is an active-low signal.

17.4.4.1.3.3 Software Flow Control

Software flow control is enabled through the enhanced feature register (UARTi.EFR_REG) and the modem control register (UARTi.MCR_REG). Different combinations of software flow control can be enabled by setting different combinations of UARTi.EFR_REG[3:0] (see Table 17-32).

Two other enhanced features relate to software flow control:

- XON any function (UARTi.MCR_REG[5]): Operation resumes after receiving any character after recognition of the XOFF character.

Note: The XON-any character is written into the RX FIFO even if it is a software flow character.

- Special character (UARTi.EFR_REG[5]): Incoming data is compared to XOFF2. When the special character is detected, the XOFF interrupt (UARTi.IIR_REG[4]) is set, but it does not halt transmission. The XOFF interrupt is cleared by a read of UARTi.IIR_REG. The special character is transferred to the RX FIFO.

Table 17-32. EFR_REG[0-3] Software Flow Control Options

Bit 3	Bit 2	Bit 1	Bit 0	Tx, Rx Software Flow Controls
0	0	X	X	No transmit flow control
1	0	X	X	Transmit XON1, XOFF1
0	1	X	X	Transmit XON2, XOFF2
1	1	X	X	Transmit XON1, XON2: XOFF1, XOFF2 ⁽¹⁾
X	X	0	0	No receive flow control
X	X	1	0	Receiver compares XON1, XOFF1
X	X	0	1	Receiver compares XON2, XOFF2
X	X	1	1	Receiver compares XON1, XON2: XOFF1, XOFF2 ⁽¹⁾

⁽¹⁾ In these cases, the XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2. XON1 is defined in the UARTi.XON1_ADDR1_REG[7:0] XON_WORD1 field, XON2 is defined in UARTi.XON2_ADDR2_REG[7:0] XON_WORD2. XOFF1 is defined in the UARTi.XOFF1_REG[7:0] XOFF_WORD1 field, XOFF2 is defined in UARTi.XOFF2_REG[7:0] XOFF_WORD2.

17.4.4.1.3.3.1 Receive (RX)

When software flow control operation is enabled, the UART compares incoming data with XOFF1/2 programmed characters (in certain cases, XOFF1 and XOFF2 must be received sequentially). When the correct XOFF characters are received, transmission stops after transmission of the current character is complete. XOFF detection also sets UARTi.IIR_REG[4] (if enabled by UARTi.IER_REG[5]) and causes the interrupt line to go low.

To resume transmission, an XON1/2 character must be received (in certain cases, XON1 and XON2 must be received sequentially). When the correct XON characters are received, UARTi.IIR_REG[4] is cleared and the XOFF interrupt disappears.

Note: When a parity, framing, or break error occurs while receiving a software flow control character, this character is treated as normal data and is written to the RX FIFO.

When XON-any and special character detect are disabled and software flow control is enabled, no valid XON or XOFF characters are written to the RX FIFO. For example, when UARTi.EFR_REG[1:0] = 0x2, if XON1 and XOFF1 characters are received, they do not get written to the RX FIFO.

When pairs of software flow characters are programmed to be received sequentially (UARTi.EFR_REG[1:0] = 0x3), the software flow characters are not written to the RX FIFO if they are received sequentially. However, received XON1/XOFF1 characters must be written to the RX FIFO if the subsequent character is not XON2/XOFF2.

17.4.4.1.3.3.2 Transmit (TX)

XOFF1: Two characters are transmitted when the RX FIFO passes the trigger level programmed by UARTi.TCR_REG[3:0].

XON1: Two characters are transmitted when the RX FIFO reaches the trigger level programmed by UARTi.TCR_REG[7:4].

Note: If software flow control is disabled after an XOFF character is sent, the module transmits XON characters automatically to enable normal transmission to proceed.

The transmission of XOFF(s)/XON(s) follows the same protocol as transmission of an ordinary byte from the TX FIFO. This means that even if the word length is set to 5, 6, or 7 characters, the 5, 6, or 7 LSBs of XOFF1/2 and XON1/2 are transmitted. The 5, 6, or 7 bits of a character are seldom transmitted, but this function is included to maintain compatibility with earlier designs.

It is assumed that software flow control and hardware flow control are never enabled simultaneously.

17.4.4.1.3.4 Autobauding Modes

In autobauding mode, the UART can extract transfer characteristics (speed, length, and parity) from an AT command (ASCII code). These characteristics are used to receive data after an "at" (AT) and to send data.

The valid AT commands follow:

AT	DATA	<CR>
at	DATA	<CR>
A/		
a/		

A line break during the acquisition of the sequence AT is not recognized, and echo functionality is not implemented in hardware.

A/ and a/ are not used to extract characteristics, but they must be recognized because of their special meaning. Either A/ or a/ is used to instruct the software to repeat the last received AT command; therefore, an a/ always follows an AT, and transfer characteristics are not expected to change between an AT and an a/.

When a valid AT is received, AT and all subsequent data, including the final <CR> (0x0D), are saved to RX FIFO. The autobaud state-machine waits for the next valid AT command. If an a/ (A/) is received, the a/ (A/) is saved into RX FIFO and the state-machine waits for the next valid AT command.

On the first successful detection of the baud rate, the UART activates an interrupt to signify that the AT (upper or lower case) sequence is detected. The UARTi.UASR_REG register reflects the correct settings for the baud rate detected. The interrupt activity can continue in this fashion when a subsequent character is received. Therefore, it is recommended that the software enable the RHR interrupt when using the autobaud mode.

The following settings are detected in autobaud mode with a module clock of 48 MHz:

- Speed: 115.2k baud, 57.6k baud, 38.4k baud, 28.8k baud, 19.2k baud, 14.4k baud, 9.6k baud, 4.8k baud, 2.4k baud, or 1.2k baud
- Length: 7 or 8 bits
- Parity: Odd, even, or space

Note: The combination of 7-bit character + space parity is not supported.

Autobauding mode is selected when the UARTi.MDR1_REG[2:0] MODE_SELECT field is set to 0x2. In the UART autobauding mode, UARTi.DLL_REG, UARTi.DLH_REG, UARTi.LCR_REG[5:0] settings are not used; instead, UASR_REG is updated with the configuration detected by the autobauding logic.

UASR_REG Autobauding Status Register Use

This register is used to set up transmission according to the characteristics of the previous reception instead of the UARTi.LCR_REG, UARTi.DLL_REG, and UARTi.DLH_REG registers when the UART is in autobauding mode.

To reset the autobauding hardware (to start a new AT detection) or to set the UART in standard mode (no autobaud), the UARTi.MDR1_REG[2:0] MODE_SELECT field must be set to reset state (0x7) and then to the UART in autobauding mode (0x2) or to the UART in standard mode (0x0).

Use limitation:

- Only 7- and 8-bit characters (5- and 6-bit not supported)
- 7-bit character with space parity not supported
- Baud rate between 1,200 and 115,200 bps (10 possibilities)

17.4.4.1.3.5 Error Detection

When the UARTi.LSR_REG register is read, UARTi.LSR_REG[4:2] reflects the error bits (BI: break condition, FE: framing error, PE: parity error) of the character at the top of the RX FIFO (next character to be read). Therefore, reading the UARTi.LSR_REG register and then reading the UARTi.RHR_REG register identifies errors in a character.

Reading the UARTi.RHR_REG register updates the BI, FE, and PE bits (see Table 17-33 for the UART mode interrupts).

The UARTi.LSR_REG [7] RX_FIFO_STS bit is set when there is an error in the RX FIFO and is cleared only when no errors remain in the RX FIFO.

Note: Reading UARTi.LSR_REG does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading UARTi.RHR_REG.

Reading UARTi.LSR_REG clears the OE bit if it is set (see Table 17-33 for the UART mode interrupts).

17.4.4.1.3.6 Overrun During Receive

Overrun during receive occurs if the RX state-machine tries to write data into the RX FIFO when it is already full. When overrun occurs, the device interrupts the MPU with UARTi.IIR_REG[5:1] IT_TYPE = 0x3 (receiver line status error) and discards the remaining portion of the frame.

Overrun also causes an internal flag to be set, which disables further reception. Before the next frame can be received, the system (MPU) must:

- Reset the RX FIFO
- Read the UARTi.RESUME_REG register (which clears the internal flag)

17.4.4.1.3.7 Time-Out and Break Conditions

17.4.4.1.3.7.1 Time-Out Counter

An RX idle condition is detected when the receiver line (uarti_rx) is high for a time equivalent to 4x programmed word length + 12 bits. uarti_rx is sampled midway through each bit.

For sleep mode, the counter is reset when there is activity on uarti_rx.

For the time-out interrupt, the counter counts only when there is data in the RX FIFO, and the count is reset when there is activity on uarti_rx or when the UARTi.RHR_REG is read.

17.4.4.1.3.7.2 Break Condition

When a break condition occurs, uarti_tx is pulled low. A break condition is activated by setting the UARTi.LCR_REG[6] BREAK_EN bit. The break condition is not aligned on word stream (that is, a break condition can occur in the middle of a character). The only way to send a break condition on a full character is as follows:

1. Reset the transmit FIFO (if enabled).
2. Wait for the transmit shift register to empty (UARTi.LSR_REG[6] TX_SR_E = 1).
3. Take a guard time according to stop-bit definition.
4. Set the BREAK_EN bit to 1.

The break condition is asserted while the BREAK_EN bit is set to 1.

The time-out counter and break condition apply only to UART modem operation and not to IrDA/CIR mode operation.

17.4.4.1.4 UART Mode Interrupt Management

The UART mode includes seven possible interrupts prioritized to six levels.

When an interrupt is generated, the interrupt identification register (UARTi.IIR_REG) sets the UARTi.IIR_REG[0] IT_PENDING bit to 0 to indicate that an interrupt is pending, and provides the type of interrupt through UARTi.IIR_REG[5:1]. Table 17-33 summarizes the interrupt control functions.

Table 17-33. UART Mode Interrupts

IIR_REG[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000001	None	None	None	None
000110	1	Receiver line status	OE, FE, PE, or BI errors occur in characters in the RX FIFO.	FE, PE, BI: Read RHR_REG. OE: Read LSR_REG.
001100	2	RX time-out	Stale data in RX FIFO	Read RHR_REG.
000100	2	RHR interrupt	DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable)	Read RHR_REG until interrupt condition disappears.
000010	3	THR interrupt	TFE (THR_REG empty) (FIFO disable)	Write to THR_REG until interrupt condition disappears.

Table 17-33. UART Mode Interrupts (continued)

IIR_REG[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
			TX FIFO below trigger level (FIFO enable)	
000000	4	Modem status	See the MSR_REG register.	Read MSR_REG .
010000	5	XOFF interrupt/special character interrupt	Receive XOFF characters/special character	Receive XON character(s), if XOFF interrupt/read of IIR_REG , if special character interrupt.
100000	6	CTS, RTS	RTS pin or CTS pin change state from active (low) to inactive (high).	Read IIR_REG .

For the receiver-line status interrupt, the RX_FIFO_STS bit (UARTi.[LSR_REG\[7\]](#)) generates the interrupt.

For the XOFF interrupt, if an XOFF flow character detection caused the interrupt, the interrupt is cleared by an XON flow character detection. If special character detection caused the interrupt, the interrupt is cleared by a read of the UARTi.[IIR_REG](#) register.

17.4.4.1.4.1 Wake-Up Interrupt

Wake-up interrupt is a special interrupt that is not designed the same way as other interrupts. This interrupt is enabled when the UARTi.[SCR_REG\[4\]](#) RX_CTS_WU_EN bit is set to 1. The UARTi.[IIR_REG](#) register is not modified when it occurs; the UART3.[SSR_REG\[1\]](#) RX_CTS_WU_STS bit must be checked to detect a wake-up event.

When a wake-up interrupt occurs, the only way to clear it is to reset the UARTi.[SCR_REG\[4\]](#) RX_CTS_WU_EN bit. This bit must be re-enabled (set to 1) after the current wake-up interrupt event is processed to detect the next incoming wake-up event.

17.4.4.2 IrDA Mode (UART3 Only)

17.4.4.2.1 IrDA Clock Generation: Baud Generator

The IrDA function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

[Figure 17-32](#) shows the baud rate generator and associated controls.

Table 17-34. IrDA Baud Rates Settings (continued)

Baud Rate	IR Mode	Baud Multiple	Encoding	DLH, DLL (Decimal)	Actual Baud Rate	Error (%)\$	Source Jitter (%)	Pulse duration
57.6 Kbps	SIR	16x	3/16	52	57.692 Kbps	+0.16	0	3.25 μ s
115.2 Kbps	SIR	16x	3/16	26	115.38 Kbps	+0.16	0	1.62 μ s
0.576 Mbps	MIR	41x/42x	1/4	2	0.5756 Mbps ⁽¹⁾	0	+1.63/- 0.80	416 ns
1.152 Mbps	MIR	41x/42x	1/4	1	1.1511 Mbps ⁽¹⁾	0	+1.63/- 0.80	208 ns
4 Mbps	FIR	6x	4 PPM	-	4 Mbps	0	0	125 ns

⁽¹⁾ Average value

Note: Baud rate error and source jitter table values do not include 48-MHz reference clock error and jitter.

17.4.4.2.3 IrDA Data Formatting

The methods described in this section apply to all IrDA modes (SIR, MIR, and FIR).

17.4.4.2.3.1 IRRX Polarity Control

The UART3.MDR2_REG[6] IRRXINVERT bit provides the flexibility to invert the uart3_rx_irrx pin in the UART module to ensure that the protocol at the output of the transceiver module has the same polarity at module level. By default, the uart3_rx_irrx pin is inverted because most transceivers invert the IR receive pin.

17.4.4.2.3.2 IrDA Reception Control

Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

Operation of the uart3_rx_irrx input can be disabled by the UART3.ACREG_REG[5] DIS_IR_RX bit.

17.4.4.2.3.3 IR Address Checking

In all IR modes, when address checking is enabled, only frames intended for the device are written to the RX FIFO. This restriction avoids receiving frames not meant for this device in a multipoint infrared environment. It is possible to program two frame addresses that the UART IrDA receives with the UART3.XON1_ADDR1_REG[7:0] XON_WORD1 and UART3.XON2_ADDR2_REG[7:0] XON_WORD2 fields.

Setting the EFR_REG[0] bit to 1 selects address1 checking. Setting the EFR_REG[1] bit to 1 selects address2 checking. Setting the EFR_REG[1:0] bit to 0 disables all address checking operations. If both bits are set, the incoming frame is checked for both private and public addresses.

If address checking is disabled, all received frames write to the reception FIFO.

17.4.4.2.3.4 Frame Closing

A transmission frame can be correctly terminated in two ways:

- Frame-length method: The frame-length method is selected by setting the UART3.MDR1_REG[7] FRAME_END_MODE bit to 0. The MPU writes the frame-length value to the UART3.TXFLH_REG and UART3.TXFLR_REG registers. The device automatically attaches end flags to the frame when the number of bytes transmitted equals the frame-length value.
- Set-EOT bit method: The set-EOT bit method is selected by setting the FRAME_END_MODE bit to 1. The MPU writes 1 to the UART3.ACREG_REG[0] EOT bit just before it writes the last byte to the TX FIFO. When the MPU writes the last byte to the TX FIFO, the device internally sets the tag bit for that character in the TX FIFO. As the TX state-machine reads data from the TX FIFO, it uses this tag-bit information to attach end flags and correctly terminate the frame.

17.4.4.2.3.5 Store and Controlled Transmission

In store and controlled transmission (SCT) mode, the MPU starts writing data to the TX FIFO. Then, after writing a part of a frame (for a bigger frame) or a whole frame (a small frame; that is, a supervisory frame), the MPU writes 1 to the UART3.ACREG_REG[2] SCTX_EN bit (deferred TX start) to start transmission.

SCT mode is enabled by setting the UART3.MDR1_REG[5] SCT bit to 1. This transmission method is different from the normal mode, in which data transmission starts immediately after data is written to the TX FIFO. SCT mode is useful for sending short frames without TX underrun.

17.4.4.2.3.6 Error Detection

When the UART3.LSR_REG register is read, the UART3.LSR_REG[4:2] field reflects the error bits [FL, CRC, ABORT] of the frame at the top of the STATUS FIFO (the next frame status to be read).

The error is triggered by an interrupt (see [Table 17-35](#) for IrDA mode interrupts). STATUS FIFO must be read until empty (a maximum of eight reads is required).

17.4.4.2.3.7 Underrun During Transmission

Underrun during transmission occurs when the TX FIFO is empty before the end of the frame is transmitted. When underrun occurs, the device closes the frame with end flags but attaches an incorrect CRC value. The receiving device detects a CRC error and discards the frame; it can then ask for a retransmission.

Underrun also causes an internal flag to be set, which disables additional transmissions. Before the next frame can be transmitted, the system (MPU) must:

- Reset the TX FIFO.
- Read the UART3.RESUME_REG register (which clears the internal flag).

This functionality can be disabled by the UART3.ACREG_REG[4] DIS_TX_UNDERRUN bit, compensated by the extension of the stop bit in transmission if the TX FIFO is empty.

17.4.4.2.3.8 Overrun During Receive

Overrun during receive for the IrDA mode has the same functionality as that for the UART mode (see [Section 17.4.4.1.3.6, Overrun During Receive](#)).

17.4.4.2.3.9 Status FIFO

In IrDA modes, a status FIFO records the received frame status. When a complete frame is received, the length of the frame and the error bits associated with the frame are written to the status FIFO.

Reading UART3.SFREGH_REG[3:0] (MSB) and UART3.SFREGL_REG[3:0] (LSB) obtains the frame length. The frame error status is read in the UART3.SFLSR_REG register. Reading the UART3.SFLSR_REG register increments the status FIFO read pointer. The status FIFO is eight entries deep and, therefore, can hold the status of eight frames.

The MPU uses the frame-length information to locate the frame boundary in the received frame data. The MPU can screen bad frames using the error status information and can later request the sender to resend only the bad frames.

This status FIFO can be used effectively in DMA mode because the MPU must be interrupted only when the programmed status FIFO trigger level is reached, not each time a frame is received.

17.4.4.2.4 SIR Mode DATA Formatting

This section provides specific instructions for SIR mode programming.

17.4.4.2.4.1 Abort Sequence

When the transmitter prematurely closes a frame, it sends the following sequence to abort: 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

A transmission frame can be aborted by setting the UART3.ACREG_REG[1] ABORT_EN bit to 1.

When this bit is set to 1, 0x7D and 0xC1 are transmitted and the frame is not terminated with CRC or stop flags.

The receiver treats a frame as an aborted frame when a 0x7D character followed immediately by a 0xC1 character is received without transparency.

CAUTION

When the transmit FIFO is not empty and the UART3.[MDR1_REG](#)[5] SCT bit is set to 1, the UART IrDA starts a new transfer with data of a previous frame when the abort frame is sent. Therefore, TX FIFO must be reset before sending an abort frame.

17.4.4.2.4.2 Pulse Shaping

The SIR mode supports both the 3/16th or the 1.6-μs pulse duration methods. The UART3.[ACREG_REG](#)[7] PULSE_TYPE bit selects the pulse width method in the transmit mode.

17.4.4.2.4.3 SIR Free Format Programming

The SIR FF mode is selected by setting the module in the UART mode (UART3.[MDR1_REG](#)[2:0] MODE_SELECT = 0x0) and the UART3.[MDR2_REG](#)[3] UART_PULSE bit to 1 to allow pulse shaping.

Because the bit format remains the same, some UART mode configuration registers must be set at specific values:

- UART3.[LCR_REG](#)[1:0] CHAR_LENGTH field = 0x3 (8 data bits)
- UART3.[LCR_REG](#)[2] NB_STOP bit = 0x0 (1 stop-bit)
- UART3.[LCR_REG](#)[3] PARITY_EN bit = 0x0 (no parity)

The UART mode interrupts are used for the SIR FF mode, but many of them are not relevant (XOFF, RTS, CTS, modem status register, etc.).

17.4.4.2.5 MIR and FIR Mode Data Formatting

This section describes common instructions for FIR and MIR mode programming.

At the end of a frame reception, the MPU reads the line status register (UART3.[LSR_REG](#)) to detect possible errors in the received frame.

When the UART3.[MDR1_REG](#)[6] SIP_MODE bit is set to 1, the TX state-machine always sends one SIP at the end of a transmission frame. However, when the SIP_MODE bit is set to 0, SIP transmission depends on the UART3.[ACREG_REG](#)[3] SEND_SIP bit.

The system (MPU) can set the SEND_SIP bit at least once every 500 ms. The advantage of this approach over the default approach is that the TX state-machine does not have to send the SIP at the end of each frame, which can reduce the overhead required.

17.4.4.2.6 IrDA Mode Interrupt Management

17.4.4.2.6.1 IrDA Interrupts

The IrDA function generates interrupts. All interrupts can be enabled/disabled by writing to the appropriate bit in the interrupt enable register (UART3.[IER_REG](#)). The interrupt status of the device can be checked at any time by reading the interrupt identification register (UART3.[IIR_REG](#)).

The UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UART3.[IER_REG](#) and UART3.[IIR_REG](#) mappings, depending on the selected mode.

The IrDA modes have eight possible interrupts (see [Table 17-35](#)). The interrupt line is activated when any of the eight interrupts is generated (there is no priority).

Table 17-35. IrDA Mode Interrupts

IIR_REG Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	RHR interrupt	DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable)	Read RHR_REG until interrupt condition disappears.
1	THR interrupt	TFE (THR_REG empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to THR_REG until interrupt condition disappears.
2	Last byte in RX FIFO	Last byte of frame in RX FIFO is available to be read at the RHR port.	Read RHR_REG .
3	RX overrun	Write to RHR_REG when RX FIFO full.	Read RESUME_REG register.
4	Status FIFO interrupt	Status FIFO triggers level reached.	Read STATUS FIFO.
5	TX status	1. THR_REG empty before EOF sent. Last bit of transmission of the IrDA frame occurred, but with an underrun error. OR 2. Transmission of the last bit of the IrDA frame completed successfully.	1. Read RESUME_REG register. OR 2. Read IIR_REG .
6	Receiver line status interrupt	CRC, ABORT, or frame-length error is written into STATUS FIFO.	Read STATUS FIFO (read until empty - maximum of eight reads required).
7	Received EOF	Received end-of-frame.	Read IIR_REG .

17.4.4.2.6.2 Wake-Up Interrupts

The wake-up interrupt for the IrDA mode has the same functionality as that for the UART mode (see [Section 17.4.4.1.4.1, Wake-Up Interrupt](#)).

CAUTION

Wake-up interface implementation in this mode is based on the UARTi_SIDLEACK low-to-high transition instead of the UARTi_SIDLEACK state.

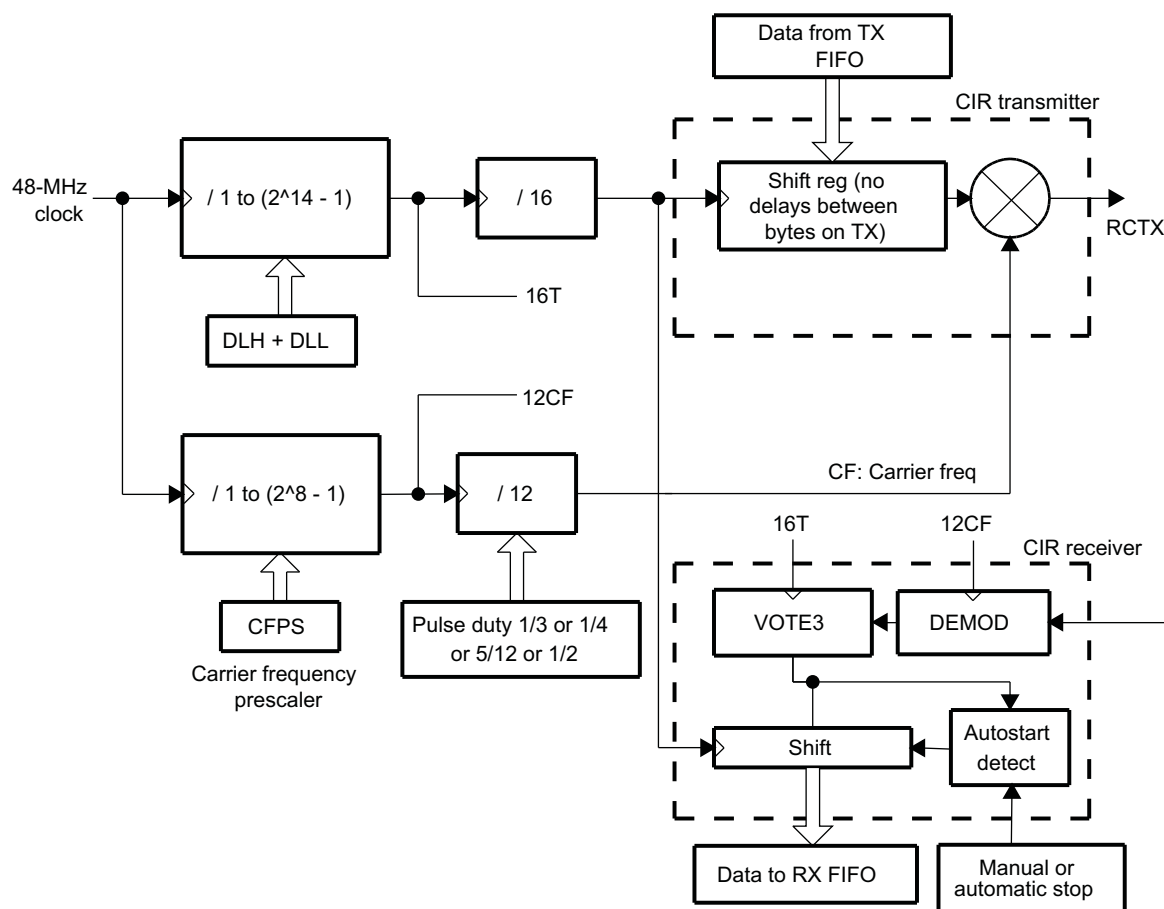

This does not ensure wake-up event generation as expected when configured in smart-idle mode and the system wakes up for a short period.

17.4.4.3 CIR Mode (UART3 Only)

17.4.4.3.1 CIR Mode Clock Generation

Depending on the encoding method (variable pulse distance/biphase), the MPU must develop a data structure that combines 1 and 0 with a t period to encode the complete frame to transmit. This can then be transmitted to the infrared output with a modulation method, as shown in [Figure 17-33](#).

Figure 17-33. CIR Mode Block Components

uart-034

Based on the requested modulation frequency, the UART3.CFPS_REG register must be set with the correct dividing value to provide the more accurate pulse frequency:

$$\text{Dividing value} = (\text{FCLK}/12)/\text{MODfreq}$$

Where:

FCLK = System clock frequency (48 MHz)

12 = Real value of baud multiple

MODfreq = Effective frequency of the modulation (MHz)

Example: For a targeted modulation frequency of 36 kHz, the CFPS_REG value must be set to 0x7 (decimal), which provides a modulation frequency of 36.04 kHz.

Note: The UART3.CFPS_REG register starts with a reset value of 105 (decimal), which translates to a frequency of 38.1 kHz.

The duty cycle of these pulses is user-defined by the pulse duty register bits in the UART3.MDR2_REG configuration register. Table 17-36 shows the duty cycle.

Table 17-36. Duty Cycle

MDR2_REG[5:4]	Duty Cycle (High Level)
00	1/4
01	1/3
10	5/12
11	

17.4.4.3.2 CIR Data Formatting

The methods described in this section apply to all CIR modes.

17.4.4.3.2.1 IRRX Polarity Control

The IRRX polarity control for the CIR mode has the same functionality as that for the IrDA mode (see [Section 17.4.4.2.3.1, IRRX Polarity Control](#)).

17.4.4.3.2.2 CIR Transmission

In transmission, the MPU software must exercise an element of real-time control to transmit data packets, each of which must be emitted at a constant delay from the start bits of each individual packet. Thus, when sending a series of packets, the packet-to-packet delay must respect a specific delay. Two methods can be used to control this delay:

- Filling the TX FIFO with a number of zero bits that are transmitted with a t period
- Using an external system timer to control the delay either between each start-of-frame or between the end of a frame and the start of the next one. This can be performed by:
 - Controlling the start of the frame using the UART3.MDR1_REG[5] SCT bit and UART3.ACREG_REG[2] SCTX_EN bit, depending on the timer status
 - Using the UART3.IIR_REG[5] TX_STATUS_IT interrupt to preload the next frame in the TX FIFO and to control the start of the timer (in case of control delay between the end of a frame and the start of the next frame).

17.4.4.3.2.3 CIR Reception

There are two methods of stopping reception:

- The MPU can disable the reception by setting the UART3.ACREG_REG[5] DIS_IR_RX bit to 1 when it detects that the reception is complete because of the large number of 0s received. To receive a new frame, the DIS_IR_RX bit must be set to 0.
- The reception stops automatically, depending on the value set in the BOF-length register (the UART3.EBLR_REG[7:0] EBLR field). If the value set in the UART3.EBLR_REG[7:0] EBLR field is different from 0, this feature is enabled and counts the number of bits received at 0.

17.4.4.3.3 CIR Mode Interrupt Management

17.4.4.3.3.1 CIR Interrupts

The CIR function generates interrupts that can be enabled/disabled by writing to the appropriate bit in the interrupt enable register (UART3.IER_REG). The interrupt status of the device can be checked at any time by reading the interrupt identification register (UART3.IIR_REG).

The UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UART3.IER_REG and UART3.IIR_REG mappings, depending on the selected mode.

[Table 17-37](#) lists the interrupt modes to be maintained. In CIR mode, the sole purpose of the UART3.IIR_REG[5] bit is to indicate that the last bit of infrared data was passed to the uart3_cts_rctx pin.

Table 17-37. CIR Mode Interrupts

IIR_REG Bit Number	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
1	THR interrupt	TFE (THR_REG empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to THR_REG until interrupt condition disappears.
2:4	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
5	TX status	Transmission of the last bit of the frame is completed successfully.	Read IIR_REG.
6:7	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode

17.4.4.3.3.2 Wake-Up Interrupts

The wake-up interrupt for the IrDA mode has the same functionality as that for the UART mode (see [Section 17.4.4.1.4.1, Wake-Up Interrupt](#)).

17.4.5 Power Management

17.4.5.1 UART Mode Power Management

17.4.5.1.1 Module Power Saving

In UART modes, sleep mode is enabled by setting the UARTi.IER_REG[4] SLEEP_MODE bit to 1 (when the UARTi.EFR_REG[4] ENHANCED_EN bit is set to 1).

Sleep mode is entered when all the following conditions exist:

- The serial data input line, uarti_rx, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- No interrupts are pending except THR interrupts.

Sleep mode is a good way to lower power consumption of the UART, but this state can be achieved only when the UART is set in modem mode. Therefore, even if the UART has no functional key role, it must be initialized in a functional mode to take advantage of sleep mode.

In sleep mode, the module clock and baud rate clock are stopped internally. Because most registers are clocked using these clocks, this greatly reduces power consumption. The module wakes up when a change is detected on the uarti_rx line, when data is written to the TX FIFO, and when there is a change in the state of the modem input pins.

An interrupt can be generated on a wake-up event by setting the UARTi.SCR_REG[4] RX_CTS_WU_EN bit to 1. See [Section 17.4.4.1.4.1, Wake-Up Interrupt](#), to understand how to manage the interrupt.

Note: There must be no writing to the divisor latches, UARTi.DLL_REG and UARTi.DLH_REG, to set the baud clock, BCLK, while in sleep mode. It is advisable to disable sleep mode using the UARTi.IER_REG[4] SLEEP_MODE bit before writing to the UARTi.DLL_REG register or the UARTi.DLH_REG register.

17.4.5.1.2 System Power Saving

Sleep and auto-idle modes are embedded power-saving features. At the system level, power-reduction techniques can be applied by shutting down certain internal clock and power domains of the device.

The UART supports an idle req/idle ack handshaking protocol. This protocol is used at the system level to shut down clocks of the UART in a clean and controlled manner and to switch the UART from interrupt-generation mode to wake-up generation mode for unmasked events (see the UARTi.SYSC_REG[2] ENAWAKEUP bit and the UARTi.WER_REG register).

For more information, see the *Power, Reset, and Clock Management* chapter.

17.4.5.2 IrDA Mode Power Management (UART3 Only)

17.4.5.2.1 Module Power Saving

In IrDA modes, sleep mode is enabled by setting the UART3.MDR[3] IR_SLEEP bit to 1.

Sleep mode is entered when all the following conditions exist:

- The serial data input line, uart3.rx_irrx, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- No interrupts are pending except THR interrupts.

The module wakes up when a change is detected on the uart3_rx_irrx line or when data is written to the TX FIFO.

17.4.5.2.2 System Power Saving

System power saving for the IrDA mode has the same functionality as that for the UART mode (see [Section 17.4.5.1.2, System Power Saving](#)).

17.4.5.3 CIR Mode Power Management (UART3 Only)

17.4.5.3.1 Module Power Saving

Module power saving for the CIR mode has the same functionality as that for the IrDA mode (see [Section 17.4.5.2.1, Module Power Saving](#)).

17.4.5.3.2 System Power Saving

System power saving for the CIR mode has the same functionality as that for the UART mode (see [Section 17.4.5.2.2, System Power Saving](#)).

17.5 UART/IrDA/CIR Basic Programming Model

17.5.1 UART Programming Model

17.5.1.1 Quick Start

This section outlines the procedure for operating the UART module with FIFO and DMA or interrupts. This 3-part procedure ensures the quick start of the UART module. It does not cover every UART module feature.

The first programming model covers software reset of the module. The second programming model deals with FIFO and DMA configuration. The last programming model deals with protocol, baud rate and interrupt configuration.

Note: Each programming model can be used independently of the other two; for instance, reconfiguring the FIFOs and DMA settings only.

Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information see [Section 17.4.3.1, Register Access Modes](#).

17.5.1.1.1 Software Reset

To clear the UART registers, perform the following steps:

1. Initiate a software reset:
Set the UARTi.[SYSC_REG](#)[1] SOFTRESET bit to 1.
2. Wait for the end of the reset operation:
Poll the UARTi.[SYSS_REG](#)[0] RESETDONE bit until it equals 1.

17.5.1.1.2 FIFOs and DMA Settings

To enable and configure the receive and transmit FIFOs and program the DMA mode, perform the following steps:

1. Switch to register configuration mode B to access the UARTi.[EFR_REG](#) register:
 - a. Save the current UARTi.[LCR_REG](#) value.
 - b. Set UARTi.[LCR_REG](#) to 0x00BF.
2. Enable register submode TCR_TLR to access UARTi.[TLR_REG](#) (part 1 of 2):
 - a. Save the UARTi.[EFR_REG](#)[4] ENHANCED_EN value.
 - b. Set the UARTi.[EFR_REG](#)[4] ENHANCED_EN bit to 1.
3. Switch to register configuration mode A to access the UARTi.[MCR_REG](#) register:
Set UARTi.[LCR_REG](#) to 0x0080.
4. Enable register submode TCR_TLR to access UARTi.[TLR_REG](#) (part 2 of 2):
 - a. Save the UARTi.[MCR_REG](#)[6] TCR_TLR value.
 - b. Set the UARTi.[MCR_REG](#)[6] TCR_TLR bit to 1.
5. Enable FIFO, load the new FIFO triggers (part 1 of 3) and the new DMA mode (part 1 of 2):
Set the following bits to the desired values:
 - UARTi.[FCR_REG](#)[7:6] RX_FIFO_TRIG
 - UARTi.[FCR_REG](#)[5:4] TX_FIFO_TRIG
 - UARTi.[FCR_REG](#)[3] DMA_MODE
 - UARTi.[FCR_REG](#)[0] FIFO_ENABLE (0: Disable the FIFO/1: Enable the FIFO)

Note: The UARTi.FCR_REG register is not readable.

6. Switch to register configuration mode B to access the UARTi.EFR_REG register:
Set UARTi.LCR_REG to 0x00BF.
7. Load the new FIFO triggers (part 2 of 3):
Set the following bits to the desired values:
 - UARTi.TLR_REG[7:4] RX_FIFO_TRIG_DMA
 - UARTi.TLR_REG[3:0] TX_FIFO_TRIG_DMA
8. Load the new FIFO triggers (part 3 of 3) and the new DMA mode (part 2 of 2):
Set the following bits to the desired values:
 - UARTi.SCR_REG[7] RX_TRIG_GRANU1
 - UARTi.SCR_REG[6] TX_TRIG_GRANU1
 - UARTi.SCR_REG[2:1] DMA_MODE_2
 - UARTi.SCR_REG[0] DMA_MODE_CTL
9. Restore the UARTi.EFR_REG[4] ENHANCED_EN value saved in Step 2a.
10. Switch to register configuration mode A to access the UARTi.MCR_REG register:
Set UARTi.LCR_REG to 0x0080.
11. Restore the UARTi.MCR_REG[6] TCR_TLR value saved in Step 4a.
12. Restore the UARTi.LCR_REG value saved in Step 1a.

Triggers are used to generate interrupt and DMA requests. See [Section 17.4.2.1.1, Transmit FIFO Trigger](#), to choose the following values:

- UARTi.FCR_REG[5:4] TX_FIFO_TRIG
- UARTi.TLR_REG[3:0] TX_FIFO_TRIG_DMA
- UARTi.SCR_REG[6] TX_TRIG_GRANU1

Triggers are used to generate interrupt and DMA requests. See [Section 17.4.2.1.2, Receive FIFO Trigger](#), to choose the following values:

- UARTi.FCR_REG[7:6] RX_FIFO_TRIG
- UARTi.TLR_REG[7:4] RX_FIFO_TRIG_DMA
- UARTi.SCR_REG[7] RX_TRIG_GRANU1

DMA mode enables the different DMA requests. See [Section 17.4.2.4, FIFO DMA Mode Operation](#), to choose the following values:

- UARTi.FCR_REG[3] DMA_MODE
- UARTi.SCR_REG[2:1] DMA_MODE_2
- UARTi.SCR_REG[0] DMA_MODE_CTL

17.5.1.1.3 Protocol, Baud Rate, and Interrupt Settings

To program the protocol, baud rate and interrupt settings, perform the following steps:

1. Disable UART to access UARTi.DLL_REG and UARTi.DLH_REG:
Set UARTi.MDR1_REG[2:0] MODE_SELECT to 0x7.
2. Switch to register configuration mode B to access the UARTi.EFR_REG register:
Set UARTi.LCR_REG to 0x00BF.
3. Enable access to UARTi.IER_REG[7:4]:
 - a. Save the UARTi.EFR_REG[4] ENHANCED_EN value.
 - b. Set the UARTi.EFR_REG[4] ENHANCED_EN bit to 1.
4. Switch to register operational mode to access the UARTi.IER_REG register:
Set UARTi.LCR_REG to 0x0000.
5. Clear the UARTi.IER_REG (UARTi.IER_REG[4] SLEEP_MODE bit to 0 to change UARTi.DLL_REG and UARTi.DLH_REG). Set UARTi.IER_REG to 0x0000.

6. Switch to register configuration mode B to access the UARTi.DLL_REG and UARTi.DLH_REG registers:
Set UARTi.LCR_REG to 0x00BF.
7. Load the new divisor value:
Set the UARTi.DLL_REG[7:0] CLOCK_LSB and UARTi.DLH_REG[5:0] CLOCK_MSB fields to the desired value.
8. Switch to register operational mode to access the UARTi.IER_REG register:
Set UARTi.LCR_REG to 0x0000.
9. Load the new interrupt configuration.(0: Disable the interrupt/1: Enable the interrupt):
Set the following bits to the desired values:
 - UARTi.IER_REG[7] CTS_IT
 - UARTi.IER_REG[6] RTS_IT
 - UARTi.IER_REG[5] XOFF_IT
 - UARTi.IER_REG[4] SLEEP_MODE
 - UARTi.IER_REG[3] MODEM_STS_IT
 - UARTi.IER_REG[2] LINE_STS_IT
 - UARTi.IER_REG[1] THR_IT
 - UARTi.IER_REG[0] RHR_IT
10. Switch to register configuration mode B to access the UARTi.EFR_REG register:
Set UARTi.LCR_REG to 0x00BF.
11. Restore the UARTi.EFR_REG[4] ENHANCED_EN value saved in Step 3a.
12. Load the new protocol formatting (parity, stop bit, char length) and switch to register operational mode:
Set UARTi.LCR_REG[7] DIV_EN to 0.
Set UARTi.LCR_REG[6] BREAK_EN to 0.
Set the following bits to the desired values:
 - UARTi.LCR_REG[5] PARITY_TYPE_2
 - UARTi.LCR_REG[4] PARITY_TYPE_1
 - UARTi.LCR_REG[3] PARITY_EN
 - UARTi.LCR_REG[2] NB_STOP
 - UARTi.LCR_REG[1:0] CHAR_LENGTH
13. Load the new UART mode:
Set UARTi.MDR1_REG[2:0] MODE_SELECT to the desired value.

See [Section 17.4.4.1.2, Choosing the Appropriate Divisor Value](#), to choose the following values:
 - UARTi.DLL_REG[7:0] CLOCK_LSB
 - UARTi.DLH_REG[5:0] CLOCK_MSB
 - UARTi.MDR1_REG[2:0] MODE_SELECT
See [Section 17.4.4.1.3.1, Frame Formatting](#), to choose the following values:
 - UARTi.LCR_REG[5] PARITY_TYPE_2
 - UARTi.LCR_REG[4] PARITY_TYPE_1
 - UARTi.LCR_REG[3] PARITY_EN
 - UARTi.LCR_REG[2] NB_STOP
 - UARTi.LCR_REG[1:0] CHAR_LENGTH

17.5.1.2 Hardware and Software Flow Control Configuration

This section outlines the programming steps to enable and configure hardware and software flow control. Hardware and software flow control cannot be used at the same time.

Note: Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see [Section 17.4.3.1, Register Access Modes](#).

17.5.1.2.1 Hardware Flow Control Configuration

To enable and configure hardware flow control, perform the following procedure:

1. Switch to register configuration mode A to access the UARTi.[MCR_REG](#) register:
 - a. Save the current UARTi.[LCR_REG](#).
 - b. Set UARTi.[LCR_REG](#) to 0x0080.
2. Enable register submode TCR_TLR to access UARTi.[TCR_REG](#) (part 1 of 2):
 - a. Save the UARTi.[MCR_REG](#)[6] TCR_TLR value.
 - b. Set UARTi.[MCR_REG](#)[6] TCR_TLR = 1.
3. Switch to register configuration mode B to access the UARTi.[EFR_REG](#) register:
Set UARTi.[LCR_REG](#) to 0x00BF.
4. Enable register submode TCR_TLR to access the UARTi.[TCR_REG](#) register (part 2 of 2):
 - a. Save the UARTi.[EFR_REG](#)[4] ENHANCED_EN value.
 - b. Set the UARTi.[EFR_REG](#)[4] ENHANCED_EN bit to 1.
5. Load the new start and halt trigger values for hardware flow control:
Set the following bits to the desired values:
 - UARTi.[TCR_REG](#)[7:4] AUTO_RTS_START
 - UARTi.[TCR_REG](#)[3:0] AUTO_RTS_HALT
6. Enable or disable receive and transmit hardware flow control mode and restore the UARTi.[EFR_REG](#)[4] ENHANCED_EN value saved in Step 4a.
Set the following bits to the desired values:
 - UARTi.[EFR_REG](#)[7] AUTO_CTS_EN (0: Disable/1: Enable)
 - UARTi.[EFR_REG](#)[6] AUTO_RTS_EN (0: Disable/1: Enable)
 Restore UARTi.[EFR_REG](#)[4] ENHANCED_EN to the saved value.
7. Switch to register configuration mode A to access UARTi.[MCR_REG](#):
Set UARTi.[LCR_REG](#) to 0x0080.
8. Restore the UARTi.[MCR_REG](#)[6] TCR_TLR value saved in Step 2a.
9. Restore the UARTi.[LCR_REG](#) value saved in Step 1a.

See [Section 17.4.4.1.3.2, Hardware Flow Control](#), to choose the following values:

- UARTi.[EFR_REG](#)[7] AUTO_CTS_EN
- UARTi.[EFR_REG](#)[6] AUTO_RTS_EN
- UARTi.[TCR_REG](#)[7:4] AUTO_RTS_START
- UARTi.[TCR_REG](#)[3:0] AUTO_RTS_HALT

17.5.1.2.2 Software Flow Control Configuration

To enable and configure software flow control, perform the following procedure:

1. Switch to register configuration mode B to access the UARTi.[EFR_REG](#) register.
 - a. Save the current UARTi.[LCR_REG](#).
 - b. Set UARTi.[LCR_REG](#) to 0x00BF.
2. Enable register submode XOFF to access the UARTi.[XOFF1_REG](#) and UARTi.[XOFF2_REG](#) registers:
 - a. Save the UARTi.[EFR_REG](#)[4] ENHANCED_EN value.
 - b. Set the UARTi.[EFR_REG](#)[4] ENHANCED_EN bit to 0.

3. Load the new software flow control characters:
Set the following bits to the desired values:
 - UARTi.XON1_ADDR1_REG[7:0] XON_WORD1
 - UARTi.XON2_ADDR2_REG[7:0] XON_WORD2
 - UARTi.XOFF1_REG[7:0] XOFF_WORD1
 - UARTi.XOFF2_REG[7:0] XOFF_WORD2
 4. Enable access to UARTi.MCR_REG[7:5] and enable register submode TCR_TLR to access UARTi.TCR_REG (part 1 of 2):
Set the UARTi.EFR_REG[4] ENHANCED_EN bit to 1.
 5. Switch to register configuration mode A to access the UARTi.MCR_REG register:
Set UARTi.LCR_REG to 0x0080.
 6. Enable register submode TCR_TLR to access UARTi.TCR_REG (part 2 of 2) and enable or disable XON any function:
 - a. Save the UARTi.MCR_REG[6] TCR_TLR value.
 - b. Set the UARTi.MCR_REG[6] TCR_TLR to 1.
Set UARTi.MCR_REG[5] XON_EN to the desired value (0: Disable/1: Enable).
 7. Switch to register configuration mode B to access the UARTi.EFR_REG register:
Set UARTi.LCR_REG to 0x00BF.
 8. Load the new start and halt trigger values for software flow control:
Set the following bits to the desired values:
 - UARTi.TCR_REG[7:4] AUTO_RTS_START
 - UARTi.TCR_REG[3:0] AUTO_RTS_HALT
 9. Enable or disable special char function and load the new software flow control mode and restore the UARTi.EFR_REG[4] ENHANCED_EN value saved in Step 2a:
Set the following bits to the desired values:
 - UARTi.EFR_REG[5] SPEC_CHAR (0: Disable/1: Enable)
 - UARTi.EFR_REG[3:0] SW_FLOW_CONTROL
 Restore UARTi.EFR_REG[4] ENHANCED_EN to the saved value.
 10. Switch to register configuration mode A to access the UARTi.MCR_REG register:
Set UARTi.LCR_REG to 0x0080.
 11. Restore the UARTi.MCR_REG[6] TCR_TLR value saved in Step 6a.
 12. Restore the UARTi.LCR_REG value saved in Step 1a.
- See [Section 17.4.4.1.3.3, Software Flow Control](#), to choose the following values:
- UARTi.EFR_REG[5] SPEC_CHAR
 - UARTi.EFR_REG[3:0] SW_FLOW_CONTROL
 - UARTi.TCR_REG[7:4] AUTO_RTS_START
 - UARTi.TCR_REG[3:0] AUTO_RTS_HALT
 - UARTi.XON1_ADDR1_REG[7:0] XON_WORD1
 - UARTi.XON2_ADDR2_REG[7:0] XON_WORD2
 - UARTi.XOFF1_REG[7:0] XOFF_WORD1
 - UARTi.XOFF2_REG[7:0] XOFF_WORD2

17.5.2 IrDA Programming Model (UART3 Only)

17.5.2.1 SIR Mode

17.5.2.1.1 Receive

The following programming model explains how to program the module in order to receive IrDA frame with parity forced to '1', baud rate = 112.5Kbs, FIFOs disable, 2 stop bits, 8 bits word length

1. **Set SIR Mode**
UART3.MDR1_REG[2:0] MODE_SELECT = 0x1
2. **Grant access to DLL_REG and DLH_REG (LCR_REG[7] DIV_EN = 0x1)**
Set parity type to forced '1' (LCR_REG[5] PARITY_TYPE2 = 0x1 / LCR_REG[3] PARITY_EN = 0x1)
Optional: Set number of stop bits to 2 (LCR_REG[2] NB_STOP = 0x1)
Optional: Set word length to 8 bits (LCR_REG[1:0] CHAR_LENGTH = 0x3)
UART3.LCR_REG = 0xA8 (0xAF with optional settings)
3. **Load the new baud rate (115.2Kbs)**
UART3.DLL_REG = 0x1A
UART3.DLH_REG = 0x00
4. **Disable access to DLL_REG and DLH_REG and grant access to MCR_REG, FCR_REG, IER_REG (LCR_REG[7] DIV_EN = 0x0)**
UART3.LCR_REG = 0x28
5. **Optional: Enable RHR interrupt**
UART3.IER_REG[0] RHR_IT = 0x1

17.5.2.1.2 Transmit

The following programming model explains how to program the module in order to transmit IrDA 6 bytes frame with no parity, baud rate = 112.5Kbs, FIFOs disable, 3/16 encoding, 2 stop bits, 7 bits word length

1. **Set SIR Mode (MDR1_REG[2:0] MODE_SELECT = 0x1)**
Set automatic SIP mode (MDR1_REG[6] SIP_MODE = 0x1)
UART3.MDR1_REG = 0x41
2. **Grant access to EFR_REG**
UART3.LCR_REG = 0xBF
3. **Enable the enhanced features (EFR_REG[4] ENAHNCED_EN = 0x1)**
UART3.EFR_REG = 0x10
4. **Grant access to DLL_REG and DLH_REG (LCR_REG[7] DIV_EN = 0x1)**
Set number of stop bits to 2 (LCR_REG[2] NB_STOP = 0x1)
Set word length to 7 bits (LCR_REG[1:0] CHAR_LENGTH = 0x2)
UART3.LCR_REG = 0x86
5. **Load the new baud rate (115.2Kbs)**
UART3.DLL_REG = 0x1A
UART3.DLH_REG = 0x00
6. **Disable access to DLL_REG and DLH_REG and grant access to MCR_REG, FCR_REG, IER_REG, BLR_REG, EBLR_REG, THR_REG (LCR_REG[7] DIV_EN = 0x0)**
UART3.LCR_REG = 0x06
7. **Force DTR output to active**
UART3.MCR_REG[0] DTR = 0x1
8. **Optional: Enable THR interrupt**
UART3.IER_REG[1] THR_IT = 0x1
9. **Set transmit frame length to 6 bytes**
UART3.TXFLL_REG = 0x06
10. **Set 7 starts of frame transmission**
UART3.EBLR_REG = 0x08
11. **Optional: Set SIR pulse width to be 1.6 us**
UART3.ACREG_REG[7] PULSE_TYPE = 0x1
12. **Load THR_REG with the desired data to be transmitted**

17.5.2.2 MIR Mode

17.5.2.2.1 Receive

The following programming model explains how to program the module in order to receive IrDA frame with no parity, baud rate = 1.152Mbps, FIFOs disable

1. **Set MIR Mode**
UART3.MDR1_REG[2:0] MODE_SELECT = 0x4
2. **Grant access to DLL_REG and DLH_REG (LCR_REG[7] DIV_EN = 0x1)**
Set number of stop bits to 2 (LCR_REG[2] NB_STOP = 0x1)
Set word length to 7 bits (LCR_REG[1:0] CHAR_LENGTH = 0x2)
UART3.LCR_REG = 0x86
3. **Load the new baud rate (1.152Mbps)**
UART3.DLL_REG = 0x01
UART3.DLH_REG = 0x00
4. **Disable access to DLL_REG and DLH_REG and grant access to MCR_REG, FCR_REG, IER_REG, BLR_REG, EBLR_REG, RHR_REG (LCR_REG[7] DIV_EN = 0x0)**
UART3.LCR_REG = 0x06
5. **Force DTR output to active (MCR_REG[0] DTR = 0x1)**
Force RTS output to active (MCR_REG[1] RTS = 0x1)
UART3.MCR_REG = 0x3
6. **Optional: Enable RHR interrupt**
UART3.IER_REG[0] RHR_IT = 0x1

17.5.2.2.2 Transmit

The following programming model explains how to program the module in order to transmit IrDA 60 bytes frame with no parity, baud rate = 1.152Mbps, FIFOs disable

1. **Set MIR Mode**
UART3.MDR1_REG[2:0] MODE_SELECT = 0x4
2. **Grant access to DLL_REG and DLH_REG (LCR_REG[7] DIV_EN = 0x1)**
Optional: Set number of stop bits to 2 (LCR_REG[2] NB_STOP = 0x1)
Set word length to 7 bits (LCR_REG[1:0] CHAR_LENGTH = 0x2)
UART3.LCR_REG = 0x82 (0x86 with optional settings)
3. **Load the new baud rate (1.152Mbps)**
UART3.DLL_REG = 0x01
UART3.DLH_REG = 0x00
4. **Disable access to DLL_REG and DLH_REG and grant access to MCR_REG, FCR_REG, IER_REG, BLR_REG, EBLR_REG, THR_REG (LCR_REG[7] DIV_EN = 0x0)**
UART3.LCR_REG = 0x02
5. **Force DTR output to active**
UART3.MCR_REG[0] DTR = 0x1
6. **Optional: Enable THR interrupt**
UART3.IER_REG[1] THR_IT = 0x1
7. **Set frame length to 60 bytes**
UART3.TXFLR_REG = 0x3C
8. **Optional: Transmit 8 additional starts of frame (MIR mode requires 2 starts anyway)**
UART3.EBLR_REG = 0x08
9. **SIP will be send at the end of transmission**
UART3.ACREG_REG[3] = 0x1
10. **Load THR_REG with the desired data to be transmitted**

17.6 UART/IrDA/CIR Registers

Table 17-38 shows the base address and address space for the UART/IrDA/CIR module instances.

Table 17-38. Instance Summary

Module Name	Base Address	Size
UART1 (UART only)	0x4806 A000	1K byte
UART2 (UART only)	0x4806 C000	1K byte
UART3 (UART/IrDA/CIR)	0x4902 0000	1K byte

17.6.1 UART/IrDA/CIR Register Mapping Summary

This section provides information about the UART/IrDA/CIR module instance in the OMAP35x. Each register in the module instance is described separately in this section. This module has multiple modes. Table 17-39 summarizes register access for different modes.

Table 17-39. UART Mode Overview

Address Offset	Registers					
	Configuration_Mode_A		Configuration_Mode_B		Operational_Mode

Table 17-55. RHR_REG

Address Offset	0x000	Instance	UART1
Physical Address	0x4806 A000		UART2
	0x4806 C000		UART3
Description	Receive holding register The receiver section consists of the receiver holding register (RHR_REG) and the receiver shift register. The RHR_REG is actually a 64-byte FIFO. The receiver shift register receives serial data from RX input. The data is converted to parallel data and moved to the RHR_REG . If the FIFO is disabled, location zero of the FIFO is used to store the single data character. Note: If an overflow occurs the data in the RHR_REG is not overwritten.

17.6.2.8 EFR_REG
Table 17-67. EFR_REG

Address Offset	0x008	Instance	UART1
Physical Address	0x4806 A008		UART2
	0x4806 C008		UART3
	0x4902 0008		
Description	Enhanced feature register This register enables or disables enhanced features. Most enhanced functions apply only to UART modes, but EFR_REG[4] enables write accesses to FCR_REG[5:4] , the TX trigger level, which is also used in IrDA modes.		
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								AUTO_CTS_EN	AUTO_RTS_EN	SPEC_CHAR	ENHANCED_EN	SW_FLOW_CONTROL			

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7	AUTO_CTS_EN	Auto-CTS enable bit (UART mode only) 0x0: Normal operation 0x1: Auto-CTS flow control is enabled; transmission is halted when the nCTS pin is high (inactive).	RW	0
6	AUTO_RTS_EN	Auto-RTS enable bit (UART mode only) 0x0: Normal operation	RW	0

Bits	Field Name	Description	Type	Reset
		0x1: Auto-RTS flow control is enabled; nRTS pin goes high (inactive) when the receiver FIFO HALT trigger level, TCR_REG[3:0] , is reached and goes low (active) when the receiver FIFO RESTORE transmission trigger level is reached.		
5	SPEC_CHAR	(UART mode only) Special character detect 0x0: Normal operation 0x1: Special character detect enable. Received data is compared with XOFF2 data. If a match occurs, the received data is transferred to RX FIFO and IIR_REG bit 4 is set to 1 to indicate that a special character was detected.	RW	0
4	ENHANCED_EN	Enhanced functions write enable bit 0x0: Disables writing to IER_REG bits [7:4], FCR_REG bits [5:4], and MCR_REG bits [7:5] 0x1: Enables writing to IER_REG bits [7:4], FCR_REG bits [5:4], and MCR_REG bits [7:5]	RW	0
3:0	SW_FLOW_CONTROL	Combinations of software flow control can be selected by programming bit [3:0]. See Table 17-32 . In IrDA mode, bits [1:0] select IR address to check. See Section 17.2.5.2.1.7 , <i>IR Address Checking</i> .	RW	0x0

17.6.2.9 LCR_REG

Table 17-69. LCR_REG

Address Offset	0x00C	Instance	UART1
Physical Address	0x4806 A00C		UART2
	0x4806 C00C		UART3
	0x4902 000C		
Description	Line control register		
	LCR_REG[6:0] define parameters of the transmission and reception for UART mode. LCR_REG[7] is used to put the module in operational mode or Configuration_Mode_A/B.		
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								DIV_EN	BREAK_EN	PARITY_TYPE2	PARITY_TYPE1	PARITY_EN	NB_STOP	CHAR_LENGTH	

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00	R	0x00
7	DIV_EN	0x0: Operational mode 0x1: Divisor latch enable; put the module in Configuration_Mode_A/B. Allows access to DLL_REG, DLH_REG, and other registers (see Section 17.6.1, UART/IrDA/CIR Register Mapping Summary). Configuration_Mode_B: LCR_REG[7:0] = 0xBF Else, Configuration_Mode_A	RW	0
6	BREAK_EN	Break control bit. UART mode only. Note: When LCR_REG[6] is set to 1, the TX line is forced to 0 and remains in this state as long as LCR_REG[6] = 1. 0x0: Normal operating condition 0x1: Forces the transmitter output to go low to alert the communication terminal. TX line is forced to 0 and remains in this state while BREAK_EN = 1.	RW	0
5	PARITY_TYPE2	Selects the forced parity format (if LCR_REG[3] = 1). UART mode only. If LCR_REG[5] = 1 and LCR_REG[4] = 0, the parity bit is forced to 1 in the transmitted and received data. If LCR_REG[5] = 1 and LCR_REG[4] = 1, the parity bit is forced to 0 in the transmitted and received data.	RW	0
4	PARITY_TYPE1	UART mode only 0x0: Odd parity is generated (if LCR_REG[3] = 1). 0x1: Even parity is generated (if LCR_REG[3] = 1).	RW	0
3	PARITY_EN	UART mode only 0x0: No parity 0x1: A parity bit is generated during transmission, and the receiver checks for received parity.	RW	0
2	NB_STOP	Specifies the number of stop bits. UART mode only. 0x0: 1 stop bit (word length = 5, 6, 7, 8) 0x1: 1.5 stop bits (word length = 5) 1 - 2 stop bits (word length = 6, 7, 8)	RW	0
1:0	CHAR_LENGTH	Specifies the word length to be transmitted or received. UART mode only. 0x0: 5 bits 0x1: 6 bits 0x2: 7 bits 0x3: 8 bits	RW	0x0

17.6.2.21 MDR2_REG

Table 17-93. MDR2_REG

Address Offset	0x024		
Physical Address	0x4806 A024	Instance	UART1
	0x4806 C024		UART2
	0x4902 0024		UART3
Description	Mode definition register 2 IR-IrDA and IR-CIR modes only MDR2_REG [0] describes the status of the interrupt in IIR_REG [5]. The IRTX_UNDERRUN bit must be read after an IIR_REG [5] TX_STATUS_IT interrupt occurs. The bits [2:1] of this register set the trigger level for the frame status FIFO (8 entries) and must be programmed before the mode is programmed in MDR1_REG [2:0].		
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								Reserved	IRRXINVERT	CIR_PULSE_MODE		UART_PULSE	STS_FIFO_TRIG		IRTX_UNDERRUN

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7	Reserved		R	0
6	IRRXINVERT	Only for IR mode (IrDA and CIR). Invert RX pin in the module before the voting or sampling system logic of the infrared block. This does not affect the RX path in UART modem modes. 0x0: Inversion is performed. 0x1: No inversion is performed.	RW	0
5:4	CIR_PULSE_MODE	CIR pulse modulation definition. Defines high level of the pulse width associated with a digit: 0x0: Pulse width of 3 from 12 cycles 0x1: Pulse width of 4 from 12 cycles 0x2: Pulse width of 5 from 12 cycles 0x3: Pulse width of 6 from 12 cycles	RW	0x00
3	UART_PULSE	UART mode only. Used to allow pulse shaping in UART mode. 0x0: Normal UART mode 0x1: UART mode with pulse shaping	RW	0
2:1	STS_FIFO_TRIG	Only for IR-IrDA mode Frame status FIFO threshold select: 0x0: 1 entry 0x1: 4 entries 0x2: 7 entries 0x3: 8 entries	RW	0x00
0	IRTX_UNDERRUN	IrDA transmission status interrupt. When the IIR_REG [5] interrupt occurs, the meaning of the interrupt is: 0x0: The last bit of the frame was transmitted successfully without error. 0x1: An underrun occurred. The last bit of the frame was transmitted but with an underrun error. The bit is reset to 0 when the RESUME_REG register is read.	R	0

17.6.2.23 SFLSR_REG

Table 17-97. SFLSR_REG

Address Offset	0x028														
Physical Address	0x4806 A028							Instance	UART1						
	0x4806 C028								UART2						
	0x4902 0028								UART3						
Description	Status FIFO line status register														
	IrDA modes only														
	Reading this register effectively reads frame status information from the status FIFO (this register does not physically exist). Reading this register increments the status FIFO read pointer (SFREGL_REG and SFREGH_REG must be read first).														
Type	R														

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Physical Address	0x4806 A038		UART2
	0x4806 C038		UART3
Description	BOF control register IrDA modes only BLR_REG[6] is used to select whether 0xC0 or 0xFF start patterns are to be used, when multiple start flags are required in SIR mode. If only one start flag is required, this is always 0xC0. If n start flags are required, either (–1) 0xC0 or (–1) 0xFF flags are sent, followed by a single 0xC0 flag (immediately preceding the first data byte).		
Type	RW

17.6.2.31 UASR_REG

Table 17-113. UASR_REG

Address Offset	0x038	Instance	UART1
Physical Address	0x4806 A038		UART2
	0x4806 C038		UART3
Description	UART autobauding status register UART autobauding mode only This status register returns the speed, the number of bits by characters, and the type of parity in UART autobauding mode. In autobauding mode, the input frequency of the UART modem must be fixed to 48 MHz. Any other module clock frequency results in incorrect baud rate recognition.		
Type	R		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Address Offset	0x03C		
Physical Address	0x4806 A03C	Instance	UART1
	0x4806 C03C		UART2
	0x4902 003C		UART3
Description	Auxiliary control register		
	IrDA-CIR mode only		
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								PULSE_TYPE	SD_MOD	DIS_IR_RX	DIS_TX_UNDERRUN	SEND_SIP	SCTX_EN	ABORT_EN	EOT_EN

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7	PULSE_TYPE	SIR pulse-width select: 0x0: 3/16 of baud-rate pulse width 0x1: 1.6 μ s	RW	0
6	SD_MOD	Primary output used to configure transceivers. Connected to the SD/MODE input pin of IrDA transceivers. 0x0: SD pin is set to high. 0x1: SD pin is set to low.	RW	0
5	DIS_IR_RX	0x0: Normal operation (RX input automatically disabled during transmit, but enabled outside of transmit operation). 0x1: Disables RX input (permanent state; independent of transmit)	RW	0
4	DIS_TX_UNDERRUN	0x0: Long stop bits cannot be transmitted. TX underrun is enabled. 0x1: Long stop bits can be transmitted. TX underrun is disabled.	RW	0
3	SEND_SIP	MIR/FIR modes only. Send serial infrared interaction pulse (SIP). If this bit is set during an MIR/FIR transmission, the SIP is sent at the end of it. This bit is automatically cleared at the end of the SIP transmission. 0x0: No action 0x1: Send SIP pulse.	RW	0
2	SCTX_EN	Store and control TX start. When MDR1_REG[5] = 1 and the MPU writes 1 to this bit, the TX state-machine starts frame transmission. This bit is self-clearing.	RW	0
1	ABORT_EN	Frame abort. The MPU can intentionally abort transmission of a frame by writing 1 to this bit. Neither the end flag nor the CRC bits are appended to the frame.	RW	0

Bits	Field Name	Description	Type	Reset
0	EOT_EN	EOT (end-of-transmission) bit. The MPU writes 1 to this bit just before it writes the last byte to the TX FIFO in the set-EOT bit frame-closing method. This bit is automatically cleared when the MPU writes to the THR_REG (TX FIFO).	RW	0

Address Offset	0x048	Instance	UART1
Physical Address	0x4806 A048		UART2
	0x4806 C048		UART3
Description	BOF length register. IR-IrDA mode only In IR-IrDA SIR operation, this register specifies the number of BOF + xBOFs to transmit. Value set into this register must consider the BOF character; therefore, to send only one BOF with no XBOF, this register must be set to 1. To send one BOF with N XBOF, this register must be set to N + 1. Furthermore, the value 0 sends 1 BOF plus 255 XBOF. In IR-IrDA MIR mode, this register specifies the number of additional start flags (MIR protocol mandates a minimum of 2 start flags).		
Type	RW

	0x4902 005C		UART3
Description	Wake-up enable register		
	The UART wake-up enable register is used to mask and unmask a UART event that subsequently notifies the system. An event is any activity in the logic that can cause an interrupt and/ or an activity that requires the system to wake up. Even if wakeup is disabled for certain events, if these events are also an interrupt to the UART, the UART still registers the interrupt as such.

Reserved								CFPS							

Bits	Field Name	Description	Type	Reset																								
15:8	Reserved	Read returns 0x00.	R	0x00																								
7:0	CFPS	Because the consumer IR works at modulation rates of 30-56.8 kHz, the 48-MHz clock must be prescaled before the clock can drive the IR logic. This register sets the divisor rate to give a range to accommodate remote-control requirements in BAUD multiples of 12x. The value of the CFPS at reset is 0105 (decimal), which equates to a 38.1-kHz output from starting conditions. The 48-MHz carrier is prescaled by the CFPS, which is then divided by the 12x BAUD multiple. Example: <table><tr><td>Target Freq (kHz)</td><td>CFPS (decimal)</td><td>Actual Freq(kHz)</td></tr><tr><td>30</td><td>133</td><td>30.08</td></tr><tr><td>32.75</td><td>122</td><td>32.79</td></tr><tr><td>36</td><td>111</td><td>36.04</td></tr><tr><td>36.7</td><td>109</td><td>36.69</td></tr><tr><td>38</td><td>105</td><td>38.1</td></tr><tr><td>40</td><td>100</td><td>40</td></tr><tr><td>56.8</td><td>70</td><td>57.14</td></tr></table> CFPS = 0 is not supported.	Target Freq (kHz)	CFPS (decimal)	Actual Freq(kHz)	30	133	30.08	32.75	122	32.79	36	111	36.04	36.7	109	36.69	38	105	38.1	40	100	40	56.8	70	57.14	RW	0x69

Inter-Integrated Circuit (I²C) Module

This chapter describes the four high-speed inter-integrated circuit (I²C) controller modules in the OMAP35x Applications Processor.

Topic	Page
18.1 High-Speed I²C Controller Overview.....	2614

18.7 High-Speed I²C Controllers Registers.....	2677
18.8 Revision History	2698

18.1 High-Speed I²C Controller Overview

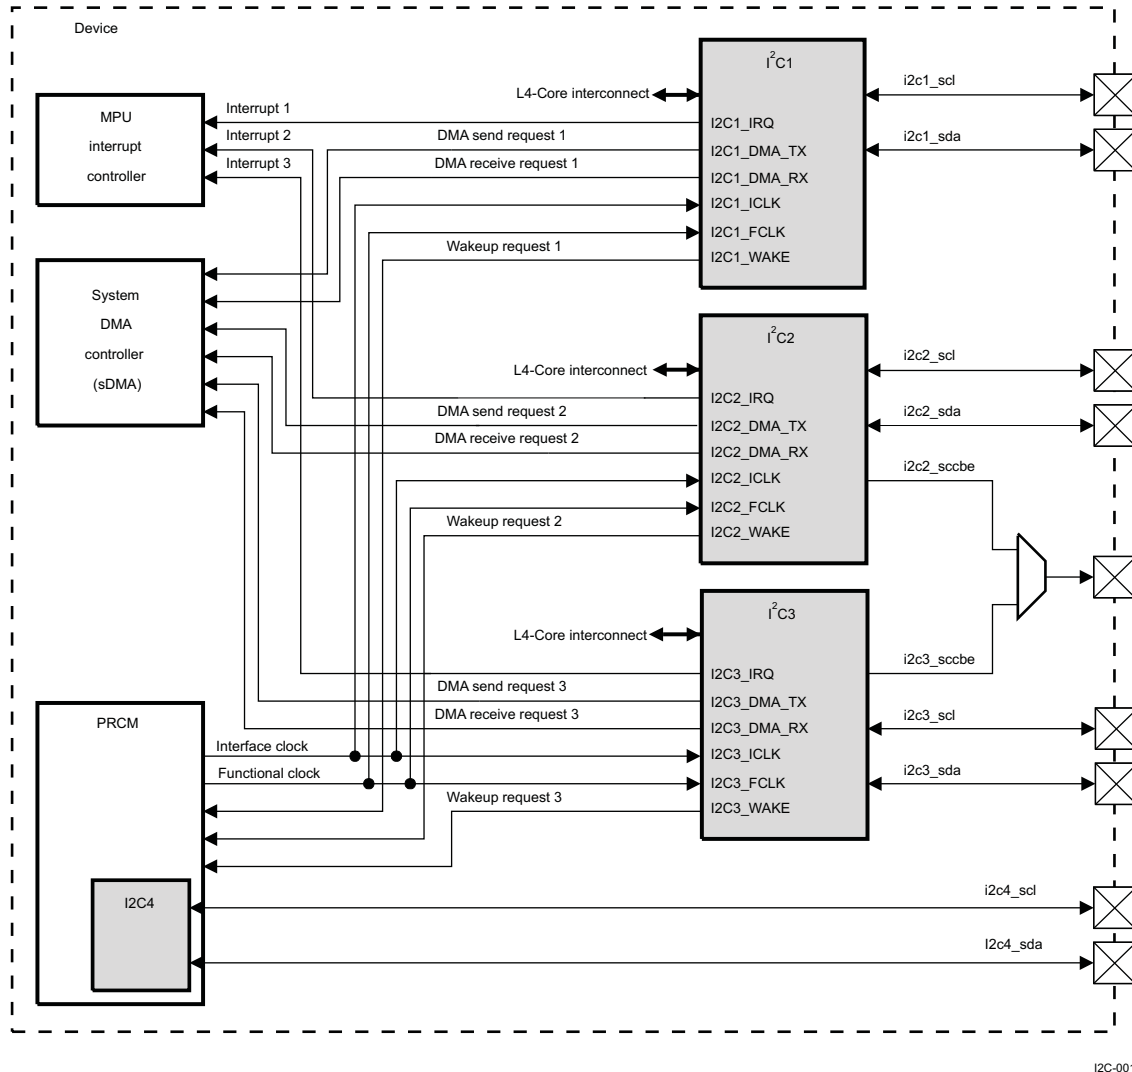

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

The device contains three multimaster high-speed (HS) inter-integrated circuit (I²C) controllers (I2C_i modules, where $i = 1, 2, 3$), each of which provides an interface between a local host (LH), such as the MPU subsystem, and any I²C-bus-compatible device that connects through the I²C serial bus. External components attached to the I²C bus can serially transmit/receive up to 8 bits of data to/from the LH device through the 2-wire I²C interface.

Each multimaster HS I²C controller can be configured to act like a slave or master I²C-compatible device. Moreover, each multimaster HS I²C controller can be configured in serial camera control bus (SCCB) mode (the SCCB is a serial bus developed by Omnivision Technologies, Inc.) to act as a master on a 2-wire SCCB bus. Only multimaster HS I²C controllers I2C2 and I2C3 can be configured in SCCB mode to act as a master device on a 3-wire SCCB bus.

The device contains an additional master transmitter HS I²C interface (I2C4) in the PRCM module to perform dynamic voltage control and power sequencing. Texas Instruments Inc. provides a global solution with the device connected to power chips (TPS65950 device). For details about the TPS65950 device, contact your TI representative.

[Figure 18-1](#) shows the HS I²C controllers in the device.

Figure 18-1. HS I²C Controllers

I2C-001

The three multimaster HS I²C controllers have the following features:

- Compliance with Philips I²C specification version 2.1
- Support for standard mode (up to 100K bits/s) and fast mode (up to 400K bits/s)
- Support for HS mode for transfer up to 3.4M bits/s
- Support for 3-wire/2-wire SCCB master mode for I2C2 and I2C3 modules, 2-wire SCCB master mode for I2C1 module, up to 100K bits/s
- 7-bit and 10-bit device addressing modes
- General call
- Start/restart/stop
- Multimaster transmitter/slave receiver mode
- Multimaster receiver/slave transmitter mode
- Combined master transmit/receive and receive/transmit mode
- Built-in FIFO for buffered read or write
 - 8 bytes for I2C1 and I2C2
 - 64 bytes for I2C3
- Module enable/disable capability
- Programmable clock generation

- 8-bit-wide data access
- Low-power consumption design
- Two DMA channels
- Wide interrupt capability

The master transmitter HS I²C controller I2C4 has the following features:

- Support of HS and fast modes
- 7-bit addressing mode only
- Master transmitter mode only
- Start/restart/stop

Note: Before using HS I²C mode, determine that the target device supports this mode.

18.2 High-Speed I²C Controller Environment

18.2.1 Multimaster HS I²C Controllers in I²C Mode

Figure 18-2 shows the multimaster HS I²C controllers and their related connections with I²C-compliant devices in I²C mode.

Figure 18-2. Multimaster HS I²C Controllers and Typical Connections to I²C Devices

I2C-002

18.2.1.1 Multimaster HS I²C Controller Pins for Typical Connections in I²C Mode

Figure 18-3 shows the multimaster HS I²C controller pins used for typical connections with I²C devices.

Figure 18-3. Multimaster HS I²C Controller Interface Signals in I²C Mode

I2C-003

18.2.1.2 I²C Interface Typical Connections

Table 18-1 lists the pins associated with the I²C interface.

Table 18-1. Input/Output

Signal Name	I/O ⁽¹⁾	Description	Reset Value
i2ci_scl	I/O(OD)	I ² C serial clock line. Open-drain output buffer. Requires external pullup resistor (Rp).	Hi-Z
i2ci_sda	I/O(OD)	I ² C serial data line. Open-drain output buffer. Requires external pullup resistor (Rp).	Hi-Z

⁽¹⁾ I = Input, O = Output, OD = Open Drain, Hi-Z = High Impedance

18.2.1.3 I²C Typical Connection Protocol and Data Format

18.2.1.3.1 Serial Data Format

The I²C controller operates in 8-bit word data format (byte write access supported for the last access). Each byte transmitted or received on the serial data line (i2ci_sda) is 8 bits long. The number of bytes that can be transmitted or received is not restricted. The data is transferred with the most significant bit (MSB) first. In receiver mode, each byte is followed by an acknowledge bit from the I²C. Figure 18-4 shows a typical I²C communication format.

Figure 18-4. I²C Data Transfer

18.2.1.3.2 Data Validity

The data on the serial data line must be stable during the high period of the clock i2ci_scl. The high and low states of the data line can change only when the clock signal on the serial clock line is low.

Figure 18-5 is an example of data validity requirements.

Figure 18-5. Bit Transfer on the I²C Bus

18.2.1.3.3 Start (S) and Stop (P) Conditions

The I²C module generates start (S) and stop (P) conditions when it is configured as a master.

- A start (S) condition is a high-to-low transition on the i2ci_sda line while i2ci_scl is high.
- A stop (P) condition is a low-to-high transition on the i2ci_sda line while i2ci_scl is high.

The bus is considered to be busy after the start (S) condition (the I2Ci.I2C_STAT[12] BB bit is 1 to indicate that the bus is busy) and free after the stop (P) condition (the I2Ci.I2C_STAT[12] BB bit is 0 to indicate that the bus is free).

Figure 18-6 shows the waveforms that occur during a start (S) and a stop (P) condition.

Figure 18-6. Start (S) and Stop (P) Condition Events

18.2.1.3.4 Addressing

The I²C module supports two data formats in fast/standard (F/S) and HS modes:

- 7-bit/10-bit addressing format
- 7-bit/10-bit addressing format with repeated start (Sr) condition

18.2.1.3.4.1 Data Transfer Format in F/S Mode

Figure 18-7 shows the I²C data transfer format in F/S mode.

Figure 18-7. I²C Data Transfer Formats in F/S Mode

(a) 7-bit addressing format

I2C-007

The first word after a start (S) condition always consists of 8 bits. In acknowledge mode, an extra dedicated acknowledgment bit is inserted after each byte.

In the addressing formats with 7-bit addresses, the first byte is composed of 7 MSB slave address bits and 1 least significant bit (LSB) R/W_ bit.

The LSB R/W_ bit of the address byte indicates the transmission direction of the data bytes that follow it. If R/W_ is 0, the master writes data to the selected slave; if it is 1, the master reads data from the slave.

In the addressing formats with 10-bit addresses, the structure of the first byte is 11110XXY, where XX is the two MSBs of the 10-bit addresses, and Y is the R/W_ bit. If the R/W_ bit is 0, the next byte contains the last 8 bits of the slave address. If the R/W_ bit is 1, the next byte contains data transmitted from the slave to the master.

18.2.1.3.4.2 Data Transfer Format in HS Mode

Figure 18-8 shows the I^2C data transfer format in HS mode.

Figure 18-8. I^2C Data Transfers in HS Mode

I2C-008

Each multimaster HS I^2C controller module can also operate in HS mode. In this case, after the start (S) condition, the module, which is in F/S mode, writes the master code address (000001XXX, where XXX is the variable portion of the master code) on the bus. No device connected on the same bus acknowledges this address. The module switches the clock to the HS clock and after a repeated start (Sr) condition, sends the slave address and the data, as shown in Figure 18-8.

Note: For more information, see *I^2C Bus Specification v2.1*, January 2000.

18.2.1.3.5 Master Transmitter

In master transmitter mode, data assembled in one of the previously described data formats is shifted out on serial data line `i2ci_sda` in synchronization with the self-generated clock pulses on serial clock line `i2ci_scl`. When the intervention of the processor is required (`I2Ci.I2C_STAT[10]` XUDF bit) after a byte has been transmitted, the clock pulses are inhibited and the serial clock line is held low.

18.2.1.3.6 Master Receiver

Master receiver mode can be entered only from master transmitter mode. With any of the address formats (a), (b), or) (see Figure 18-7), if `R/W_` is high, the module enters master receiver mode after the slave address byte and bit `R/W_` have been transmitted. Serial data bits received on bus line `i2ci_sda` are shifted in synchronization with the self-generated clock pulses on `i2ci_scl`. When the intervention of the processor is required (`I2Ci.I2C_STAT[11]` ROVR bit) after a byte has been transmitted, the clock pulses are inhibited and the serial clock line is held low. At the end of a transfer, a stop (P) condition is generated.

18.2.1.3.7 Slave Transmitter

Slave transmitter mode can be entered only from slave receiver mode. With any of the address formats (a), (b), or) (see Figure 18-7), the slave transmitter mode is entered if the slave address byte is the same as its own address, and when the `R/W_` bit transmitted by the master transmitter is high. The slave transmitter shifts the serial data out on data line `i2ci_sda` in synchronization with the clock pulses that are generated by the master device. It does not generate the clock, but it can hold clock line `i2ci_scl` low when intervention of the LH is required (`I2Ci.I2C_STAT[10]` XUDF bit).

18.2.1.3.8 Slave Receiver

In slave receiver mode, serial data bits received on bus line `i2ci_sda` are shifted-in in synchronization with the clock pulses on `i2ci_scl` that are generated by the master device. The slave receiver does not generate the clock, but it can hold the serial clock line low when intervention of the LH is required (`I2Ci.I2C_STAT[11]` ROVR bit) after a byte is received.

18.2.1.3.9 Bus Arbitration

If two or more master transmitters start a transmission on the same bus almost simultaneously, an arbitration procedure is invoked. This arbitration procedure uses the data presented on the serial bus by the competing transmitters. When a transmitter senses that a high signal it has presented on the bus has been overruled by a low signal, it switches to the slave receiver mode, sets the arbitration lost flag (I2Ci.I2C_STAT[0] AL bit), and generates the arbitration lost interrupt. Figure 18-9 shows the arbitration procedure between two devices. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

Figure 18-9. Arbitration Between Master Transmitters

18.2.1.3.10 I²C Clock Generation and Synchronization

Under normal conditions, only one master device generates the clock signal i2ci_scl. During the arbitration procedure, however, there are two or more master devices, and the clock must be synchronized so that the data output can be compared. The wired-AND property of the clock line means that the device that first generates a low period of the clock line overrules the other devices. At this high-low transition, the clock generators of the other devices are forced to start generating their own low periods. The clock line is then held low by the device with the longest low period, while the other devices that finish their low periods must wait for the clock line to be released before starting their high periods. A synchronized signal on the clock line is thus obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period.

If a device pulls down the clock line for a longer time, all clock generators must enter the wait state. In this way, a slave can slow down a fast master, and the slow device can create enough time to store a received byte or prepare a byte to be transmitted. Figure 18-10 shows clock synchronization.

Figure 18-10. Synchronization of I²C Clock Generators

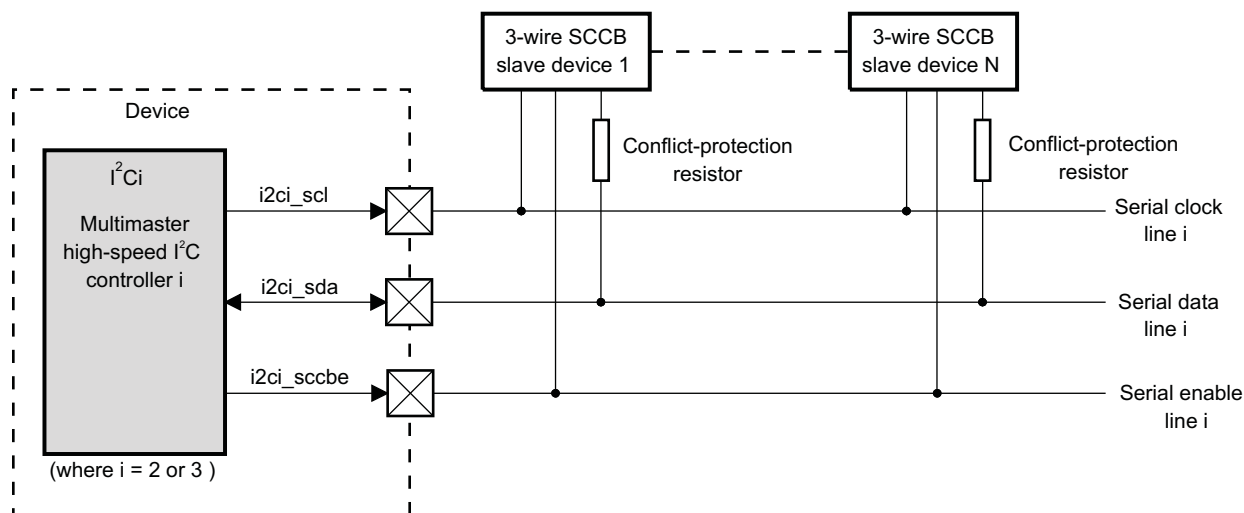

18.2.2 Multimaster High-Speed I²C Controllers in SCCB Mode

The serial camera control bus is a 3-wire serial bus developed by Omnivision Technologies, Inc. The SCCB can also operate in a modified 2-wire serial mode. For details, see the SCCB specifications version 2.1 document at http://www.ovt.com/pdfs/ds_note.pdf.

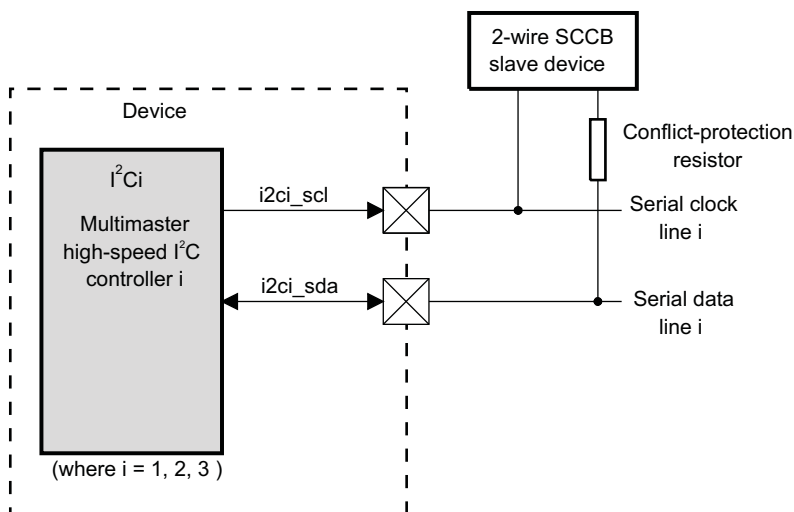

The multimaster HS I²C controllers support the 2-wire SCCB protocol in master mode. Only the I2C2 and I2C3 modules support the 3-wire SCCB protocol in master mode.

Figure 18-11 shows the multimaster HS I²C controllers and their related connections with 3-wire or 2-wire SCCB-compliant devices.

Figure 18-11. Multimaster HS I²C Controllers and Typical Connections to SCCB Devices

(a) Typical connection with 3-wire SCCB devices

(b) Typical connection with 2-wire SCCB devices

I2C-011

Note: Only one 2-wire SCCB slave device can be connected to the 2-wire SCCB bus.

18.2.2.1 Multimaster HS I²C Controller Pins for Typical Connections in SCCB Mode

Figure 18-12 shows the multimaster HS I²C controller pins used for typical connections with 3-wire or 2-wire SCCB devices.

Figure 18-12. Multimaster HS I²C Controller Interface Signals in SCCB Mode

18.2.2.2 SCCB Interface Typical Connections

Table 18-2 lists the pins associated with the SCCB interface.

Table 18-2. Input/Output Description

Signal Name	I/O ⁽¹⁾	Description	Reset Value	I2Ci.I2C_CON[15] I2C_EN bit = 0
i2ci_scl	O	SCCB serial clock line. Standard CMOS output buffer.	Hi-Z	High
i2ci_sda	I/O(OD)	SCCB serial data line. Standard CMOS 3-state output buffer. Requires external conflict-protection resistor for each slave device connected to the bus.	Hi-Z	Hi-Z
i2ci_sccb_e ⁽²⁾	O	SCCB enable line. Standard CMOS output buffer.	High	High

⁽¹⁾ I = Input, O = Output, OD = Open Drain, Hi-Z = High Impedance

⁽²⁾ Signal used for the 3-wire SCCB protocol only

Note: As they share the same ball, the i2c2_sccb_e and i2c3_sccb_e signals are not available at the same time. For detailed information about pin configuration, refer to the *System Control Module* chapter.

The I2C1 module does not provide any i2c1_sccb_e signal at the chip boundary of the device; thus, this module does not support the 3-wire SCCB protocol

18.2.2.3 SCCB Typical Connection Protocol and Data Format

18.2.2.3.1 Serial Transmission Timing Diagram

Figure 18-13 is the timing diagram of the 3-wire SCCB data transmission.

Figure 18-13. 3-wire SCCB Transmission Timing Diagram

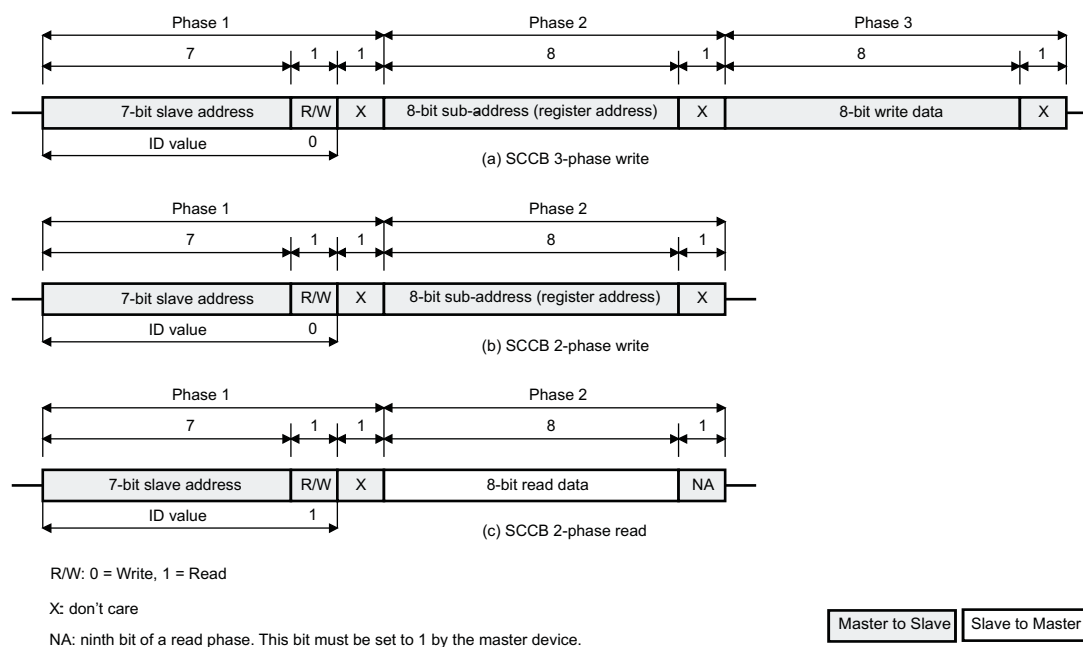

Note: When operating in 2-wire SCCB mode, the i2ci_sccbe signal is not used by the 2-wire SCCB-compliant slave device attached to the 2-wire SCCB bus.

18.2.2.3.2 SCCB Transmission Data Formats

Figure 18-14 describes the data format of the three kinds of transmission.

Figure 18-14. SCCB Transmission Data Formats

I2C-014

The basic element of a data transmission is a phase. A phase contains 9 bits, which consist of an 8-bit sequential data transmission followed by a ninth bit. The ninth bit is a don't-care bit (X) or an NA bit, depending on whether the data transmission is a write or a read. The maximum number of phases that can be included in a transmission is three. The MSB is always asserted first for each phase.

A data transmission is one of three types:

- **3-phase write transmission:** The 3-phase write transmission cycle (see (a) of [Figure 18-14](#)) is a full write operation in which the master can write 1 byte of data to a specific slave(s). The 7-bit slave address in the ID value identifies the specific slave that the master intends to access. The subaddress identifies the register location of the specified slave. The write data contains 8-bit data that the master intends to write over the content of this specific address. The ninth bit of each of the three phases is a don't-care bit (X bit).
- **2-phase write transmission:** The 2-phase write transmission cycle is followed by a 2-phase read transmission cycle (see below). The purpose of issuing a 2-phase write transmission cycle (see (b) of [Figure 18-14](#)) is to identify the subaddress of some specific slave from which the master intends to read data for the following 2-phase read transmission cycle. The ninth bit of each phase is a don't-care bit (X bit).
- **2-phase read transmission:** Either a 3-phase or a 2-phase write transmission cycle must be asserted ahead of a 2-phase read transmission cycle. The 2-phase read transmission cycle (see) of [Figure 18-14](#)) has no ability to identify the subaddress. The 2-phase write transmission cycle contains read data of 8 bits and a ninth don't-care bit or NA bit. The master must drive the NA bit at logical 1.

In each transmission type, phase 1 (7-bit slave address of the ID value) is asserted by the master to identify the selected slave to which the data is read or written. Each slave has a unique 7-bit slave address. The 7-bit slave address of the ID value comprises 7 bits, from bit 7 to bit 1, that can identify up to 128 slaves. The eighth bit, bit 0, is the read/write selector bit that specifies the transmission direction of the current cycle. A logical 0 represents a write cycle and a logical 1 represents a read cycle. The ninth bit of phase 1 is a don't-care bit (X bit).

Phase 2 (subaddress/read data) is asserted by either the master (subaddress) or the slave(s) (read data). A phase 2 transmission asserted by the master identifies the subaddress of the slave(s) the master intends to access. A phase 2 transmission asserted by the slave(s) indicates the read data that the master will receive. The slave(s) recognize the subaddress of this read data according to the previous 3-phase or 2-phase write transmission cycle. The ninth bit is defined as a don't-care bit (X bit) when the master asserts phase 2. The ninth bit is defined as an NA bit when the slave(s) assert the phase 2 transmission. The master is responsible for a logical 1 during the period of the NA bit.

Phase 3 (write data) is asserted by the master only. This phase contains the data the master intends to write to the slave(s). Because the master is asserting the transmission, the ninth bit of the phase 3 transmission is defined as a don't-care bit (X bit).

Note: A multimaster HS I²C controller configured in SCCB mode can perform two operations:

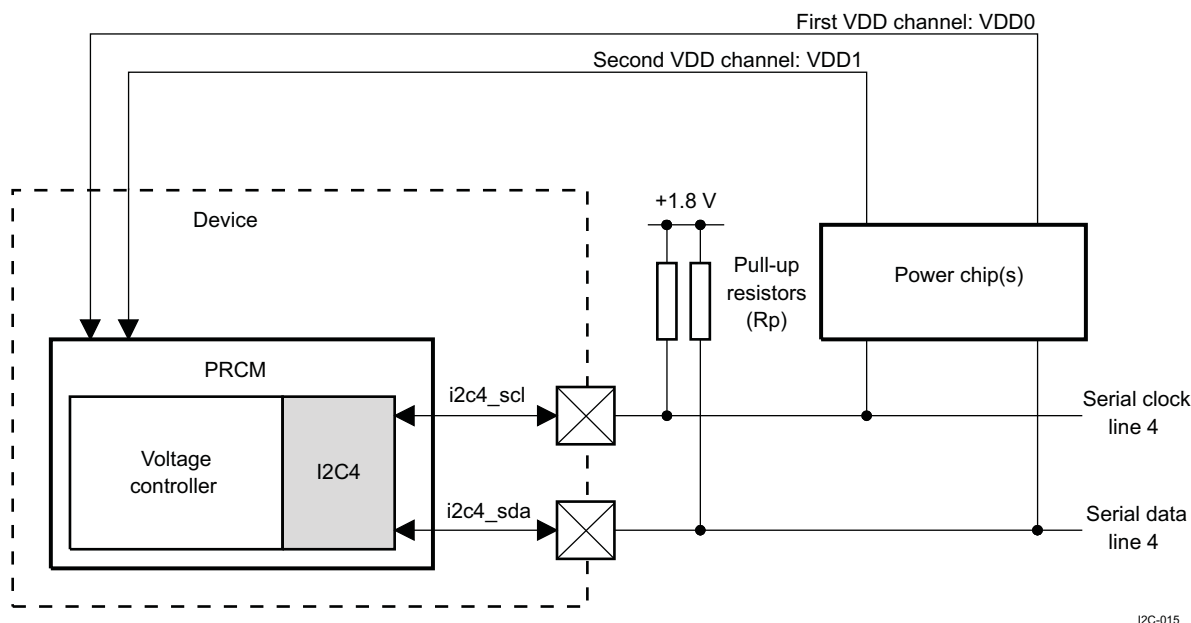

- Writing a single byte to an SCCB slave device by using the 3-phase write transmission cycle
 - Reading a single byte from an SCCB slave device by using the 2-phase write transmission cycle followed by the 2-phase read transmission cycle
-

18.2.3 High-Speed I²C Controller for Communication With Power Chip(s)

The master transmitter HS I²C controller I2C4 interfaces between the and external power chip(s) for voltage control. This module is always configured as an I²C master transmitter; it does not support the SCCB protocol. For a definition of master transmitter mode, see [Section 18.2.1.3.5, Master Transmitter](#).

[Figure 18-15](#) shows a typical connection between the master transmitter HS I²C controller I2C4 of the device and external power chip(s).

Figure 18-15. Typical Connection Between the HS I²C Controller and Power Chip(s)

18.2.3.1 HS I²C Controller I2C4 Pins for Typical Connections

Figure 18-16 shows the HS I²C controller I2C4 pins used for typical connections with power chips.

Figure 18-16. HS I²C Controller I2C4 Interface Signals

18.2.3.2 HS I²C Controller I2C4 Interface Typical Connections

Table 18-3 lists the pins associated with the I²C interface of the HS I²C controller I2C4 of the device.

Table 18-3. Input/Output Description

Signal Name	I/O ⁽¹⁾	Description	Reset Value
i2c4_scl	I/O(OD)	I ² C serial clock line. Open-drain output buffer. Requires external pullup resistor (Rp).	Hi-Z
i2c4_sda	I/O(OD)	I ² C serial data line. Open-drain output buffer. Requires external pullup resistor (Rp).	Hi-Z

⁽¹⁾ I = Input, O = Output, OD = Open Drain, Hi-Z = High Impedance

18.2.3.3 I²C Typical Connections Protocol and Data Format for I2C4

18.2.3.3.1 Serial Data Format

The serial data format is the same as described in [Section 18.2.1.3.1, Serial Data Format](#).

18.2.3.3.2 Data Validity

The data validity is the same as described in [Section 18.2.1.3.2, Data Validity](#).

18.2.3.3.3 Start (S) and Stop (P) Conditions

The start (S) and stop (P) conditions are the same as described in [Section 18.2.1.3.3, Start \(S\) and Stop \(P\) Conditions](#).

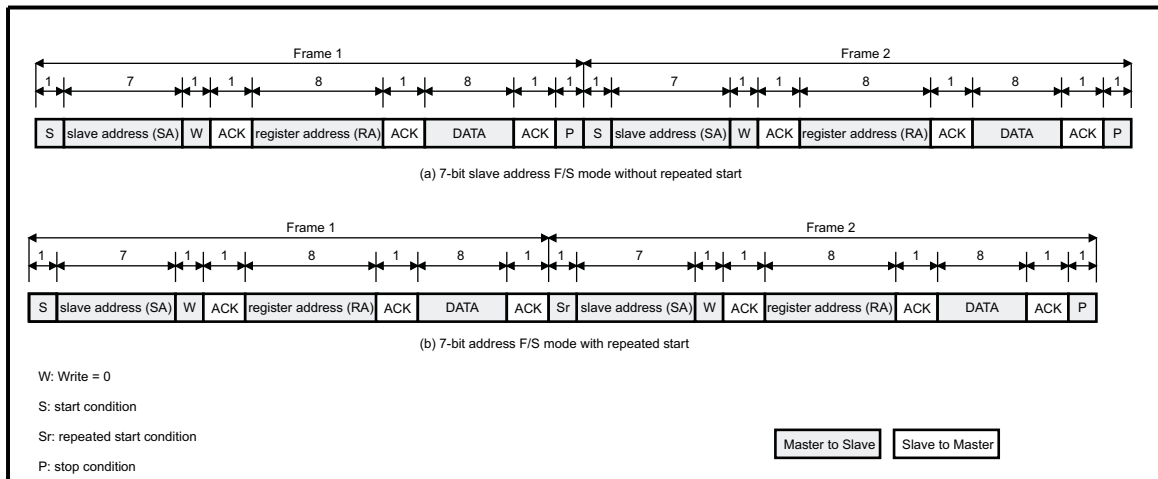

18.2.3.3.4 Addressing

The master transmitter HS I²C controller I2C4 supports only the 7-bit addressing mode. For each frame, the master writes the 8-bit value (DATA) in the register specified by the 8-bit register address (RA) of the slave addressed by the slave address (SA).

18.2.3.3.4.1 Data Transfer Format in F/S Mode

[Figure 18-17](#) shows the I²C data transfer format in F/S mode for the I2C4 module.

Figure 18-17. I²C Data Transfer Format in F/S Mode for the I2C4 Module

I2C-017

18.2.3.3.4.2 Data Transfer Format in HS Mode

Figure 18-18 shows the I^2C data transfer format in HS mode for the I2C4 module.

I2C-018

18.3 High-Speed I²C Controller Integration

Figure 18-19 shows the integration of the four HS I²C controllers in the device.

Figure 18-19. HS I²C Controller Integration

18.3.1 Clocking, Reset, and Power-Management Scheme

18.3.1.1 Clocks

18.3.1.1.1 Module Clocks

Each multimaster HS I²C controller is clocked with an independent functional clock of 96 MHz (I2Ci_FCLK) and an interface clock (I2Ci_ICLK) for interfacing with L4-Core interconnect. These clocks are provided by the PRCM module.

The SYS_CLK clock provided by the clock generator of the PRCM module is connected to the functional and interface clocks of the HS I²C controller I2C4. For detailed information about the module clocking, see the *Power, Reset, and Clock Management* chapter.

The interface clock can be enabled or disabled for each multimaster HS I²C controller by setting the following bits in the PRCM module:

- PRCM.CM_ICLKEN1_CORE[15] EN_I2C1 bit for the I2C1 module
- PRCM.CM_ICLKEN1_CORE[16] EN_I2C2 bit for the I2C2 module
- PRCM.CM_ICLKEN1_CORE[17] EN_I2C3 bit for the I2C3 module

The functional clock can also be enabled or disabled for each multimaster HS I²C controller by setting the following bits in the PRCM module:

- PRCM.CM_FCLKEN1_CORE[15] EN_I2C1 bit for the I2C1 module
- PRCM.CM_FCLKEN1_CORE[16] EN_I2C2 bit for the I2C2 module
- PRCM.CM_FCLKEN1_CORE[17] EN_I2C3 bit for the I2C3 module

The functional clock is processed by a prescaler block to produce the internal sampling clock. This clock is generated by the I²C prescaler block. The prescaler block consists of the I2Ci.I2C_PSC[7:0] PSC bit field (where I = 1, 2, 3) that is used to divide down the functional clock to obtain an internal sampling clock with a frequency value of I2Ci_FCLK/(I2Ci.I2C_PSC[7:0] PSC bit field value + 1, where I = 1, 2, 3).

Note: The I2C4.I2C_PSC[7:0] PSC bit field of the I2C4 module is not accessible by software. For details about the bit rates available for the I2C4 module, see [Section 18.4.7](#).

18.3.1.2 Power Management

18.3.1.2.1 Module Power Saving

This section describes power-saving techniques for the multimaster HS I²C controllers. To conserve power, whenever no activity is detected on the L4-Core interconnect interface of the module, each of these modules supports an automatic idle mode that is enabled or disabled by setting the I2Ci.I2C_SYSC[0] AUTOIDLE bit.

When this bit is asserted (set to 1), if no activity is detected on the L4-Core interface, the automatic idle mode is enabled and the interface clock I2Ci_ICLK is disabled internally to the module, thus reducing power consumption.

When new activity is detected on the L4-Core interconnect interface of the module, the clock restarts with no latency penalty. After reset, the automatic idle mode is disabled; thus, this mode must be enabled by software for reduced power consumption.

18.3.1.2.2 System Power Management

As part of the system-wide power-management scheme, each multimaster HS I²C controller supports a communication protocol with the PRCM module to request the module to enter a low-power mode. When a module acknowledges a low-power mode request from the PRCM module, the interface and/or the functional clocks are gated off at the PRCM clock generator. Because the clocks are disabled at the source, the low-power mode offers lower power consumption than the internal clock autogating method used by local power management.

The PRCM.CM_ICLKEN1_CORE[15] EN_I2C1, PRCM.CM_ICLKEN1_CORE[16] EN_I2C2, and PRCM.CM_ICLKEN1_CORE[17] EN_I2C3 bits in the PRCM module control the interface clocks of the I2C1, I2C2, and I2C3 modules, respectively.

The PRCM.CM_FCLKEN1_CORE[15] EN_I2C1, PRCM.CM_FCLKEN1_CORE[16] EN_I2C2, and PRCM.CM_FCLKEN1_CORE[17] EN_I2C3 bits in the PRCM module control the functional clocks of the I2C1, I2C2, and I2C3 modules, respectively.

For details about clock enabling/disabling in the PRCM module, see the *Power, Reset, and Clock Management* chapter.

Each multimaster HS I²C controller can be configured through the I2Ci.I2C_SYSC[4:3] IDLEMODE field as one of the following acknowledgment modes:

- Force-idle mode (I2Ci.I2C_SYSC[4:3] IDLEMODE field = b00): The module immediately enters idle mode on receiving a low-power-mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state.
- No-idle mode (I2Ci.I2C_SYSC[4:3] IDLEMODE field = b01): The module never enters idle mode.
- Smart-idle mode (I2Ci.I2C_SYSC[4:3] IDLEMODE field = b10): After receiving a low-power-mode request from the PRCM module, the module enters idle mode only after all asserted output interrupts are acknowledged and there is no pending internal event.

Note: The value I2Ci.I2C_SYSC[4:3] IDLEMODE field = b11 must not be used.

Table 18-4 describes the multimaster HS I²C controller power management modes.

Table 18-4. Multimaster HS I²C Controller Power Management Modes

Power management mode requested by the PRCM module	I2Ci.I2C_SYSC[4:3] IDLEMODE field value (where I = 1, 2, 3)
Force-idle	b00
No-idle	b01
Smart-idle	b10
Reserved (not used)	b11

The PRCM module gates the interface and/or the functional clocks after receiving the acknowledgment of the I2Ci module (where i = 1, 2, 3). The I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY bit field indicates the state of the interface and functional clocks of the module when in idle mode. Table 18-5 lists the value of the I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY field and indicates the state of the interface and functional clocks at the PRCM clock generator output in idle mode.

Table 18-5. State of the Interface and Functional Clocks when the Module is in Idle Mode

I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY field value (where I = 1, 2, 3)	Interface clock	Functional clock
b00	OFF	OFF
b01	OFF	ON
b10	ON	OFF
b11	ON	ON

Note: The PRCM.CM_AUTOIDLE1_CORE[15] AUTO_I2C1, PRCM.CM_AUTOIDLE1_CORE[16] AUTO_I2C2, and PRCM.CM_AUTOIDLE1[17] AUTO_I2C3 bits control, for each multimaster HS I²C controller, whether the L4-Core interconnect interface clock is enabled or disabled in synchronization with the CORE power domain state transition (see the *Power, Reset, and Clock Management* chapter).

Note: The voltage controller, in which the HS I2C controller I2C4 is implemented, has no idle request/acknowledge mechanism. The idle modes for the voltage controller are directly managed by the PRM module. For details, see the *Power, Reset, and Clock Management* chapter.

18.3.1.2.3 Wake-up Capability

Each multimaster HS I²C controller I2Ci can wake up the system by generating a wake-up request through the I2Ci_WAKE signal connected to the PRCM module.

The wake-up request is composed of the merge of all wake-up events. Each wake-up event can be separately enabled or disabled by setting the corresponding bit in the I2Ci.I2C_WE register.

The global wake-up capability of the module can be enabled or disabled by setting the I2Ci.I2C_SYSC[2] ENAWAKEUP bit (1: enabled, 0: disabled).

Figure 18-20 shows the wake-up generation flow.

Figure 18-20. Wake-up Generation Flow

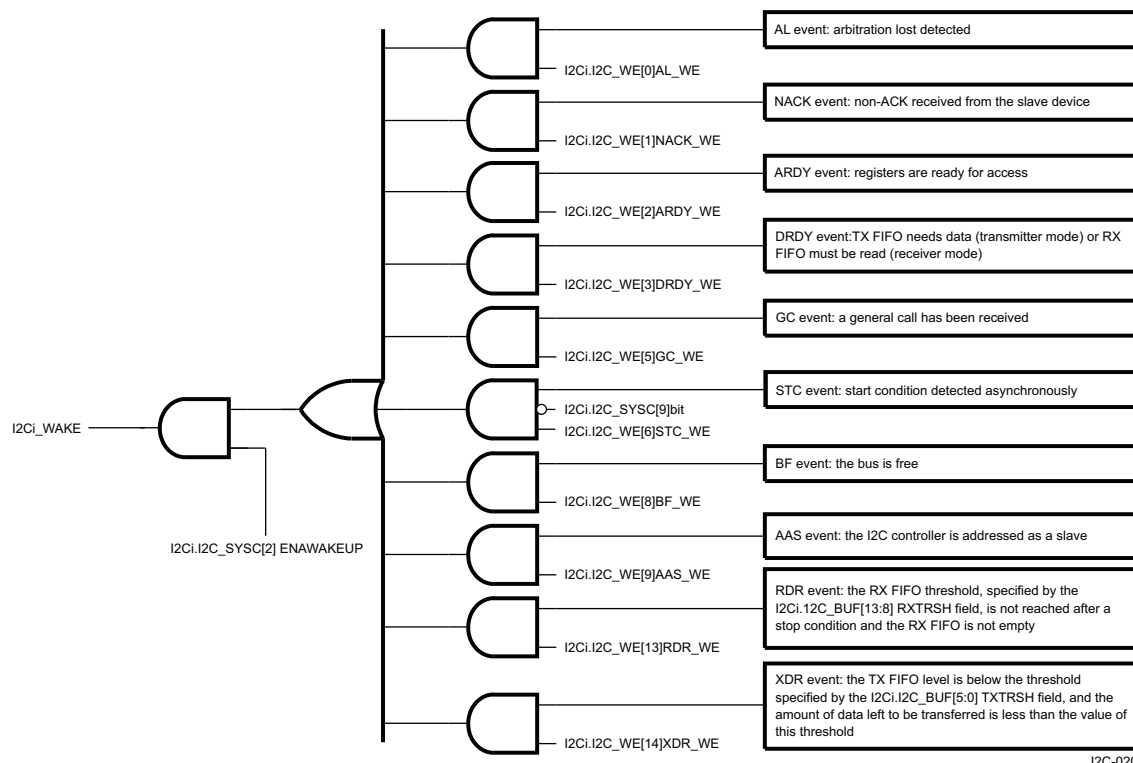

Table 18-6 lists all wake-up events with the corresponding enable/disable bit in the I2Ci.I2C_WE register.

Table 18-6. Wake-up Events

Wake-up Event Name	Supported Configuration Mode	Enable/Disable bit ⁽¹⁾	Event Generated When:
AL event	I ² C mode only	I2Ci.I2C_WE[0] AL_WE	The I2Ci module in the device loses the arbitration of the I ² C bus in master transmitter mode.
NACK event	I ² C mode only	I2Ci.I2C_WE[1] NACK_WE	A nonacknowledgment has been generated on the I ² C bus, indicating a transmission error.
ARDY event	I ² C receive mode and SCCB read mode	I2Ci.I2C_WE[2] ARDY_WE	The current transaction is finished and the module registers can be accessed.
DRDY event	I ² C and SCCB modes	I2Ci.I2C_WE[3] DRDY_WE	The TX FIFO needs some data to be transferred or the RX FIFO must be read.
GC event	I ² C mode only	I2Ci.I2C_WE[5] GC_WE	A general call is received on the I ² C bus.

⁽¹⁾ To enable the corresponding wake-up event generation, set the bit to 1. To disable the corresponding wake-up event generation, set the bit to 0.

Table 18-6. Wake-up Events (continued)

Wake-up Event Name	Supported Configuration Mode	Enable/Disable bit ⁽¹⁾	Event Generated When:
STC event ⁽²⁾	I ² C mode only	I2Ci.I2C_WE[6] STC_WE	A start (S) condition is detected on the I ² C bus. ⁽³⁾
BF event	I ² C and SCCB modes	I2Ci.I2C_WE[8] BF_WE	The bus is free and the LH can initiate its own transfer.
AAS event	I ² C mode only	I2Ci.I2C_WE[9] AAS_WE	An external master I ² C device addresses the module of the device to inform the LH that it can check which of its own addresses was used by the external master I ² C device to access the module of the device.
RDR event	I ² C receive mode only	I2Ci.I2C_WE[13] RDR_WE	The module, configured as a receiver, has detected a stop (P) condition on the I ² C bus and the RX FIFO threshold (I2Ci.I2C_BUF[13:8] RTRSH field value + 1) is not reached and the RX FIFO is not empty. This allows the module to inform the LH that it can check the amount of data to be transferred from the RX FIFO.
XDR event	I ² C master transmit mode only	I2Ci.I2C_WE[14] XDR_WE	The TXFIFO level is below the threshold (I2Ci.I2C_BUF[5:0] XTRSH field value + 1) and the amount of data left to be transferred is less than this threshold. This allows the module to inform the LH that it can check the amount of data to be written to the TX FIFO.

⁽²⁾ Wake-up event asynchronously detected.

⁽³⁾ This event must not be enabled if the functional clock cannot be disabled.

Note: With the exception of the STC event, the functional clock must be active for wake-up event detection to occur. The HS I²C controller I2C4 has no wake-up capability.

18.3.1.3 Resets

18.3.1.3.1 Hardware Reset

The three multimaster HS I²C controllers receive their reset signal CORE_RST (the reset signal of the CORE power domain) from the PRCM module.

The master transmitter HS I²C controller I2C4 gets its reset signal PRM_RSTPWON from the reset manager in the PRCM module.

18.3.1.3.2 Software Reset

Each multimaster HS I²C controller supports the software reset by accessing the I2Ci.I2C_SYSC[1] SRST bit (1: reset, 0: normal mode).

The software reset status can be checked by accessing the I2Ci.I2C_SYSS[0] RDONE bit (1: reset is done, 0: reset is ongoing).

To do a software reset, the following steps must be done:

1. Ensure that the module is disabled (clear the I2Ci.I2C_CON[15] I2C_EN bit to 0).
2. Set the I2Ci.I2C_SYSC[1] SRST bit to 1.
3. Enable the module by setting I2Ci.I2C_CON[15] I2C_EN bit to 1.
4. Check the I2Ci.I2C_SYSS[0] RDONE bit until it is set to 1 to indicate the software reset is complete.

Note: The I2Ci.I2C_CON[15] I2C_EN bit can hold the functional clock domain of the multimaster HS I²C controller in reset after the device reset has been released. When the system bus reset is removed, this bit remains cleared. The functional part of the I²C controller is held in reset state while this bit is 0, and all configuration registers can be accessed.

The I2Ci.I2C_CON[15] I2C_EN bit must be set to 1 to enable the functional part of the I²C controller.

The I2Ci.I2C_SYSS[0] RDONE bit is asserted only after the module is enabled by setting the I2Ci.I2C_CON[15] I2C_EN bit to 1.

18.3.1.4 Power Domain

The three multimaster HS I²C controllers are connected to the CORE power domain, whereas the HS I²C controller I2C4 belongs to the WKUP power domain.

18.3.2 Hardware Requests

18.3.2.1 DMA Requests

Each multimaster HS I²C controller can generate two DMA requests to the system DMA (sDMA) controller. Table 18-7 lists the DMA requests with mapping on the sDMA controller.

Table 18-7. Multimaster HS I²C Controller DMA Requests

Name	Source	Destination (sDMA controller)	Description
I2C1_DMA_TX	I2C1	S_DMA_26	I2C1 DMA write request to inform the sDMA to write new data in the I2C1.I2C_DATA[7:0] register
I2C1_DMA_RX	I2C1	S_DMA_27	I2C1 DMA read request to inform the sDMA to read the data in the I2C1.I2C_DATA[7:0] register
I2C2_DMA_TX	I2C2	S_DMA_28	I2C2 DMA write request to inform the sDMA to write new data in the I2C2.I2C_DATA[7:0] register
I2C2_DMA_RX	I2C2	S_DMA_29	I2C2 DMA read request to inform the sDMA to read the data in the I2C2.I2C_DATA[7:0] register
I2C3_DMA_TX	I2C3	S_DMA_24	I2C3 DMA write request to inform the sDMA to write new data in the I2C3.I2C_DATA[7:0] register
I2C3_DMA_RX	I2C3	S_DMA_25	I2C3 DMA read request to inform the sDMA to read the data in the I2C3.I2C_DATA[7:0] register

Note: The HS I²C controller I2C4 does not generate any DMA request.

18.3.2.2 Interrupt Requests

Each multimaster HS I²C controller can generate an interrupt I2Ci_IRQ to the MPU subsystem. Table 18-8 lists the interrupt requests with the mapping on the MPU interrupt controller.

Table 18-8. Multimaster HS I²C Controller Interrupt Requests

Name	Source	Destination (MPU interrupt controller)
I2C1_IRQ	I2C1	M_IRQ_56
I2C2_IRQ	I2C2	M_IRQ_57
I2C3_IRQ	I2C3	M_IRQ_61

An event can generate an interrupt request when the corresponding mask bit in the I2Ci.I2C_IE register is set to 1. Table 18-9 summarizes the events causing the generation of an interrupt request.

Table 18-9. Multimaster HS I²C Controller Interrupt Events

Event name	Supported configuration mode	Status bit	Mask bit	This event happens when:
AL event	I ² C mode only	I2Ci.I2C_STAT [0] AL	I2Ci.I2C_IE[0] AL_IE	Two or more I ² C master devices initiate a transfer and the I ² C module I2Ci in the device loses arbitration of the I ² C bus.
NACK event	I ² C mode only	I2Ci.I2C_STAT [1] NACK	I2Ci.I2C_IE[1] NACK_IE	A nonacknowledgment has been received. In master mode, the transfer is automatically ended by generating a stop condition on the bus. The I2Ci.I2C_CON[1] STP, I2Ci.I2C_CON[10] MST and I2Ci.I2C_CON[9] TRX bits are automatically cleared to 0 (slave receiver mode). TX and RX FIFOs must be cleared (I2Ci.I2C_BUF[6] TXFIFO_CLR and I2Ci.I2C_BUF[14] RXFIFO_CLR bits set to 1).
ARDY event	I ² C and SCCB modes	I2Ci.I2C_STAT [2] ARDY	I2Ci.I2C_IE[2] ARDY_IE	One of the following cases occurs: <ul style="list-style-type: none"> In I²C master receiver mode, the I2Ci.I2C_CON[1] STP bit is set to 1, the I2Ci.I2C_CNT[15:0] DCOUNT field value is 0, and the RX FIFO is empty. In I²C master transmitter mode, the I2Ci.I2C_CON[1] STP bit is set to 1 and the I2Ci.I2C_CNT[15:0] DCOUNT field value is 0. In I²C master transmitter mode, the I2Ci.I2C_CON[1] STP bit is cleared to 0 and the I2Ci.I2C_CNT[15:0] DCOUNT field value passed 0. In I²C master receiver mode, the I2Ci.I2C_CON[1] STP bit is set to 1, the I2Ci.I2C_CNT[15:0] DCOUNT field value passed 0, and the RX FIFO is empty. In I²C slave transmitter mode, a stop or start (S) condition is received from the external I²C master device. In I²C slave receiver mode, a stop or start (S) condition is received from the external I²C master device and the RX FIFO is empty. In SCCB master transmitter or receiver mode, a stop (P) condition is detected.
RRDY event	I ² C receive mode and SCCB read mode	I2Ci.I2C_STAT [3] RRDY	I2Ci.I2C_IE[3] RRDY_IE	The RX FIFO level is above the threshold (I2Ci.I2C_BUF[13:8] RTRSH field value + 1).
XRDY event	I ² C transmit mode and SCCB write mode	I2Ci.I2C_STAT [4] XRDY	I2Ci.I2C_IE[4] XRDY_IE	The module requires new data to be served. A master transmitter module requests new data when the TX FIFO level is below the threshold (I2Ci.I2C_BUF[5:0] XTRSH field value + 1) and the required amount of data to be transmitted specified by the I2Ci.I2C_BUFSTAT[5:0] TXSTAT field is greater than the threshold. A slave transmitter requests new data when the TX FIFO is below the threshold (if the I2Ci.I2C_BUF[5:0] XTRSH field value is greater than 1), or when there is a read request from the external master device (for each acknowledge received from the master) when the I2Ci.I2C_BUF[5:0] XTRSH field value is 1.
GC event	I ² C mode only	I2Ci.I2C_STAT [5] GC	I2Ci.I2C_IE[5] GC_IE	The module detects a general call on the I ² C bus (all bits of the address cleared to 0).
STC event	I ² C mode only	I2Ci.I2C_STAT [6] STC	I2Ci.I2C_IE[6] STC_IE	The module is in idle mode and a start (S) condition is asynchronously detected on the I ² C bus and signaled with a wakeup. When the active mode is restored and the interrupt generated, this bit indicates the reason for the wakeup. See ⁽¹⁾ .

⁽¹⁾ The interrupt request generation on an STC event must be enabled only if the module is configured to allow the possibility of switching off the functional clock while in idle state (the I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY field set to b00 or b01). The first transfer (corresponding to the detected start (S) condition) is lost, and is used only to restore the active mode of the module. On the I²C bus, the external master that generated the transfer detects this behavior as a nonacknowledge to the address phase and may possibly restart the transfer.

Table 18-9. Multimaster HS I²C Controller Interrupt Events (continued)

Event name	Supported configuration mode	Status bit	Mask bit	This event happens when:
AERR event	I ² C and SCCB modes	I2Ci.I2C_STAT [7] AERR	I2Ci.I2C_IE[7] AERR_IE	A write access to the I2Ci.I2C_DATA register by the LH through the L4-Core interconnect is performed while the TX FIFO is full or a read access to the I2Ci.I2C_DATA register by the LH through the L4-Core interconnect is performed while the RX FIFO is empty. When the RX FIFO is empty, the read of the RX FIFO returns the previous read data value. When the TX FIFO is full, a write in the TX FIFO is ignored.
BF event	I ² C and SCCB modes	I2Ci.I2C_STAT [8] BF	I2Ci.I2C_IE[8] BF_IE	The I ² C bus becomes free (after a transfer is ended on the bus and a stop (P) condition is detected).
AAS event	I ² C mode only	I2Ci.I2C_STAT [9] AAS	I2Ci.I2C_IE[9] AAS_IE	The module has recognized its own slave address or an alternate Own Address, or a general call (all address bits cleared to 0).
RDR event	I ² C receive mode only	I2Ci.I2C_STAT [13] RDR	I2Ci.I2C_IE[13] RDR_IE	The module is configured as a receiver, a stop (P) condition was received on the I ² C bus, and the RX FIFO level is below the threshold (I2Ci.I2C_BUF[13:8] RTRSH field value + 1).
XDR event	I ² C master transmit mode only	I2Ci.I2C_STAT [14] XDR	I2Ci.I2C_IE[14] XDR_IE	The module is configured as a master transmitter, the TX FIFO level is below the threshold (I2Ci.I2C_BUF[5:0] XTRSH field value + 1), and the amount of data still to be transferred is less than this threshold.

When an interrupt request is generated, the software must read the I2Ci.I2C_STAT register to check which event caused the interrupt request generation, process accordingly, and acknowledge each processed event by writing 1 to the corresponding bit in the I2Ci.I2C_STAT register.

Note: The I2Ci.I2C_STAT[9] AAS status bit, corresponding to the AAS event, can be cleared in two ways:

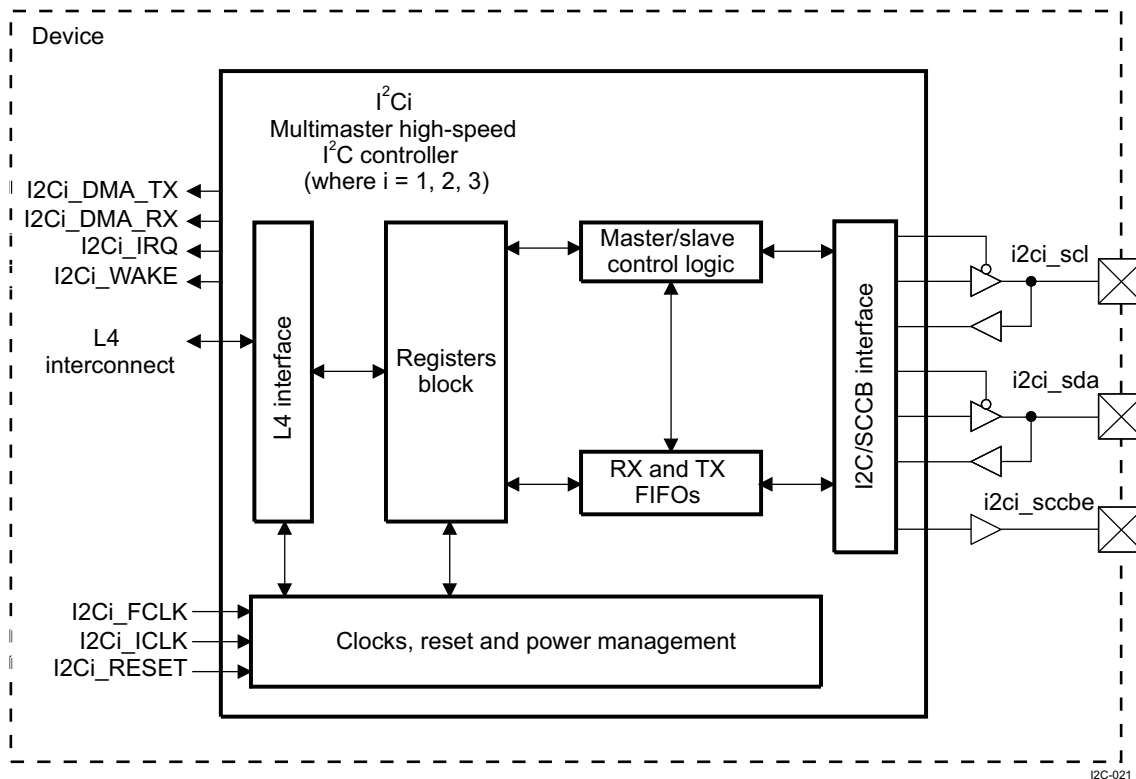

- If the I2Ci.I2C_IE[9] AAS_IE bit is set to 1 (interrupt generation enabled), the status bit is cleared by writing 1 to the I2Ci.I2C_STAT[9] AAS status bit
- If the I2Ci.I2C_IE[9] AAS_IE bit is cleared to 0 (interrupt generation disabled), the status bit is cleared when a new start or stop (P) condition is detected on the I²C bus.

18.4 High-Speed I²C Controller Functional Description

18.4.1 Block Diagram

Figure 18-21 is a functional block diagram of the multimaster I²C HS controller.

Figure 18-21. Multimaster HS I²C Controller Block Diagram

Note: The i2c1_sccb signal is not available.

The three multimaster HS I²C controllers can be configured in F/S I²C mode, in HS I²C mode, or in SCCB mode. The operation mode is selected by configuring the I2Ci.I2C_CON[13:12] OPMODE field.

Table 18-10 lists the available operation modes.

Table 18-10. Operation Mode Selection

Operation Mode	I2Ci.I2C_CON[13:12] OPMODE field value
Fast/standard (F/S) I ² C	0x0
High-speed (HS) I ² C	0x1
SCCB	0x2
Reserved (not used)	0x3

18.4.2 Transmit Mode in I²C Mode

This mode is available for master or slave. The master and slave modes are configurable with the I2Ci.I2C_CON[10] MST bit (0: slave mode, 1: master mode).

In master mode, the transmit mode is configured by setting the I2Ci.I2C_CON[9] TRX bit to 1. The MPU subsystem puts the data to transmit in the TX FIFO by writing to the I2Ci.I2C_DATA[7:0] DATA bit field.

The transmitter can write new data to this register when the I2Ci.I2C_STAT[4] XRDY bit is set to 1, or when the I2Ci.I2C_STAT[14] XDR bit is set to 1 according to the draining mechanism description.

A master transmitter requests new data if the I2Ci.I2C_CNT[15:0] DCOUNT bit field value is not 0. A slave transmitter requests new data if a read is performed by the external master.

Note: The HS I2C controller I2C4 is configured in master transmitter mode, and its configuration cannot be changed.

18.4.3 Receive Mode in I²C Mode

This mode is available for master or slave. In master mode, it is configured by clearing the I2Ci.I2C_CON[9] TRX bit to 0.

The MPU subsystem can read new data from the I2Ci.I2C_DATA[15:0] DCOUNT bit field when the I2Ci.I2C_STAT[3] RRDY bit is set to 1, or when the I2Ci.I2C_STAT[13] RDR bit is set according to the draining mechanism description.

Each time the I2Ci.I2C_STAT[3] RRDY bit is set to 1, if the interrupt is enabled (the I2Ci.I2C_IE[3] RRDY_IE bit must be set to 1), the I²C controller generates an interrupt to the MPU subsystem.

Note: In interrupt mode, the MPU subsystem must read this bit after each read in the I2Ci.I2C_DATA register to ensure that no other data is waiting for the FIFO to be read. For a new interrupt to be received, the I2Ci.I2C_STAT[3] RRDY bit must be cleared in the interrupt routine.

If the DMA receive mode is enabled (the I2Ci.I2C_BUF[15] RDMA_EN bit is set), this bit is forced to 0 and no interrupt is generated; instead, a DMA RX request to the sDMA controller is generated.

18.4.4 FIFO Management

Each multimaster HS I²C controller implements two internal 8-bit FIFOs, the RX and TX FIFOs.

Table 18-11 lists the depth of these FIFOs, depending on the instance of the I²C controller.

Table 18-11. RX and TX FIFO Depths

I ² C Controller Instance	RX and TX FIFO Depth (in bytes)
I2C1	8
I2C2	8
I2C3	64

The depth of the RX and TX FIFOs can be checked by reading the I2Ci.I2C_BUFSTAT[15:14] FIFODEPTH bit field (0x0: 8 bytes, 0x1: 16 bytes, 0x2: 32 bytes, and 0x3: 64 bytes).

18.4.4.1 FIFO Interrupt Mode Operation

In FIFO interrupt mode (relevant interrupts enabled by the I2Ci.I2C_IE register), the processor is informed of the receiver and transmitter status by an interrupt signal. These interrupts are raised when the RX/TX FIFO thresholds (defined by the I2Ci.I2C_BUF[13:8] RTRSH field value + 1 for the RX FIFO or the I2Ci.I2C_BUF[5:0] XTRSH field value + 1 for the TX FIFO) are reached; the interrupt signals instruct the LH to transfer data to the destination (from the I²C controller module in receive mode and/or from any source to the I²C controller FIFO in transmit mode).

Figure 18-22 and Figure 18-23 show receive and transmit operations, respectively, from a FIFO management point of view.

Figure 18-22. Receive FIFO Interrupt Request Generation

I2C-022

In Figure 18-22, the RRDY interrupt condition shows that the condition for generating an RRDY interrupt is achieved. The interrupt request is generated when this signal is active, and it can be cleared only by the LH by writing 1 in the I2Ci.I2C_STAT[3] RRDY bit. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In receive mode, an RRDY interrupt is generated as soon as the FIFO reaches its receive threshold (I2Ci.I2C_BUF[13:8] RTRSH field value + 1). The interrupt can be deasserted only when the LH has handled enough bytes to make the number of bytes in the RX FIFO lower than the programmed threshold. For each interrupt, the LH can be configured to read a number of bytes equal to the value of the RX FIFO threshold.

Note: In SCCB mode, the RX and TX threshold values must be set to 1 by setting the I2Ci.I2C_BUF[13:8]RTRSH and I2Ci.I2C_BUF[5:0]XTRSH fields to 0x0.

Figure 18-23. Transmit FIFO Interrupt Request Generation

I2C-023

In Figure 18-23, the XRDY interrupt condition shows that the condition for generating an XRDY interrupt is achieved. The interrupt request is generated when TX FIFO is empty or when the TX FIFO threshold is not reached, and the LH can clear the XRDY status bit by writing 1 in the I2Ci.I2C_STAT[4] XRDY bit after transmitting the configured number of bytes. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In interrupt mode, the module offers two options for the LH application to handle the interrupts:

- When detecting an interrupt request (XRDY/RRDY type), the LH can write/read 1 data byte to/from the TX/RX FIFO and then clear the interrupt. The module reasserts the interrupt until the interrupt condition is no longer met.
- When detecting an interrupt request (XRDY/RRDY type), the LH can be programmed to write/read the number of data bytes specified by the corresponding FIFO threshold (I2Ci.I2C_BUF[5:0] XTRSH field value + 1 for the TX threshold or I2Ci.I2C_BUF[13:8] RTRSH field value + 1 for the RX threshold). In this case, the interrupt condition is cleared and the next interrupt is asserted again when the XRDY/RRDY condition is met again.

If the second-interrupt-serving approach is used, an additional mechanism (draining feature) is implemented for cases where the transfer length is not a multiple of the FIFO threshold value (see [Section 18.4.4.4](#)).

Note: In slave transmit mode (the I2Ci.I2C_CON[10] MST bit is cleared and the I2Ci.I2C_CON[9] TRX bit is set to 1), the draining feature must not be used, because the transfer length is not known at configuration time, and the external master can end the transfer at any point by not acknowledging 1 data byte. If the draining feature is used in slave transmit mode, data can remain in the TX FIFO without being transmitted over the I²C bus. In this case, the TX FIFO must be cleared by setting the I2Ci.I2C_BUF[6] TXFIFO_CLR bit.

18.4.4.2 FIFO Polling Mode Operation

In FIFO polled mode (the I2Ci.I2C_IE[4] XRDY_IE and I2Ci.I2C_IE[3] RRDY_IE bits are disabled, and the I2Ci.I2C_BUF[15] RDMA_EN and I2Ci.I2C_BUF[7] XDMA_EN bits are disabled), the status of the module (receiver or transmitter) can be checked by polling the I2Ci.I2C_STAT[4] XRDY and the I2Ci.I2C_STAT[3] RRDY bits (the I2Ci.I2C_STAT[13] RDR and I2Ci.I2C_STAT[14] XDR bits can also be polled if the draining feature is enabled). The I2Ci.I2C_STAT[4] XRDY and I2Ci.I2C_STAT[3] RRDY bits accurately reflect the interrupt conditions described in the discussion of the FIFO interrupt mode operation.

18.4.4.3 FIFO DMA Mode Operation (I²C Mode Only)

In receive mode, a DMA request is generated by the I2Ci_DMA_RX signal as soon as the RX FIFO exceeds its threshold level (I2Ci.I2C_BUF[13:8] RTRSH field value + 1). This request is deasserted when the number of bytes defined by the threshold level is read by the sDMA controller.

[Figure 18-24](#) shows the DMA request generation in receive mode.

Figure 18-24. Receive FIFO DMA Request Generation

In transmit mode, a DMA request is automatically asserted by the I2Ci_DMA_TX signal when the TX FIFO is empty. This request is deasserted when the number of bytes (I2Ci.I2C_BUF[5:0] XTRSH field value + 1) is written in the FIFO by the sDMA controller. If an insufficient number of bytes is written, the DMA request remains active. Figure 18-25 and Figure 18-26 show the DMA TX transfers with different values for the I2Ci.I2C_BUF[5:0] XTRSH field.

Figure 18-25. Transmit FIFO Request Generation (High Threshold)

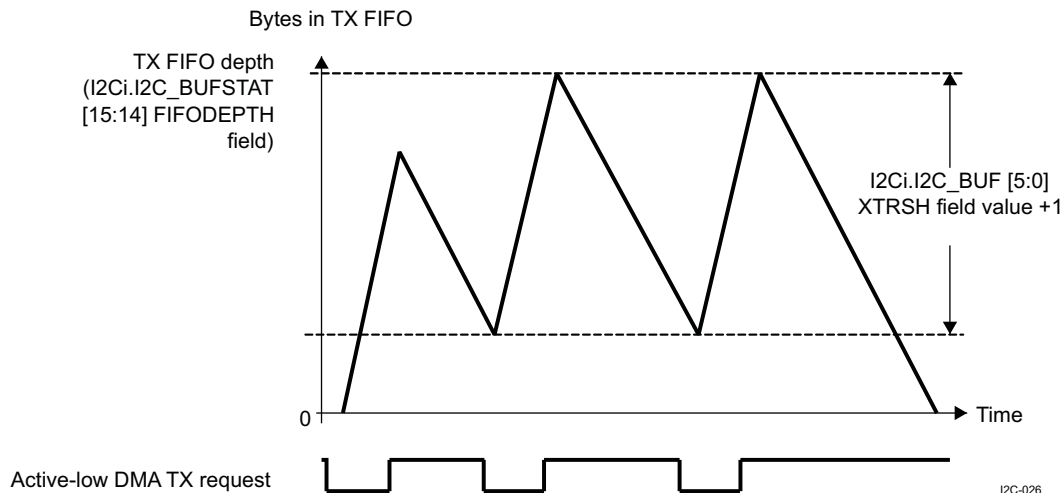

Figure 18-26. Transmit FIFO Request Generation (Low Threshold)

Note: In SCCB mode, the RX and TX threshold values must be set to 1 by setting the I2Ci.I2C_BUF[13:8]RTRSH and I2Ci.I2C_BUF[5:0]XTRSH fields to 0x0.

18.4.4.4 Draining Feature (I²C Mode Only)

The draining feature is implemented to handle the end of a transfer whose length is not a multiple of the FIFO threshold values (I2Ci.I2C_BUF[13:8] RTRSH field value + 1 for the RX threshold and I2Ci.I2C_BUF[5:0] XTRSH field value + 1 for the TX threshold). It also offers the possibility of transferring the remaining number of bytes (because the threshold is not reached).

This feature prevents the LH or the sDMA controller from trying more FIFO accesses than necessary (for example, to generate at the end of a transfer a DMA RX request having fewer bytes in the FIFO than the configured DMA transfer length). Otherwise, an AERR interrupt is generated by the I2Ci.I2C_STAT[7] AERR status bit.

The draining mechanism generates an interrupt using the I2Ci.I2C_STAT[13] RDR or the I2Ci.I2C_STAT[14] XDR status bit at the end of the transfer, informing the LH that it must check the amount of data left to be transferred (the I2Ci.I2C_BUFSTAT[13:8] RXSTAT or I2Ci.I2C_BUFSTAT[5:0] TXSTAT fields) and enable the draining feature of the DMA controller by reconfiguring the DMA transfer length according to this value (when the DMA mode is enabled) or perform only the required number of data accesses (when the DMA mode is disabled).

In receive mode (master or slave), if the RX FIFO threshold (I2Ci.I2C_BUF[13:8] RTRSH field value + 1) is not reached, but the transfer ends on the I²C bus and there is still data in the RX FIFO (less than the threshold), the receive draining interrupt (the I2Ci.I2C_STAT[13] RDR status bit) is asserted to inform the LH that it can read the amount of data in the FIFO (the I2Ci.I2C_BUFSTAT[13:8] RXSTAT field). The LH performs a number of data read accesses equal to the I2Ci.I2C_BUFSTAT[13:8] RXSTAT field value (interrupt or polling mode), or reconfigures the sDMA controller with the required value to drain the FIFO.

In master transmit mode, if the TX FIFO threshold (I2Ci.I2C_BUF[5:0] XTRSH field value + 1) is not reached, but the amount of data remaining to be written in the TX FIFO is less than the threshold, the transmit draining interrupt (the I2Ci.I2C_STAT[14] XDR status bit) is asserted to inform the LH that it can read the amount of data remaining to be written in the TX FIFO (the I2Ci.I2C_BUFSTAT[5:0] TXSTAT field). The LH must write the required number of data bytes specified by the I2Ci.I2C_BUFSTAT[5:0] TXSTAT field value or reconfigure the sDMA controller with the value required to transfer the last bytes to the FIFO.

In master mode, the LH can alternately skip the checking of the I2Ci.I2C_BUFSTAT[5:0] TXSTAT and I2Ci.I2C_BUFSTAT[13:8] RXSTAT field values, because it can obtain this information internally (by computing the I2Ci.I2C_CNT[15:0] DATACOUNT field value modulo I2Ci.I2C_BUF[13:8] RTRSH or I2Ci.I2C_BUF[5:0] XTRSH).

By default, the draining feature is disabled; it can be enabled using the I2Ci.I2C_IE[14] XDR_IE or I2Ci.I2C_IE[13] RDR_IE bits (default disabled) only for transfers with lengths not equal to the threshold values (I2Ci.I2C_BUF[5:0] XTRSH field value + 1 for the TX threshold or I2Ci.I2C_BUF[13:8] RTRSH field value + 1 for the RX threshold).

18.4.5 Programmable Multislave Channel Feature (I²C Mode Only)

This feature allows each multimaster HS I²C controller to be addressed using four separate Own Addresses configured in the I2Ci.I2C_OAx registers (with x = 0, 1, 2, 3). An additional register (I2Ci.I2C_ACTOA) is used to indicate to the LH which address is used by the external master to communicate with the I²C controller.

Each Own Address can be independently configured in 7-bit or 10-bit mode by setting the corresponding bit (I2Ci.I2C_CON[7] XOA0, I2Ci.I2C_CON[6] XOA1, I2Ci.I2C_CON[5] XOA2, or I2Ci.I2C_CON[4] XOA3).

18.4.6 Automatic Blocking of the I²C Clock Feature (I²C Mode Only)

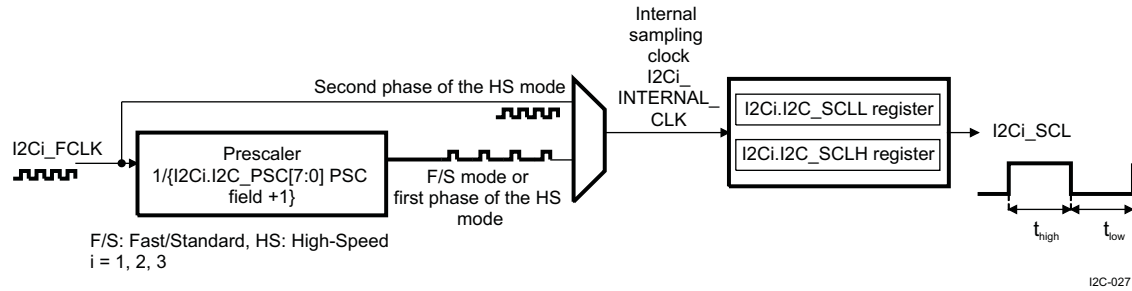

This feature offers the possibility for the LH to command the blocking of the I²C clock after the slave addressing phase, when the I²C controller is addressed by an external master device using a certain Own Address.

The release of the I²C clock (i2ci_scl signal, with l = 1, 2, 3) can be performed independently for each Own Address (I2Ci.I2C_OAi registers, with l = 0, 1, 2, 3) by deasserting the corresponding bit in the I2Ci.I2C_SBLOCK register.

18.4.7 Clocking

Figure 18-27 shows the I²C clock generation of the HS I²C controllers.

Figure 18-27. I²C Clock Generation

Each multimaster HS I²C controller uses the I2Ci_FCLK functional clock in the PRCM module. The internal sampling clock I2Ci_INTERNAL_CLK is generated by dividing the functional clock by (I2Ci.I2C_PSC[7:0] PSC field value + 1) in F/S mode, in SCCB mode, or in the first phase of HS mode; or by directly using the functional clock in the second phase of HS mode (prescaler is bypassed).

The low time of the I2Ci_SCL signal is determined by the I2Ci.I2C_SCLL[7:0] SCLL field in F/S mode, in SCCB mode, or in the first phase of HS mode; or by the I2Ci.I2C_SCLL[15:8] HSSCLL field in the second phase of HS mode.

The high time of the I2Ci_SCL signal is determined by the I2Ci.I2C_SCLH[7:0] SCLH field in F/S mode, in SCCB mode, or in the first phase of HS mode; or by the I2Ci.I2C_SCLH[15:8] HSSCLH field in the second phase of HS mode.

Table 18-12 lists the t_{LOW} and t_{high} values in master mode only (in slave mode, the I²C controller does not generate the I²C clock).

Table 18-12. t_{LOW} and t_{high} Values of the I²C Clock

Mode	I2Ci_INTERNAL_CLK	t_{LOW}	t_{high}
F/S, SCCB, or HS first phase	I2Ci_FCLK / (I2Ci.I2C_PSC[7:0] PSC field + 1)	(I2Ci.I2C_SCLL[7:0] SCLL field value + 7) x I2Ci_INTERNAL_CLK period	(I2Ci.I2C_SCLH[7:0] SCLH field value + 5) x I2Ci_INTERNAL_CLK period
HS second phase	I2Ci_FCLK	(I2Ci.I2C_SCLL[15:8] HSSCLL field value + 7) x I2Ci_INTERNAL_CLK period	(I2Ci.I2C_SCLH[15:8] HSSCLH field value + 5) x I2Ci_INTERNAL_CLK period

Note: For HS mode, both the I2Ci.I2C_SCLL[15:8] HSSCLL and I2Ci.I2C_SCLL[7:0] SCLL fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

For HS mode, both the I2Ci.I2C_SCLH[15:8] HSSCLH and I2Ci.I2C_SCLH[7:0] SCLH fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

CAUTION

During active mode (I2Ci.I2C_CON[15] I2C_EN bit is set to 1), make no changes to the I2Ci.I2C_SCLL and I2Ci.I2C_SCLH registers. Changes may result in unpredictable behavior.

Table 18-13 lists the register values for obtaining the maximum I²C bit rates and the maximum period of the filtered spikes in F/S mode and HS mode.

Table 18-13. Register Values for Maximum I²C Bit Rates in I²C F/S, I²C HS, and SCCB Modes⁽¹⁾

	I ² C Mode for I2Ci, where I = 1, 2, 3			Description	SCCB Mode for I2Ci, where I = 1, 2, 3		I ² C Mode only for I2C4						
	Standard Mode	Fast Mode	High-Speed Mode										
I2Ci_FCLK frequency (MHz)	96				96		12	13	19.2	26	38.4	SYS_CLK clock frequency	
I2Ci.I2C_PSC[7:0] PSC field minimum value	23	9	4	Prescaler value for F/S and HS modes	4	Prescaler value for SCCB mode	Not accessible by software						
I2Ci_INTERNAL_CLK frequency (MHz)	4	9.6	19.2		19.2								
I2Ci.I2C_SCLL[7:0] SCLL field minimum value	13	5	17	Value for F/S mode and first phase of HS mode	89	Value for SCCB mode	Not accessible by software					F/S mode and first phase in HS mode maximum bit rate	
I2Ci.I2C_SCLH[7:0] SCLH field minimum value	15	7	19	Value for F/S mode and first phase of HS mode	91	Value for SCCB mode							Not accessible by software
Maximum bit rate (Mbps)	0.1	0.4	0.4	F/S mode and first phase in HS mode maximum bit rate	0.1	SCCB mode maximum bit rate	0.4						
Maximum filter period (ns)	250	104	50		50		50						
I2Ci.I2C_SCLL[15:8] HSSCLL field minimum value				8	Values for second phase of HS mode			Not accessible by software					
I2Ci.I2C_SCLH[15:8] HSSCLH field minimum value				10	Values for second phase of HS mode								
HS mode maximum bit rate (Mbps)				3.31	HS mode maximum bit rate			0.8	0.87	1.28	1.73	2.56	HS mode maximum bit rate according to the corresponding SYS_CLK clock frequency
Maximum filter period (ns)				10				10					

⁽¹⁾ Programmable fields are in bold.

Note: Each multimaster HS I²C controller can be used with an internal secondary pullup. This pullup is mandatory when the I²C controller is configured in HS mode for a bit rate of 3.4M bps, and the bus line capacitance exceeds 45 pF. Pullups can be programmed through the CONTROL.CONTROL_DEVCONF1[12] I2C1HSMASER bit for I2C1, the CONTROL.CONTROL_DEVCONF1[13] I2C2HSMASER bit for I2C2, and the CONTROL.CONTROL_DEVCONF1[14] I2C3HSMASER bit for I2C3.

The maximum bit rate specified by the SCCB specifications is 100K b/s.

18.4.8 Noise Filter

The noise filter is used to suppress any noise that is 50 ns or less in case of F/S and SCCB operation modes, and any noise that is 10 ns or less in case of HS mode operation. The noise filter is always one period of the I2Ci_INTERNAL_CLK clock. This way, for HS mode operation (prescaler bypassed), the filter suppresses spikes of less than 10.4 ns.

For SCCB modes (for example, I2Ci.I2C_PSC[7:0] PSCbit field = 4), the maximum width of suppressed spikes is 52 ns.

To ensure correct filtering, the prescaler must be programmed accordingly by the I2Ci.I2C_PSC[7:0] PSC bit field.

18.4.9 System Test Mode

A system test mode is available for multimaster HS I²C controller module testing. This mode is enabled by setting the I2Ci.I2C_SYSTEST[15] ST_EN to 1. When this bit is cleared to 0, the I²C controller is configured in normal operation mode.

In system test mode, the I2Ci_SYSTEST[13:12] TMODE bit field selects the type of test. Table 18-14 lists the tests available for the multimaster HS I²C controllers.

Table 18-14. List of tests for the Multimaster HS I²C Controllers

I2Ci.I2C_SYSTEST[13:12] TMODE field value	Test	Description
b00	Functional mode	Normal operation mode
b01	Reserved (not used)	
b10	Test of i2ci_scl serial clock line	The i2ci_scl line is driven with a permanent clock as if mastered with the parameters set in the I2Ci.I2C_PSC, I2Ci.I2C_SCLL, and I2Ci.I2C_SCLH registers.
b11	Loop-back mode + i2ci_scl/ i2ci_sda/ i2ci_sccb input/output	In the master transmit mode only, data transmitted out of the I2Ci.I2C_DATA register (write action) is received in the same I2Ci.I2C_DATA register through an internal path through the FIFO buffers. The DMA and interrupt requests are normally generated if they are enabled. Moreover, the i2ci_scl, i2ci_sda, and i2ci_sccb lines are controlled with the I2Ci.I2C_SYSTEST[4:0] bits.

Note: When the I2Ci.I2C_SYSTEST[13:12] TMODE field = b11, the I²C controller must be configured in I²C F/S (I2Ci.I2C_CON[13:12] OPMODE = b00) or I²C HS mode (I2Ci.I2C_CON[13:12] OPMODE = b01). The loop-back mode is not available in SCCB mode (I2Ci.I2C_CON[13:12] OPMODE = b10).

Note: In normal operation mode (I2Ci.I2C_SYSTEST[15] ST_EN clear to 0), the I2Ci.I2C_SYSTEST[4:0] bits that control the i2ci_scl, i2ci_sda, and i2ci_sccb lines in system test mode are read-only bits.

In system test mode (I2Ci.I2C_SYSTEST[15] ST_EN set to 1), the I2Ci.I2C_STAT[5:0] status bits can be set to 1 when the I2Ci.I2C_SYSTEST[11] SSB bit is set to 1. Clearing the I2Ci.I2C_SYSTEST[11] SSB bit to 0 does not clear the I2Ci.I2C_STAT[5:0] status bits to 0. The I2Ci.I2C_STAT[5:0] status bits can be cleared to 0 only by writing 1 in the corresponding bits.

18.4.10 Write and Read Operations in SCCB Mode

In SCCB mode, the multimaster HS I²C controller can write or read a single byte to or from the external SCCB device.

To write a single byte to the external SCCB device, the multimaster HS I²C controller must be configured in multimaster transmitter mode by setting the I2Ci.I2C_CON[10] MST and I2Ci.I2C_CON[9] TRX bits to 1. The external device slave address (7-bit address of the ID value) is set in the I2Ci.I2C_SA register; the register address (8-bit subaddress in the external SCCB device) is set in the I2Ci.I2C_OA0 register. The 8-bit data to be transmitted is written by the LH in the I2Ci.I2C_DATA register.

To read a single byte from the external SCCB device, the multimaster HS I²C controller must be configured in multimaster receiver mode by setting the I2Ci.I2C_CON[10] MST to 1 and by clearing the I2Ci.I2C_CON[9] TRX bit to 0. The external device slave address (7-bit address of the ID value) is set in the I2Ci.I2C_SA register; the register address (8-bit subaddress in the external SCCB device) is set in the I2Ci.I2C_OA0 register. The 8-bit data received from the external SCCB device is read by the LH from the I2Ci.I2C_DATA register.

Note: In SCCB mode, the RX and TX thresholds must be set to 1 by configuring the I2Ci.I2C_BUF[13:8] RTRSH and I2Ci.I2C_BUF[5:0]XTRSH fields to 0x0.

18.4.11 Power Chip Communication Operations

The master transmitter HS I²C controller I2C4 inside the voltage controller of the PRM module is used to send power-sequencing commands from two voltage processors or configuration commands from the LH to external power chip(s).

For voltage control operations, the LH must set the slave address of the first power chip in the PRCM.PRM_VC_SMPS_SA[6:0] SA0 field, and the slave address of the second power chip (if necessary) in the PRCM.PRM_VC_SMPS_SA[22:16] SA1 field.

The LH must also configure the specific registers in the voltage controller of the PRCM module, for the voltage control and power-sequencing functions.

A high-priority bypass mode is available to allow the LH to configure the external power chip(s) through the I²C bus. To write an 8-bit data to the configuration registers of an external power chip, the LH must set the 7-bit external power chip slave address in the PRCM.PRM_VC_BYPASS_VAL[6:0] SLAVEADDR field, the configuration register address in the PRCM.PRM_VC_BYPASS_VAL[15:8] REGADDR field, and the 8-bit data in the PRCM.PRM_BYPASS_VAL[23:16] register.

For details about voltage control, see the *Power, Reset, and Clock Management* chapter.

18.5 High-Speed I²C Controller Basic Programming Model

18.5.1 Multimaster HS I²C Controller Basic Programming Model in I²C Mode

This section describes the programming model of the multimaster HS I²C controllers configured in I²C mode.

18.5.1.1 Main Program

18.5.1.1.1 Configure the Module Before Enabling the I²C Controller

Before enabling the I²C controller, perform the following steps:

1. Enable the functional and interface clocks (see [Section 18.3.1.1.1](#)).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock (I2Ci_INTERNAL_CLK) by programming the corresponding value in the I2Ci.I2C_PSC[3:0] PSC field. This value depends on the frequency of the functional clock (I2Ci_FCLK). Because this frequency is 96MHz, the I2Ci.I2C_PSC[7:0] PSC field value is 0x7.
3. Program the I2Ci.I2C_SCLL[7:0] SCLL and I2Ci.I2C_SCLH[7:0] SCLH fields to obtain a bit rate of 100K bps or 400K bps. These values depend on the internal sampling clock frequency (see [Table 18-12](#)).
4. (Optional) Program the I2Ci.I2C_SCLL[15:8] HSSCLL and I2Ci.I2C_SCLH[15:8] HSSCLH fields to obtain a bit rate of 400K bps or 3.4M bps (for the second phase of HS mode). These values depend on the internal sampling clock frequency (see [Table 18-12](#)).
5. (Optional) If a bit rate of 3.4M bps is used and the bus line capacitance exceeds 45 pF, program the CONTROL.CONTROL_DEVCONF1[12] I2C1HSMASMASTER bit for I2C1, the CONTROL.CONTROL_DEVCONF1[13] I2C2HSMASMASTER bit for I2C2, or the CONTROL.CONTROL_DEVCONF1[14] I2C3HSMASMASTER bit for I2C3.
6. Configure the Own Address of the I²C controller by storing it in the I2Ci.I2C_OAO register. Up to four Own Addresses can be programmed in the I2Ci.I2C_OAi registers (with I = 0, 1, 2, 3) for each I²C controller.

Note: For a 10-bit address, set the corresponding expand Own Address bit in the I2Ci.I2C_CON register.

7. Set the TX threshold (in transmitter mode) and the RX threshold (in receiver mode) by setting the I2Ci.I2C_BUF[5:0]XTRSH field to (TX threshold - 1) and the I2Ci.I2C_BUF[13:8]RTRSH field to (RX threshold - 1), where the TX and RX thresholds are greater than or equal to 1.
8. Take the I²C controller out of reset by setting the I2Ci.I2C_CON[15] I2C_EN bit to 1.

18.5.1.1.2 Initialize the I²C Controller

To initialize the I²C controller, perform the following steps:

1. Configure the I2Ci.I2C_CON register:
 - For master or slave mode, set the I2Ci.I2C_CON[10] MST bit (0: slave, 1: master).
 - For transmitter or receiver mode, set the I2Ci.I2C_CON[9] TRX bit (0: receiver, 1: transmitter).
2. If using an interrupt to transmit/receive data, set to 1 the corresponding bit in the I2Ci.I2C_IE register (the I2Ci.I2C_IE[4] XRDY_IE bit for the transmit interrupt, the I2Ci.I2C_IE[3] RRDY bit for the receive interrupt).
3. If using DMA to receive/transmit data, set to 1 the corresponding bit in the I2Ci.I2C_BUF register (the I2Ci.I2C_BUF[15] RDMA_EN bit for the receive DMA channel, the I2Ci.I2C_BUF[7] XDMA_EN bit for the transmit DMA channel).

18.5.1.1.3 Configure Slave Address and the Data Control Register

In master mode, configure the slave address register by programming the I2Ci.I2C_SA[9:0] SA field and the number of data bytes (I²C data payload) associated with the transfer by programming the I2Ci.I2C_CNT[15:0] DCOUNT field.

Note: For a 10-bit address, set the I2Ci.I2C_CON[8] XSA bit to 1.

18.5.1.1.4 Initiate a Transfer

Poll the I2Ci.I2C_STAT[12] BB bit. If it is cleared to 0 (bus not busy), configure the I2Ci.I2C_CON[0] STT and I2Ci.I2C_CON[1] STP bits. To initiate a transfer, the I2Ci.I2C_CON[0] STT bit must be set to 1, and it is not mandatory to set the I2Ci.I2C_CON[1] STP bit to 1.

18.5.1.1.5 Receive Data

Poll the I2Ci.I2C_STAT[3] RRDY bit, or use the RRDY interrupt (the I2Ci.I2C_IE[3] RRDY_IE bit must be set to 1) or the DMA RX channel (the I2Ci.I2C_BUF[15] RDMA_EN bit must be set to 1) to read the receive data in the I2Ci.I2C_DATA register.

If the transfer length does not equal the RX FIFO threshold (I2Ci.I2C_BUF[13:8]RTRSH field + 1), use the draining feature (enable the RDR interrupt by setting the I2Ci.I2C_IE[13] RDR_IE bit to 1).

Note: In receive mode only, the I2Ci.I2C_STAT[11] ROVR (receive overrun) bit indicates whether the receiver has experienced overrun. An overrun condition occurs when the shift register and the RX FIFO are full. An overrun condition does not result in data loss; the I²C controller simply holds the serial clock line i2ci_scl to low to prevent other bytes from being received.

The I2Ci.I2C_STAT[7] AERR bit is set to 1 when a read access is performed in the I2Ci.I2C_DATA register while the RX FIFO is empty. The corresponding interrupt can be enabled by setting the I2Ci.I2C_IE[7] AERR_IE bit to 1.

18.5.1.1.6 Transmit Data

Poll the I2Ci.I2C_STAT[4] XRDY bit, or use the XRDY interrupt (the I2Ci.I2C_IE[4] XRDY_IE bit must be set to 1) or the DMA TX channel (the I2Ci.I2C_BUF[7] XDMA_EN bit must be set to 1) to write data to the I2Ci.I2C_DATA register.

If the transfer length does not equal the TX FIFO threshold (I2Ci.I2C_BUF[5:0] XTRSH field + 1), use the draining feature (enable the XDR interrupt by setting the I2Ci.I2C_IE[14] XDR_IE bit to 1).

Note: In transmit mode only, the I2Ci.I2C_STAT[10] XUDF bit indicates whether the transmitter has experienced underflow.

In master transmit mode, underflow occurs when the shift register and the TX FIFO are empty and there are still some bytes to transmit (the I2Ci.I2C_CNT[15:0] DCOUNT field value is not 0).

In slave transmit mode, underflow occurs when the shift register and the TX FIFO are empty and the external I²C master device still requests data bytes to be read.

The I2Ci.I2C_STAT[7] AERR bit is set to 1 when a write access is performed in the I2Ci.I2C_DATA register while the TX FIFO is full. The corresponding interrupt can be enabled by setting the I2Ci.I2C_IE[7] AERR_IE bit to 1.

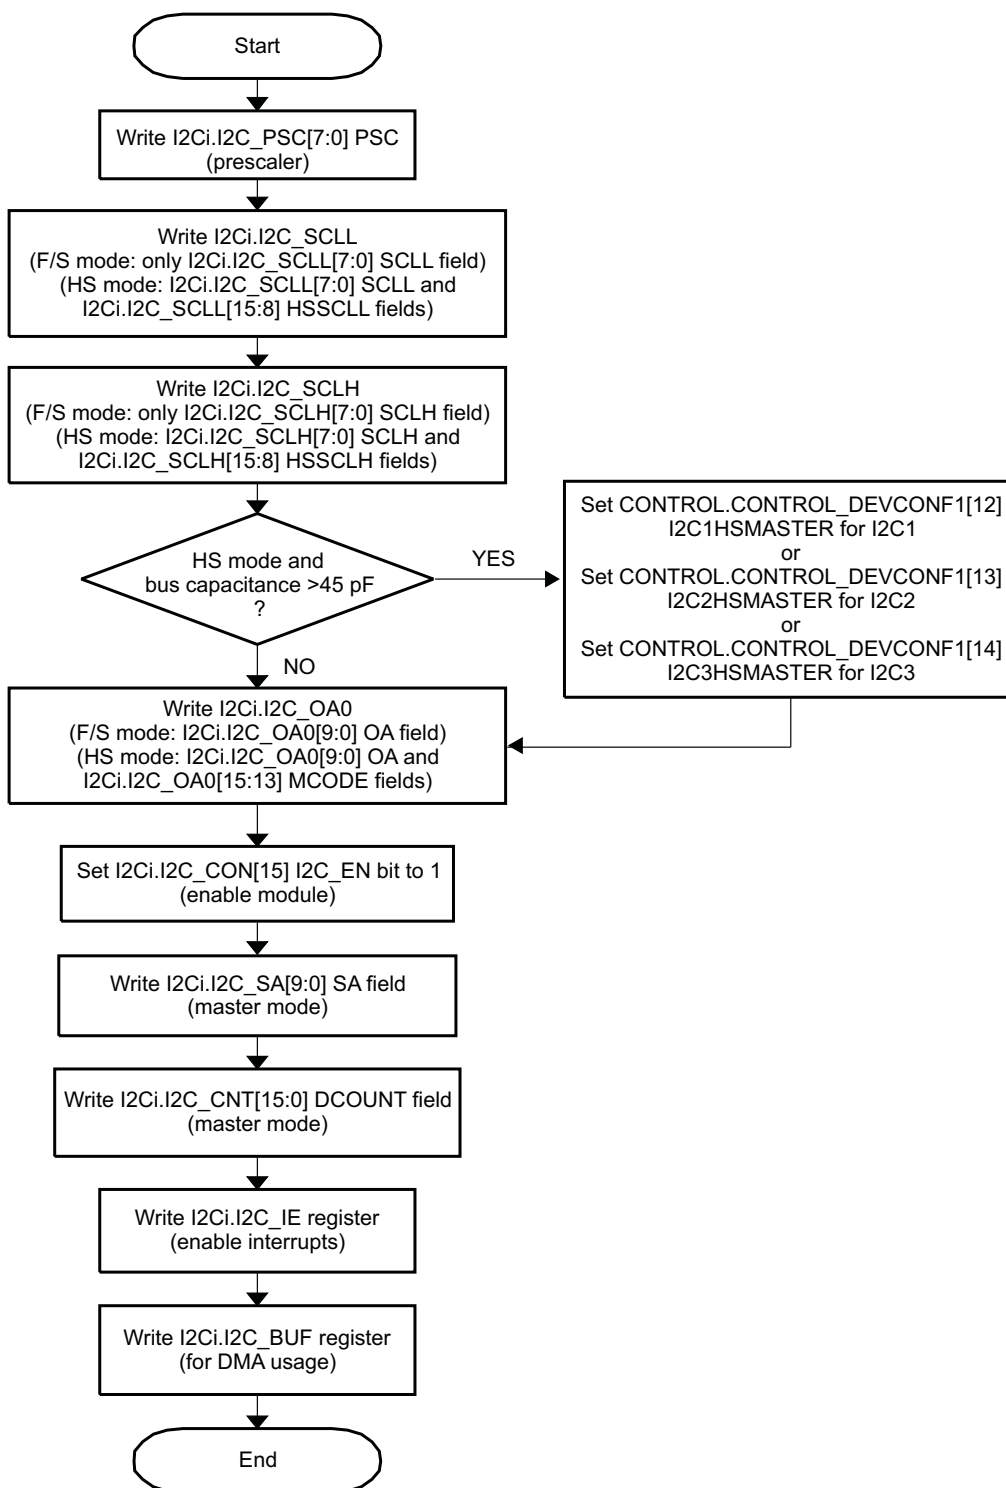

18.5.1.2 Interrupt Subroutine Sequence

1. Test for arbitration lost (I2Ci.I2C_STAT[0] AL status bit) and resolve accordingly.
2. Test for no acknowledgment (I2Ci.I2C_STAT[1] NACK status bit) and resolve accordingly.
3. Test for register access ready (I2Ci.I2C_STAT[2] ARDY status bit) and resolve accordingly.
4. Test for receive data ready (I2Ci.I2C_STAT[3] RRDY status bit) and resolve accordingly.
5. Test for transmit data ready (I2Ci.I2C_STAT[4] XRDY status bit) and resolve accordingly.
6. Test for general call (I2Ci.I2C_STAT[5] GC status bit) and resolve accordingly.
7. Test for start (S) condition (I2Ci.I2C_STAT[6] STC status bit) and resolve accordingly. For this test, the functional clock must be inactive.
8. Test for access error (I2Ci.I2C_STAT[7] AERR status bit) and resolve accordingly.
9. Test for bus free (I2Ci.I2C_STAT[8] BF status bit) and resolve accordingly.

18.5.1.3 Programming Flow Diagrams

Figure 18-28 through Figure 18-36 are procedure flowcharts for programming the F/S and HS I²C modes.

Figure 18-29. I²C Master Transmitter Mode, Polling Method, in F/S and HS Modes

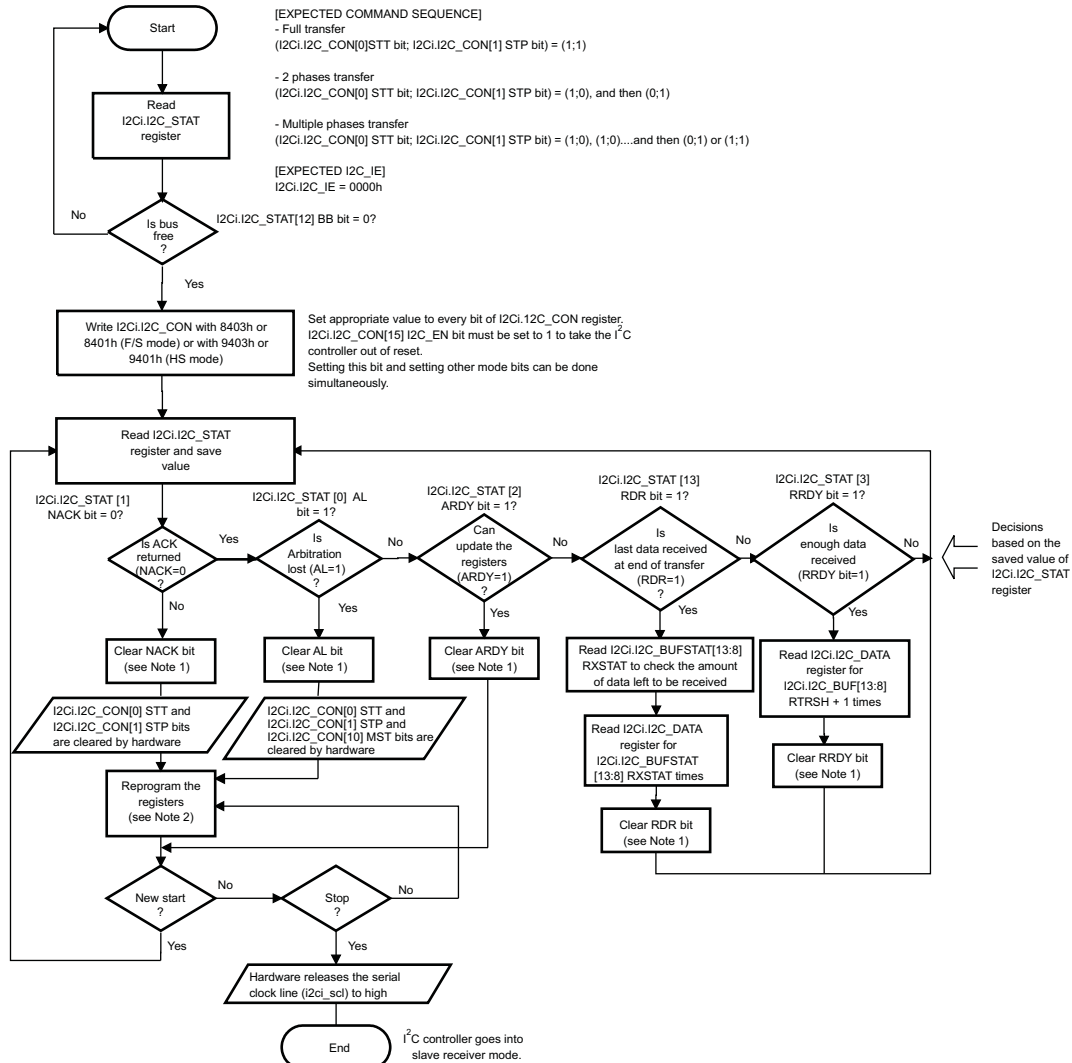

I2C-029

Notes:

1. The NAK, AL, ARDY, XDR, and XRDY bits are cleared by writing 1 to each corresponding bit in the I2Ci.I2C_STAT register.
2. Reprogram the registers means: I2Ci.I2C_CON[11] STB and/or I2Ci.I2C_CON[10] MST bit and/or I2Ci.I2C_SA[9:0] SA register and/or I2Ci.I2C_CNT[15:0] DCOUNT register and/or I2Ci.I2C_CON[0] STT bit and/or I2Ci.I2C_CON[1] STP bit.

Note: In HS mode, the repeated start (Sr) condition and the clock frequency switching are automatically generated by the multimaster HS I²C controller.

Figure 18-30. I²C Master Receiver Mode, Polling Method, in F/S and HS Modes

I2C-030

Notes:

1. The NAK, AL, ARDY, RDR, and RRDY bits are cleared by writing 1 to each corresponding bit in the I2C_I2C_STAT register.
2. Reprogram registers means: I2C_I2C_CON[11] STB and/or I2C_I2C_CON[10] MST bit and/or I2C_I2C_SA[9:0] SA register and/or I2C_I2C_CNT[15:0] DCOUNT register and/or I2C_I2C_CON[0] STT bit and/or I2C_I2C_CON[1] STP bit.

Figure 18-31. I²C Master Transmitter Mode, Interrupt Method, in F/S and HS Modes

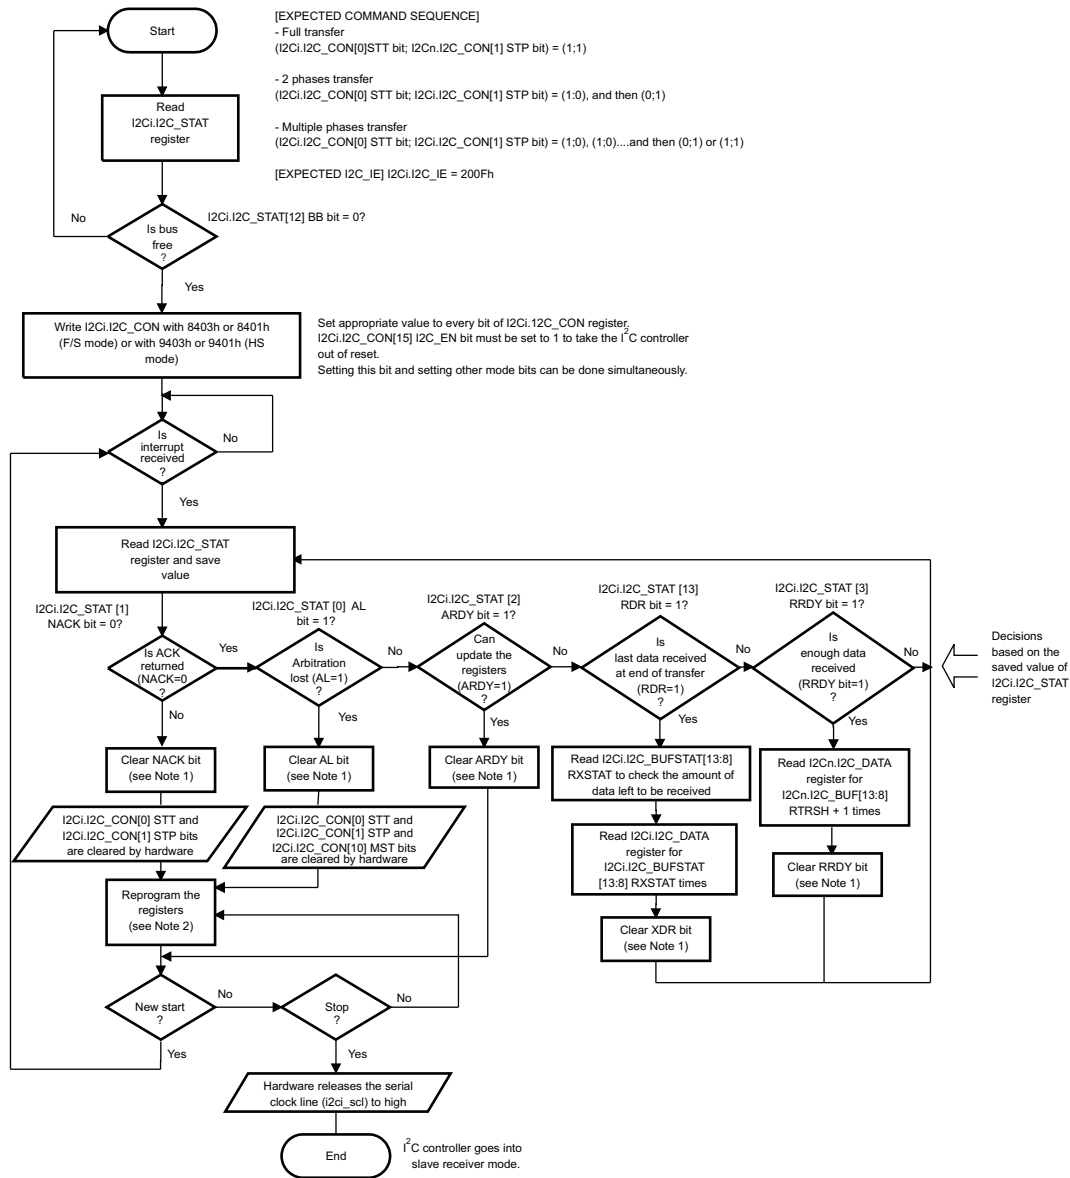

I2C-031

Notes:

1. The NAK, AL, ARDY, XDR, and XRDY bits are cleared by writing 1 to each corresponding bit in the I2C_I2C_STAT register.
2. Reprogram registers means: I2C_I2C_CON[11] STB and/or I2C_I2C_CON[10] MST bit and/or I2C_I2C_SA[9:0] SA register and/or I2C_I2C_CNT[15:0] DCOUNT register and/or I2C_I2C_CON[0] STT bit and/or I2C_I2C_CON[1] STP bit.

Note: In HS mode, the repeated start (Sr) condition and the clock frequency switching are automatically generated by the multimaster HS I²C controller.

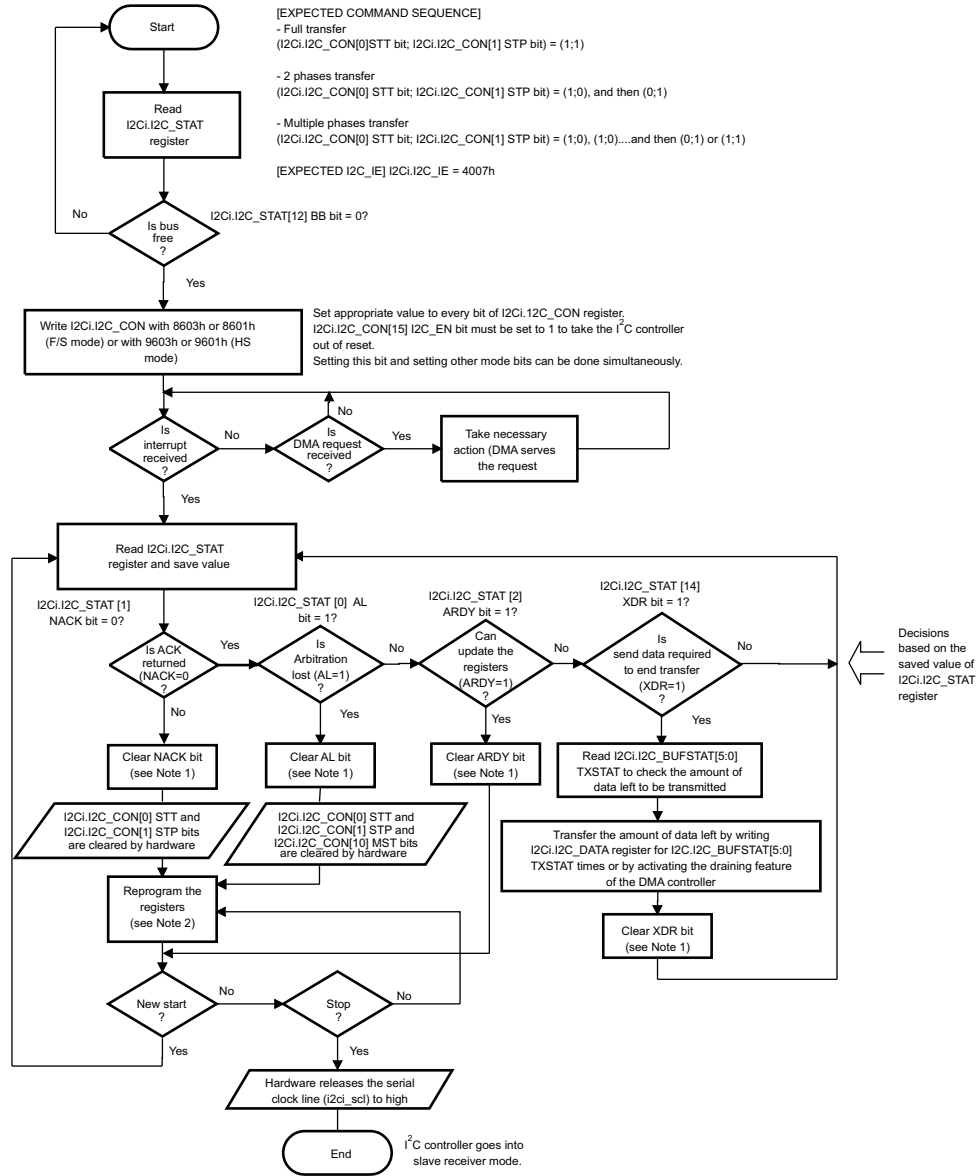

Figure 18-32. I²C Master Receiver Mode, Interrupt Method, in F/S and HS Modes

I2C-032

Notes:

1. The NAK, AL, ARDY, RDR, and RRDY bits are cleared by writing 1 to each corresponding bit in the I2Ci.I2C_STAT register.
2. Reprogram registers means: I2Ci.I2C_CON[11] STB and/or I2Ci.I2C_CON[10] MST bit and/or I2Ci.I2C_SA[9:0] SA register and/or I2Ci.I2C_CNT[15:0] DCOUNT register and/or I2Ci.I2C_CON[0] STT bit and/or I2Ci.I2C_CON[1] STP bit.

Figure 18-33. I²C Master Transmitter Mode, DMA Method in F/S and HS Modes

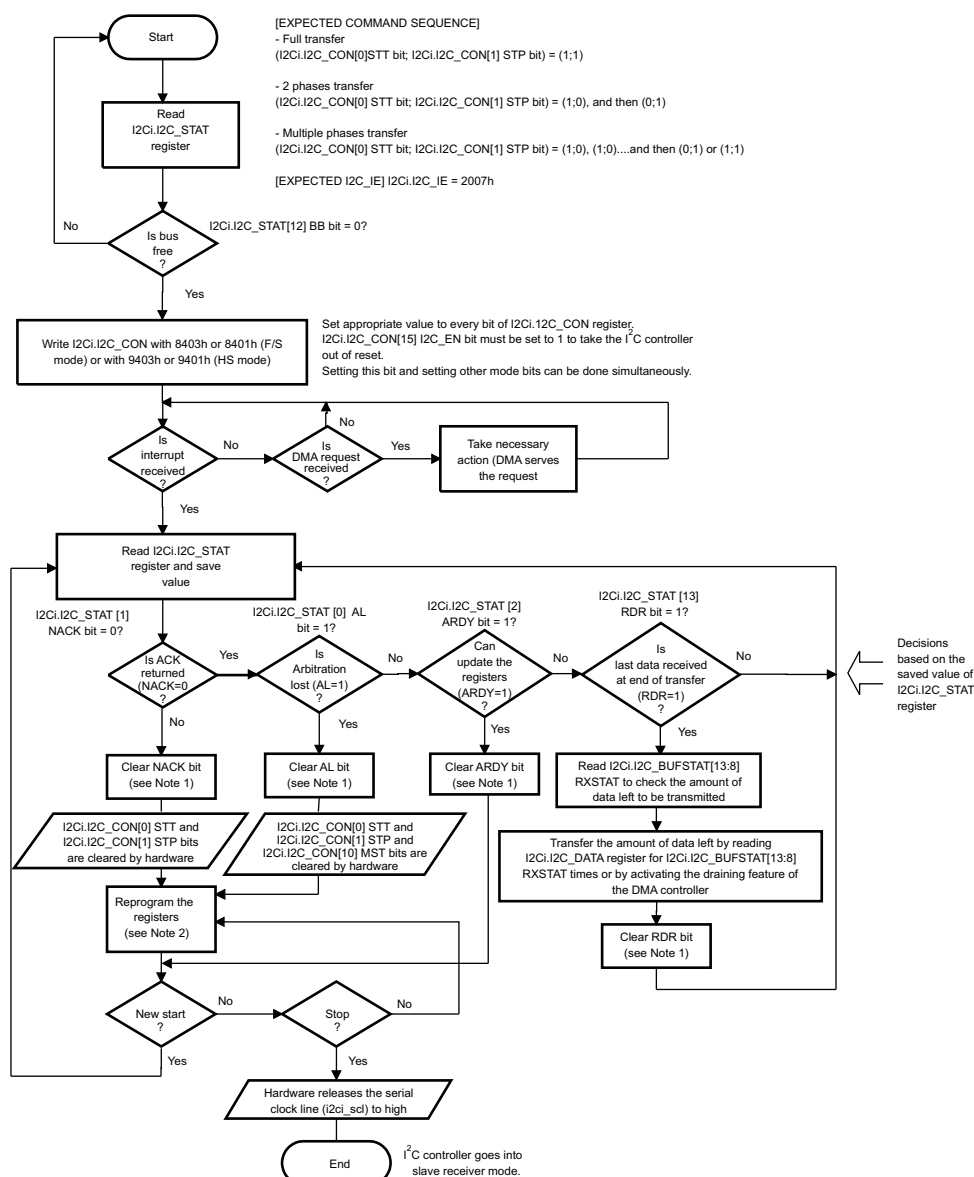

I2C-033

Notes:

1. The NAK, AL, ARDY, and XDR bits are cleared by writing 1 to each corresponding bit in the I2Ci.I2C_STAT register.
2. Reprogram registers means: I2Ci.I2C_CON[11] STB and/or I2Ci.I2C_CON[10] MST bit and/or I2Ci.I2C_SA[9:0] SA register and/or I2Ci.I2C_CNT[15:0] DCOUNT register and/or I2Ci.I2C_CON[0] STT bit and/or I2Ci.I2C_CON[1] STP bit.

Note: In HS mode, the repeated start (Sr) condition and the clock frequency switching are automatically generated by the multimaster HS I²C controller.

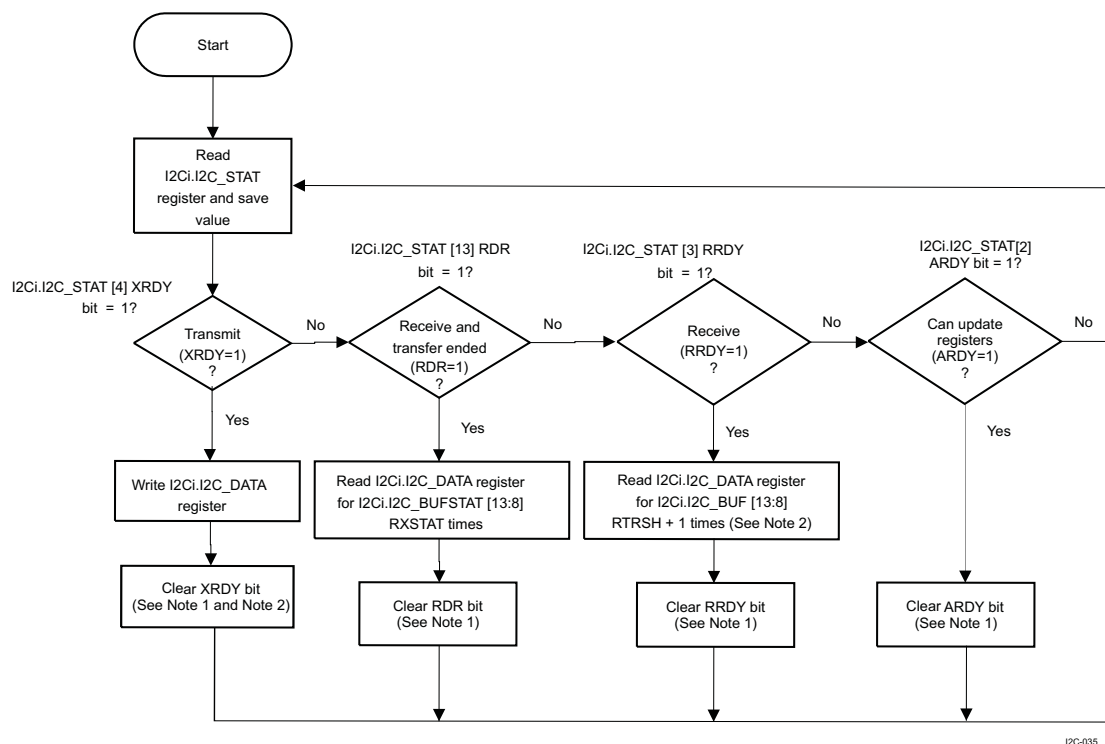

Figure 18-34. I²C Master Receiver Mode, DMA Method in F/S and HS Modes

I2C-034

Notes:

1. The NAK, AL, ARDY and RDR bits are cleared by writing 1 to each corresponding bit in the I2Ci.I2C_STAT register.
2. Reprogram registers means: I2Ci.I2C_CON[11] STB and/or I2Ci.I2C_CON[10] MST bit and/or I2Ci.I2C_SA[9:0] SA register and/or I2Ci.I2C_CNT[15:0] DCOUNT register and/or I2Ci.I2C_CON[0] STT bit and/or I2Ci.I2C_CON[1] STP bit.

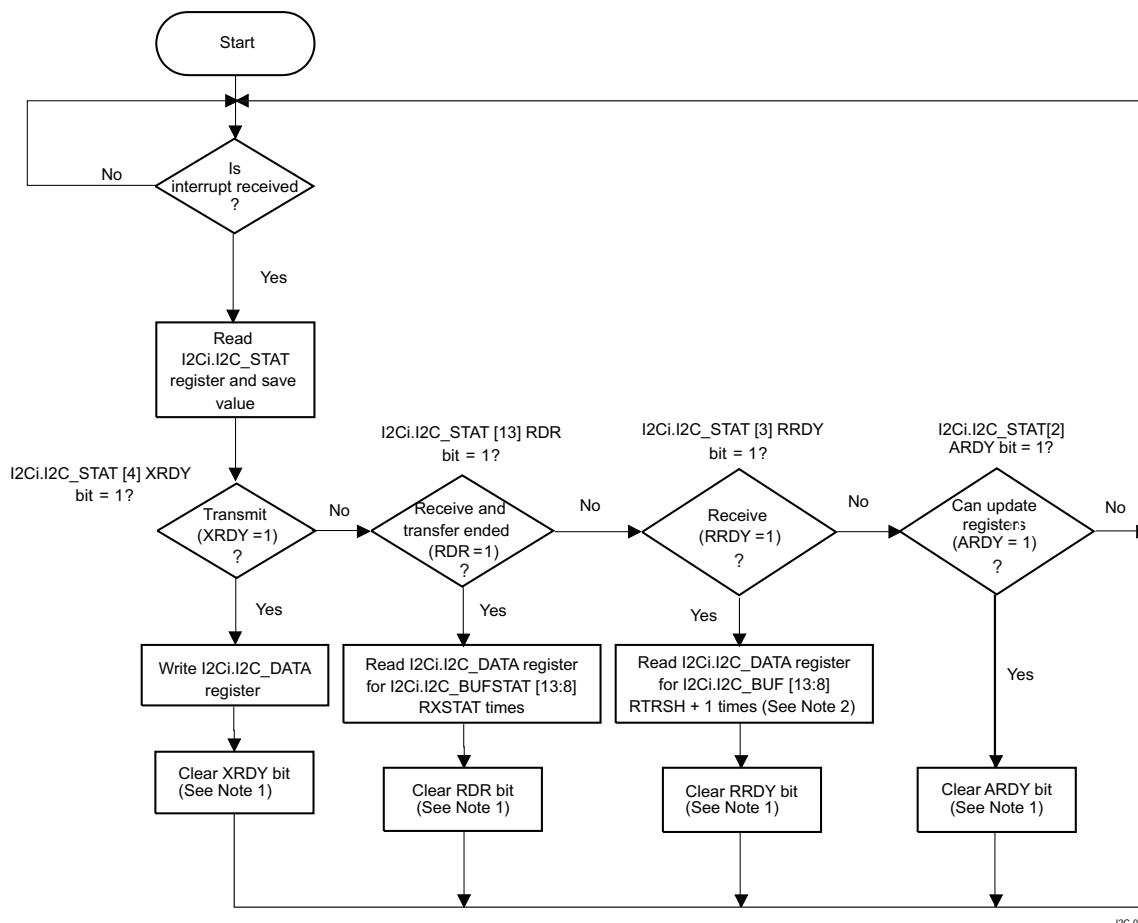

Figure 18-35. I²C Slave Transmitter/Receiver Mode, Polling

Notes:

1. The XRDY, RDR, RRDY and ARDY bits are cleared by writing 1 to each corresponding bit in the I2Ci.I2C_STAT register.
2. In slave transmitter mode, the amount of data requested by the external master I²C device is unknown; thus, the I2Ci.I2C_BUF[5:0] XTRSH field must be configured to 0x0 (TX threshold = 1).

Figure 18-36. I²C Slave Transmitter/Receiver Mode, Interrupt

Notes:

1. The XRDY, RDR, RRDY and ARDY bits are cleared by writing 1 to each corresponding bit in the I2Ci.I2C_STAT register.
2. In slave transmitter mode, the amount of data requested by the external master I²C device is unknown; thus, the I2Ci.I2C_BUF[5:0] XTRSH field must be configured to 0x0 (TX threshold = 1).

18.5.2 High-Speed I²C Controller Basic Programming Model in SCCB Mode

This section describes the programming model of the multimaster HS I²C controllers configured in SCCB mode.

18.5.2.1 Main Program

18.5.2.1.1 Configure the Module Before Enabling the I²C Controller

Before enabling the I²C controller, perform the following steps:

1. Enable the functional and interface clocks (see [Section 18.3.1.1.1](#)).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock (I2Ci_INTERNAL_CLK) by programming the corresponding value in the I2Ci.I2C_PSC[7:0] PSC field. This value depends on the frequency of the functional clock (I2Ci_FCLK). Because this frequency is 96MHz, the I2Ci.I2C_PSC[7:0] PSC field value is 0x7.

3. Program the I2Ci.I2C_SCLL[7:0] SCLL and I2Ci.I2C_SCLH[7:0] SCLH fields to obtain a bit rate of 100K bps (maximum authorized bit rate in SCCB mode). This value depends on the internal sampling clock frequency (see Table 18-12).
4. Configure the 7-bit slave address (ID value) by storing it in the I2Ci.I2C_SA register.
5. Configure the 8-bit register address (subaddress) by storing it in the I2Ci.I2C_OA0 register.
6. Configure the I2Ci.I2C_BUF[13:8]RTRSH field to 0x0 (RX threshold to 1) and the I2Ci.I2C_BUF[5:0]XTRSH field to 0x0 (TX threshold to 1).
7. Take the I²C controller out of reset by setting the I2Ci.I2C_CON[15] I2C_EN bit to 1.

18.5.2.1.2 Initialize the I²C Controller

To initialize the I²C controller, perform the following steps:

1. Configure the I2Ci.I2C_CON register:
 - In SCCB mode, only the master mode is supported; set the I2Ci.I2C_CON[10] MST bit to 1.
 - For transmitter mode (write to the external SCCB device register) or receiver mode (read from the external SCCB device register), set the I2Ci.I2C_CON[9] TRX bit (0: receiver, 1: transmitter).
2. If using an interrupt to transmit/receive data, set to 1 the corresponding bit in the I2Ci.I2C_IE register (the I2Ci.I2C_IE[4] XRDY_IE bit for the transmit interrupt, the I2Ci.I2C_IE[3] RRDY bit for the receive interrupt).

18.5.2.1.3 Initiate a Transfer

Poll the I2Ci.I2C_STAT[12] BB bit. If it is cleared to 0 (bus not busy), set the I2Ci.I2C_CON[0] STT bit to 1. Because a transfer allows the LH to write or read only a single byte to or from the external SCCB device, the transmission automatically stops at the end of the transfer. When the transfer is complete, the I2Ci.I2C_STAT[2] ARDY bit is set to 1. In SCCB mode, the I2Ci.I2C_CON[1] STP bit is not used.

18.5.2.1.4 Receive Data

Poll the I2Ci.I2C_STAT[3] RRDY bit, or use the RRDY interrupt (the I2Ci.I2C_IE[3] RRDY_IE bit must be set to 1) to read the receive data in the I2Ci.I2C_DATA register.

Note: In SCCB mode, the I2Ci.I2C_BUF[13:8] RTRSH field (RX threshold) must be set to a value of 0x0 (RX threshold = 1).

18.5.2.1.5 Transmit Data

Poll the I2Ci.I2C_STAT[4] XRDY bit, or use the XRDY interrupt (the I2Ci.I2C_IE[4] XRDY_IE bit must be set to 1) to write the data to the I2Ci.I2C_DATA register.

Note: In SCCB mode, the I2Ci.I2C_BUF[5:0] XTRSH field (TX threshold) must be set to a value of 0x0 (TX threshold = 1).

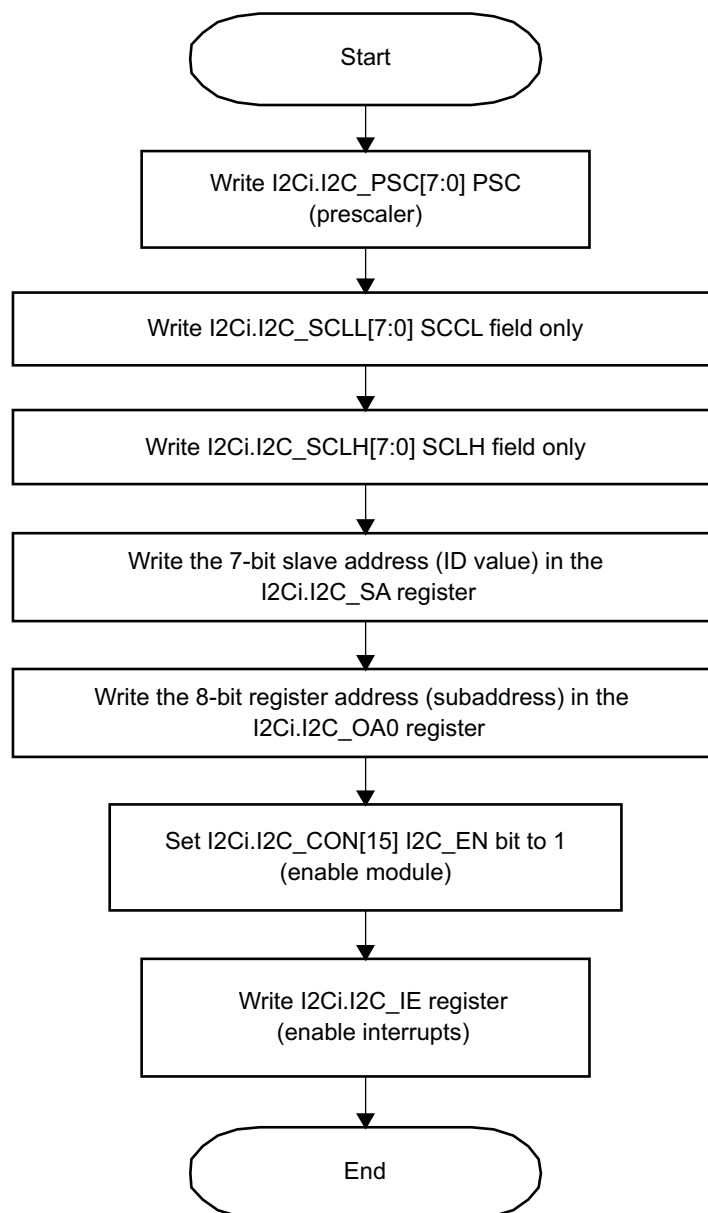

18.5.2.2 Interrupt Subroutine Sequence

1. Test for register access ready (I2Ci.I2C_STAT[2] ARDY status bit) and resolve accordingly.
2. Test for receive data ready (I2Ci.I2C_STAT[3] RRDY status bit) and resolve accordingly.
3. Test for transmit data ready (I2Ci.I2C_STAT[4] XRDY status bit) and resolve accordingly.

18.5.2.3 Programming Flow Diagrams

Figure 18-37 through Figure 18-41 are procedure flowcharts for programming the SCCB mode.

Figure 18-37. SCCB Setup Procedure

Note: The RRDY and ARDY bits are cleared by writing 1 in the corresponding bit in the I2Ci.I2C_STAT register.

18.5.3 Master Transmitter HS I²C Controller I2C4 Basic Programming Model for Communication With Power Chips

This section describes the programming model of the master transmitter HS I²C controller I2C4 for communication with one or more power chips. The HS I²C controller I2C4 allows the two voltage processors and the two voltage Finite State Machines (FSMs) in the PRCM module of the device to be interfaced to external power chips through the I²C bus for dynamic voltage control of two power supplies and power sequencing. The primary programming tasks are to set up the configuration registers according to the external power supply chip(s) being used.

18.5.3.1 Configure the Voltage Controller Registers

To use the voltage control function, the LH must configure the following registers in the voltage controller of the PRCM module:

- The voltage configuration register address for each VDD channel in the PRCM.PRM_VC_SMPS_RA register
- The ON/ON-low-power-Retention/OFF command configuration register address for each VDD channel in the PRCM.PRM_VC_SMPS_CMD_RA register
- The set of ON/ON-low-power/Retention/OFF voltage/mode values in the PRCM.PRM_VC_CMD_VAL_0 register for the first VDD channel and the PRCM.PRM_VC_CMD_VAL_1 register for the second VDD channel
- The VDD channels configuration selection in the PRCM.PRM_VC_CH_CONF register

For details about voltage controller register configuration, see the *Power, Reset, and Clock Management* chapter.

18.5.3.2 Configure the Master Transmitter HS I²C Controller I2C4

At power-on reset, the I2C4 is in HS mode (PRCM.PRM_VC_I2C_CFG[3] HSEN bit). In HS mode, the LH must configure the master code value for the preamble I²C high-speed transmission by configuring the PRCM.PRM_VC_I2C_CFG[2:0] MCODE field. If the external power chips do not support the I²C HS mode, the HS mode can be disabled and F/S mode enabled by clearing the PRCM.PRM_VC_I2C_CFG[3] HSEN bit to 0.

By default, the repeated start operation is enabled (PRCM.PRM_VC_I2C_CFG[4] SREN bit set to 1 at power-on reset). In F/S mode, the repeated start operation can be disabled by clearing the PRCM.PRM_VC_I2C_CFG[4] SREN bit to 0.

18.5.3.3 Configure the External Power Chip(s)

The LH can send configuration commands from one bypass input to the external power chip(s), using the same I²C interface. The configuration commands sent through the bypass input have a higher priority than the commands sent by the voltage processors. To send a configuration command, the LH must process as follows:

- Check whether the transmission of a configuration command is ongoing by polling the PRCM.PRM_VC_BYPASS_VAL[24]VALID bit (1: a transmission is ongoing, 0: a new transmission can start).
- Set the external power chip 7-bit slave address in the PRCM.PRM_VC_BYPASS_VAL[6:0] SLAVEADDR field, set the configuration register address of the external power chip in the PRCM.PRM_VC_BYPASS_VAL[15:8] REGADDR field, and set the data to be written to the external power chip configuration register in the PRCM.PRM_VC_BYPASS_VAL[23:16] DATA field.
- Set the PRCM.PRM_VC_BYPASS_VAL[24]VALID bit to 1 to send the configuration command to the external power chip. The configuration command is sent as soon as the ongoing transmission initiated by the voltage processors or the voltage FSM(s) completes.

18.6 High-Speed Multimaster I²C Use Cases and Tips

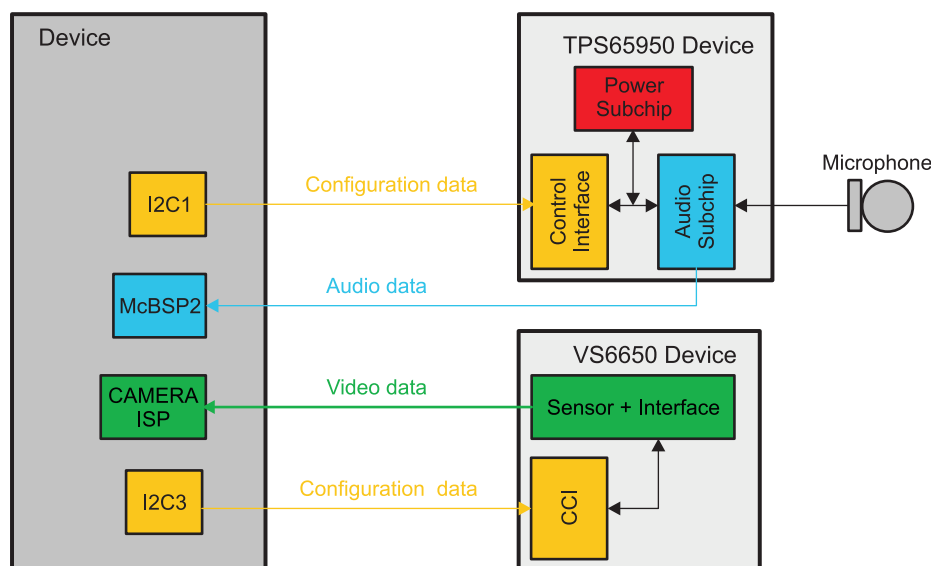

18.6.1 Camcorder Use Case: How to Configure the I²C Modules When Connecting TPS65950 Companion chip and VS6650 Digital Camera Device

18.6.1.1 Overview

In a whole Camcorder use case, the TPS65950 companion chip and the VS6650 digital camera device are configured by the I²C modules inside the OMAP35x Applications Processor.

The I2C1 module is in charge of configuring the TPS65950 companion chip whereas the I2C3 module is in charge of configuring the VS6650 digital camera device.

Figure 18-42. Overview

108-042

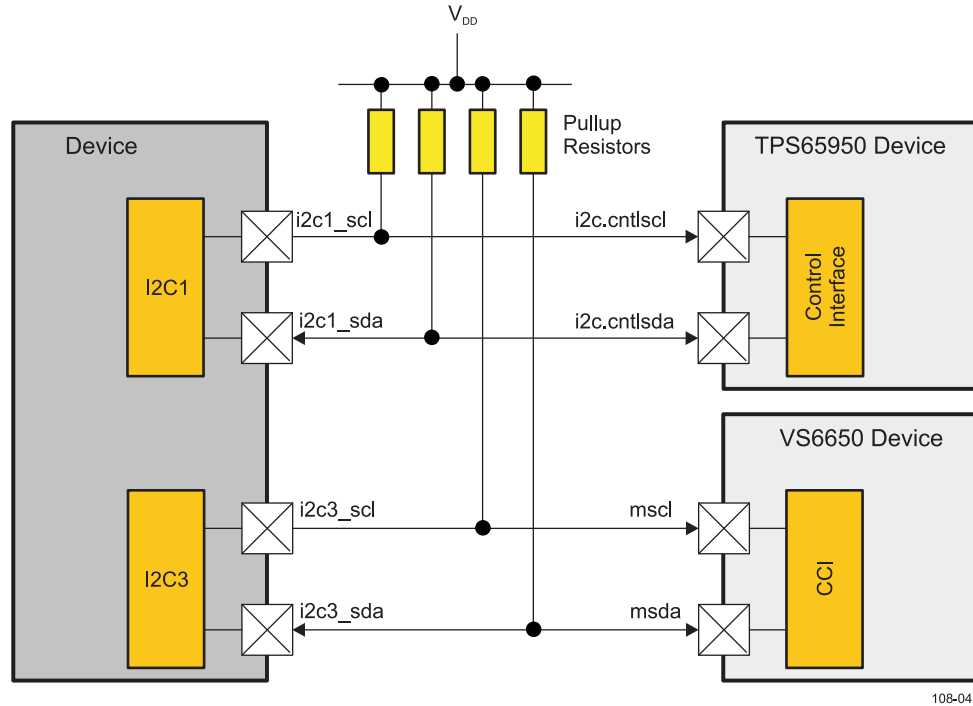

For the Camcorder use case, the configuration of the I²C modules inside the OMAP35x Applications Processor is the following:

- Master mode: the I²C clocks are generated by the I²C modules inside the OMAP35x Applications Processor.
- Transmit mode: the I²C modules write data into the TPS65950 companion chip and the VS6650 digital camera device.
- No start-byte generation.
- Fast/standard (F/S) mode at 100 kbps.
- 7-bit addressing mode to address the TPS65950 companion chip and the VS6650 digital camera device registers.
- Polling method to access the TPS65950 companion chip and the VS6650 digital camera device registers.

18.6.1.2 Environment

In this use case, the control interface of the TPS65950 companion chip is connected to the I2C1 module whereas the communication control interface (CCI) of the VS6650 digital camera device is connected to the I2C3 module.

Figure 18-43. Environment

18.6.1.2.1 Data Transfer Formats

The data transfer format for configuring the TPS65950 companion chip and the VS6650 digital camera device is shown as follows:

Figure 18-44. Data Transfer Format

(a) Writing into an external I²C device, 7-bit addressing mode

(b) I2C1 Module writing into the TPS65950 companion chip

(c) I2C3 Module writing into the VS6650 digital camera device

To configure a TPS65950 companion chip register, two data bytes must be transmitted by the I2C1 module: the register address (1 byte), and the register value (1 byte).

To configure a VS6650 digital camera device register, three data bytes must be transmitted by the I2C3 module: the index most-significant byte (1 byte), the index less-significant byte (1 byte), the register value (1 byte).

18.6.1.3 Programming Flow

18.6.1.3.1 Initial Configuration

The initialization of the I2Ci module (where I = 1, 3) is done in four parts:

1. I2Ci module interface and functional clocks enabling.
2. I2Ci module clock generation configuration.
3. I2Ci module mode configuration.
4. I2Ci module slave address configuration.
5. I2Ci module enabling.

See [Figure 18-45](#) for the corresponding programming flowchart.

18.6.1.3.1.1 I2Ci Module Interface and Functional Clocks Enabling

To enable the interface and functional clocks of the I2Ci module, the following steps must be done:

1. Enable the interface clock for the I2Ci module (set the PRCM.CM_ICLKEN1_CORE[15] EN_I2C1 bit to 1 for the I2C1 module and the PRCM.CM_ICLKEN1_CORE[17] EN_I2C3 bit to 1 for the I2C3 module).
2. Enable the functional clock for the I2Ci module (set the PRCM.CM_FCLKEN1_CORE[15] EN_I2C1 bit to 1 for the I2C1 module and the PRCM.CM_FCLKEN1_CORE[17] EN_I2C3 bit to 1 for the I2C3 module).

[Table 18-15](#) shows all the register to be configured for the I2C1 and I2C3 modules initialization.

Table 18-15. Registers Print for the I2Ci Module Initialization

Register name	Address	Value	Value description
PRCM.CM_ICLKEN1_CORE	0x4800 4A10	0x0002 8000	I2C1 and I2C3 interface clocks enabled
PRCM.CM_FCLKEN1_CORE	0x4800 4A00	0x0002 8000	I2C1 and I2C3 functional clocks enabled

18.6.1.3.1.2 I2Ci Module Clock Generation Configuration

To configure the clock generation of the I2Ci modules, the following steps must be done:

1. Configure the I2Ci.I2C_PSC[3:0] PSC field to 0x17.
2. Configure the I2Ci.I2C_SCLL[7:0] SCLL field to 0x0D.
3. Configure the I2Ci.I2C_SCLH[7:0] SCLH field to 0x0F.

By programming these values, the I²C clock rate is configured to 100 kbps for the I2Ci modules.

[Table 18-16](#) shows all the registers to be configured for the I2Ci module clock generation configuration.

Table 18-16. Registers Print for the I2Ci Module Clock Generation Configuration

Register name	Address	Value	Value description
I2C1.I2C_PSC	0x4807 0030	0x0017	PSC[3:0] field set to 0x17 for the I2C1 module
I2C1.I2C_SCLL	0x4807 0034	0x000D	SCLL[7:0] field set to 0x0D for the I2C1 module
I2C1.I2C_SCLH	0x4807 0038	0x000F	SCLH[7:0] field set to 0x0F for the I2C1 module

Table 18-16. Registers Print for the I2Ci Module Clock Generation Configuration (continued)

Register name	Address	Value	Value description
I2C3.I2C_PSC	0x4806 0030	0x0017	PSC[3:0] field set to 0x17 for the I2C3 module
I2C3.I2C_SCLL	0x4806 0034	0x000D	SCLL[7:0] field set to 0x0D for the I2C3 module
I2C3.I2C_SCLH	0x4806 0038	0x000F	SCLH[7:0] field set to 0x0F for the I2C3 module

18.6.1.3.1.3 I2Ci Module Mode Configuration

To configure the I2Ci modules in F/S (Fast/Standard) mode, set the I2Ci.I2C_CON[13:12] OPMODE field to 0x0.

Table 18-17. Registers Print for the I2Ci Slave Address Configuration

Register name	Address	Value	Value description
I2C1.I2C_CON	0x4807 0024	0x0000	OPMODE[13:12] configured to 0x0 for I2C1 (Fast/Standard mode)
I2C3.I2C_CON	0x4806 0024	0x0000	OPMODE[13:12] configured to 0x0 for I2C3 (Fast/Standard mode)

18.6.1.3.1.4 I2Ci Module Slave Address Configuration

To configure the slave address of the I2Ci modules, the following steps must be done:

1. Enable the 7-bit addressing mode by clearing the I2Ci.I2C_CON[8] XSA bit to 0 because the I²C addresses of the TPS65950 companion chip and the VS6650 digital camera device are 7-bit wide.
2. Configure the I2C1.I2C_SA[9:0] SA field to 0x48, 0x49, 0x4A or 0x4B, so that the I2C1 module can access the TPS65950 companion chip registers. The slave address configured into the I2C1.I2C_SA[9:0] SA field depends on the TPS65950 companion chip register. For more information, see the *TPS65950 OMAP Power Management and System Companion Device Technical Reference Manual*.
3. Configure the I2C3.I2C_SA[9:0] SA field to 0x10, so that the I2C3 module can access the VS6650 digital camera device registers. For more information, see the ST VS6650 datasheet.

Table 18-18 shows all the registers to be configured for the I2Ci slave address configuration.

Table 18-18. Registers Print for the I2Ci Slave Address Configuration

Register name	Address	Value	Value description
I2C1.I2C_CON	0x4807 0024	0x0000	XSA bit is cleared to 0 for the I2C1 module
I2C3.I2C_CON	0x4806 0024	0x0000	XSA bit is cleared to 0 for the I2C3 module
I2C1.I2C_SA	0x4807 002C	0x0048, or 0x0049, or 0x004A, or 0x004B	Slave address of the TPS65950 companion sub-chip for the I2C1 module
I2C3.I2C_SA	0x4806 002C	0x0010	Slave address of the VS6650 digital camera device for the I2C3 module

18.6.1.3.1.5 I2Ci Module Enabling

To enable the I2Ci modules, set the I2Ci.I2C_CON[15] I2C_EN bit to 1.

Table 18-25 shows all the registers to be configured for the I2Ci slave address configuration.

Table 18-19. Registers print for the I2Ci Module Enabling

Register name	Address	Value	Value description
I2C1.I2C_CON	0x4807 0024	0x8000	I2C1 module enabled
I2C3.I2C_CON	0x4806 0024	0x8000	I2C3 module enabled

18.6.1.3.2 Operational mode

Writing a byte into a TPS65950 companion chip or VS6650 digital camera device register is done in five parts:

1. Transfer configuration.
2. I2Ci bus status checking.
3. Transfer initiation.
4. Data transfer.
5. Transfer completion.

See [Figure 18-46](#) for the I2C1 programming flowchart and to [Figure 18-47](#) for the I2C3 programming flowchart.

18.6.1.3.2.1 Transfer Configuration

To configure the transfer for the I2Ci module, the following steps must be done:

1. Configure the I2Ci.I2C_CNT[15:0] DCOUNT field to the number of data bytes to be transmitted: 0x02 to transmit 2 bytes to the TPS65950 companion chip by the I2C1 module, 0x03 to transmit 3 bytes to the VS6650 digital camera device by the I2C3 module.
2. Set the I2Ci.I2C_CON[10] MST bit to 1 (master mode).
3. Set the I2Ci.I2C_CON[9] TRX bit to 1 (transmit mode).

[Table 18-20](#) shows all the registers to be configured for the transfer configuration.

Table 18-20. Registers Print for the Transfer Configuration

Register name	Address	Value	Value description
I2C1.I2C_CNT	0x4807 0018	0x0002	Set the number of transmitted bytes to 0x02 for the I2C1 module
I2C1.I2C_CON	0x4807 0024	0x8600	MST and TRX bits are set to 1 for the I2C1 module (master transmit mode)
I2C3.I2C_CNT	0x4806 0018	0x0003	Set the number of transmitted bytes to 0x03 for the I2C3 module
I2C3.I2C_CON	0x4806 0024	0x8600	MST and TRX bits are set to 1 for the I2C3 module (master transmit mode)

18.6.1.3.2.2 I2Ci Bus Status Checking

Before initiating a transfer, the status of the I2Ci bus must be checked by polling the I2Ci.I2C_STAT[12] BB bit. The transfer will be initiated only when the I2Ci.I2C_STAT[12] BB bit is set to 0 by the I2Ci module.

[Table 18-21](#) shows all the registers to be configured for the I2Ci bus status checking.

Table 18-21. Registers Print for the I2Ci Bus Status Checking

Register name	Address	Value	Value description
I2C1.I2C_STAT	0x4807 0008	0x1000	BB bit is set to 1 when the I2C1 bus is busy

Table 18-21. Registers Print for the I2Ci Bus Status Checking (continued)

Register name	Address	Value	Value description
I2C3.I2C_STAT	0x4806 2008	0x1000	BB bit is set to 1 when the I2C3 bus is busy

18.6.1.3.2.3 Transfer Initiation

Once the I2Ci bus is free, the transfer can be initiated by setting the I2Ci.I2C_CON[0] STT bit (start). The I2Ci.I2C_CON[1] STP bit (stop) can also be set to 1 as soon as the I2Ci.I2C_CON[0] STT bit is cleared to 0 by the I2Ci module in order to generate a stop condition at the end of the transfer.

Table 18-22 shows all the registers to be configured for the transfer initiation.

Table 18-22. Registers Print for the Transfer Initiation

Register name	Address	Value	Value description
I2C1.I2C_CON	0x4807 0024	0x8601	STT bit is set to 1 for the I2C1 module
I2C3.I2C_CON	0x4806 0024	0x8601	STT bit is set to 1 for the I2C3 module
I2C1.I2C_CON	0x4807 0024	0x8602	STP bit is set to 1 for the I2C1 module when the STT bit is cleared by the I2C1 module
I2C3.I2C_CON	0x4806 0024	0x8602	STP bit is set to 1 for the I2C3 module when the STT bit is cleared by the I2C3 module

Note: As soon as the I2Ci.I2C_CON[0] STT bit is set to 1, a start condition is generated on the I2Ci bus, and the I2Ci.I2C_CON[0] STT bit is automatically cleared to 0 by the I2Ci module.

The I2Ci.I2C_CON[1] STP bit is automatically cleared to 0 at the end of the transfer, when the stop condition is generated on the I2Ci bus.

18.6.1.3.2.4 Data transfer

After the generation of the start condition on the I2Ci bus, the slave address programmed in the I2Ci.I2C_SA[9:0] SA field is automatically transmitted on the bus, followed by the R_Wn bit (set to 0) and an acknowledge bit is transmitted by the external I²C device to the I2Ci module.

Each time a data byte is requested to be transmitted, the I2Ci.I2C_STAT[4] XRDY bit is set to 1 by the I2Ci module. When it occurs, the data byte must be written into the I2Ci.I2C_DATA register and the I2Ci.I2C_STAT[4] XRDY bit must be cleared by setting it to 1. A software time-out counter can be implemented in order to detect when no data request is generated by the hardware.

The number of data bytes requested to be transmitted is configured in the I2Ci.I2C_CNT[15:0] DCOUNT field. This number is set to 0x02 for the I2C1 module and set to 0x03 for the I2C3 module.

Note: The transmit FIFO threshold must be configured to 1 by configuring the I2Ci.I2C_BUF[5:0] XTRSH field to 0x00 (done by default).

Table 18-23 shows all the registers to be configured for the data transfer.

Table 18-23. Registers Print for the Data Transfer

Register name	Address	Value	Value description
I2C1.I2C_STAT	0x4807 0008	0x0010	The XRDY is set to 1 by the I2C1 module
I2C3.I2C_STAT	0x4806 0008	0x0010	The XRDY is set to 1 by the I2C3 module

18.6.1.3.2.5 Transfer Completion

Once all data bytes have been transmitted, the stop condition is generated on the I2C_i bus and the I2C_i.I2C_STAT[2] ARDY status bit is set to 1 by the hardware.

[Table 18-24](#) shows all the registers to be configured for the transfer completion.

Table 18-24. Registers Print for the Transfer Completion

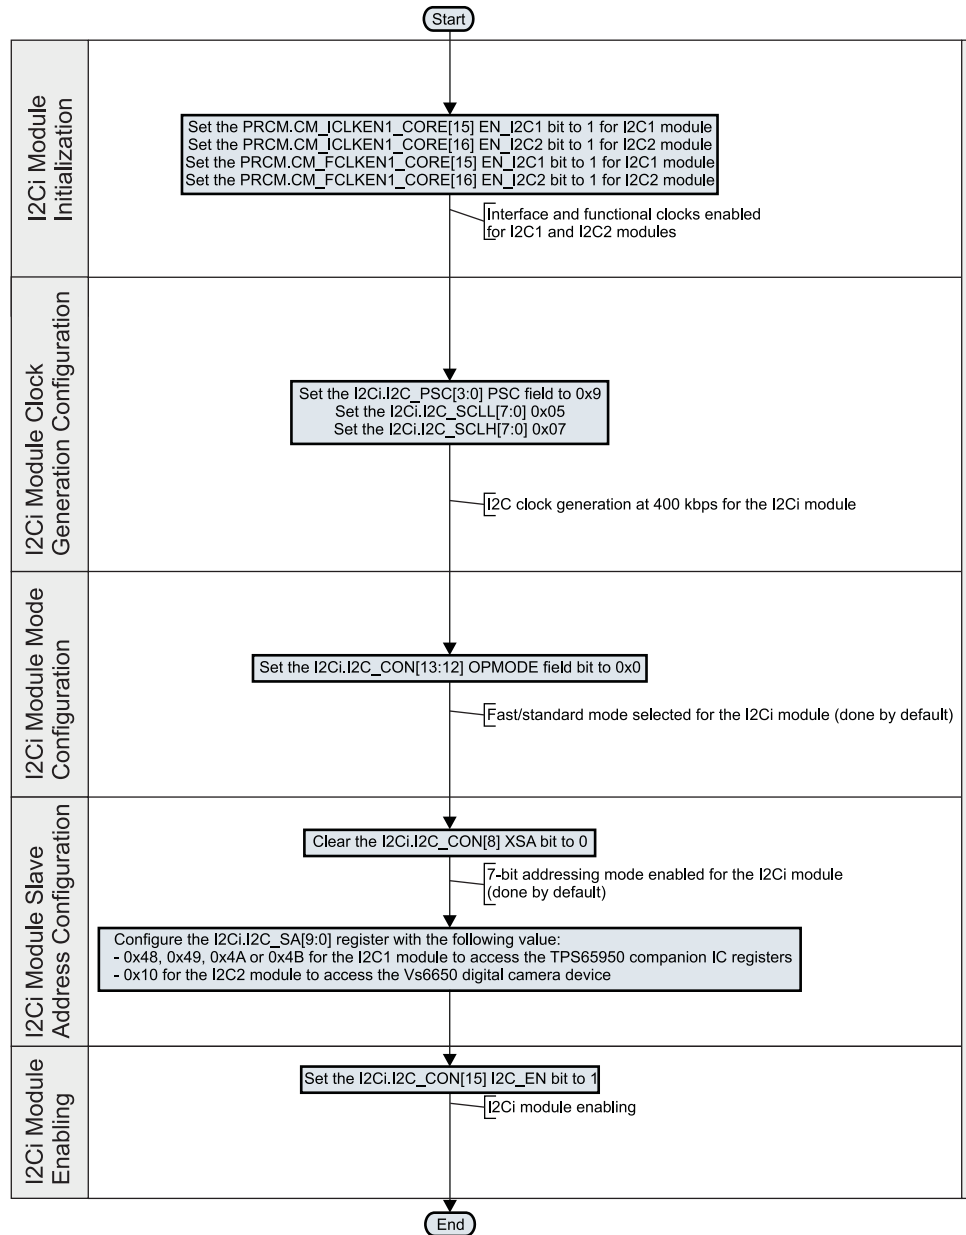

Register name	Address	Value	Value description
I2C1.I2C_STAT	0x4807 0024	0x8604	The ARDY is set to 1 by the I2C1 module (transfer completed)
I2C3.I2C_STAT	0x4806 0024	0x8604	The ARDY is set to 1 by the I2C3 module (transfer completed)

18.6.1.3.3 Flowcharts

18.6.1.3.3.1 Initial Configuration Flowchart

Figure 18-45 describes the programming flowchart corresponding to the initial configuration. See Section 18.6.1.3.1 for more information.

Figure 18-45. Initial Configuration Flowchart

18.6.1.3.3.2 Operational Mode Flowchart

Figure 18-46 describes the programming flowchart for writing a data byte into the TPS65950 companion chip by the I2C1 module. See Section 18.6.1.3.2 for more information. See Table 18-25 for more information about variables and constants used in the programming flowcharts in Figure 18-46 and Figure 18-47.

Figure 18-46. Data Writing into the TPS65950 Companion Chip Register by the I2C1 Module

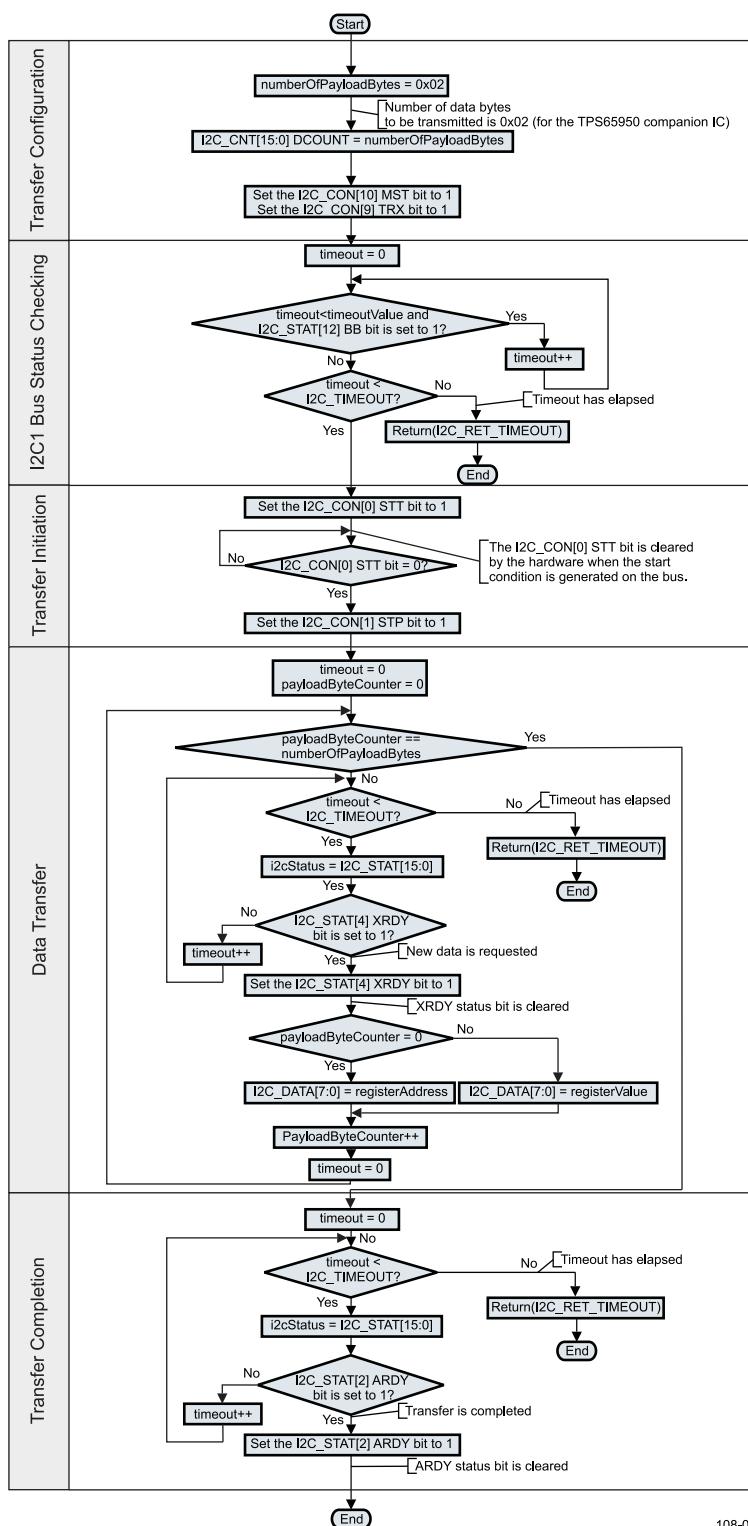

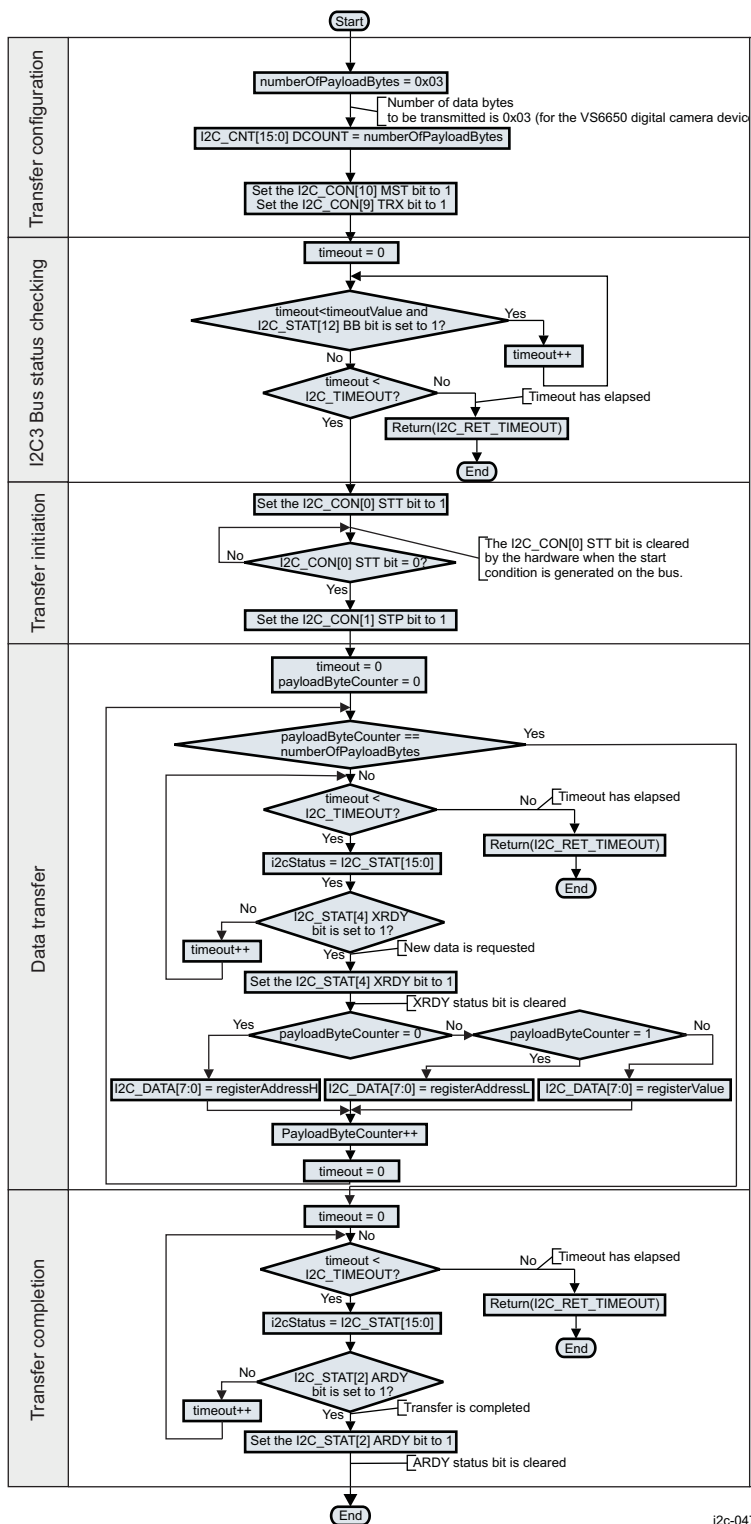

Figure 18-47 describes the programming flowchart for writing a data byte into the VS6650 digital camera device by the I2C3 module. See [Section 18.6.1.3.2](#) for more information.

Figure 18-47. Data Writing into the VS6650 Digital Camera Device Register by the I2C3 Module

The variables and constants used in the programming flowcharts are described in the [Table 18-25](#).

Table 18-25. Variables and Constants

Variable or Constant Name	Type	Tested Value	Description
numberOfPayloadBytes	16-bit unsigned	-	This variable contains the number of data bytes to be transmitted to the external device.
timeout	32-bit unsigned	-	This variable is the timeout counter. When it reaches the I2C_TIMEOUT value, it indicates that the timeout has elapsed.
I2C_TIMEOUT	32-bit unsigned	100 000	This constant contains the maximum value that can be reached by the timeout variable.
payloadByteCounter	16-bit unsigned	-	This variable is a counter that counts the data bytes transmitted to the external device.
registerAddress	8-bit unsigned	-	This variable contains the address of the TPS65950 companion chip register that must be written.
registerAddressM	8-bit unsigned	-	This variable contains the most-significant byte address of the VS6650 digital camera device register that must be written.
registerAddressL	8-bit unsigned	-	This variable contains the less-significant byte address of the VS6650 digital camera device register that must be written.
registerValue	8-bit unsigned	-	This variable contains the value to be written into the external device register

18.7 High-Speed I²C Controllers Registers

CAUTION

The I2Ci registers are limited to 16 bit and 8 bit data accesses, 32 bit data access is not allowed and can corrupt register content.

Note: For details about the master transmitter HS I²C controller I2C4, see the *Power, Reset, and Clock Management* chapter.

Table 18-26 provides the instance summary.

Table 18-26. Instance Summary

Module Name	Base Address	Size
I2C1	0x4807 0000	128 bytes
I2C2	0x4807 2000	128 bytes
I2C3	0x4806 0000	128 bytes

18.7.1 Multimaster HS I²C Controller Register Mapping Summary

Table 18-27 lists the I2Ci registers (where I = 1, 2 and 3).

Table 18-27. Register Summary

Bits	Field Name	Description	Type	Reset
31:16	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0000
15	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0
14	XDR_IE	Transmit Draining interrupt enable. Mask or unmask the interrupt signaled by the bit in I2C_STAT[XDR] . 0x0: Transmit Draining interrupt disabled 0x1: Transmit Draining interrupt enabled	RW	0
13	RDR_IE	Receive Draining interrupt enable. Mask or unmask the interrupt signaled by the bit in I2C_STAT[RDR] . 0x0: Receive Draining interrupt disabled 0x1: Receive Draining interrupt enabled	RW	0
12:10	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0
9	AAS_IE	Addressed as Slave interrupt enable. Mask or unmask the interrupt signaled by the bit in I2C_STAT[AAS] . 0x0: Addressed as Slave interrupt disabled 0x1: Addressed as Slave interrupt enabled	RW	0
8	BF_IE	Bus Free interrupt enable. Mask or unmask the interrupt signaled by the bit in I2C_STAT[BF] . 0x0: Bus Free interrupt disabled 0x1: Bus Free interrupt enabled	RW	0
7	AERR_IE	Access Error interrupt enable. Mask or unmask the interrupt signaled by the bit in I2C_STAT[AERR] . 0x0: Access Error interrupt disabled 0x1: Access Error interrupt enabled	RW	0
6	STC_IE	Start Condition interrupt enable. Mask or unmask the interrupt signaled by the bit in I2C_STAT[STC] . 0x0: Start Condition interrupt disabled 0x1: Start Condition interrupt enabled	RW	0
5	GC_IE	General Call interrupt enable. Mask or unmask the interrupt signaled by the bit in I2C_STAT[GC] . 0x0: General Call interrupt disabled 0x1: General Call interrupt enabled	RW	0
4	XRDY_IE	Transmit Data Ready interrupt enable. Mask or unmask the interrupt signaled by the bit in I2C_STAT[XRDY] . 0x0: Transmit Data Ready interrupt disabled 0x1: Transmit Data Ready interrupt enabled	RW	0
3	RRDY_IE	Receive Data Ready interrupt enable. Mask or unmask the interrupt signaled by the bit in I2C_STAT[RRDY] .	RW	0

Bits	Field Name	Description	Type	Reset
2	ARDY_IE	0x0: Receive Data Ready interrupt disabled	RW	0
		0x1: Receive Data Ready interrupt enabled		
1	NACK_IE	Register Access Ready interrupt enable. Mask or unmask the interrupt signaled by the bit in I2C_STAT[ARDY].	RW	0
		0x0: Register Access Ready interrupt disabled		
0	AL_IE	0x1: Register Access Ready interrupt enabled	RW	0
		No Acknowledgment interrupt enable. Mask or unmask the interrupt signaled by the bit in I2C_STAT[NACK].		
		0x0: No Acknowledge interrupt disabled		
		0x1: No Acknowledge Ready interrupt enabled		
		Arbitration Lost interrupt enable. Mask or unmask the interrupt signaled by the bit in I2C_STAT[AL].	RW	0
		0x0: Arbitration Lost interrupt disabled		
		0x1: Arbitration Lost interrupt enabled

Bits	Field Name		Description																								Type		Reset			
31:16	Reserved		Write 0s for future compatibility. Read returns 0.																								RW		0x0000			
15	Reserved		Write 0s for future compatibility. Read returns 0.																								RW		0			
14	XDR		Transmit Draining IRQ status																								RW		0			
Read 0x0: Transmit draining inactive																																

Bits	Field Name	Description	Type	Reset
		Read 0x1: Transmit draining active Write 0x0: No effect Write 0x1: Clear this bit to 0		
13	RDR	Receive Draining IRQ status Read 0x0: Receive draining inactive Read 0x1: Receive draining active Write 0x0: No effect Write 0x1: Clear this bit to 0	RW	0
12	BB	Bus busy status. Read-only bit. Writing this bit does not affect the read value. Read 0x0: Bus is free. Read 0x1: Bus is occupied.	R	0
11	ROVR	Receive overrun status. Read-only bit. Writing this bit does not affect the read value. Read 0x0: Normal operation Read 0x1: Receiver overrun	R	0
10	XUDF	Transmit underflow status. Read-only bit. Writing this bit does not affect the read value. Read 0x0: Normal operation Read 0x1: Transmit underflow	R	0
9	AAS	Address recognized as slave IRQ status Read 0x0: No action Read 0x1: Address recognized Write 0x0: No effect Write 0x1: Clear this bit to 0.	RW	0
8	BF	Bus Free IRQ status Read 0x0: No action Read 0x1: Bus free Write 0x0: No effect Write 0x1: Clear this bit to 0.	RW	0
7	AERR	Access Error IRQ status Read 0x0: No action Read 0x1: Access error Write 0x0: No effect Write 0x1: Clear this bit to 0.	RW	0
6	STC	Start Condition IRQ status Read 0x0: No action Read 0x1: Start condition detected Write 0x0: No effect Write 0x1: Clear this bit to 0.	RW	0
5	GC	General Call IRQ status. Set to 1 when general call address detected. Interrupt signaled to MPU subsystem Read 0x0: No general call detected Read 0x1: General call address detected Write 0x0: No effect Write 0x1: Clear this bit to 0.	RW	0
4	XRDY	Transmit Data Ready IRQ status. Set to 1 in transmit mode when new data is requested for transmission. When this bit is set to 1, an interrupt is signaled to MPU subsystem Read 0x0: No transmit data is requested for transmission Read 0x1: Transmit data is requested for transmission Write 0x0: No effect Write 0x1: Clear this bit to 0.	RW	0

Bits	Field Name	Description	Type	Reset
3	RRDY	Receive Data Ready IRQ status. Set to 1 when in receive mode, causing new data to be able to be read. When this bit is set to 1, an interrupt is signaled to MPU subsystem. Read 0x0: No data available Read 0x1: Receive data available Write 0x0: No effect Write 0x1: Clear this bit to 0.	RW	0
2	ARDY	Register Access Ready IRQ status. Setting this bit to 1 indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to MPU subsystem. Read 0x0: Module busy Read 0x1: Access ready Write 0x0: No effect Write 0x1: Clear this bit to 0.	RW	0
1	NACK	No Acknowledgment IRQ status. This bit is set when No Acknowledgment has been received. An interrupt is signaled to MPU subsystem. In master mode, the transfer is automatically ended by generating a stop condition on the bus. The I2Ci.I2C_CON[1] STP, I2Ci.I2C_CON[10] MST and I2Ci.I2C_CON[9] TRX bits are automatically cleared to 0 (slave receiver mode). TX and RX FIFOs must be cleared (I2Ci.I2C_BUF[6] TXFIFO_CLR and I2Ci.I2C_BUF[14] RXFIFO_CLR bits set to 1). Read 0x0: Normal operation Read 0x1: No Acknowledge detected Write 0x0: No effect Write 0x1: Clear this bit to 0.	RW	0
0	AL	Arbitration Lost IRQ status. This bit is set automatically by the hardware when the I2C controller inside the device loses arbitration in master transmit mode. An interrupt is signaled to MPU subsystem. Read 0x0: Normal operation Read 0x1: Arbitration loss detected Write 0x0: No effect Write 0x1: Clear this bit to 0.	RW	0

[Table 18-70](#) lists the changes made since the previous version of this document.

Table 18-70. Document Revision History

Reference	Additions/Modifications/Deletions
Global	Changed TWL4030 to TPS65950.
Section 18.3.1.2.2	Changed 6th paragraph.
Table 18-32	Changed bits 10 and 11 to reserved.
Table 18-38	Added table note.

Multichannel Serial Port Interface (McSPI)

This chapter describes the four multichannel serial port interface (McSPI) modules for the OMAP35x Applications Processor.

Topic	Page
19.1 McSPI Overview	2700
19.2 McSPI Environment.....	2703
19.3 McSPI Functional Interface	2706
19.4 McSPI Integration	2711
19.5 McSPI Functional Description	2715
19.6 McSPI Basic Programming Model	2736
19.7 McSPI Use Cases and Tips	2757
19.8 McSPI Registers	2763
19.9 Revision History	2785

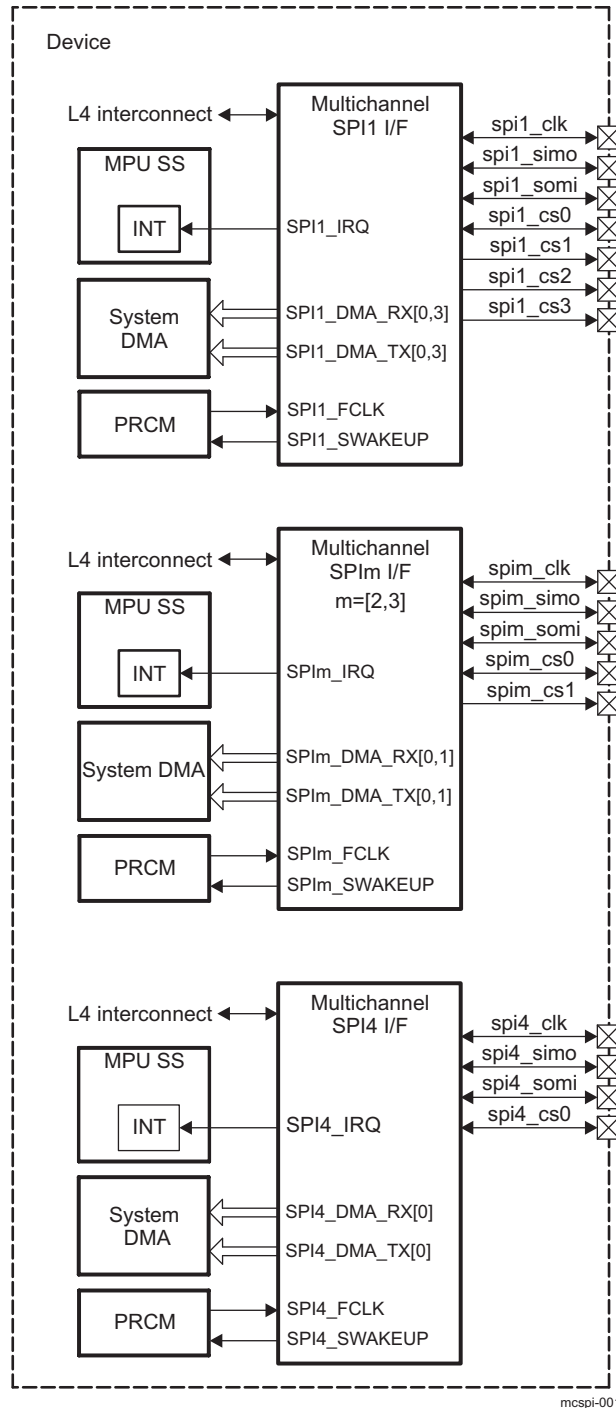

19.1 McSPI Overview

The multichannel serial port interface (McSPI) is a master/slave synchronous serial bus. There are four separate McSPI modules (SPI1, SPI2, SPI3, and SPI4) in the device (see [Figure 19-1](#)). The McSPI modules differ as follows: SPI1 supports up to four peripherals, SPI2 and SPI3 support up to two peripherals, and SPI4 supports only one peripheral.

Note: In this chapter, $m=[1,4]$ represents the module instance and x represents the channel in signal and register naming. There are four McSPI instances. Each module instance has different channel numbers:

- SPI1: 4 channels (if $m=1$, $x=4$)
 - SPI2: 2 channels (if $m=2$, $x=2$)
 - SPI3: 2 channels (if $m=3$, $x=2$)
 - SPI4: 1 channel (if $m=4$, $x=1$)
-

Figure 19-1. Multichannel Modules SPI1, SPI2, SPI3, and SPI4

The McSPI instances include the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of SPI word lengths ranging from 4 bits to 32 bits
- Up to four master channels or single channel in slave mode
- Master multichannel mode:
 - Full duplex/half duplex
 - Transmit-only/receive-only/transmit-and-receive modes

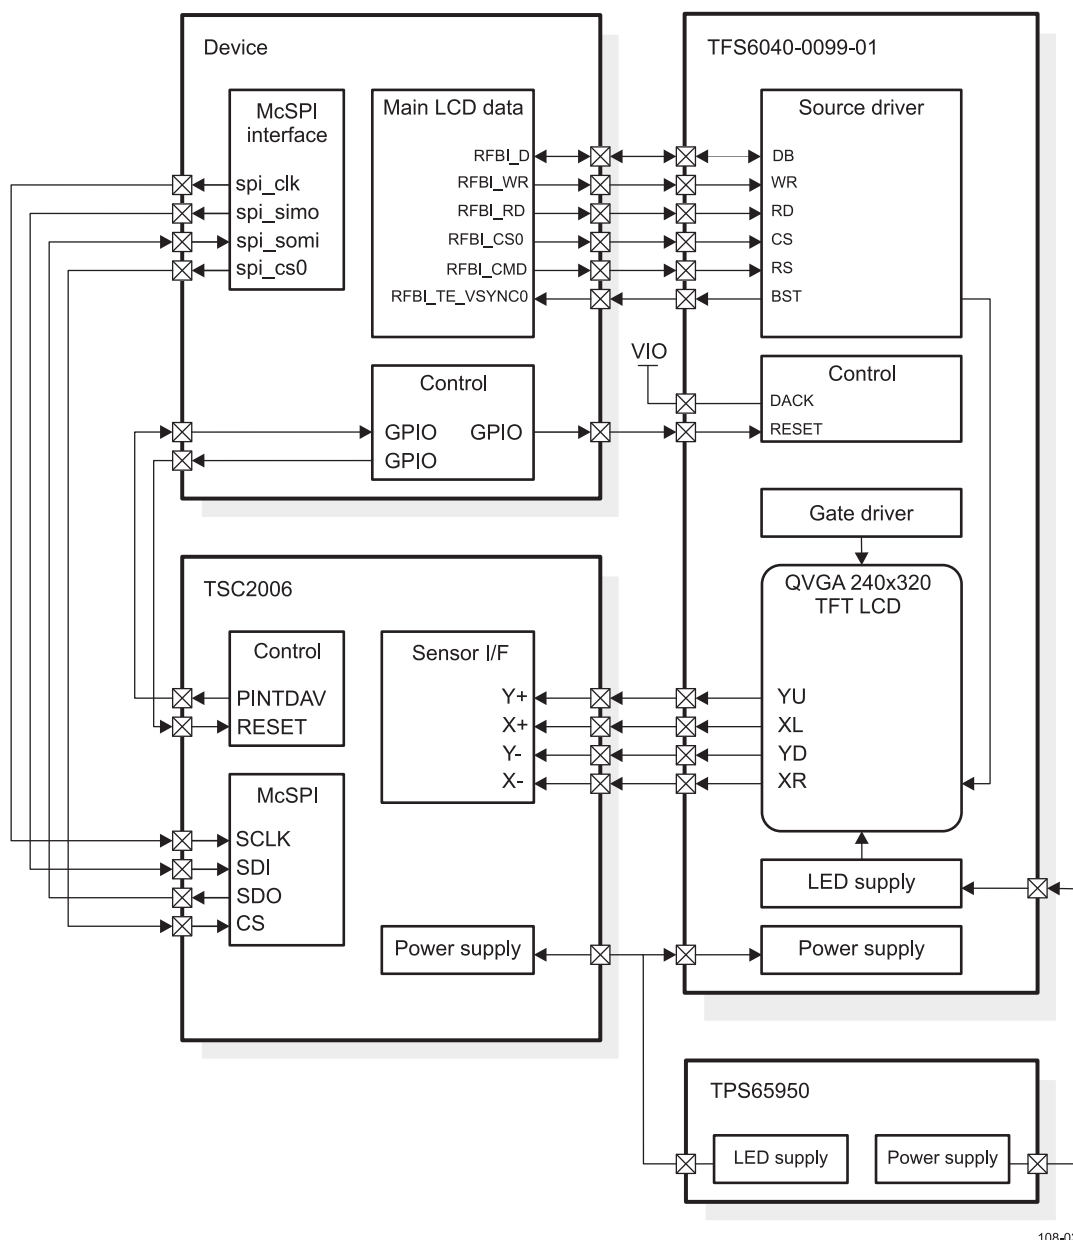

- Flexible I/O port controls per channel
 - Two direct memory access (DMA) requests (read/write) per channel
- Single interrupt line for multiple interrupt source events
- Power management through wake-up capabilities
- Enable the addition of a programmable start-bit for SPI transfer per channel (start-bit mode)
- Support start-bit write command
- Support start-bit pause and break sequence
- 64 bytes built-in FIFO available for a single channel

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

19.2 McSPI Environment

Figure 19-2 shows a simplified overview of a typical application system using the McSPI. This example is based on a TFS chipset (TFS6040-0098), including a 2.2-inch color-active matrix thin-film transistor (TFT) liquid crystal display (LCD) with a light-emitting diode (LED) front light, a four-wire resistive touch-screen panel, and LCD controllers. This chipset is associated with the TSC2005 or TSC2006 touch-screen controller, powered by a TPS65950 power-management unit, and driven by the device. The McSPI device interface is set to master mode; the touch-screen McSPI controller interface operates in slave mode.

Figure 19-2. Typical Application using the McSPI

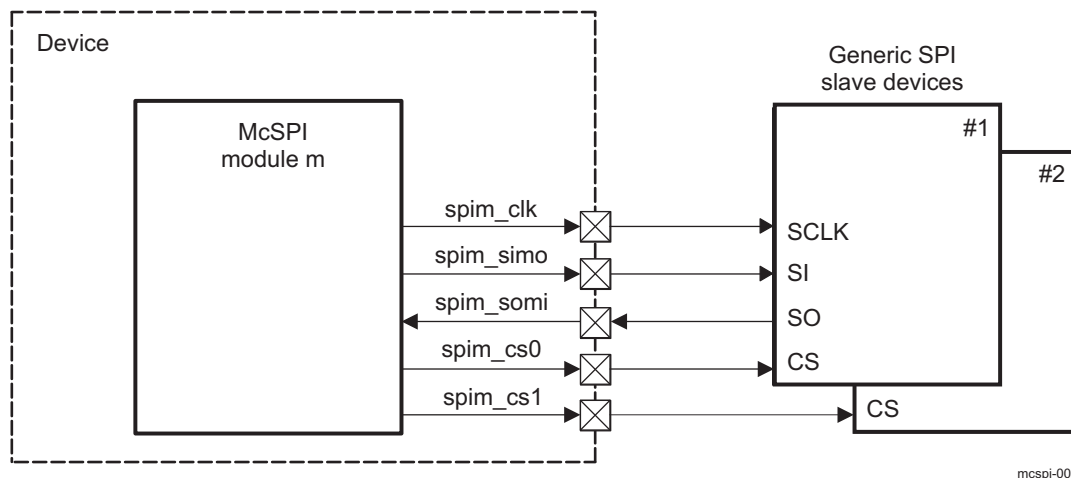

108-034

Figure 19-3 through Figure 19-8 show master mode and slave mode configurations. Each mode can be wired on a single-duplex or full-duplex configuration.

19.2.1 SPI Interface in Master Mode

Figure 19-3 shows a case in master mode (full-duplex) where the McSPI module is connected with two slave devices.

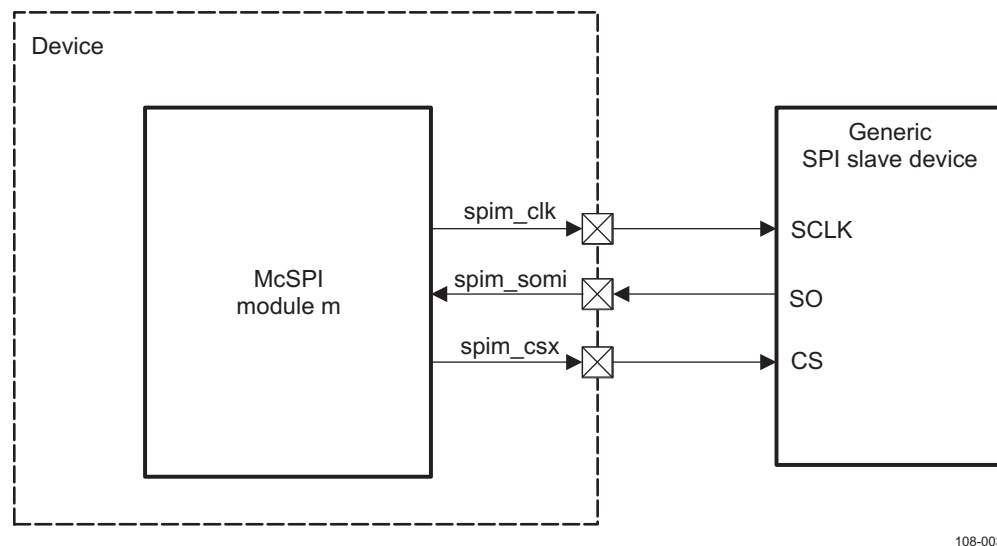

Figure 19-3. McSPI Master Mode (Full-Duplex)

Note: In this case $m=[1,3]$.

Figure 19-4 shows the master single mode, which can also be configured in receive-only mode.

Figure 19-4. McSPI Master Single Mode (Receive-Only)

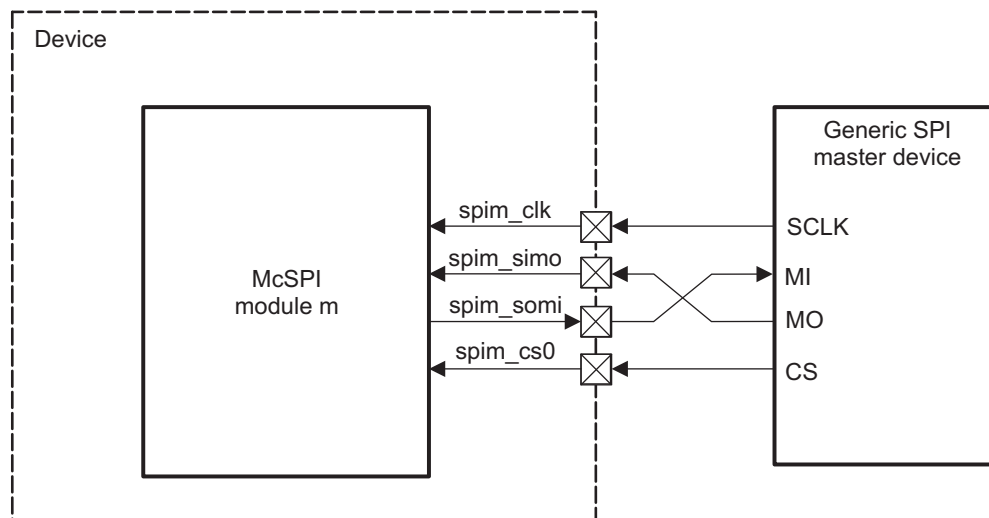

19.2.2 SPI Interface in Slave Mode

Figure 19-5 shows a case in slave mode (full-duplex).

Note: Only channel 0 can be configured as slave, but the chip-enable signal can be connected to any `SPIM_CSX` pin and then rerouted internally to channel 0 (`SPIm.MCSPI_CHxCONF[22:21]` `SPIENSLV` field (with $x=0$)). For more information, see [Section 19.5.3, Slave Mode](#).

Figure 19-5. McSPI Slave Mode (Full Duplex)

108-004

Figure 19-6 shows the slave single mode, which can also be configured in transmit-only mode.

19.3 McSPI Functional Interface

19.3.1 Basic McSPI Pins for Master Mode

Figure 19-7 shows all of the McSPI interface signals in master mode.

Figure 19-7. McSPI Interface Signals in Master Mode

Table 19-1 describes the McSPI I/O in master mode.

Table 19-1. McSPI I/O Description (Master Mode)

Signal Name	I/O	Description	Reset ⁽¹⁾
spim_clk	O	SPIm module serial clock	Unknown
spim_simo	O	SPIm module serial data master out (slave input, master output)	Unknown
spim_somi	I	SPIm module serial data master input (slave output, master input)	-
SPIM_CSX	O	SPIm module chip-select x output	Low

⁽¹⁾ After reset, the SPI modules are in slave mode by default. This paragraph implies that the McSPI module is configured in slave mode. (See the MCSPI_MODULCTRL[2] MS bit in Module Control Register (MCSPI_MODULCTRL).)

19.3.2 Basic McSPI Pins for Slave Mode

Figure 19-8 shows all of the McSPI interface signals in slave mode.

Figure 19-8. McSPI Interface Signals in Slave Mode

Table 19-2 describes the McSPI I/O in slave mode.

Table 19-2. McSPI I/O Description (Slave Mode)

Signal Name	I/O	Description	Reset ⁽¹⁾
spim_clk	I	SPIm module serial clock	Unknown
spim_simo	I	SPIm module serial data master out (slave input, master output)	Unknown
spim_somi	O	SPIm module serial data master input (slave output, master input)	-
SPIM_CSX	I	SPIm module chip-select x output	Low

⁽¹⁾ After reset, the SPI modules are in slave mode by default. This paragraph implies that the McSPI module is configured in slave mode. (See the MCSPI_MODULCTRL[2] MS bit in Module Control Register (MCSPI_MODULCTRL).)

19.3.3 Multichannel SPI Protocol and Data Format

The synchronous SPI protocol allows a master device to initiate serial data transfers to a slave device. A slave select line (SPIM_CSX) allows selection of an individual slave SPI device. Slave devices that are not selected do not interfere with SPI bus activities.

McSPI offers the flexibility to modify the following parameters to adapt to the device features:

- Word length
McSPI supports any SPI word ranging from 4 bits to 32 bits long (SPIm.MCSPI_CHxCONF[11:7] WL field).
SPI word length can be changed between transmissions to allow the master device to communicate with peripheral slaves that have different requirements.
- SPI enable (SPIM_CSX, for channel x of instance m)
The polarity of the SPI enable signals is programmable (SPIm.MCSPI_CHxCONF[6] EPOL bit). SPIM_CSX signals can be active high or low.
The assertion of the SPIM_CSX signals is programmable and can be manually or automatically asserted. The manual assertion mode is available in single master mode only. SPIM_CSX can be kept active between words with the SPIm.MCSPI_CHxCONF[20] FORCE bit.
Two consecutive words for two different slave devices can go along with active SPIM_CSX signals with different polarity (see the example in [Section 19.6, McSPI Basic Programming Model](#)).
- Programmable start-bit
In start-bit mode a start-bit is added before the SPI word length to indicate how the next SPI word must be handled. The start-bit is enabled by setting SPIm.MCSPI_CHxCONF[23] SBE bit to 1. The SPIm.MCSPI_CHxCONF[24] SBPOL bit defines the polarity of the start-bit.
- Programmable SPI clock
 - Bit rate
In master mode, the baud rate of the SPI serial clock is programmable using the 48-MHz reference clock (from the power, reset, and clock management [PRCM] module). [Table 19-3](#) gives the spim_clk bit rates obtained for data transfer when programming the clock divider (SPIm.MCSPI_CHxCONF[5:2] CLKD bit field).

Table 19-3. SPI Master Clock Rates

Divider	Bit Rate (Peak)
1	48 Mbps
2	24 Mbps
4	12 Mbps
8	6 Mbps
16	3 Mbps
32	1.5 Mbps
64	750 Kbps
128	375 Kbps

Table 19-3. SPI Master Clock Rates (continued)

Divider	Bit Rate (Peak)
256	~187 Kbps
512	~93.7 Kbps
1024	~46.8 Kbps
2048	~23.4 Kbps
4096	~11.7 Kbps

For slave mode, see your device-specific data manual.

– Polarity and phase

The polarity (the SPIm.MCSPI_CHxCONF[1] POL bit) and the phase (the SPIm.MCSPI_CHxCONF[0] PHA bit) of the SPI serial clock (spim_clk) are configurable to offer four combinations. Software selects the right combination, depending on the device. See [Table 19-4](#) and [Figure 19-9](#).

Table 19-4. Phase and Polarity Combinations

Polarity (POL)	Phase (PHA)	SPI Mode	Comments
0	0	Mode 0	spim_clk is active high and sampling occurs on the rising edge.
0	1	Mode 1	spim_clk is active high and sampling occurs on the falling edge.
1	0	Mode 2	spim_clk is active low and sampling occurs on the falling edge.
1	1	Mode 3	spim_clk is active low and sampling occurs on the rising edge.

Figure 19-9. Phase and Polarity Combinations

108-009

19.3.3.1 Transfer Format

In both master and slave modes, McSPI drives the data lines when SPIM_CSX is asserted.

Each word is transmitted starting with the most-significant bit (MSB).

This section explains the two cases of data transmission determined by the clock phase (PHA) and the type of data transmission using a start-bit (SBE) called the start-bit mode:

- Transmission in mode 0 and mode 2 (PHA = 0)

When PHA = 0, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid one half cycle of spim_clk after the SPIM_CSX assertion.

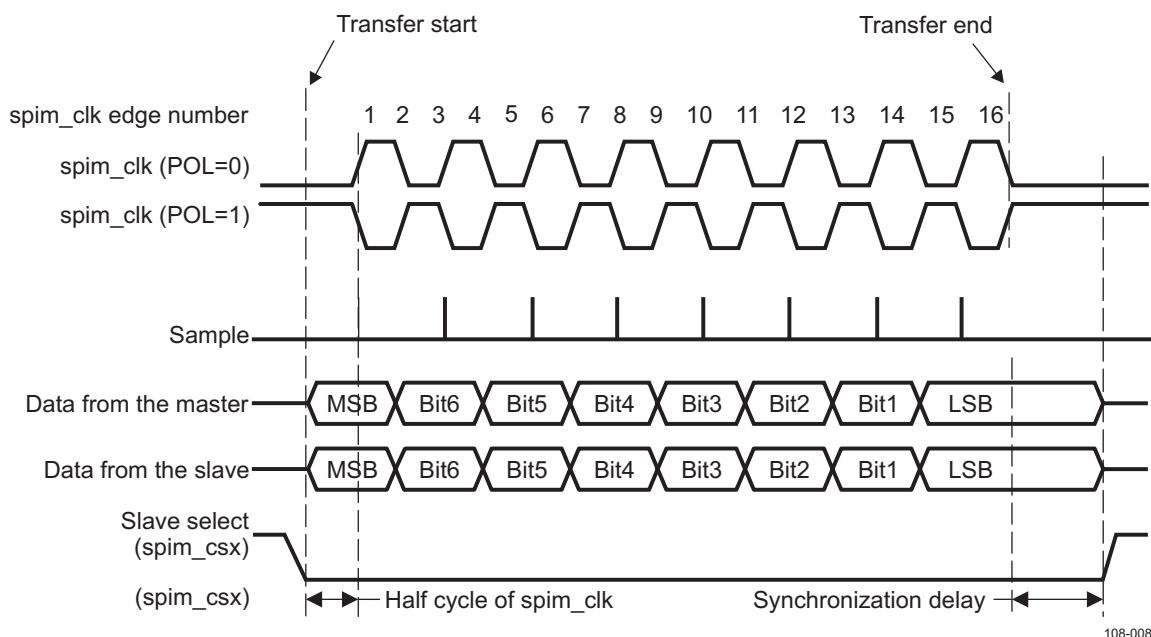

Therefore, the first edge of the spim_clk line is used by the master to sample the first data bit sent by

the slave. On the same edge, the first data bit sent by the master is sampled by the slave.

On the next `spim_clk` edge, the received data bit is shifted into the receive shift register and a new data bit is transmitted on the serial data line.

This process continues for a number of pulses on the `spim_clk` line defined by the SPI word length programmed in the master device, with data being latched on odd-numbered edges and shifted on even-numbered edges. See [Figure 19-10](#).

Figure 19-10. Full-Duplex Transfer Format with PHA = 0

- Transmission in mode 1 and mode 3 (PHA = 1)

When PHA = 1, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid on the following `spim_clk` edge (one half cycle later). This is the sampling edge for the master and slave. A synchronization delay is added between the `SPIM_CSX` activation and the first `spim_clk` edge.

The received data bit is shifted into the shift register on the third `spim_clk` edge.

This process continues for a number of pulses on the `spim_clk` line defined by the SPI word length programmed in the master device, with data being latched on even-numbered edges and shifted on odd-numbered edges.

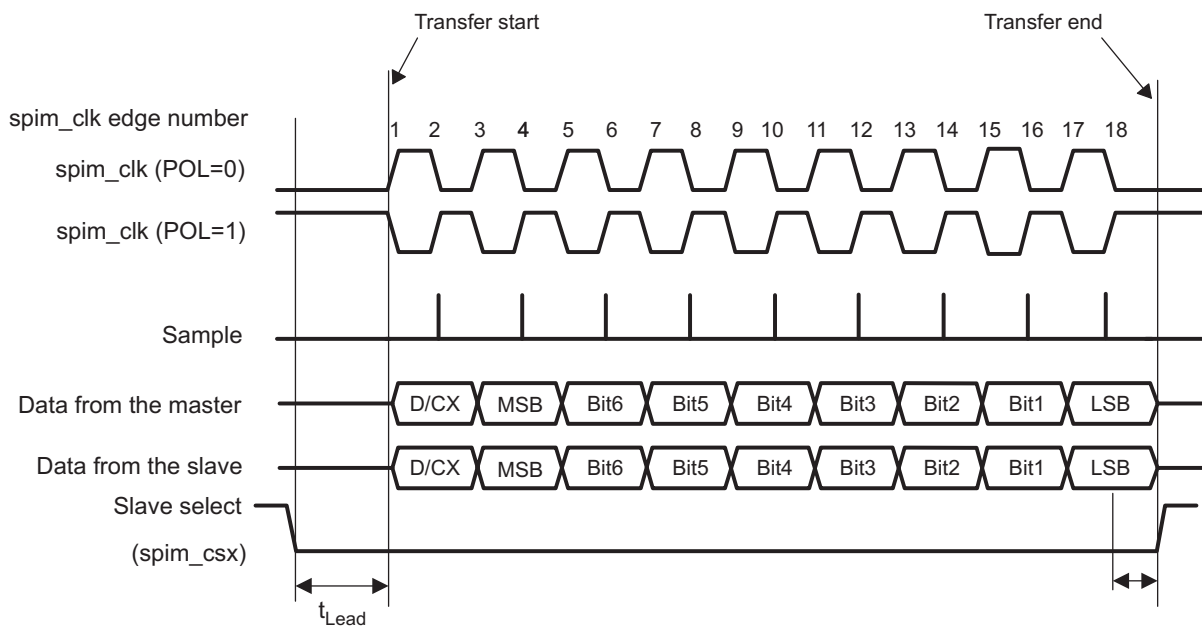

Note: The minimum synchronization delay is one cycle of `spim_clk`, if the `spim_clk` frequency equals the `SPIM_FCLK` (McSPI functional clock) frequency in master mode. The minimum synchronization delay is one-half cycle of `spim_clk`, if the `spim_clk` frequency is lower than the `SPIM_FCLK` frequency in both master and slave modes.

- Transmission with a start-bit (SBE = 1)

When the `SPIM_MCSPI_CHXCONF[23]` SBE bit = 1, a start-bit is added before the MSB to indicate whether the next SPI word must be handled as a command or as data.

[Figure 19-11](#) shows an example of a data transfer with an extra start-bit.

Figure 19-11. Extended SPI Transfer with a Start-Bit (SBE = 1)

19.4 McSPI Integration

19.4.1 McSPI Description

Figure 19-12 highlights the McSPI module integration in the device.

19.4.2 Clocking, Reset, and Power-Management Scheme

19.4.2.1 Clocking

Each McSPI module is clocked with an independent functional clock of 48 MHz from the PRCM module (SPIIm_FCLK with $m = [1,4]$) and with an interface clock, CORE_L4_ICLK (L4 interconnect):

- SPIIm_FCLK is the McSPI module m functional clock and is used to clock the McSPI internal logic. The source of SPIIm_FCLK is the PRCM CORE_48M_FCLK output clock.
- SPIIm_ICLK is the McSPI module m interface clock and is used to synchronize the McSPI L4 port to the L4 interconnect. All accesses from the interconnect are synchronous with SPIIm_ICLK. The source of SPIIm_ICLK is the PRCM CORE_L4_ICLK output clock.

From a global system power management perspective, when one or both of the McSPI clocks is not required, the McSPI module can be deactivated at the PRCM level in the corresponding registers.

Table 19-5 describes the McSPI module PRCM clock control bits.

Table 19-5. McSPI Clocks

McSPI Clock	Associated PRCM Clock Output	Enable Bit	Autoidle Bit
SPIIm_FCLK	CORE_48M_FCLK	PRCM.CM_FCLKEN1_CORE.EN_M CSPIIm (with $m=[1,4]$)	N/A

Table 19-5. McSPI Clocks (continued)

McSPI Clock	Associated PRCM Clock Output	Enable Bit	Autoidle Bit
SPI _m _ICLK	CORE_L4_ICLK	PRCM.CM_ICLKEN1_CORE.EN_M CSPI _m (with m=[1,4])	PRCM.CM_AUTOIDLE1_CORE.AUTO _MCSPIm (with m=[1,4])

Notes:

- The PRCM CORE_48M_FCLK output is gated at the PRCM level, assuming that all modules sharing it are disabled in the corresponding register. Disabling the McSPI module is a necessary but insufficient condition.
- The PRCM CORE_L4_ICLK output is gated at the PRCM level, assuming that all modules sharing it are disabled in the corresponding register. Disabling the McSPI module is a necessary but insufficient condition.
- The PRCM.CM_AUTOIDLE1_CORE bit is used to link/unlink the McSPI module from CORE_L4_ICLK-related clock domain transitions.

For more information about source clocks gating and domain transitions, see the *Power, Reset, and Clock Management* chapter. For more information on power saving management, see [Section 19.5.7](#).

19.4.2.2 Power Domain

The McSPI modules belong to the CORE power domain (see [Table 19-6](#)).

Table 19-6. Power Domain

Peripherals	Power Domain
McSPI modules	CORE power domain

19.4.2.3 Hardware Reset

As part of the CORE power domain, CORE_RST is issued by the PRCM module (for more information about the CORE power domain implementation and CORE_RST signal, see the *Power, Reset, and Clock Management* chapter). The module is reset by hardware when an active-low reset signal is asserted. The hardware reset signal has a global reset effect on the module. All configuration registers and all state-machines are reset in all clock domains (see [Table 19-7](#)).

Table 19-7. McSPI Hardware Reset

Peripherals	Name	Comments
McSPI module	CORE_RST	Same as global reset

19.4.2.4 Software Reset

The SPI_m.MCSPI_SYSCONFIG[1] SOFTRESET bit controls the software reset of the SPI interface. Writing 1 to this bit enables active software reset functionality, which is equivalent to a hardware reset. The bit is automatically reset by hardware.

Note: The SPI_m.MCSPI_SYSCONFIG register is not sensitive to software reset.

19.4.3 Hardware Requests

19.4.3.1 DMA Requests

Each channel includes two DMA requests, one for reception and one for transmission (see [Table 19-8](#)).

Table 19-8. DMA Requests

Attributes	DMA Request	Name	Mapping	Comments
SPI1				
	8	SPI1_DMA_TX0	S_DMA_34	Destination is system DMA (sDMA).
		SPI1_DMA_RX0	S_DMA_35	
		SPI1_DMA_TX1	S_DMA_36	
		SPI1_DMA_RX1	S_DMA_37	
		SPI1_DMA_TX2	S_DMA_38	
		SPI1_DMA_RX2	S_DMA_39	
		SPI1_DMA_TX3	S_DMA_40	
		SPI1_DMA_RX3	S_DMA_41	
SPI2				
	4	SPI2_DMA_TX0	S_DMA_42	Destination is sDMA.
		SPI2_DMA_RX0	S_DMA_43	
		SPI2_DMA_TX1	S_DMA_44	
		SPI2_DMA_RX1	S_DMA_45	
SPI3				
	4	SPI3_DMA_TX0	S_DMA_14	Destination is sDMA.
		SPI3_DMA_RX0	S_DMA_15	
		SPI3_DMA_TX1	S_DMA_22	
		SPI3_DMA_RX1	S_DMA_23	
SPI4				
	2	SPI4_DMA_TX0	S_DMA_69	Destination is sDMA.
		SPI4_DMA_RX0	S_DMA_70	

19.4.3.2 Interrupt Requests

Each McSPI module handles one interrupt line (see [Table 19-9](#)).

Table 19-9. Interrupt Requests

Attributes	Interrupt Request	Name	Mapping	Comments
SPI1				
	1	SPI1_IRQ	M_IRQ_65	Destination is the microprocessor unit (MPU) interrupt controller.
SPI2				
	1	SPI2_IRQ	M_IRQ_66	Destination is the MPU interrupt controller.
SPI3				
	1	SPI3_IRQ	M_IRQ_91	Destination the MPU interrupt controller.
SPI4				
	1	SPI4_IRQ	M_IRQ_48	Destination is the MPU interrupt controller.

19.4.3.3 Wake-Up Requests

[Table 19-10](#) lists the wake-up requests.

Table 19-10. Wake-Up Requests

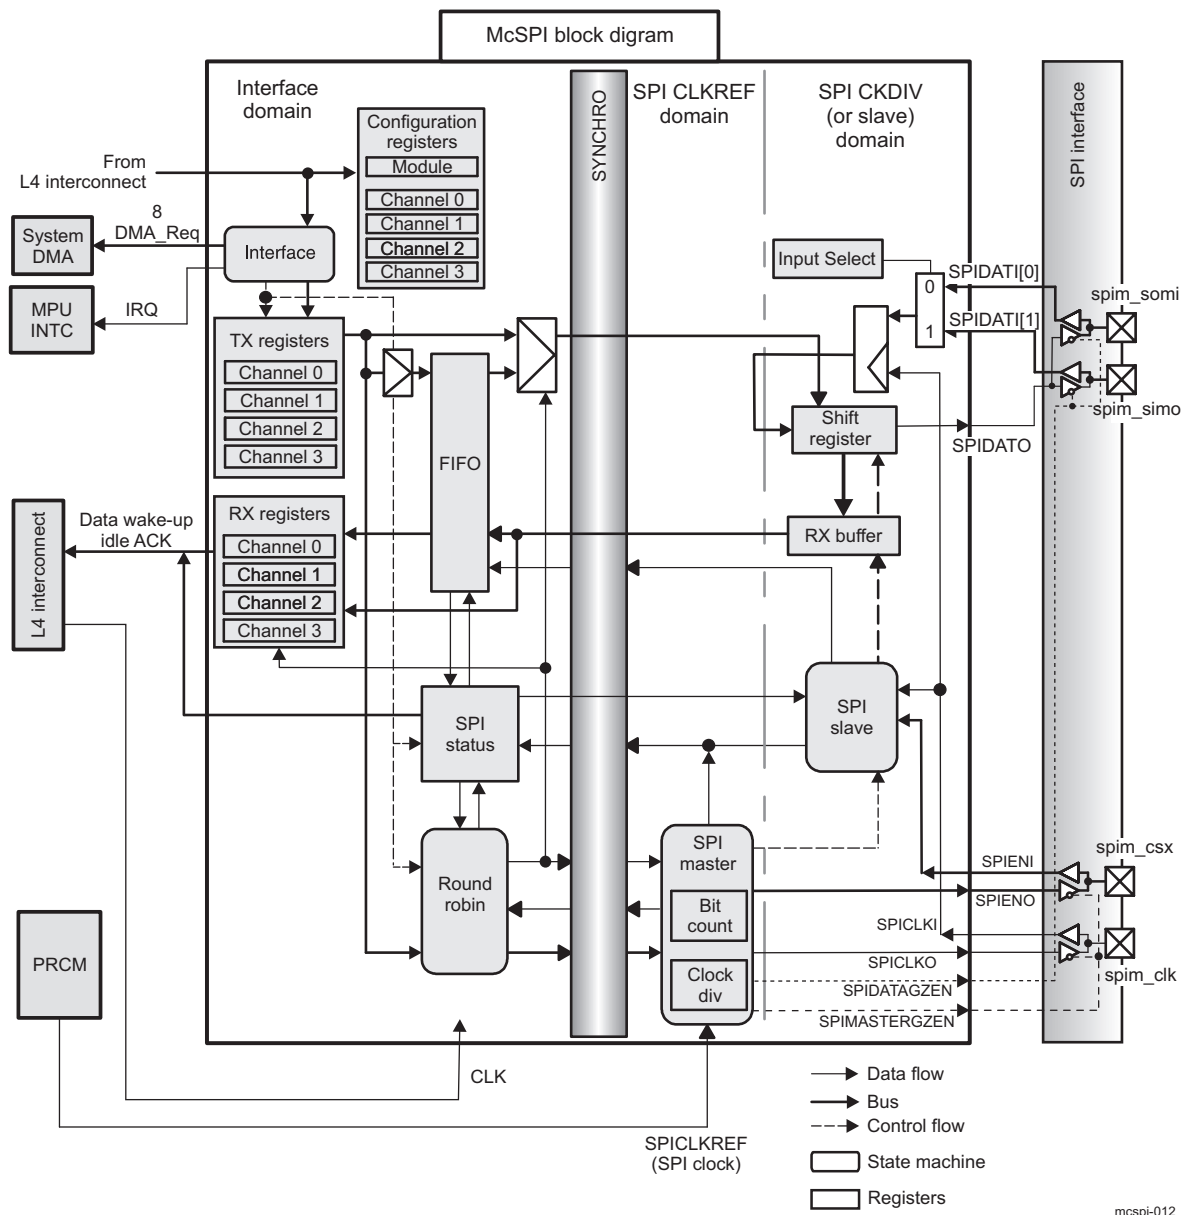

Attributes	Wake Request	Name	Mapping	Comments
SPI1				
	1	spi1_cs0	SPI1_SWAKEUP	Destination is the PRCM module.
SPI2				
	1	spi2_cs0	SPI2_SWAKEUP	Destination is the PRCM module.
SPI3				
	1	spi3_cs0	SPI3_SWAKEUP	Destination is the PRCM module.
SPI4				
	1	spi4_cs0	SPI4_SWAKEUP	Destination is the PRCM module.

19.5 McSPI Functional Description

19.5.1 McSPI Block Diagram

Figure 19-13 shows the McSPI module.

Figure 19-13. McSPI Block Diagram

mcspl-012

19.5.2 Master Mode

19.5.2.1 Master Mode Features

The McSPI master mode supports multichannel communication with up to four independent SPI communication channel contexts. The McSPI initiates a data transfer on the data lines (spim_simo and spim_somi) and generates clock (spim_clk) and control signals (SPIM_CSX).

Connected to multiple external devices, the McSPI exchanges data with one SPI device at a time through two main modes (available in slave mode):

- Two-data-pins interface mode (transmit-and-receive mode for full-duplex transmission)
- Single-data-pin interface mode (recommended for half-duplex transmission)

Two DMA request events (read and write) allow synchronized accesses of the DMA controller with the activity of McSPI.

Three interrupt events can be used for data transmission and reception in master mode (for more information on interrupts, see [Section 19.5.5.1, Interrupt Events in Master Mode](#)).

19.5.2.2 Master Transmit-and-Receive Mode (Full Duplex)

In full-duplex transmission, data is transmitted (shifted out serially on `spim_simo`) and received (shifted in serially on `spim_somi`) simultaneously on separate data lines.

The master transmit-and-receive mode is programmable per channel (the `SPIm.MCSPI_CHxCONF[13:12]` TRM field).

Channel access to the shift registers for transmission/reception is based on the `MCSPI_TXx` transmitter register state, the `MCSPI_RXx` receiver register state, and round robin arbitration.

Channels that meet the following rules are included in the round robin list of active channels scheduled for transmission and/or reception. The arbiter skips channels that do not meet the rules and searches in the rotation for the next enabled channel.

- Rule 1: Only enabled channels (the `SPIm.MCSPI_CHxCTRL[0]` EN bit) can be scheduled for transmission and/or reception.
- Rule 2: If its `MCSPI_TXx` transmitter register is not empty (the `SPIm.MCSPI_CHxSTAT[1]` TXS bit), an enabled channel can be scheduled when the shift register is assigned. If the `MCSPI_TXx` register is empty when the shift register is assigned, the `TXx_UNDERFLOW` event is activated, and the next enabled channel with new data to transmit is scheduled (see also the transmit-only mode).
- Rule 3: An enabled channel can be scheduled if its receive register is not full (the `SPIm.MCSPI_CHxSTAT[0]` RXS bit) when the shift register is assigned (see also the receive-only mode). Therefore, the `MCSPI_RXx` register cannot be overwritten. Note that the `SP11.MCSPI_IRQSTATUS[3]` `RX0_OVERFLOW` bit is never set to this mode.

When SPI word transfer completes (the `SPIm.MCSPI_CHxSTAT[2]` EOT bit is set), the updated `MCSPI_TXx` register of the next scheduled channel is loaded into the shift register. The serialization (transmit-and-receive) starts depending on the channel communication configuration. When serialization completes, the received data transfers to the channel receive register.

The serial clock (`spim_clk`) synchronizes shifting and sampling of the information on the two serial data lines (`spim_simo` and `spim_somi`). Each time a bit transfers out from the master, 1 bit transfers in from the slave.

[Figure 19-14](#) shows an example of a full-duplex system with a master device (McSPI module *m*) on the left and a slave device on the right. After eight cycles of the serial clock `spim_clk`, WordA transfers from the master to the slave. At the same time, WordB transfers from the slave to the master.

Figure 19-14. SPI Full-Duplex Transmission (Example)

108-013

19.5.2.3 Master Transmit-Only Mode (Half Duplex)

The master transmit-only mode prevents the MPU from reading the `MCSPi_RXx` register (minimizing data movement) when only transmission is meaningful.

The master transmit-only mode is programmable per channel (the `SPIm.MCSPi_CHxCONF[13:12]` TRM field). Transmission starts only after data is loaded into the `MCSPi_TXx` register.

Rule 1 and Rule 2, defined in Section 19.5.2.2, are applicable in this mode.

Rule 3, defined in Section 19.5.2.2, is not applicable.

In master transmit-only mode, the `MCSPi_RXx` register state FULL does not prevent transmission and the `MCSPi_RXx` register is always overwritten with the new SPI word. This event is not significant when only transmission is meaningful. Thus, the `RX0_OVERFLOW` bit in the `SPIm.MCSPi_IRQSTATUS` register is never set in this mode.

The hardware automatically disables the `RX_FULL` interrupt and the DMA read requests.

The transfer status is given by the `SPIm.MCSPi_CHxSTAT[2]` EOT bit.

19.5.2.4 Master Receive-Only Mode (Half Duplex)

The master receive mode prevents the MPU from refilling the `MCSPi_TXx` register (minimizing data movement) when only reception is meaningful.

The master receive mode is programmable per channel (the `SPIm.MCSPi_CHxCONF[13:12]` TRM field).

The master receive-only mode enables channel scheduling only on the empty state of the `MCSPi_RXx` register.

Rule 1 and Rule 3, defined in Section 19.5.2.2, are applicable in this mode.

Rule 2, defined in Section 19.5.2.2, is not applicable.

In the master receive-only mode, software must write dummy data to the `MCSPi_TXx` register. Only one dummy write is enough to receive any number of words from the slave. Software should ensure that the `MCSPi_TXx` register is always full (the `TXx_EMPTY` bits of `SPIm.MCSPi_IRQSTATUS`) when receiving. The content of the `MCSPi_TXx` register is always loaded into the shift register when the shift register is assigned. After writing the dummy data to the `MCSPi_TXx` register, the `TXx_EMPTY` and `TXx_UNDERFLOW` bits in the `SPIm.MCSPi_IRQSTATUS` register are never set in receive-only mode.

The SPI_m.MCSPI_CHxSTAT[2] EOT bit gives the status of serialization. The RX_x_FULL bits of the SPI_m.MCSPI_IRQSTATUS register are set when received data is loaded from the shift register to the corresponding MCSPI_RX_x register. The SPI_m.MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set in this mode.

19.5.2.5 Single-Channel Master Mode

When the McSPI is configured as a master device with a single enabled channel, the assertion of the SPIM_CSX signal can be controlled in two different ways:

- If the MCSPI_MODULCTRL[0] SINGLE bit is set to 0, SPIM_CSX assertion/deassertion after each SPI word is automatically controlled by the McSPI module (see subsections of [Section 19.5.2.1, Master Mode Features](#)).
- If the MCSPI_MODULCTRL[0] SINGLE bit and the MCSPI_CHxCONF[20] FORCE bit are set to 1: SPIM_CSX assertion/deassertion is controlled by software (see [Section 19.5.2.5.1, Programming Tips When Switching to Another Channel](#)).

19.5.2.5.1 Programming Tips when Switching to Another Channel

When a single channel is enabled and data transfer is ongoing:

- Wait for completion of the SPI word transfer (wait until the SPI_m.MCSPI_CHxSTAT[2] EOT bit is set to 1) before disabling the current channel and enabling a different channel.
- Disable the current channel first, and then enable the other channel.

19.5.2.5.2 Force SPIM_CSX Mode

Continuous transfers are manually allowed by keeping the SPIM_CSX signal active for successive SPI words transfer. Several sequences (configuration/enable/disable of the channel) can be run without deactivating the SPIM_CSX line. This mode is supported by all channels and any master sequence can be used (transmit-receive, transmit-only, receive-only).

Keeping the SPIM_CSX active mode is supported when:

- A single channel is used (with the SPI_m.MCSPI_MODULCTRL[0] SINGLE bit set to 1).
- Transfer parameters are loaded in the configuration register of the appropriate channel (SPI_m.MCSPI_CHxCONF).

The state of the SPIM_CSX signal is programmable.

- Writing 1 to the SPI_m.MCSPI_CHxCONF[20] FORCE bit drives the SPIM_CSX line high when the SPI_m.MCSPI_CHxCONF[6] EPOL bit is set to 0. SPIM_CSX is driven low when the SPI_m.MCSPI_CHxCONF[6] EPOL bit is set to 1.
- Writing 0 to the SPI_m.MCSPI_CHxCONF[20] FORCE bit drives the SPIM_CSX line low when the SPI_m.MCSPI_CHxCONF[6] EPOL bit is set to 0. SPIM_CSX is driven high when the SPI_m.MCSPI_CHxCONF[6] EPOL bit is set to 1.
- A single channel is enabled (the SPI_m.MCSPI_CHxCTRL[0] EN bit is set to 1). The first enabled channel activates the SPIM_CSX line.

When the channel is enabled, the SPIM_CSX signal activates with the programmed polarity. As in the multichannel master mode, the transfer start depends on the status of the MCSPI_TX_x register (the SPI_m.MCSPI_CHxSTAT[1] TXS bit), the status of the MCSPI_RX_x register (the SPI_m.MCSPI_CHxSTAT[1] RXS bit), and the defined mode (the SPI_m.MCSPI_CHxCONF[13:12] TRM field) of the channel enabled.

The SPI_m.MCSPI_CHxSTAT[2] EOT bit gives the transfer status of each SPI word. The RX_x_FULL bit in the SPI_m.MCSPI_IRQSTATUS register is set when received data is loaded from the shift register to the MCSPI_RX_x register.

A change in the configuration parameters is propagated directly on the SPI interface. If the SPIM_CSX signal is activated, ensure that the configuration is changed only between SPI words to avoid corrupting the current transfer.

Note: To avoid data corruption, SPIM_CSX polarity and spim_clk phase and spim_clk polarity must not be modified when the SPIM_CSX signal is activated.

A delay between SPI words that requires the connected SPI slave device to switch from one configuration (transmit-only for instance) to another (receive-only for instance) must be handled by software.

At the end of the last SPI word, the channel must be deactivated (the SPIm.MCSPI_CHxCTRL[0] EN bit set to 0) and SPIM_CSX can be forced to its inactive state using the SPIm.MCSPI_CHxCONF[20] FORCE bit.

Figure 19-15 and Figure 19-16 show successive transfers with SPIM_CSX maintained active low with a different configuration for each SPI word in single-data-pin and dual-data-pin interface modes, respectively.

Figure 19-15. Continuous Transfers with SPIM_CSX Maintained Active (Single-Data-Pin Interface Mode)

Figure 19-16. Continuous Transfers with SPIM_CSX Maintained Active (Dual-Data-Pin Interface Mode)

Note: The turbo mode described in Section 19.5.2.5.3, *Turbo Mode*, maintains SPIM_CSX in active mode when the following conditions are met:

- A single channel is explicitly used (the SPIm.MCSPI_MODULCTRL[0] SINGLE bit is set to 1).
- Turbo mode is enabled in the configuration of the channel. (The SPIm.MCSPI_CHxCONF[19] TURBO bit is set to 1.)

19.5.2.5.3 Turbo Mode

The turbo mode improves the throughput of the SPI interface when a single channel is enabled by allowing transfers until the shift register and the MCSPI_Rxx register are full. The turbo mode is useful (time savings) when a transfer exceeds two words. This mode is programmable per channel (via the SPI1.MCSPI_CHxCONF[9] TURBO bit).

When several channels are enabled, the TURBO bit has no effect and the channel access to the shift registers remains as previously described.

In turbo mode, Rule 1 and Rule 2 applies, but Rule 3 does not (see [Section 19.5.2.2](#)). An enabled channel can be scheduled if its receive register is full (the SPIm.MCSPI_CHxSTAT[0] RXS bit) at the time of the shift-register assignment until the shift register is full.

The MCSPI_RXx register cannot be overwritten in turbo mode. Consequently, the SPIm.MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set in this mode.

19.5.2.6 Start Bit Mode

In start bit mode, an extended bit is added before the SPI word in order to indicate whether the next SPI word must be handled as a command or as data. This feature is only available in master mode. The start bit mode cannot be used at the same time as turbo mode and/or force SPIM_CSX mode. In this case, only one channel can be used; round-robin arbitration is not possible.

This mode is programmable per channel by setting the SPIm.MCSPI_CHxCONF[23] SBE bit to 1. The polarity of the extended bit is programmable per channel. When the SPIm.MCSPI_CHxCONF[24] SBPOL bit is set to 0, the SPI word must be handled as a command. When the SPIm.MCSPI_CHxCONF[24] SBPOL bit is set to 1, the SPI word must be handled as data. Moreover, start-bit polarity can be changed dynamically during start bit transfer without disabling the channel for reconfiguration; in this case, users must configure the SPIm.MCSPI_CHxCONF[24] SBPOL bit before writing the SPI word to be transmitted to the TX register.

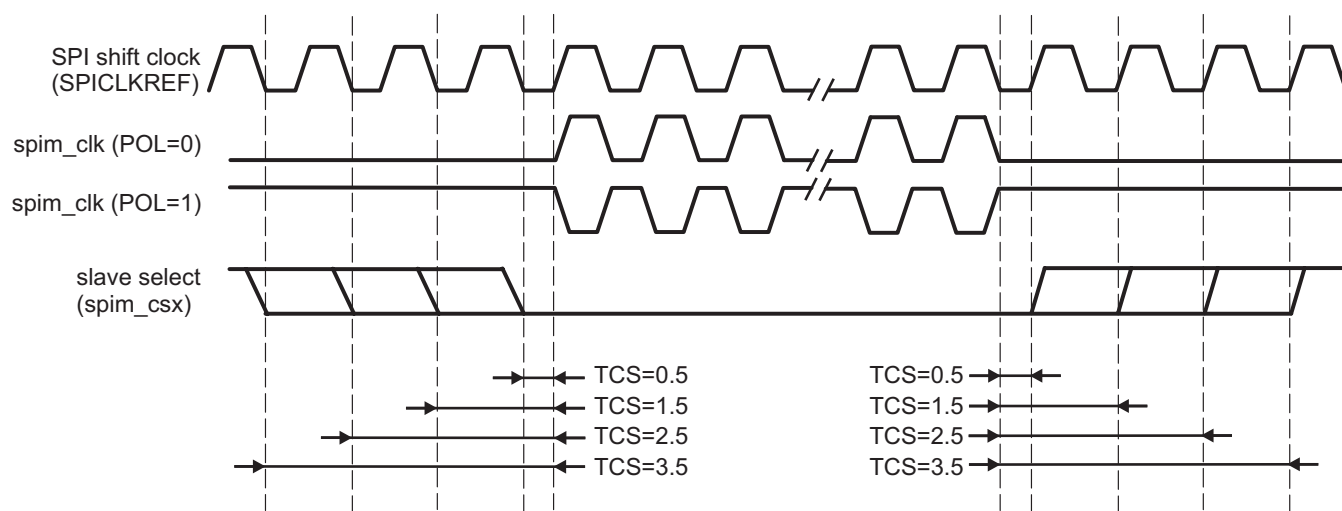

19.5.2.7 Chip-Select Timing Control

The chip select timing control is only available in master mode with automatic chip select generation (MCSPI_MODULCTRL[0] SINGLE bit field set to 0), to add a programmable delay between chip select assertion and first clock edge, or chip select removal and last clock edge.

This mode is programmable per channel (the TCS bit of the SPIm.MCSPI_CHxCONF register).

[Figure 19-17](#) shows the chip-select SPIEN timing control.

Figure 19-17. Chip-Select SPIEN Timing Controls

108-016

Note: Because of the design implementation for transfers using a clock divider ratio set to 1 (clock bypassed), a half cycle must be added to the value between chip-select assertion and the first clock edge with PHA = 1 or between chip-select removal and the last clock edge with PHA = 0.

19.5.2.8 Programmable SPI Clock (spim_clk)

In master mode, the baud rate of the SPI serial clock is programmable.

An internal reference clock, SPIm_FCLK, is used as input of a programmable divider (the SPIm.MCSPI_CHxCONF[5:2] CLKD field) to generate the bit rate of the serial output clock spim_clk. Table 19-11 summarizes the supported divisor values.

Table 19-11. SPI Master Clock Rates

Divider	Bit Rate (Peak)
1	48 Mbps
2	24 Mbps
4	12 Mbps
8	6 Mbps
16	3 Mbps
32	1.5 Mbps
64	750 Kbps
128	375 Kbps
256	~187 Kbps
512	~93.7 Kbps
1024	~46.8 Kbps
2048	~23.4 Kbps
4096	~11.7 Kbps
8192 and higher: division not supported	

19.5.2.8.1 Clock Ratio Granularity

By default the clock division ratio is defined by the SPIm.MCSPI_CHxCONF[5:2] CLKD bit field with power of two granularity leading to a clock division in range 1 to 4096, in this case the duty cycle is always 50%. With the SPIm.MCSPI_CHxCONF[29] CLKG bit, clock division granularity can be changed to one clock cycle, in that case the SPIm.MCSPI_CHxCTRL[15:8] EXTCLK bit field is concatenated with SPIm.MCSPI_CHxCONF[5:2] CLKD bit field to give a 12-bit width division ratio in range 1 to 4096.

When granularity is one clock cycle (CLKG set to 1), for odd value of clock ratio the clock high level lasts one clock cycle more than low level depending on SPIm.MCSPI_CHxCONF[1] POL bit and SPIm.MCSPI_CHxCONF[0] PHA bit refer to Table 19-12.

Table 19-12. CLKSPIO High/Low Time Computation

Clock ratio Fratio	CLKSPIO High Time	CLKSPIO Low Time
1	T _{high_ref}	T _{low_ref}
Even ≥ 2	T _{ref} * (Fratio/2)	T _{ref} * (Fratio/2)
Odd ≥ 3 (POL=PHA)	T _{ref} * (Fratio-1) / 2	T _{ref} * (Fratio+1) / 2
Odd ≥ 3 (POL≠PHA)	T _{ref} * (Fratio+1) / 2	T _{ref} * (Fratio-1) / 2

Note: Fratio = spi1_clk frequency (Fout) division ratio.
 Thigh = spi1_clk High Time period.
 Tlow = spi1_clk Low Time period.
 T_ref = SPI1_FCLK period.
 Thigh_ref = SPI1_FCLK high Time period.
 Tlow_ref = SPI1_FCLK low Time period.

If CLKG = 1: Fratio = EXTCLK concatenated with CLKD + 1 as shown below:

Fratio - 1											
11	10	9	8	7	6	5	4	3	2	1	0
SPI1.[15:8] EXTCLK bit field								SPI1.[5:2] CLKD bit field			
15	14	13	12	11	10	9	8	5	4	3	2

For odd ratio values, the duty cycle is calculated as below:

$$\text{Duty_cycle} = (1 - 1/\text{Fratio})/2$$

Table 19-13 shows clock granularity examples with a clock source frequency of 48 MHz.

Table 19-13. Clock Granularity Examples

EXTCLK	CLKD	CLKG	Fratio	PHA	POL	Thigh (ns)	Tlow (ns)	Tperiod (ns)	Duty Cycle	Fout (MHz)
X	0	0	1	X	X	10.4	10.4	20.8	50-50	48
X	1	0	2	X	X	20.8	20.8	41.6	50-50	24
X	2	0	4	X	X	41.6	41.6	83.2	50-50	12
X	3	0	8	X	X	83.2	83.2	166.4	50-50	6
0	0	1	1	X	X	10.4	10.4	20.8	50-50	48
0	1	1	2	X	X	20.8	20.8	41.6	50-50	24
0	2	1	3	1	0	41.6	20.8	62.4	66-33	16
0	2	1	3	1	1	20.8	41.6	62.4	33-66	16
0	3	1	4	X	X	41.6	41.6	83.2	50-50	12
5	0	1	81	1	0	852.8	832	1684.8	50.6-49.4	0.592
5	7	1	88	X	X	915.2	915.2	1830.4	50-50	0.545

19.5.3 Slave Mode

To select the McSPI slave mode, set the SPI1.MCSPI_MODULCTRL[2] MS bit.

A McSPI slave device can be connected to up to four external SPI master devices but handles transactions with one SPI master device at a time.

In slave mode, the McSPI initiates data transfer on the data lines (spim_simo and spim_somi) when it is selected by an active control signal (SPIM_CSX) and receives an SPI clock (spim_clk) from the external SPI master device. Only channel 0 can be configured as a slave. In slave mode, the McSPI uses the edge of spim_csx to detect word length. For this reason, spim_csx must become inactive between each word.

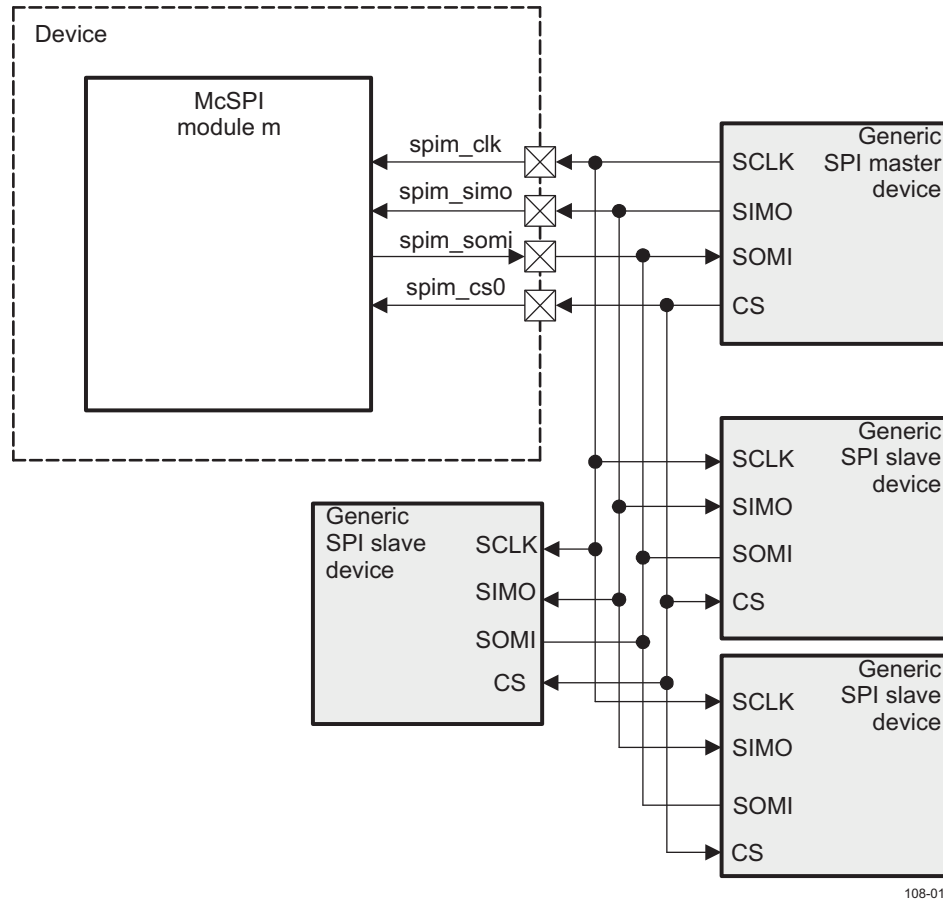

The McSPI does not support spim_csx active between SPI words. It uses the edge to detect word length.

19.5.3.1 Dedicated Resources

Only channel 0 can be enabled in slave mode. In this section registers name such as SPI1.MCSPI_CHxCTRL stand for SPI1.MCSPI_CH0CTRL where x=0 (channel 0 control register).

Figure 19-18 shows an example of four slaves wired on a single master device.

Figure 19-18. Example of McSPI Slave with One Master and Multiple Slave Devices on Channel 0

108-017

The channel 0 in slave mode has the following resources:

- Its own channel enable, programmable with the SPIm.MCSPI_CHxCTRL[0] EN bit (with x=0). This channel must be enabled before transmission and reception.
- For this mode, the slave-select signal can be detected on any one of the SPIM_CSX ports. This is programmable with the SPIm.MCSPI_CHxCONF[22:21] SPIENSLV field (with x=0).
- Its own transmitter register, SPIm.MCSPI_TXx (with x=0), on top of the common transmit shift register. If the MCSPI_TXx register is empty, the SPIm.MCSPI_CHxSTAT[1] TXS bit (with x=0) is set. If McSPI is selected by an external master (the active signal on the SPIM_CSX port assigned to channel 0), the MCSPI_TXx register content of channel 0 is always loaded into the shift register, whether its content is updated or not. The MCSPI_TXx register must be loaded before McSPI is selected by a master.
- Its own receiver register, SPIm.MCSPI_RXx (with x=0), on top of the common receive shift register. If the MCSPI_RXx register is full, the SPIm.MCSPI_CHxSTAT[0] RXS bit (with x=0) is set.

Note: The MCSPI_TXx register and MCSPI_RXx registers of the other channels are not used. Reading from or writing to a channel register other than channel 0 has no effect.

- Its own communication configuration with the following parameters through the SPIm.MCSPI_CHxCONF register (with x=0):
 - Transmit and receive modes, programmable with the TRM field
 - Interface mode (two data pins or single data pin) and data pins assignment, both programmable with the IS and DPE bits. (The SPIm modules are in slave mode after reset and must be properly configured for the modules to act in master mode.)
 - SPI word length, programmable with the WL bit
 - SPIM_CSX polarity, programmable with the EPOL bit

- spim_clk polarity, programmable with the POL bit
- spim_clk phase, programmable with the PHA bit

The spim_clk frequency of a transfer is controlled by the external SPI master connected to the McSPI slave device. The SPIm.MCSPI_CHxCONF[5:2] CLKD field (with x=0) is not used in slave mode.

Note: The configuration of the channel can be loaded in the SPIm.MCSPI_CHxCONF register (with x=0) only when the channel is disabled.

- Two DMA request events, read and write, synchronize read/write accesses of the DMA controller with the activity of McSPI. DMA requests are asserted using the SPIm.MCSPI_CHxCONF[15] DMAR bit (with x=0) for reading and the SPIm.MCSPI_CHxCONF[14] DMAW bit (with x=0) for writing.
- Four interrupt events (see [Section 19.5.5.2, Interrupt Events in Slave Mode](#))

19.5.3.2 Slave Transmit-and-Receive Mode

The slave receive mode is programmable (set the SPIm.MCSPI_CHxCONF[13:12] TRM field (with x=0) to 0x0).

In slave transmit-and-receive mode, the MCSPI_TXx register must be loaded before McSPI is selected by an external SPI master device.

After a channel is enabled, transmission and reception proceed with interrupt and DMA request events.

The MCSPI_TXx register content is always loaded in the shift register whether it is updated or not. The event TXx_UNDERFLOW is activated accordingly and does not prevent transmission.

When an SPI word transfer completes (the SPIm.MCSPI_CHxSTAT0[2] EOT bit (with x=0) set to 1), the received data is transferred to the channel receive register.

To use McSPI as a slave transmit-only device, the RXx_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled due to the MCSPI_RXx register state (see [Section 19.5.5.2, Interrupt Events in Slave Mode](#)).

19.5.3.3 Slave Transmit-Only Mode

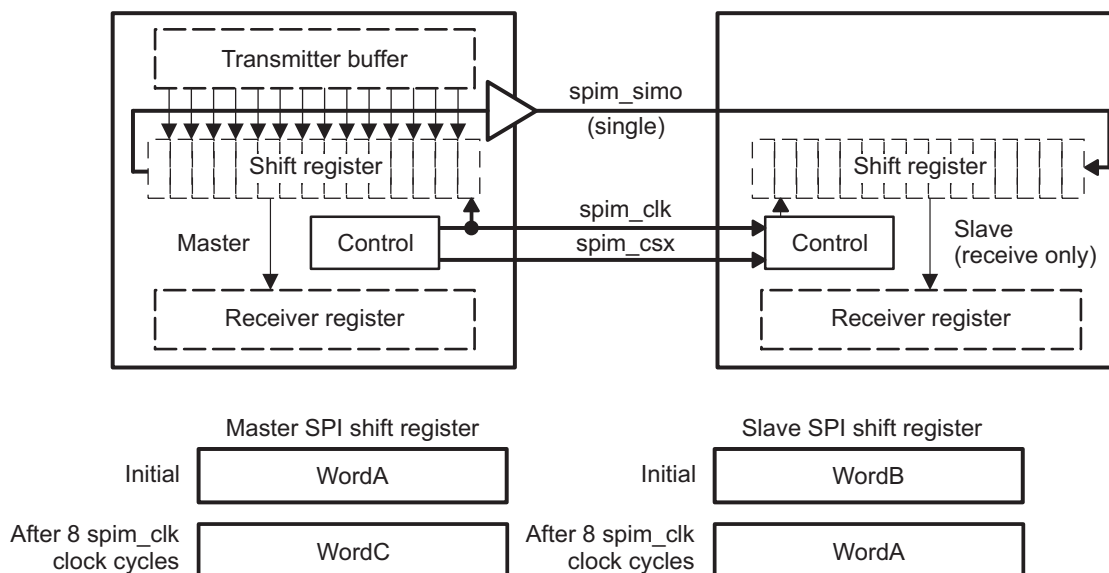

The slave transmit-only mode is programmable (set the SPIm.MCSPI_CHxCONF[13:12] TRM field (with x=0) to 0x2) and avoids the requirement for the MPU to read the MCSPI_RXx register (minimizing data movement) only when transmission is meaningful.

To use the McSPI as a slave transmit-only device, the RXx_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled because of the MCSPI_RXx register state.

When the SPI word transfer completes, the SPIm.MCSPI_CHxSTAT[2] EOT bit is set (with x=0).

[Figure 19-19](#) shows a half-duplex system with a master device on the left and a transmit-only slave device on the right. Each time a bit transfers out from the slave device, 1 bit transfers in the master. After eight cycles of the serial clock spim_clk, WordB transfers from the slave to the master.

Figure 19-20. SPI Half-Duplex Transmission (Receive-Only Slave)

108-032

19.5.4 FIFO Buffer Management

The McSPI controller has a built-in 64 bytes buffer to unload DMA or interrupt handler and improve data throughput.

This buffer can be used by only one channel at once and is selected by setting `SPIm.MCSPI_CHxCONF[28]` FFER bit or `SPIm.MCSPI_CHxCONF[27]` FFEW bit to 1. If several channel are selected and several FIFO enable bitfields set to 1, the controller forces buffer not to be used, it is the responsibility of the driver to set only one FIFO enable bitfield.

The buffer can be used in the modes defined below:

- Master or Slave mode.
- Transmit only, Receive only or Transmit/Receive mode. In Transmit/Receive mode the buffer is used in only one direction data path.
- Single channel or turbo mode, or in normal round robin mode. In round robin mode the buffer is used by only one channel.
- Every word length `SPIm.MCSPI_CHxCONF[11:7]` WL are supported.

In Transmit/Receive mode, the buffer can be use for transmit (see [Figure 19-21](#)) or receive (see [Figure 19-22](#)) directions or for both transmit and receive directions (see [Figure 19-23](#)). In Transmit/Receive mode, if only one direction is chosen, the full buffer is used for this direction. In both directions, the buffer is split into two 32 bytes buffers, one for each direction. See Buffer In Transmit/Receive mode.

Figure 19-21. Buffer Use in Transmit Direction Only

Figure 19-22. Buffer Use in Receive Direction Only

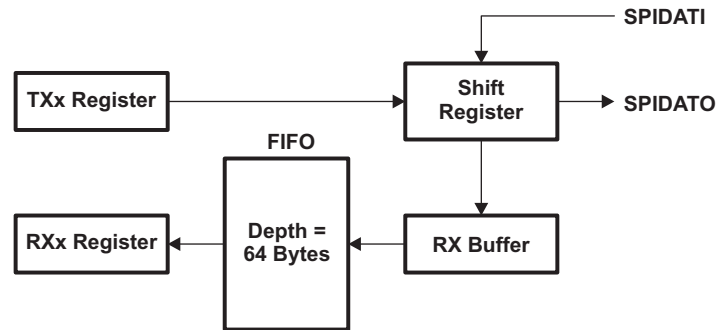

Figure 19-23. Buffer Use in Transmit/Receive Direction

Two levels SPIm.MCSPI_XFERLEVEL[5:0] AEL and SPIm.MCSPI_XFERLEVEL[13:8] AFL rule the buffer management. The granularity of these levels is one byte, then it is not aligned with SPI word length. It is the responsibility of the driver to set these values as a multiple of SPI word length defined in WL. Table 19-14 shows the number of byte written in the FIFO depending on the word length.

Table 19-14. FIFO writes, Word length relationship

SPI Word Length WL	$3 \leq WL \leq 7$	$8 \leq WL \leq 15$	$16 \leq WL \leq 31$
Number of byte written in the FIFO	1 byte	2 bytes	4 bytes

The FIFO buffer pointers are reset when the corresponding channel is enabled or FIFO configuration changes.

19.5.4.1 Buffer Almost Full

The MCSPI_XFERLEVEL[13:8] AFL bit field is needed when the buffer is used to receive SPI word from a slave (MCSPI_CHxCONF[28] FFER bit must be set to 1). It defines the Almost Full buffer status. See Figure 19-24.

When FIFO pointer reaches this level an interrupt or a DMA request is sent to the MPU to enable system to read AFL+1 bytes from Receive register. Be careful AFL+1 must correspond to a multiple value of MCSPI_CHxCONF[11:7] WL bit field.

When DMA is used, the request is de-asserted after the first Receive register read.

No new request will be asserted again as long as system has not performed the right number of read accesses.

Figure 19-24. Buffer Almost Full Level (AFL)

Note: [MCSPI_IRQSTATUS](#) register bits are not available in DMA mode. In DMA mode, the SPI_{Im}_DMA_RXx request is asserted on the same conditions than the [MCSPI_IRQSTATUS](#) RXx_FULL flag.

19.5.4.2 Buffer Almost Empty

The [MCSPI_XFERLEVEL](#)[5:0] AEL bit field is needed when the buffer is used to transmit SPI word to a slave ([MCSPI_CHxCONF](#)[27] FFEW bit must be set to 1). It defines the Almost Empty buffer status. See [Figure 19-25](#).

When FIFO pointer has not reached this level an interrupt or a DMA request is sent to the MPU to enable system to write AEL+1 bytes to Transmit register. Be careful AEL+1 must correspond to a multiple value of [MCSPI_CHxCONF](#)[11:7] WL bit field.

When DMA is used, the request is de-asserted after the first Transmit register write.

No new request will be asserted again as long as system has not performed the right number of write accesses.

Figure 19-25. Buffer Almost Empty Level (AEL)

Note: [MCSPI_IRQSTATUS](#) register bits are not available in DMA mode. In DMA mode, the SPI_{Im}_DMA_TXx request is asserted on the same conditions than the [MCSPI_IRQSTATUS](#) TXx_EMPTY flag.

19.5.4.3 End of Transfer Management

When the FIFO buffer is enabled for a channel, the user shall previously configure in the [MCSPI_XFERLEVEL](#) register the AEL and AFL levels and especially the [MCSPI_XFERLEVEL\[31:16\]](#) WCNT bit field to define the number of SPI words to be transferred using the FIFO before enabling the channel.

This counter allows the controller to stop the transfer correctly after a defined number of SPI word transfers. If WCNT is set to 0x0000, the counter is not used and the user must stop the transfer manually by disabling the channel, in this case the user does not know how many SPI transfers have been done. For received words, software shall poll the CHxSTAT[5] RXFFE bit and read the [MCSPI_RXx](#) Receive register to empty the FIFO buffer.

When the End Of Word count interrupt is generated ([MCSPI_IRQSTATUS\[17\]](#) EOW bit set), the user can disable the channel and poll the [MCSPI_CHxSTAT\[5\]](#) RXFFE bit to know it lasts SPI words in the FIFO buffer and read them.

No new request will be asserted again as long as system has not performed the right number of write accesses.

19.5.5 Interrupts

Each channel can issue interrupt events.

Each interrupt event has status bits in the SPIm.[MCSPI_IRQSTATUS](#) register (RXx_FULL, TXx_UNDERFLOW, TXx_EMPTY, ...) with x = [0,3] that indicate if service is required. Each status bit has an interrupt enable bit (a mask) in the SPIm.[MCSPI_IRQENABLE](#) register (RXx_FULL_ENABLE, TXx_UNDERFLOW_ENABLE, TXx_EMPTY_ENABLE, ...).

When an interrupt occurs and a mask is later applied on it, the interrupt line is not asserted again, even if the interrupt source is not serviced.

The McSPI supports interrupt-driven and polling operations.

19.5.5.1 Interrupt Events in Master Mode

In master mode, the interrupt events related to the [MCSPI_TXx](#) register state are TXx_EMPTY and TXx_UNDERFLOW. The interrupt event related to the [MCSPI_RXx](#) register state is RXx_FULL.

19.5.5.1.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its [MCSPI_TXx](#) register is empty (transient event). Enabling a channel automatically triggers this event, except in master receive-only mode (see [Section 19.5.2.4, Master Receive-Only Mode](#)). When the FIFO buffer is enabled ([MCSPI_CHxCONF\[27\]](#) FFEW bit set to 1), the [MCSPI_IRQSTATUS](#) TXx_EMPTY bit is set as soon as there is enough space in buffer to write a number of bytes defined by the [MCSPI_XFERLEVEL\[5:0\]](#) AEL bit field.

The [MCSPI_TXx](#) register must be loaded with data to remove the source of the interrupt; the SPIm.[MCSPI_IRQSTATUS](#) TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event will be asserted as soon as the MPU has not performed the number of write into the [MCSPI_TXx](#) register defined by [MCSPI_XFERLEVEL\[5:0\]](#) AEL bit field. It is the responsibility of the MPU to perform the right number of writes.

19.5.5.1.2 TXx_UNDERFLOW

The event TXx_UNDERFLOW is activated when the channel is enabled and if the [MCSPI_TXx](#) register or if the FIFO is empty (not updated with new data) when an external master device starts a data transfer with the McSPI (transmit and receive).

The TXx_UNDERFLOW is a harmless warning in master mode.

To avoid having TXx_UNDERFLOW event at the beginning of a transmission, the event TXx_UNDERFLOW is not activated when no data has been loaded into the MCSPI_TXx register since channel has been enabled. To avoid having TXx_UNDERFLOW event, the MCSPI_TXx register must be loaded seldom.

The SPI.MCSPI_IRQSTATUS TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

19.5.5.1.3 RXx_FULL

The RXx_FULL event is activated when channel is enabled and MCSPI_RXx register becomes filled (transient event). When FIFO buffer is enabled (MCSPI_CHxCONF[28] FFER bit set to 1), the RXx_FULL is asserted as soon as the number of bytes holds in the FIFO to be read reaches the MCSPI_XFERLEVEL[13:8] AFL threshold.

The MCSPI_RXx register must be read to remove the source of the interrupt; the MCSPI_IRQSTATUS RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event will be asserted as soon as the MPU has not performed AFL+1 reads into MCSPI_RXx. It is the responsibility of MPU to perform the right number of reads.

19.5.5.1.4 End of Word Count

The MCSPI_IRQSTATUS[17] EOW event (End Of Word count) is activated when channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller had performed the number of transfer defined in the MCSPI_XFERLEVEL[31:16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enable and this interrupt is not generated.

The End of Word count interrupt also indicates that the SPI transfer is halt on channel using the FIFO buffer as soon as MCSPI_XFERLEVEL[31:16] WCNT is not reloaded and the channel is not re-enabled.

The MCSPI_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

19.5.5.2 Interrupt Events in Slave Mode

In slave mode, the interrupt events related to the MCSPI_TXx register state are TXx_EMPTY and TXx_UNDERFLOW. The interrupt events related to the MCSPI_RXx register state are RXx_FULL and RX0_OVERFLOW (channels 1, 2, and 3 do not have a receiver overflow status bit). See the MCSPI_IRQSTATUS register.

19.5.5.2.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its MCSPI_TXx register is empty. Enabling the channel automatically raises this event. If the FIFO buffer is enabled (MCSPI_CHxCONF[27] FFEW bit set to 1), the TXx_EMPTY event is asserted as soon as there is enough space in buffer to write a number of byte defined by the MCSPI_XFERLEVEL[5:0] AEL bit field.

The MCSPI_TXx register must be loaded with data to remove the source of the interrupt; the SPI.MCSPI_IRQSTATUS TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event will be asserted as soon as the MPU has not performed the number of write into the MCSPI_TXx register defined by MCSPI_XFERLEVEL[5:0] AEL bit field. It is the responsibility of the MPU to perform the right number of writes.

19.5.5.2.2 TXx_UNDERFLOW

The TXx_UNDERFLOW event is activated when a channel is enabled and if the MCSPI_TXx register is empty (not updated with new data) when an external master device starts a data transfer with the McSPI (transmit and receive).

When FIFO is enabled, the data emitted while underflow event is raised is not the last data written in the FIFO but the next data in the FIFO (an old transmitted value or a dummy data if the FIFO has been reset).

TXx_UNDERFLOW indicates an error (data loss) in slave mode.

To avoid having a TXx_UNDERFLOW event at the beginning of a transmission, the TXx_UNDERFLOW event is not activated when data is not loaded into the [MCSPI_TXx](#) register because the channel is enabled.

The SPIm.[MCSPI_IRQSTATUS](#) TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

19.5.5.2.3 RXx_FULL

The RXx_FULL event is activated when a channel is enabled and the [MCSPI_RXx](#) register is being filled (transient event). When FIFO buffer is enabled ([MCSPI_CHxCONF](#)[28] FFER bit set to 1), RXx_FULL is asserted as soon as there is a number of bytes holds in buffer to read defined by the [MCSPI_XFERLEVEL](#)[13:8] AFL bit field.

The [MCSPI_RXx](#) register must be read to remove the source of the interrupt; the SPIm.[MCSPI_IRQSTATUS](#) RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event will be asserted as soon as the MPU has not performed AFL+1 reads into [MCSPI_RXx](#). It is the responsibility of MPU to perform the right number of reads.

19.5.5.2.4 RX0_OVERFLOW

The RX0_OVERFLOW event is activated in slave mode in either transmit-and-receive or receive-only mode, when a channel is enabled and the [MCSPI_RXx](#) register or FIFO is full when a new SPI word is received. The [MCSPI_RXx](#) register is always overwritten with the new SPI word. If the FIFO is enabled data within the FIFO are overwritten, it must be considered as corrupted. The RX0_OVERFLOW event should not appear in slave mode using the FIFO.

The RX0_OVERFLOW indicates an error (data loss) in slave mode.

The [MCSPI_IRQSTATUS](#)[3] RX0_OVERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

19.5.5.2.5 End of Word Count

The [MCSPI_IRQSTATUS](#)[17] EOW event (End Of Word count) is activated when channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller had performed the number of transfer defined in the [MCSPI_XFERLEVEL](#)[31:16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The End of Word count interrupt also indicates that the SPI transfer is halt on channel using the FIFO buffer as soon as WCNT is not reloaded and channel re-enabled.

The [MCSPI_IRQSTATUS](#)[17] EOW interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

19.5.5.3 Interrupt-Driven Operation

An interrupt enable bit, in SPIm.[MCSPI_IRQENABLE](#) register, can be set to enable each event to generate interrupt requests when the corresponding event occurs. Status bits are automatically set by hardware logic conditions.

When an event occurs (the single interrupt line is asserted), the MPU must:

- Read the SPIm.[MCSPI_IRQSTATUS](#) register to identify which event occurred.

- Read the [MCSPI_RXx](#) register that corresponds to the event to remove the source of an RXx_FULL event or write into the [MCSPI_TXx](#) register that corresponds to the event to remove the source of a TXx_EMPTY event. No action is required to remove the source of the WKS (wake-up), TXx_UNDERFLOW, and RX0_OVERFLOW events.
- Write 1 into the corresponding bit of the SPI1.[MCSPI_IRQSTATUS](#) register to clear an interrupt status and then release the interrupt line.

The interrupt status bit must always be reset after channel enabling and before events are enabled as interrupt sources.

19.5.5.4 Polling

When the interrupt capability of an event is disabled in the SPI1.[MCSPI_IRQENABLE](#) register, the interrupt line is not asserted, but the status bits in the SPI1.[MCSPI_IRQSTATUS](#) register can be polled by software to detect when the corresponding event occurs.

Once the expected event occurs:

- RXx_FULL: To remove the source of the event, the MPU must read the corresponding [MCSPI_RXx](#) register.
- TXx_EMPTY: To remove the source of the event, the MPU must write into the corresponding [MCSPI_TXx](#) register.
- WKS (wake-up), TXx_UNDERFLOW, and RX0_OVERFLOW: No action is required to remove the source of the event.

To clear an interrupt, set the corresponding status bit of the SPI1.[MCSPI_IRQSTATUS](#) register to 1. This does not affect the interrupt line state.

19.5.6 DMA Requests

The sDMA controller module manages DMA accesses. The sDMA controller advantage is to lower the MPU charge for data transfers.

Each McSPI channel can issue DMA requests if they are enabled. There are two DMA request lines per McSPI channel (one for read and one for write).

The DMA read request line is asserted when the McSPI channel is enabled and new data is available in the receive register of the McSPI channel. A DMA read request can be individually masked with the SPI1.[MCSPI_CHxCONF](#)[15] DMAR bit. The DMA read request line is deasserted on read completion of the [MCSPI_RXx](#) register of the McSPI channel.

The DMA write request line is asserted when the McSPI channel is enabled and the [MCSPI_TXx](#) register of the McSPI channel is empty. A DMA write request can be individually masked with the SPI1.[MCSPI_CHxCONF](#)[14] DMAW bit. The DMA write request line is de-asserted on load completion of the [MCSPI_TXx](#) register of the channel.

19.5.7 Power Saving Management

Power consumption can be optimized by switching off internal clocks (interface and functional clock) when there is no activity. The McSPI is compliant with the idle and wake-up system handshake protocol.

19.5.7.1 Normal Mode

In normal mode, internal SPI module clocks are automatically switched off (autogating) when there is no activity in slave or master mode.

Autogating of the module interface clock and functional clock occurs when the following conditions are met:

- The SPI1.[MCSPI_SYSCONFIG](#)[0] AUTOIDLE bit is set.
- In master mode, there is no data to transmit or receive in all channels.
- In slave mode, the McSPI is not selected by the external master and there are no register accesses.

Autogating of the module interface clock and functional clock stops when the following conditions are met:

- In master mode, an internal access occurs.
- In slave mode, an internal access occurs or the McSPI is selected by the external master.

19.5.7.2 Idle Mode

At the PRCM module level, when all conditions are met to shut off the CORE_48M_FCLK or CORE_L4_ICLK output clocks (see the *Power, Reset, and Clock Management* chapter for details), the PRCM module automatically launches a hardware handshake protocol to ensure that the McSPI is ready to have its clocks switched off. Namely, the PRCM module asserts an idle request to the McSPI.

Although this handshake is completely hardware-oriented and out of software control, the method in which the McSPI module acknowledges the PRCM idle request is configurable through the McSPI.SYSCONFIG[4:3] SIDLEMODE bit.

The following list details the settings of the SIDLEMODE bit and the related acknowledgment modes:

- Force-idle mode (the SPI.MCSPI_SYSCONFIG[4:3] SIDLEMODE bit set to 0x0): the McSPI module acknowledges unconditionally the idle request from the PRCM module, regardless of its internal operations. This mode must be used carefully in this case because it does not prevent the loss of data when the clock is switched off.
- No-idle mode the (SIDLEMODE bit set to 0x1): The McSPI module never acknowledges an idle request from the PRCM module and is secure from a module point of view because it ensures that the clocks remain active. However, it is not efficient to save power because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
- Smart-idle mode (the SIDLEMODE bit set to 0x2): The McSPI module acknowledges the idle request, basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs, or DMA requests are treated. This is the best approach for an efficient system power management.

When configured in smart-idle mode, the McSPI module also offers an additional granularity on the CORE_48M_FCLK and CORE_L4_ICLK gating. The SPI.MCSPI_SYSCONFIG[9:8] CLOCKACTIVITY bit field determines which clock shuts down (the CORE_48M_FCLK, the CORE_L4_ICLK, neither clock, or both clocks).

The CLOCKACTIVITY setting is used internally to McSPI to determine on which part of the module the conditions to acknowledge the PRCM idle request are tested. For example, if CORE_48M_FCLK is not shut down on a PRCM idle request, McSPI considers only CORE_L4_ICLK and the associated pending activities before acknowledging the request.

Some McSPI features are associated with CORE_L4_ICLK and others with CORE_48M_FCLK. Using the CLOCKACTIVITY bit field along with the smart-idle mode ensures that the features associated with the clock that remains active are always enabled, even if McSPI acknowledges an idle request.

The following list details CLOCKACTIVITY settings and the associated features:

- CLOCKACTIVITY set to 00: ICLK OFF and FCLK OFF, both ICLK and FCLK are taken into account for generating the acknowledge. This setting also means that both FCLK and ICLK are likely to be shut down on a PRCM idle request.
- CLOCKACTIVITY set to 01: ICLK ON and FCLK OFF, ICLK is not shut down on a PRCM idle request; only FCLK is concerned.
- CLOCKACTIVITY set to 10: ICLK OFF and FCLK ON, FCLK is not shut down on a PRCM idle request; only ICLK is concerned.
- CLOCKACTIVITY set to 11: ICLK ON and FCLK ON, none of the clocks are shut down. This means McSPI can potentially acknowledge the idle request without checking the internal functionalities linked to its clocks.

CAUTION

The PRCM module does not have a hardware means of reading the CLOCKACTIVITY settings. Therefore, the software must ensure consistent programming between the CLOCKACTIVITY and the PRCM CORE_48M_FCLK and CORE_L4_ICLK control bits. If the McSPI is disabled in both the CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its idle request, which is acknowledged regardless of the features associated with the McSPI clocks. This can lead to unpredictable behavior.

19.5.7.2.1 Wake-Up Event in Smart-Idle Mode

The module wake-up feature is enabled when both the SPIm.MCSPI_SYSCONFIG[2] ENAWAKEUP and SPIm.MCSPI_WAKEUPENABLE[0] WKEN bits are set. Wake-up capability is relevant only when the module is configured in slave mode.

The module generates an asynchronous wake-up request to the system power manager to switch the interface clock and the functional clock back. A wake-up is requested when channel 0 is enabled and an asynchronous selection occurs on the spim.csx port associated with channel 0 (see the definition for the SPIm.MCSPI_CHxCONF SPIENSLV field (with x=0) in the register description table).

After the McSPI wake-up request, the system power manager must reactivate the interface clock:

- *Before the beginning* of the second SPI word serialization when McSPI is in slave transmit-only mode or in slave transmit-and-receive mode
- *Before the end* of the second received SPI word in slave receive-only mode. To avoid data loss, the first received SPI word must be read from the SPIm.MCSPI_RXx register (with x=0) before the completion of the second SPI word serialization.

Table 19-15 lists the supported cases in wake-up mode.

Table 19-15. Smart-Idle Mode and Wake-Up Capabilities

Mode	Interface Clock	SPI Clock Ref	Functionality	Wakeup Event
Master	Must be maintained	Must be maintained	Full functionality, but the module does not generate a new interrupt or DMA request until the system exits wake-up mode.	No wake-up event
Slave	Can be switched off	Can be switched off	An SPI word can be transmitted and/or received, but the module does not generate any new interrupts or DMA requests until the system exits wake-up mode.	The module asynchronously sends a wake-up request if an event on the SPIM_CSX port associated to channel 0 is detected.

In wake-up mode, the interrupt and DMA request lines are no longer asserted.

Any access to the module in wake-up mode generates an error as long as the interface clock is alive.

19.5.7.2.2 Transitions from Smart-Idle Mode to Normal Mode

The McSPI detects the end of the wake period through the idle and wake-up hardware handshake protocol.

The interrupt status register (the SPIm.MCSPI_IRQSTATUS[16] WKS bit) is updated with the event causing the wake-up; the wake-up event at the origin of the transition to the normal mode is converted to its corresponding interrupt when enabled by the SPIm.MCSPI_IRQENABLE[16] WKE bit or the DMA request.

Interrupts and wake-up events have independent enable/disable controls, accessible through the SPIm.MCSPI_IRQENABLE and SPIm.MCSPI_WAKEUPENABLE registers. Software must ensure the overall consistency.

The interrupt status register SPIm.MCSPI_IRQSTATUS is updated with the event causing the wake-up; the wake-up event at the origin of the transition to normal mode is converted to its corresponding interrupt request or DMA request. The module is fully operational.

19.5.7.2.3 Force-Idle Mode

Force-idle mode is enabled and exited as follows:

- Force-idle mode is enabled when the SPIm.MCSPI_SYSCONFIG[4:3] SIDLEMODE field is set to 0x0. In force-idle mode, McSPI responds unconditionally to the idle request by deasserting unconditionally the interrupt and DMA request lines, if asserted. In addition, the wake-up capability is totally inhibited even if both the SPIm.MCSPI_SYSCONFIG[2] ENAWAKEUP and SPIm.MCSPI_WAKEUPENABLE[0] WKEN bits are set.

The transition from normal mode to idle mode does not affect the interrupt event bits of the SPIm.MCSPI_IRQSTATUS register.

In force-idle mode, the module must be disabled so the interrupt and DMA request lines are likely deasserted. The interface clock and SPI clock provided to the McSPI can be switched off.

An idle request during an SPI data transfer can lead to an unexpected and unpredictable result. The software must avoid such a request.

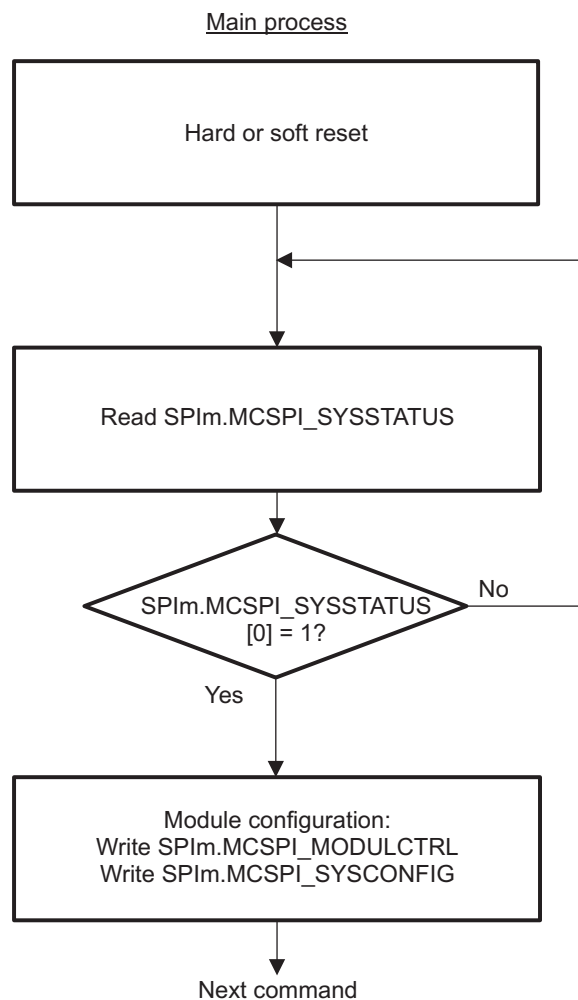

- The module exits force-idle mode through the idle and wake-up hardware handshake protocol. The module is fully operational. The interrupt and DMA request lines are optionally asserted one clock cycle later.

19.6 McSPI Basic Programming Model

19.6.1 Initialization of Modules

Figure 19-26 shows the overview of the module initialization flow process. Section 19.6.2 and Section 19.6.3 show the steps required to configure McSPI modes.

Figure 19-26. Module Initialization Flow

108-018

Note: Before the SPIm.MCSPI_SYSSTATUS[0] RESETDONE bit is set, the CLK and CLKSPIREF clocks must be provided to the module.

To avoid unpredictable behavior, reset the module before changing from master mode to slave mode, or vice versa.

19.6.2 Transfer Procedures without FIFO

In the subsections below, the transfer procedures are described without FIFO using (MCSPI_CHxCONF[27:28] FFER and FFEW = 0).

The McSPI allows the transfer of one or more words based on the different modes:

- Master normal, master turbo, slave
- Transmit-and-receive, transmit-only, receive-only
- Write and read requests: Interrupts, DMA

- spi1_csx line assertion/deassertion: Automatic, manual

For these flows, the host process contains the main process and the interrupt routines. The interrupt routines are called on the interrupt signals or by an internal call if the module is used in polling mode.

19.6.2.1 Common Transfer Procedure

Figure 19-27 shows the main sequence common to all transfers. In multichannel master mode, the flows of different channels can be run simultaneously.

Figure 19-27. Common Transfer Sequence: Main Process

108-030

19.6.2.2 End-of-Transfer Procedure

For transfers carried out with DMA or interrupt mode, the end of transfer must be achieved by following the steps shown in the flowcharts corresponding to Table 19-16, which summarizes the end-of-transfer types per transfer mode and provides cross-references for further information.

Table 19-16. End-of-Transfer Sequences

		Transmit Receive		Transmit Only		Receive Only	
		Interrupt	DMA	Interrupt	DMA	Interrupt	DMA
Master normal	End of transfer sequence	See Section 19.6.2.3		See Section 19.6.2.4	See Section 19.6.2.4	See Section 19.6.2.5.1	See Section 19.6.2.5.1
	Minimum number of words	1	1	1	1	1	1
	DMA transfer size ⁽¹⁾		w		w		w – 1
Master turbo	End of transfer sequence	See Section 19.6.2.3		See Section 19.6.2.4	See Section 19.6.2.4	See Section 19.6.2.5.2	See Section 19.6.2.5.2
	Minimum number of words	1	1	1	1	2	3
	DMA transfer size ⁽¹⁾		w		w		w – 2
Slave	End of transfer sequence	See Section 19.6.2.3		See Section 19.6.2.4	See Section 19.6.2.4	See Section 19.6.2.5.3	
	Minimum number of words	1	1	1	1	1	1
	DMA transfer size ⁽¹⁾		w		w	w	w

⁽¹⁾ w = number of words to transfer

The different sequences can be merged in one process to manage transfers of several types. The end-of-transfer sequences are described from the start of the channel.

In these sequences and in later sections of this chapter, some software variables are used:

- WRITE_COUNT (= 0 at initialization): Contains the number of words to transfer
- READ_COUNT (= 0 at initialization): Contains the number of words to receive
- CHANNEL_ENABLE (= false at initialization)
- LAST_TRANSFER (= false at initialization): Indicates that the last word is in transmission
- LAST_REQUEST (= false at initialization): Indicates that the last request is in progress

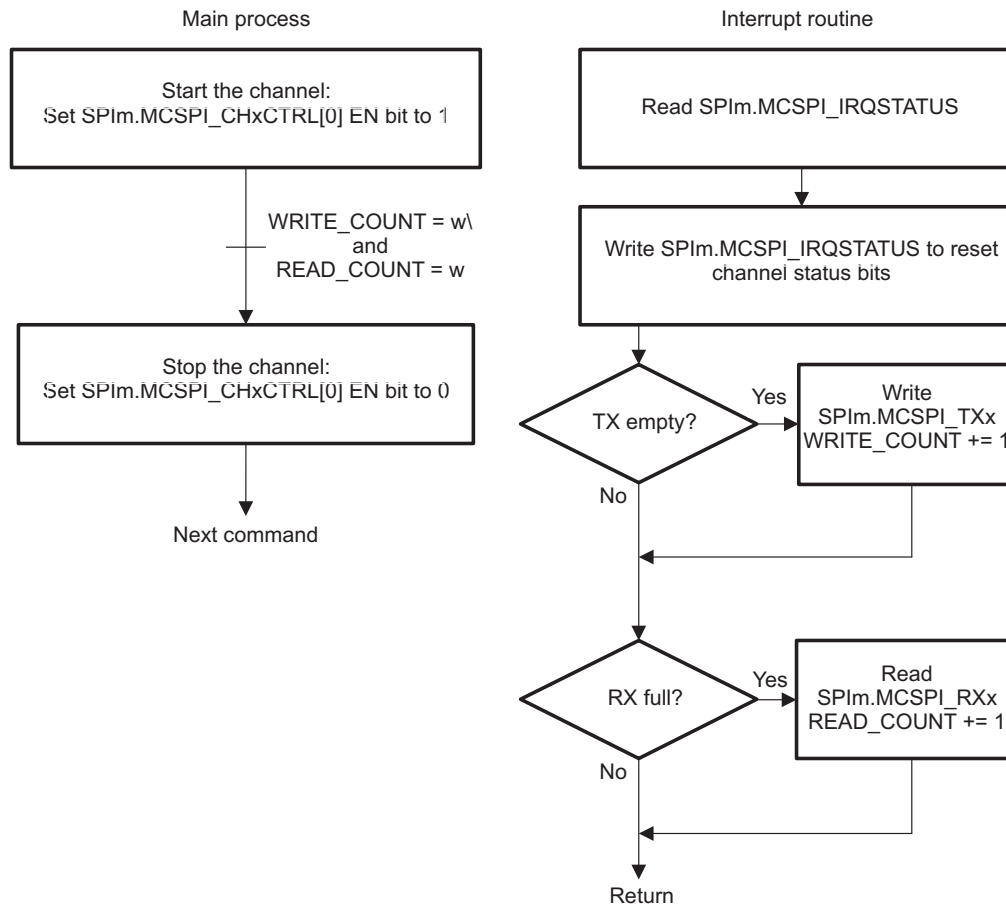

All variables are initialized before starting the channel.

19.6.2.3 Transmit and Receive Procedure

Figure 19-28 shows the handling procedure for words received and transmitted by interrupt in master and slave modes. The main process flow shows how the end of the transfer must be done after all words are received for this mode.

If the requests are configured in DMA, WRITE_COUNT and READ_COUNT are assigned with the value w when the DMA handler completes w interface accesses.

Figure 19-28. Transmit and Receive (Master and Slave)

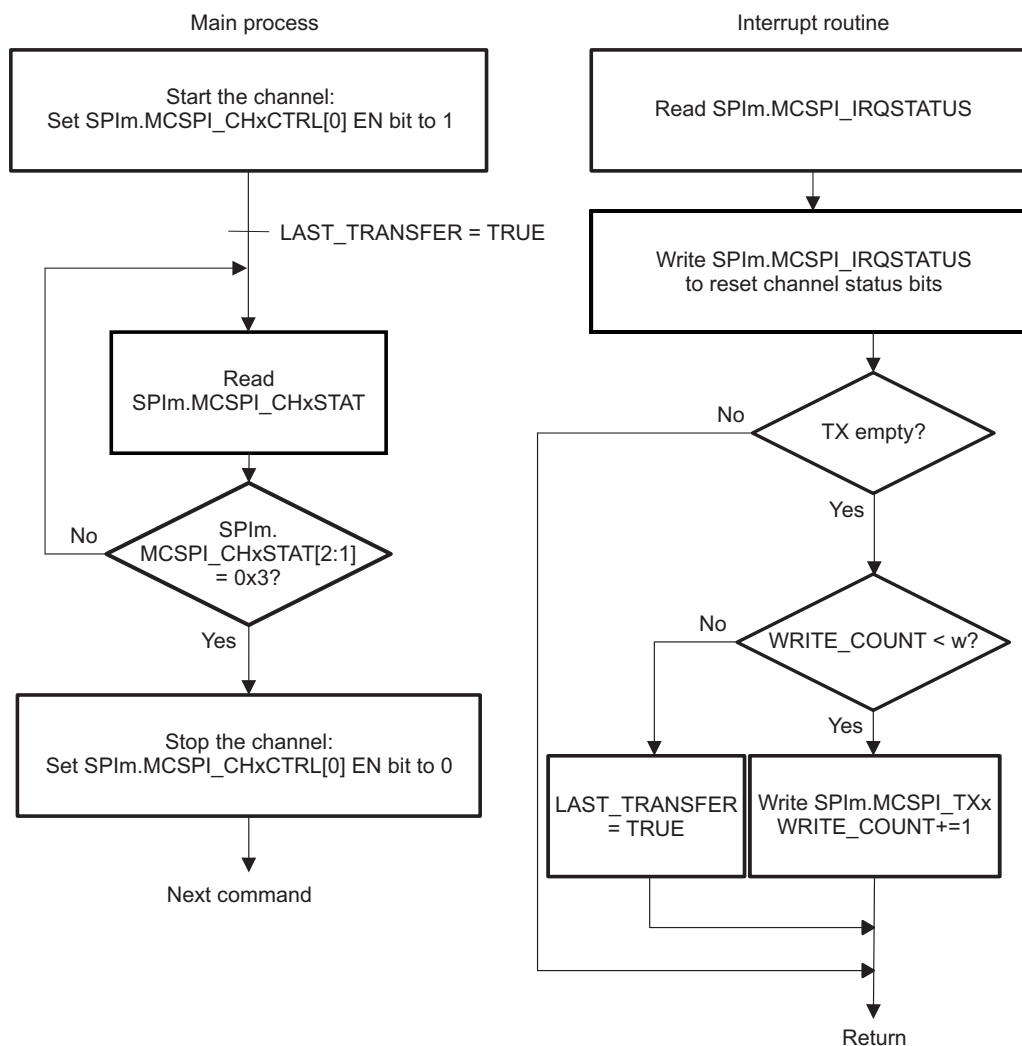

108-033

19.6.2.4 Transmit-Only Procedure

19.6.2.4.1 Based on Interrupt Requests

Figure 19-29 shows the handling procedure for words transmitted by interrupt in transmit-only mode. The main process flow shows how the end-of-transfer must be done after all words are received for this mode.

Figure 19-29. Transmit-Only with Interrupts (Master and Slave)

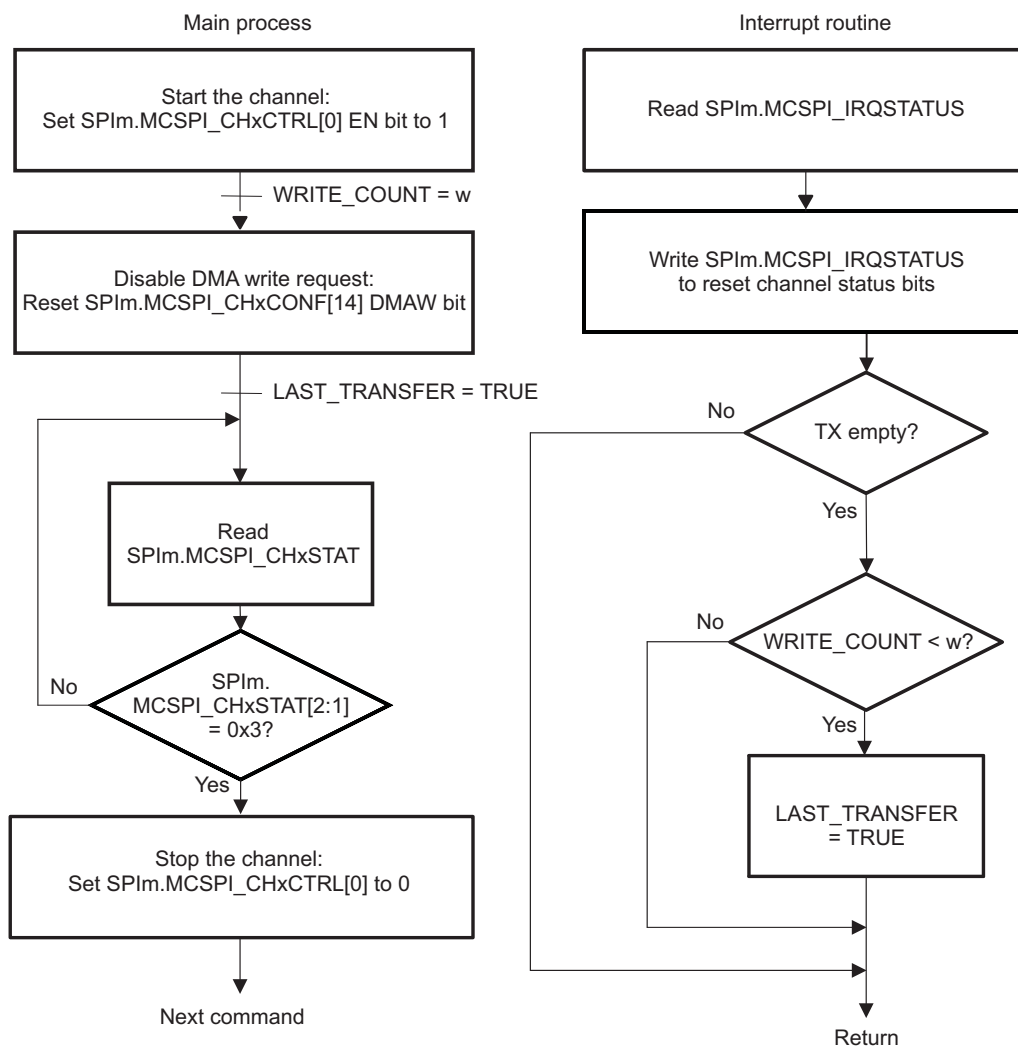

108-023

19.6.2.4.2 Transmit-Only Based on DMA Write Requests

In Figure 19-30, the main process shows completion of the transfer of words in transmit-only mode with DMA write requests.

When the DMA handler completes w interface accesses, WRITE_COUNT is assigned the value w .

Figure 19-30. Transmit-Only with DMA (Master and Slave)

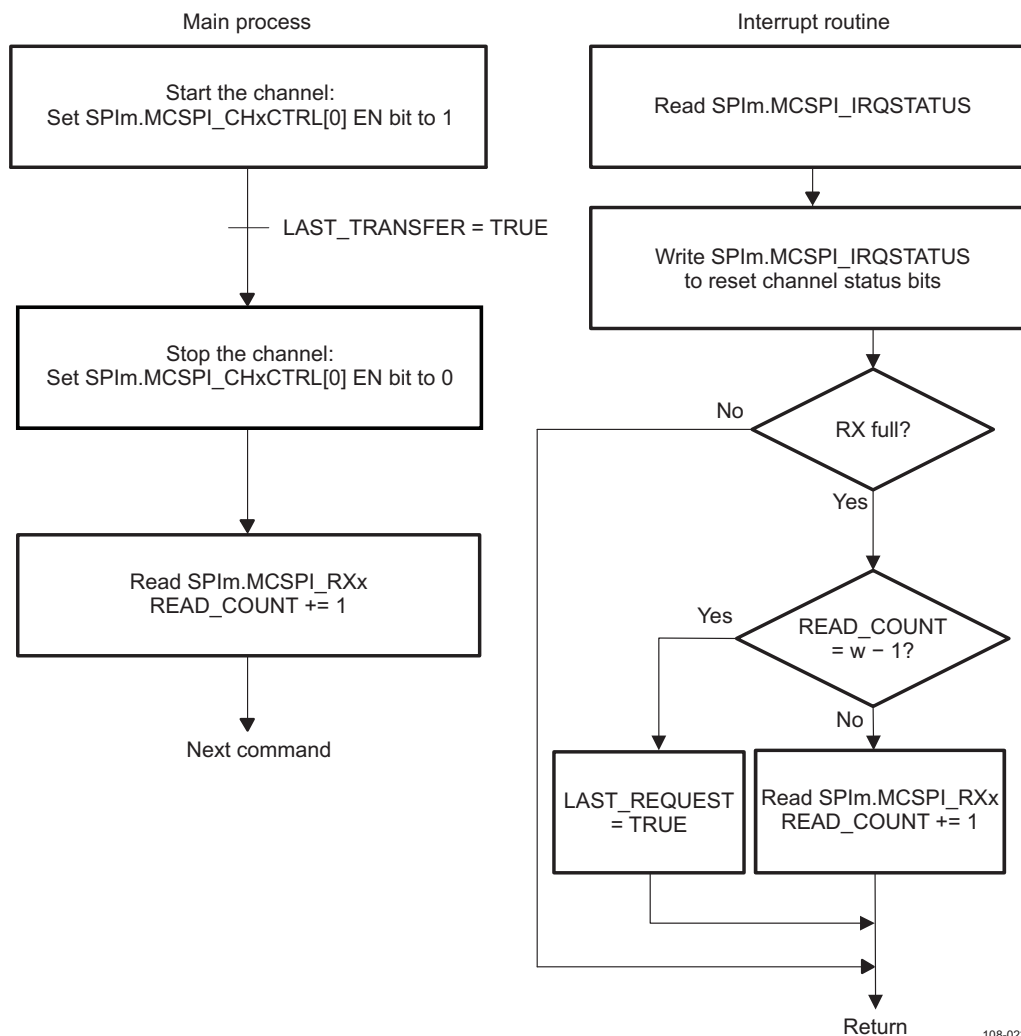

108-024

19.6.2.5 Receive-Only Procedure

19.6.2.5.1 Master Normal Receive-Only Procedure

19.6.2.5.1.1 Based on Interrupt Requests

Figure 19-31 shows the handling procedure for words received by interrupt in master normal receive-only mode. The main process flow shows how the end-of-transfer must be done after all words are received for this mode.

Figure 19-31. Receive Only with Interrupt (Master Normal)

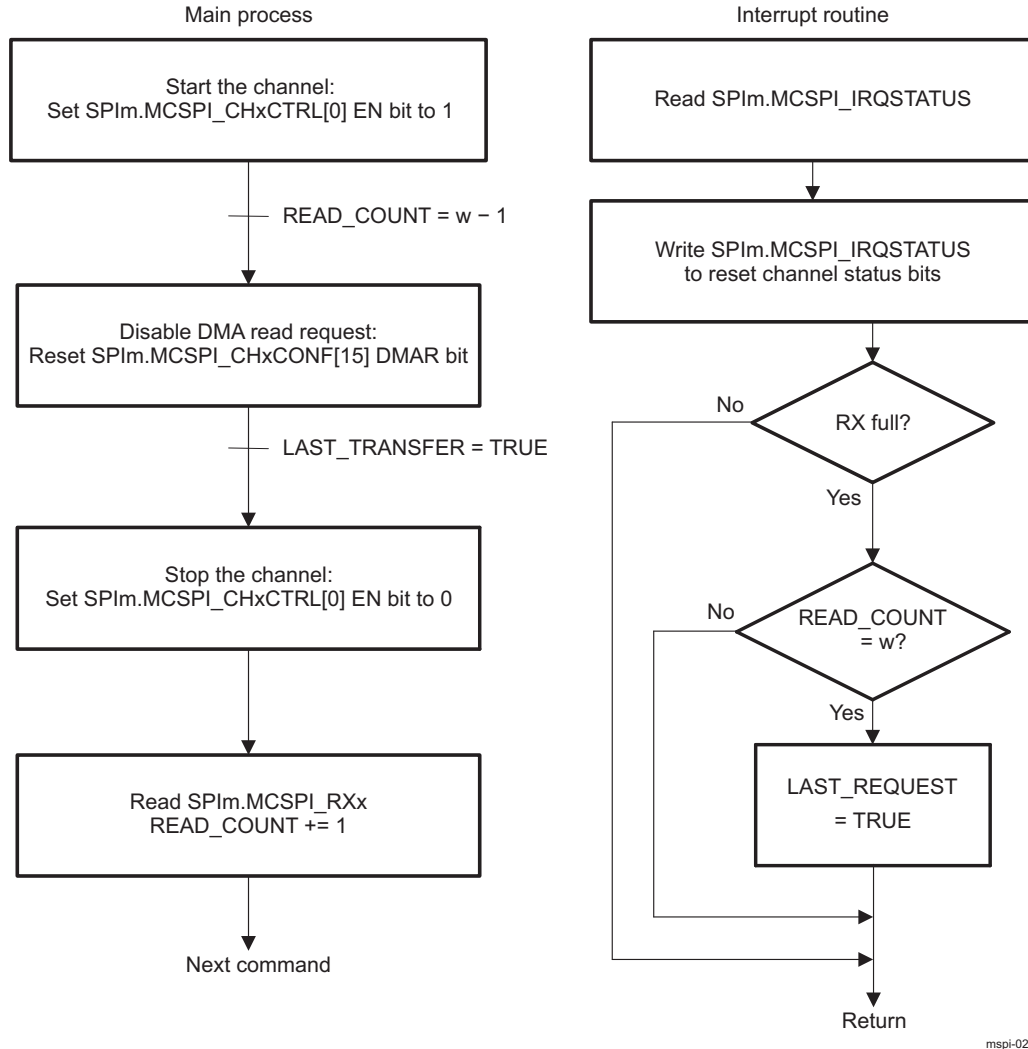

108-022

19.6.2.5.1.2 Receive-Only Based on DMA Read Requests

In [Figure 19-32](#), the main process shows the completion of a word transfer in receive-only mode with DMA read requests.

When the DMA handler completes $w - 1$ interface accesses, **READ_COUNT** is assigned the value $w - 1$.

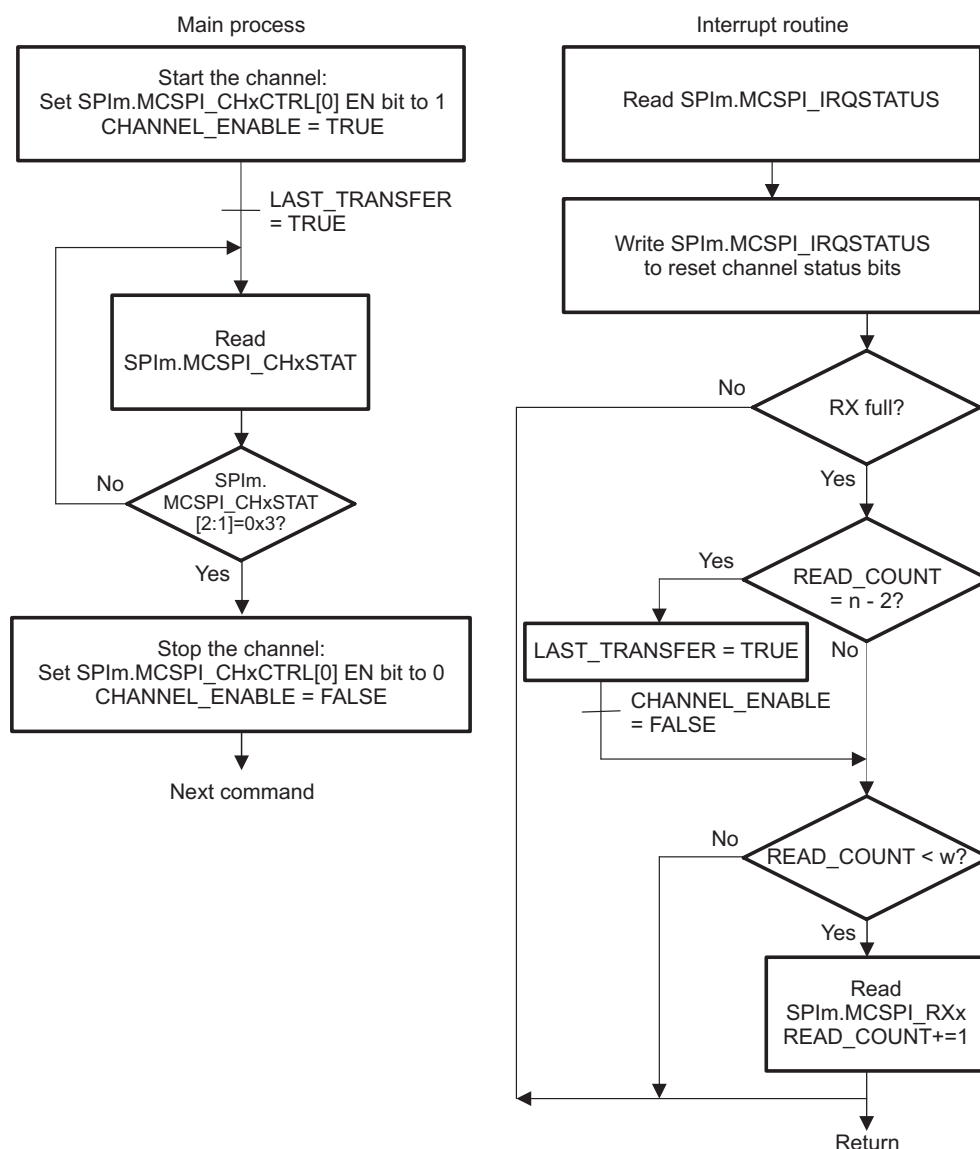

Figure 19-32. Receive-Only with DMA (Master Normal)

19.6.2.5.2 Master Turbo Receive-Only Procedure

19.6.2.5.2.1 Based on Interrupt Requests

Figure 19-33 shows the handling procedure for words received by interrupt in master turbo receive-only mode. The main process shows how the end-of-transfer must be done after all words are received for this mode.

Figure 19-33. Receive-Only with Interrupt (Master Turbo)

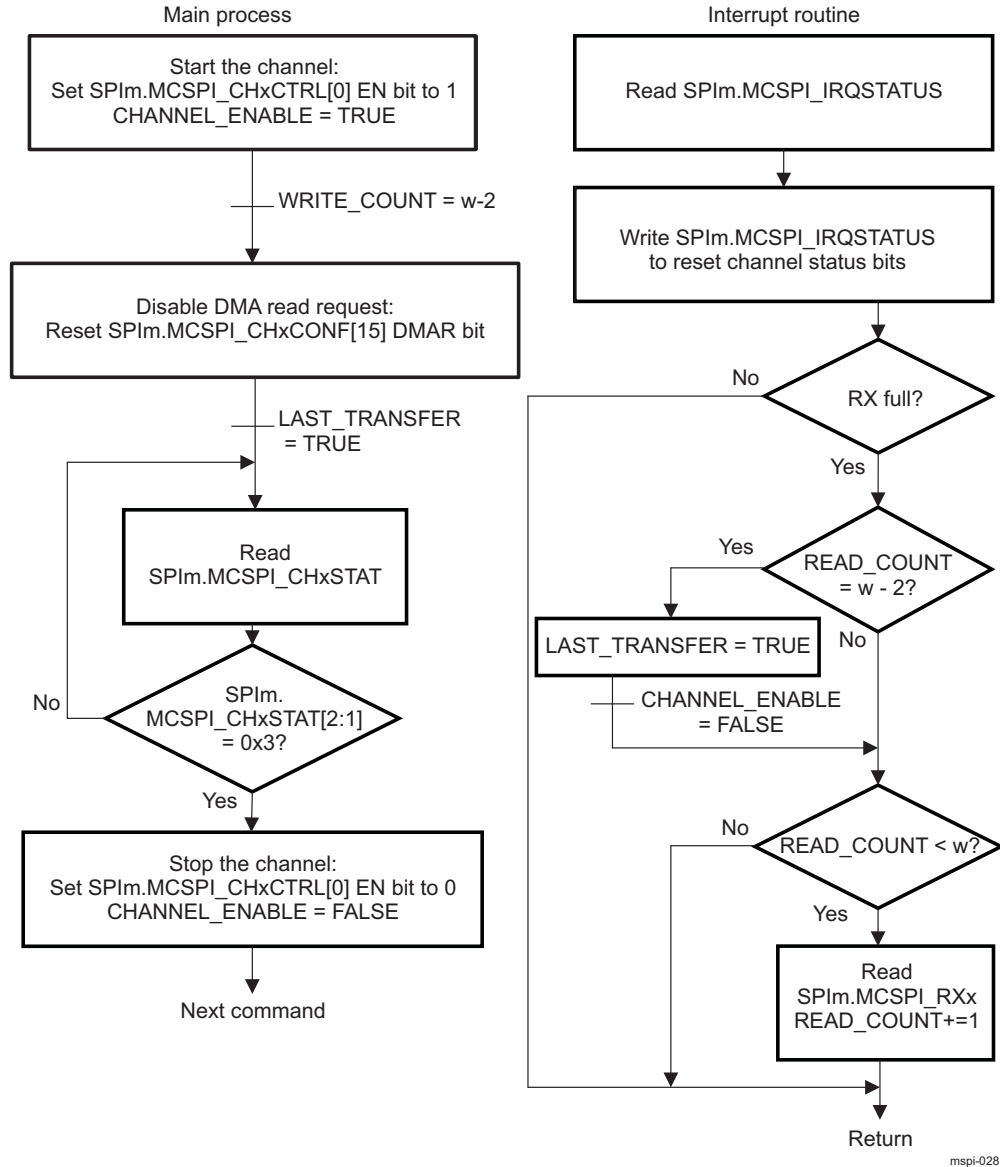

108-027

19.6.2.5.2.2 Based on DMA Read Requests

In [Figure 19-34](#), the main process shows the completion of a word reception in master turbo receive-only mode with DMA write requests.

When the DMA handler completes $w - 2$ interface accesses, `READ_COUNT` is assigned the value $w - 2$.

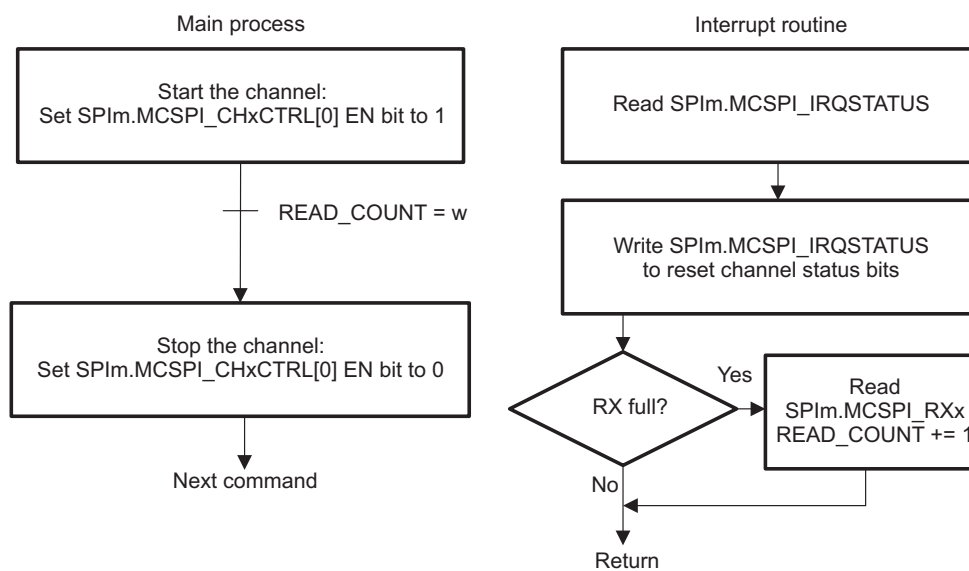

Figure 19-34. Receive-Only with DMA (Master Turbo)

19.6.2.5.3 Slave Receive-Only Procedure

Figure 19-35 shows the handling procedure for words received by interrupt in slave receive-only mode. The main process shows how the end-of-transfer must be done after all words are received for this mode.

If the requests are configured in DMA, READ_COUNT is assigned the value w when the DMA handler completes w interface processes.

Figure 19-35. Receive Only (Slave)

108-035

19.6.2.6 McSPI Configuration and Operations Example

This section details an example of a typical configuration.

Figure 19-36 shows an implementation of successive transfers between two devices (slave) and the McSPI1 (master) in transmit-and-receive mode.

McSPI1 is the master, and spi1_simo shifts out the data to the external slaves. spi1_somi is connected to the data output port of two slave devices. The McSPI1 controls the first device with the spi1_cs0 signal (active low) for the exchange of 9-bit words synchronized with an active-high SPI clock.

The second device is controlled by the spi1_cs1 control signal (active high) for the exchange of 4-bit words synchronized with a SPI clock (active low) with a slower frequency than used with the first slave device.

Figure 19-36. Two SPI Transfers with PHA = 0 (Flexibility of McSPI)

mcspi-036

This section details the steps required for this type of transmission.

19.6.2.6.1 McSPI Initialization Sequence

As shown in Figure 19-26, the McSPI module must first reset all registers and all state-machines.

For a software reset:

1. Set the SPI1.MCSPI_SYSCONFIG[1] SOFTRESET bit to 1.
2. Read the SPI1.MCSPI_SYSSTATUS[0] RESETDONE bit and check that it is set to 1.

19.6.2.6.2 Operations for the First Slave (On Channel 0)

19.6.2.6.2.1 Programming in Polling Mode

19.6.2.6.2.1.1 Mode Selection

The SPI1.MCSPI_CHxCONF register (with x = 0) allows configuration of the operating mode:

1. Set the SPI1.MCSPI_CHxCONF[18] IS bit to 0 for the spi1_somi pin in receive mode.
2. Set the SPI1.MCSPI_CHxCONF[17] DPE1 bit to 0 and the SPI1.MCSPI_CHxCONF[16] DPE0 bit to 1 for the spi1.simo pin in transmit mode.
3. Set the SPI1.MCSPI_CHxCONF[13:12] TRM field to 0x0 for transmit and receive mode.
4. Write 0x8 in the SPI1.MCSPI_CHxCONF[11:7] WL field for 9-bit word length.

5. Set the SPI1.MCSPI_CHxCONF[6] EPOL bit to 1 for spi1_cs0 activated low during active state.
6. Set the SPI1.MCSPI_CHxCONF[1] POL bit to 0 for spi1_clk held high during active state.
7. Set the SPI1.MCSPI_CHxCONF[0] PHA bit to 0 for data latched on odd-numbered edges of the SPI clock.

Clock Initialization and spi1_cs0 Enable

In master mode, the SPI must provide the clock and enable the channel:

8. Set the SPI1.MCSPI_MODULCTRL[2] MS bit to 0 to provide the clock.
9. Set the SPI1.MCSPI_CHxCTRL[0] EN bit to 1 (where x = 0) to enable channel 0.

19.6.2.6.2.1.2 Write Operation

1. Write 1 to the SPI1.MCSPI_IRQSTATUS[0] TX0_EMPTY bit to reset the status.
2. Write the command/address or data value in the SPI1.MCSPI_TX0 register to transmit the value.
3. If the SPI1.MCSPI_IRQSTATUS[0] TX0_EMPTY bit is set to 1, write 1 to it and return to Step 2 (polling method).

19.6.2.6.2.1.3 Read Operation

1. Read the SPI1.MCSPI_IRQSTATUS[2] RX0_FULL bit and if it is set to 1, go to Step 2.
2. If the SPI1.MCSPI_IRQSTATUS[2] RX0_FULL bit is set to 1, write 1 to it and return to Step 1 (polling method).

Note: Write and read operations can be performed simultaneously.

19.6.2.6.3 Programming in Interrupt Mode

This section follows the flow of [Figure 19-26](#).

1. Initialize software variables: WRITE_COUNT = 0 and READ_COUNT = 0.
2. Initialize interrupts: Write 0x7 in the SPI1.MCSPI_IRQSTATUS[3:0] field and set the SPI1.MCSPI_IRQENABLE[3:0] field to 0x7.
3. Follow the steps described in [Section 19.6.2.6.2.1.1, Mode Selection](#).
4. If WRITE_COUNT = w and READ_COUNT = w, write SPI1.MCSPI_CHxCTRL[0] = 0x0 (x = 0) to stop the channel.

This interrupt routine follows the flow of [Table 19-16](#) and [Figure 19-28](#).

1. Read the SPI1.MCSPI_IRQSTATUS[3:0] field.
2. If the SPI1.MCSPI_IRQSTATUS[0] TX0_EMPTY bit is set to 1:
 - a. Write the command/address or data value in SPI1.MCSPI_TXx (where x = 0).
 - b. WRITE_COUNT += 1
 - c. Write SPI1.MCSPI_IRQSTATUS[0] = 0x1.
3. If the SPI1.MCSPI_IRQSTATUS[2] RX0_FULL bit is set to 1:
 - a. Read SPI1.MCSPI_RXx (where x = 0)
 - b. READ_COUNT += 1
 - c. Write SPI1.MCSPI_IRQSTATUS[2] = 0x1

19.6.2.6.4 Operations for the Second Slave (Channel 1) in Polling Mode

19.6.2.6.4.1 Mode Selection

The SPI1.MCSPI_CHxCONF register (with x = 1) allows configuration of the operating mode:

1. Set the SPI1.MCSPI_CH1CONF[18] IS bit to 0 for the spi1_somi pin in receive mode.
2. Set the SPI1.MCSPI_CH1CONF[17] DPE1 bit to 0 and the SPI1.MCSPI_CH1CONF[16] DPE0 bit to 1 for the spi1_somi pin in transmit mode.
3. Set the SPI1.MCSPI_CH1CONF[13:12] TRM field to 0x0 for transmit-and-receive mode.

4. Write 0x3 in the SPI1.MCSPI_CH1CONF[11:7] WL field.
5. Set the SPI1.MCSPI_CH1CONF[6] EPOL bit to 0 for spi1_cs1 activated high during the active state.
6. Set the SPI1.MCSPI_CH1CONF[1] POL bit to 1 for spi1_clk held low during the active state.
7. Set the SPI1.MCSPI_CH1CONF[0] PHA bit to 1 for data latched on even numbered edges of spi1_clk.

Clock Initialization and spi1_cs1 Enable

The SPI1.MCSPI_MODULCTRL[2] MS bit was set to 0 (providing the clock).

In master mode, the SPI must provide the clock and enable the channel:

8. Set the SPI1.MCSPI_CH0CTRL[0] EN bit to 0 to disable channel 0, and set the SPI1.MCSPI_CH1CTRL[0] EN bit to 1 to enable channel 1.

Note: Read and write operations for the second slave are identical to those for the first slave.

19.6.2.6.4.2 Write Operation

1. Write 1 to the SPI1.MCSPI_IRQSTATUS[4] TX1_EMPTY bit to reset the status.
2. Write the command/address or data value in the SPI1.MCSPI_TX1 register to transmit the value.
3. If the SPI1.MCSPI_IRQSTATUS[4] TX1_EMPTY bit is set to 1, write 1 to it and return to Step 2 (polling method).

19.6.2.6.4.3 Read Operation

1. Read the SPI1.MCSPI_IRQSTATUS[6] RX1_FULL bit and if it is set to 1, go to Step 2.
2. If the SPI1.MCSPI_IRQSTATUS[6] RX1_FULL bit is set to 1, write 1 to it and return to Step 1 (polling method).

Note: Write and read operations can be performed simultaneously.

19.6.3 Transfer Procedures with FIFO

In the subsections below, the transfer procedures are described with FIFO using (MCSPI_CHxCONF[27:28] FFER or/and FFEW = 1).

The MCSPI module allows the transfer of one or more words, according to different modes:

- Master normal, master turbo, slave
- Transmit-and-receive, transmit-only, receive-only
- Write and read requests: Interrupts, DMA

For these flows, the host process contains the main process and the interrupt routine, which is called on the IRQ signals or by an internal call if the module is used in polling mode.

19.6.3.1 Common Transfer Procedure

The common transfer sequence is the host sequence for a transfer of any type defined above.

In multichannel, only one channel can use the FIFO. Before enabling the FIFO for a channel (FFExW and FFExR bits in the MCSPI_CHx_CONF register), the host must ensure that the FIFO is not enabled for another channel, even if these channels are not used.

In transmit/receive mode, the FIFO can be enabled for write or read request only, without FIFO for the other request.

In slave mode, only channel 0 only can be activated. The correct SPIM_CSX line is chosen in the MCSPI_CH0CONF register with the SPIENSLV bits.

The MCSPI module can start the transfer only when the first write request is released by writing the MCSPI_TXx register, even in receive-only mode (only one write request occurs in this case). [Figure 19-37](#) shows the main process of the common transfer sequence.

Figure 19-37. Common Transfer Sequence/Main Process

mcspi-041

The MCSPI module can start the transfer only after the first write request is released by writing the [MCSPI_TXx](#) register, even in receive-only mode (only one write request occurs in this case).

This first write request can be managed by the IRQ routine or DMA handler, as are as other requests. It appears in [Figure 19-37](#) to show this point.

The end of the transfer (dotted line in [Figure 19-37](#)) is more complex and depends on the transfer type. [Table 19-17](#) describes the different types of end-of-transfer and the transfer types to which they are applicable.

Table 19-17. End-of-Transfer Types

Word Count	Transmit/Receive	Transmit Only	Receive Only
Yes	See Section 19.6.3.2 , <i>Transmit-Receive With Word Count.</i>	See Section 19.6.3.4 , <i>Transmit-Only.</i>	See Section 19.6.3.5 , <i>Receive-Only With Word Count.</i>
No	See Section 19.6.3.3 , <i>Transmit-Receive Without Word Count.</i>	See Section 19.6.3.4 , <i>Transmit-Only.</i>	See Section 19.6.3.6 , <i>Receive-Only Without Word Count.</i>

The sequence differs depending on whether word count is used ([MCSPI_XFERLEVEL](#): WCNT is set or not). The AEL and/or AFL values can be different, but they must be multiples of the word size in the FIFO: 1, 2, or 4 bytes, according to word length.

In these sequences, the transfer to execute has a size of N words.

When accessing the FIFO, only one word is written or read for each OCP access.

In these sequences, the number of words written or read for each write or read FIFO request is:

- write_request_size
- read_request_size

If they are not submultiples of N, the last request sizes are:

- last_write_request_size (< write_request_size)
- ast_read_request_size. (< read_request_size)

The different sequences can be merged in one process to manage transfers of several types.

The end-of-transfer sequences are described from the start of the channel.

In these sequences, some soft variables are used:

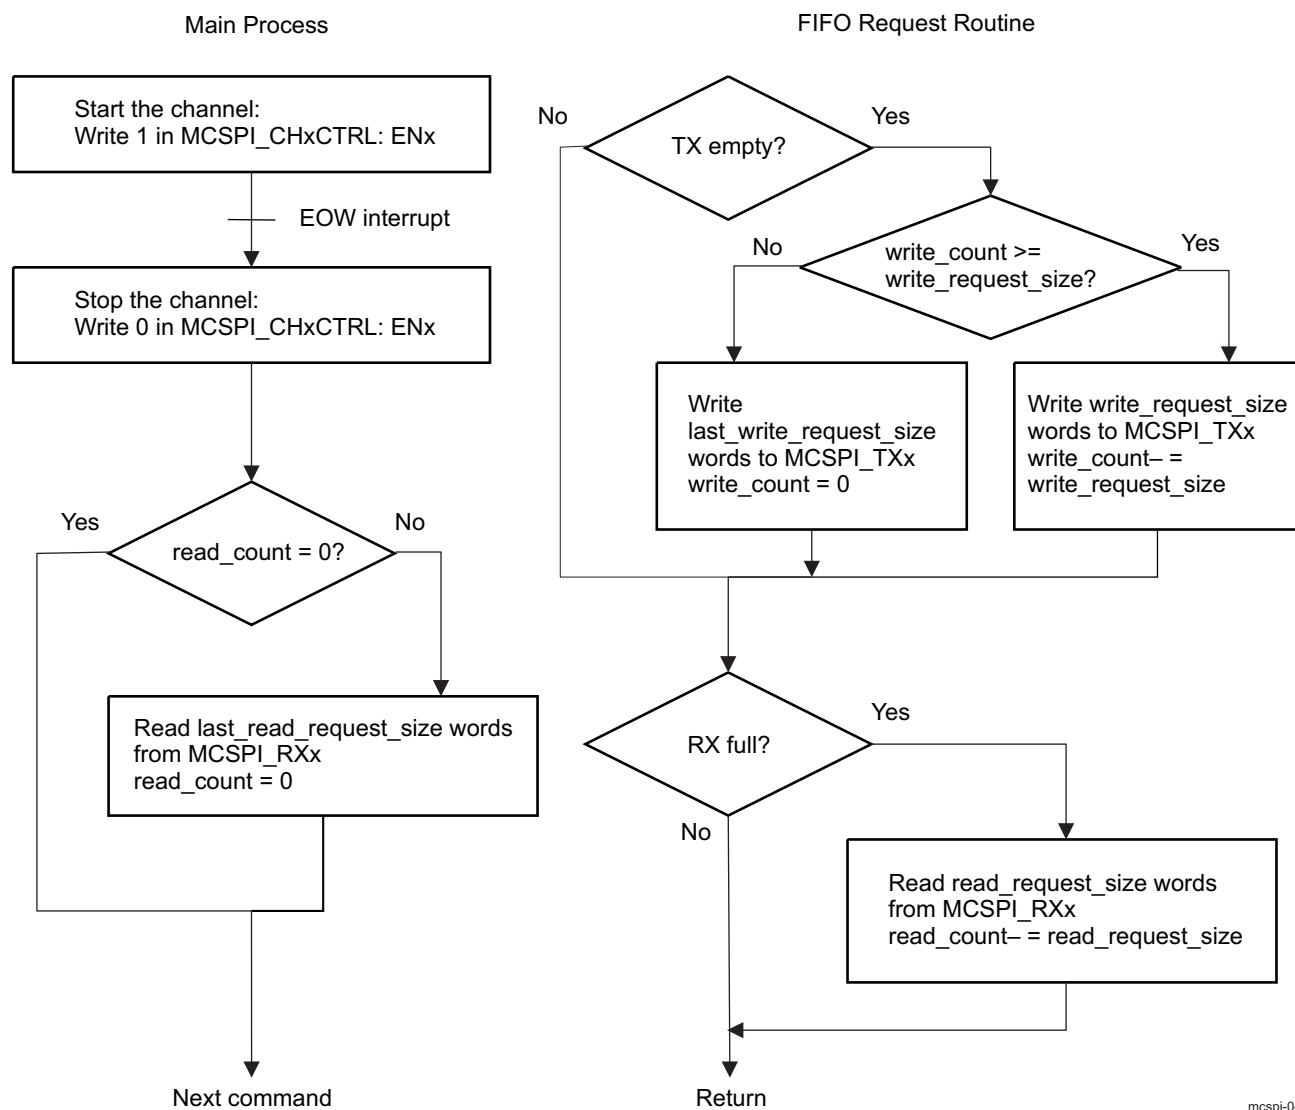

- write_count = N
- read_count = N
- last_request = FALSE

They are initialized before starting the channel.

19.6.3.2 Transmit-Receive Procedure with Word Count (WCNT≠0)

Figure 19-38 shows the flow of a transfer in transmit-receive mode, with word count.

Figure 19-38. Transmit-Receive with Word Count

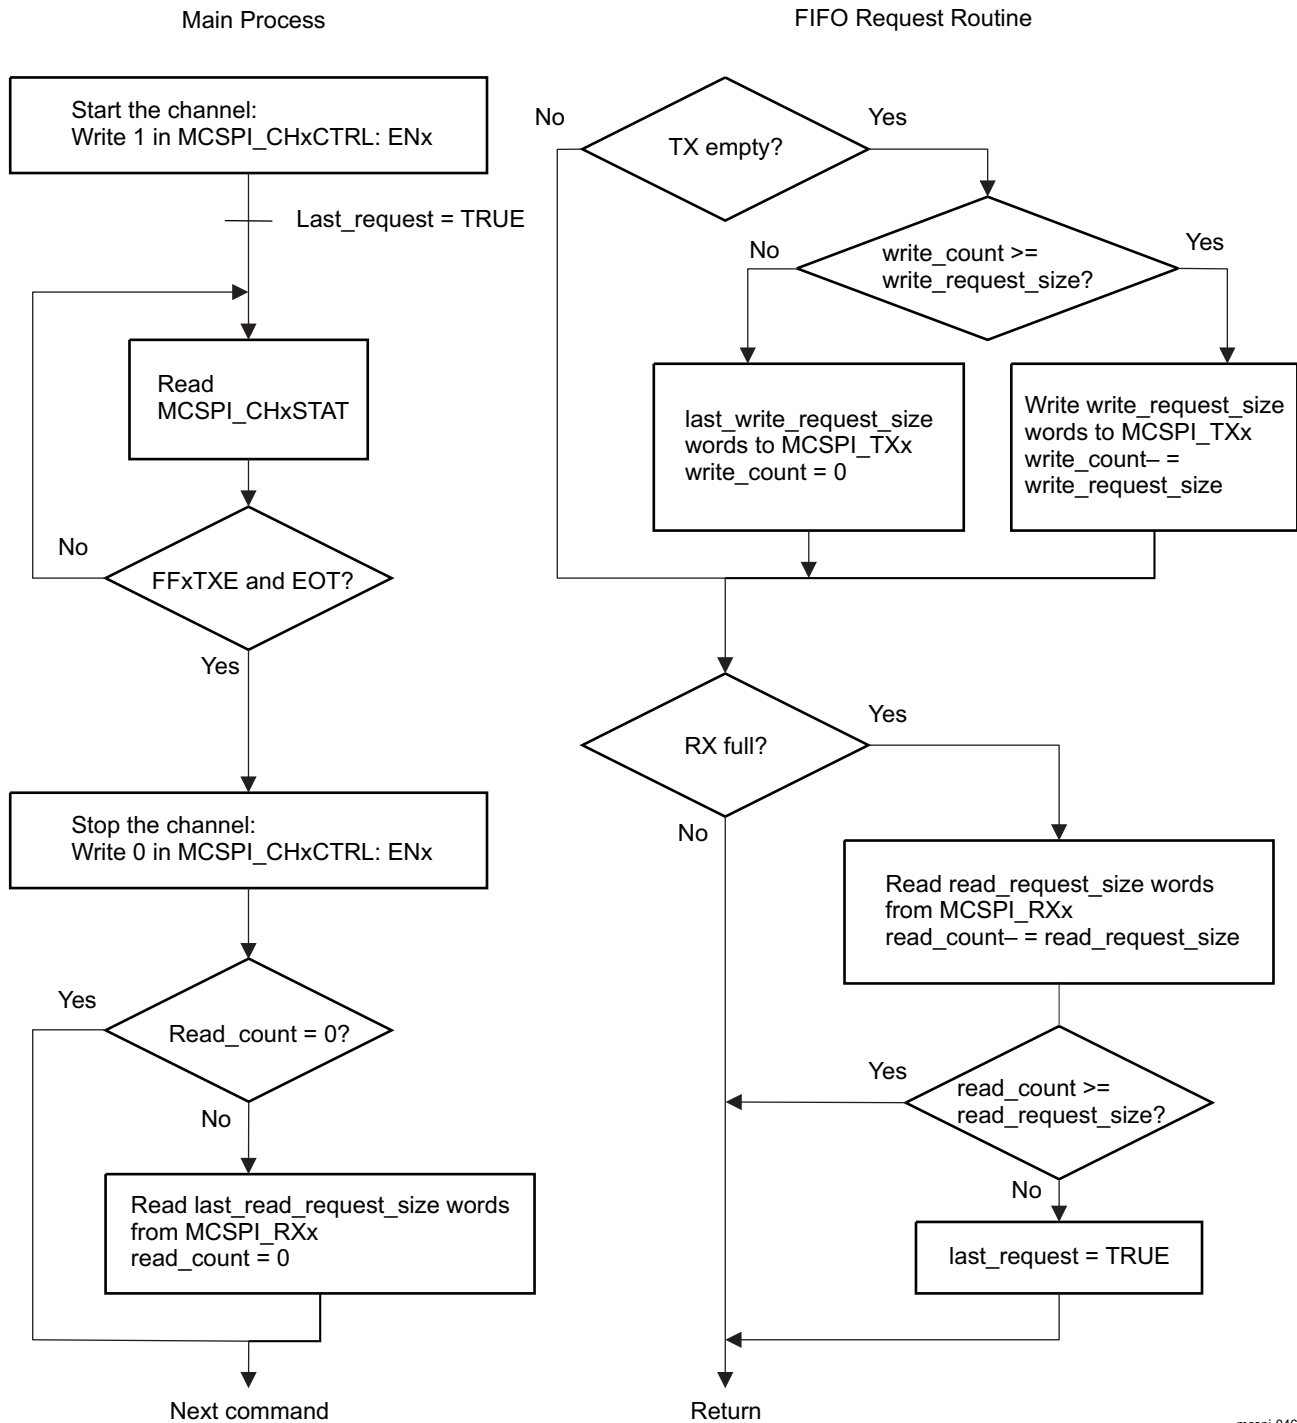

mcspi-042

19.6.3.3 Transmit-Receive Procedure without Word Count (WCNT=0)

Figure 19-39 shows the flow of a transfer in transmit-receive mode, without word count.

Figure 19-39. Transmit-Receive without Word Count

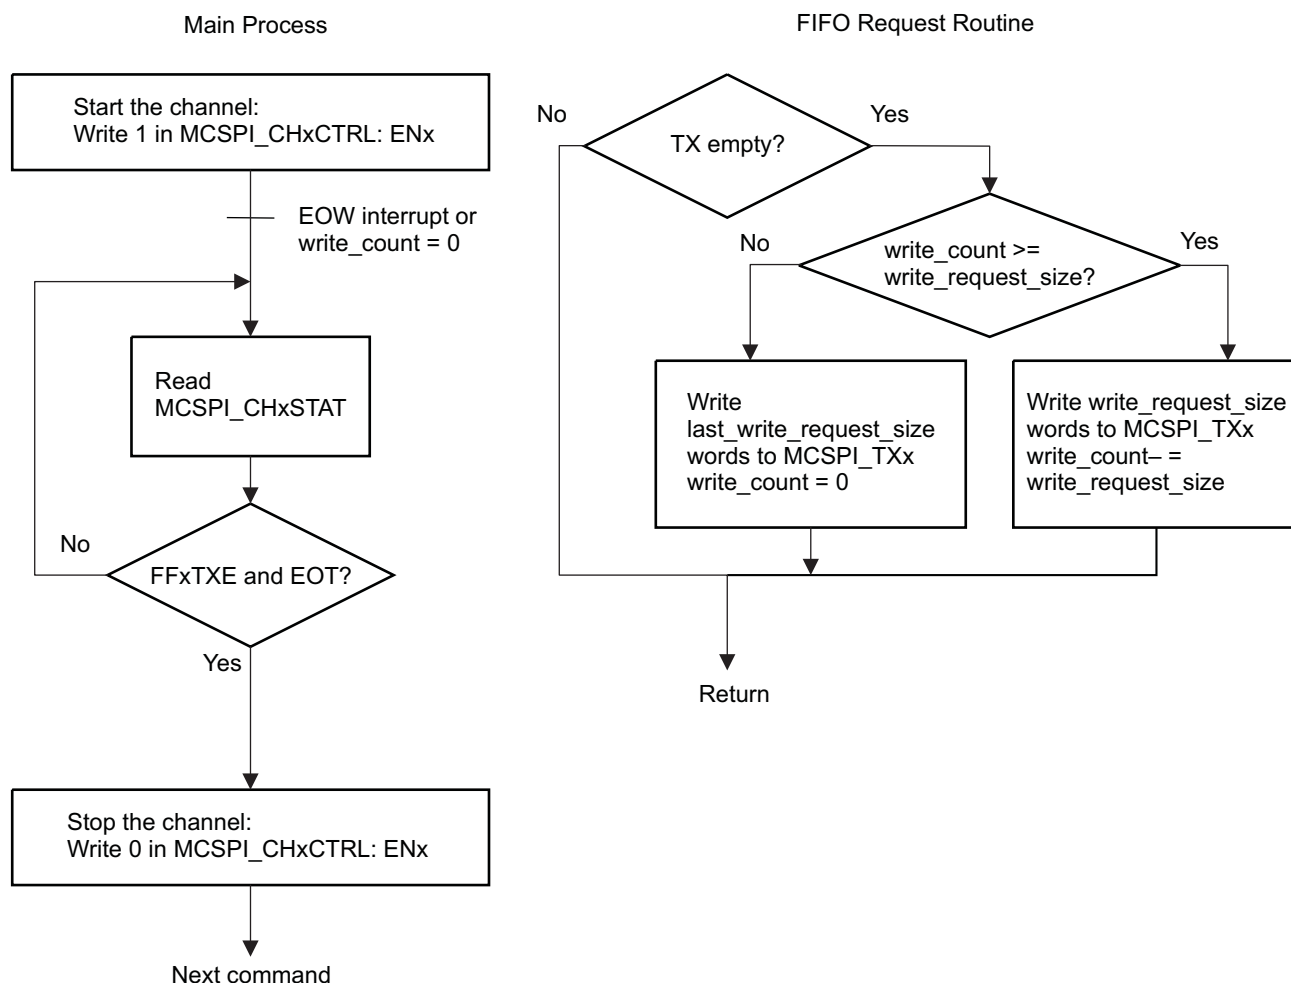

mcspl-046

19.6.3.4 Transmit-Only Procedure

Figure 19-40 shows the flow of a transfer in transmit only mode, with or without word count.

Figure 19-40. Transmit-Only

mcspi-047

The difference between word count enabled or not is the condition after starting the channel:

- Word count enable: Wait for EOW interrupt.
- Word count disable: Wait for write_count = 0.

19.6.3.5 Receive-Only Procedure with Word Count (WCNT≠0)

Figure 19-41 shows the flow of a transfer in receive-only mode, with word count.

Figure 19-41. Receive-Only with Word Count

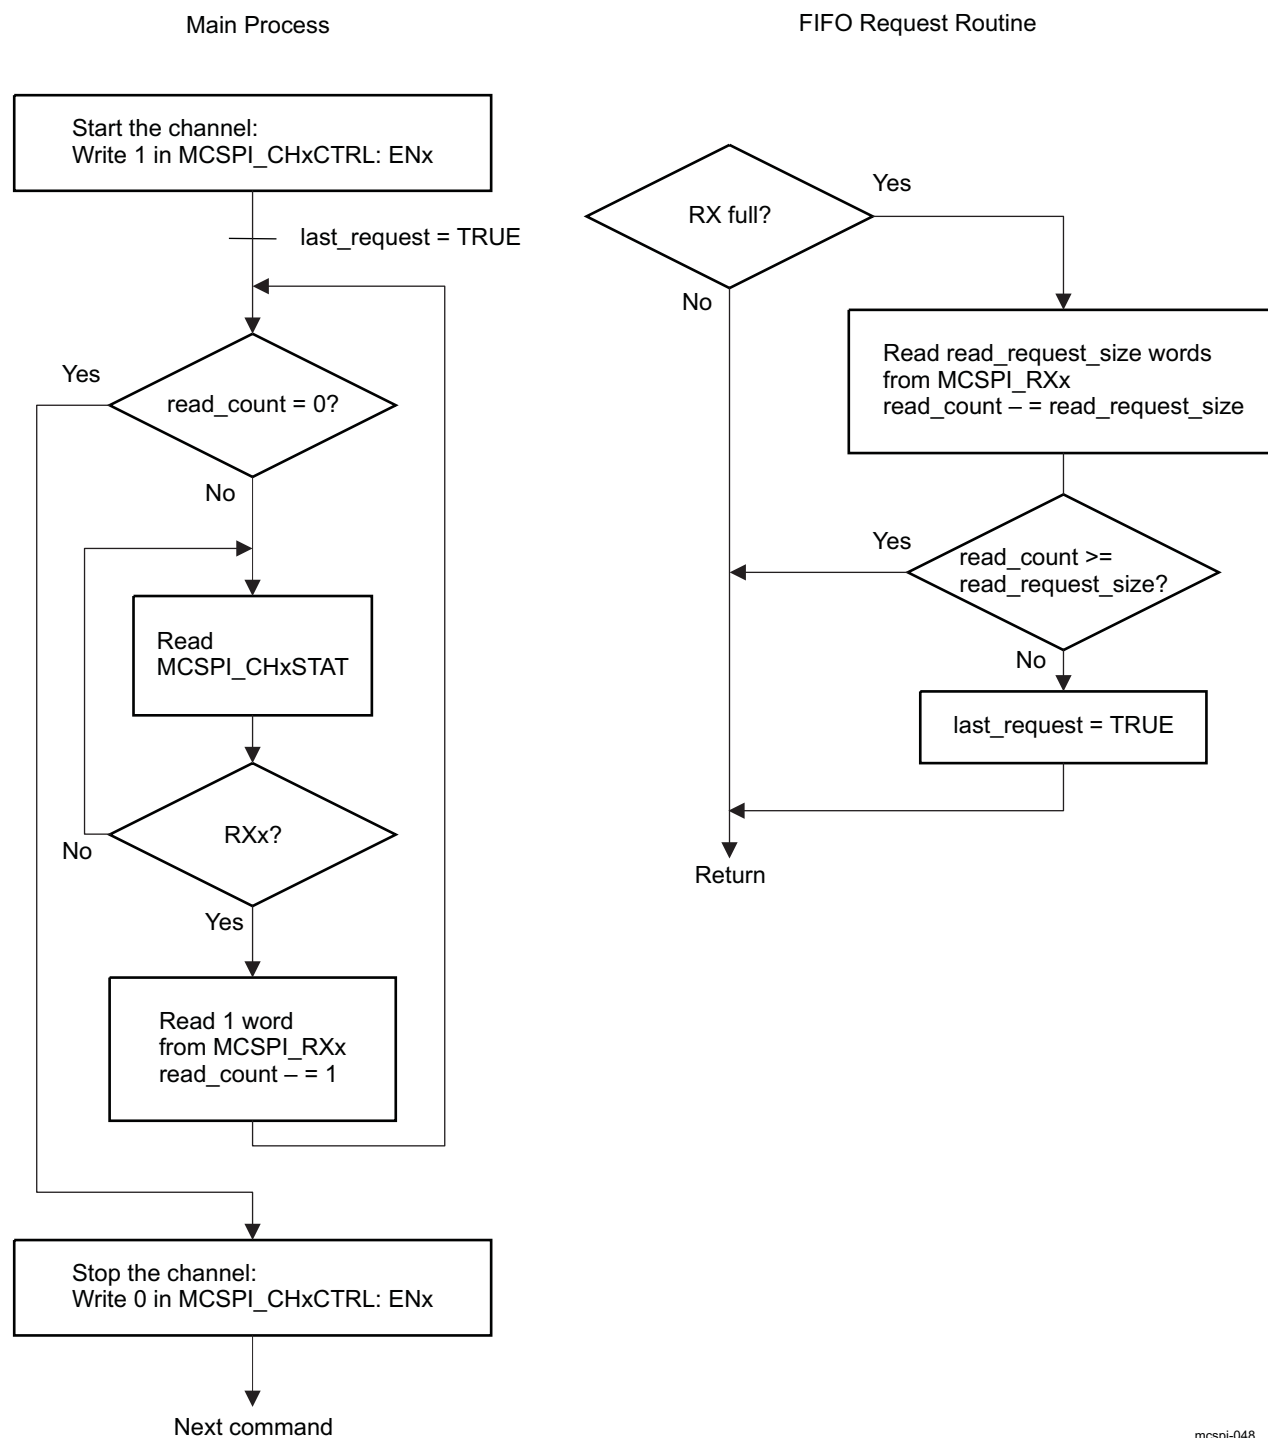

mcspi-045

19.6.3.6 Receive-Only Procedure without Word Count (WCNT=0)

Figure 19-42 shows the flow of a transfer in receive-only mode, without word count.

Figure 19-42. Receive-Only without Word Count

19.7 McSPI Use Cases and Tips

19.7.1 How to Configure the McSPI Interface when Connected with an EPSON VGA FlatLink™ 3G Device

19.7.1.1 Overview

This section deals with configuring an EPSON VGA FlatLink™3G device through the McSPI interface. Before transferring data from the external SDRAM memory to the external EPSON VGA display (Figure 19-43), the display subsystem must be set up via the McSPI interface. Several commands must be sent to the EPSON VGA for its configuration.

Figure 19-43. Overview

108-037

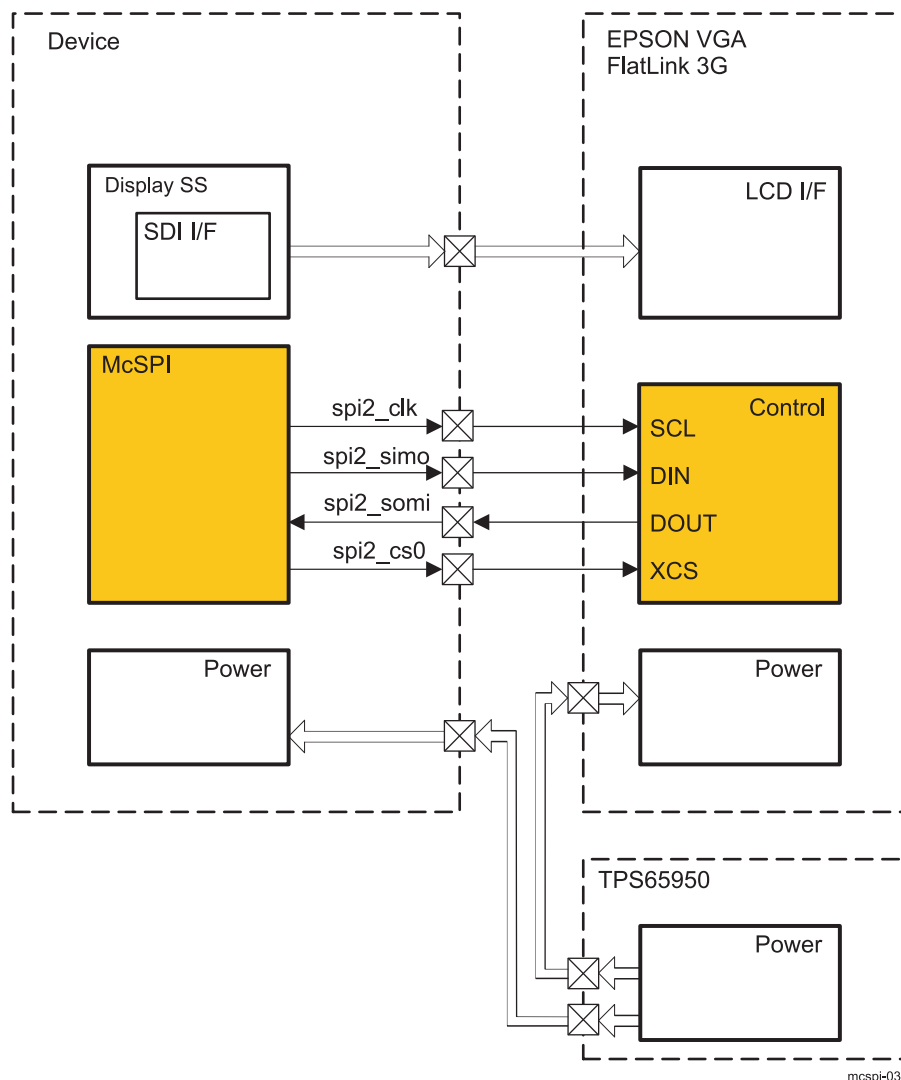

In this use case the configuration is the following:

- McSPI2 channel 0 in master mode, EPSON VGA display in slave mode
- Transmit-only and receive-only modes
- No DMA requests and no interrupts used: transmit and receive flag polling

19.7.1.2 Environment

In this use case, the EPSON VGA is connected to the device through channel 0 of the McSPI instance 2 as shown in Figure 19-44 (through `mcspi2_somi`, `mcspi2_simo`, `mcspi2_cs0`).

The display clocks are provided to the EPSON VGA by the device display subsystem. The display configuration clock comes from the McSPI interface (`mcspi2_clk`).

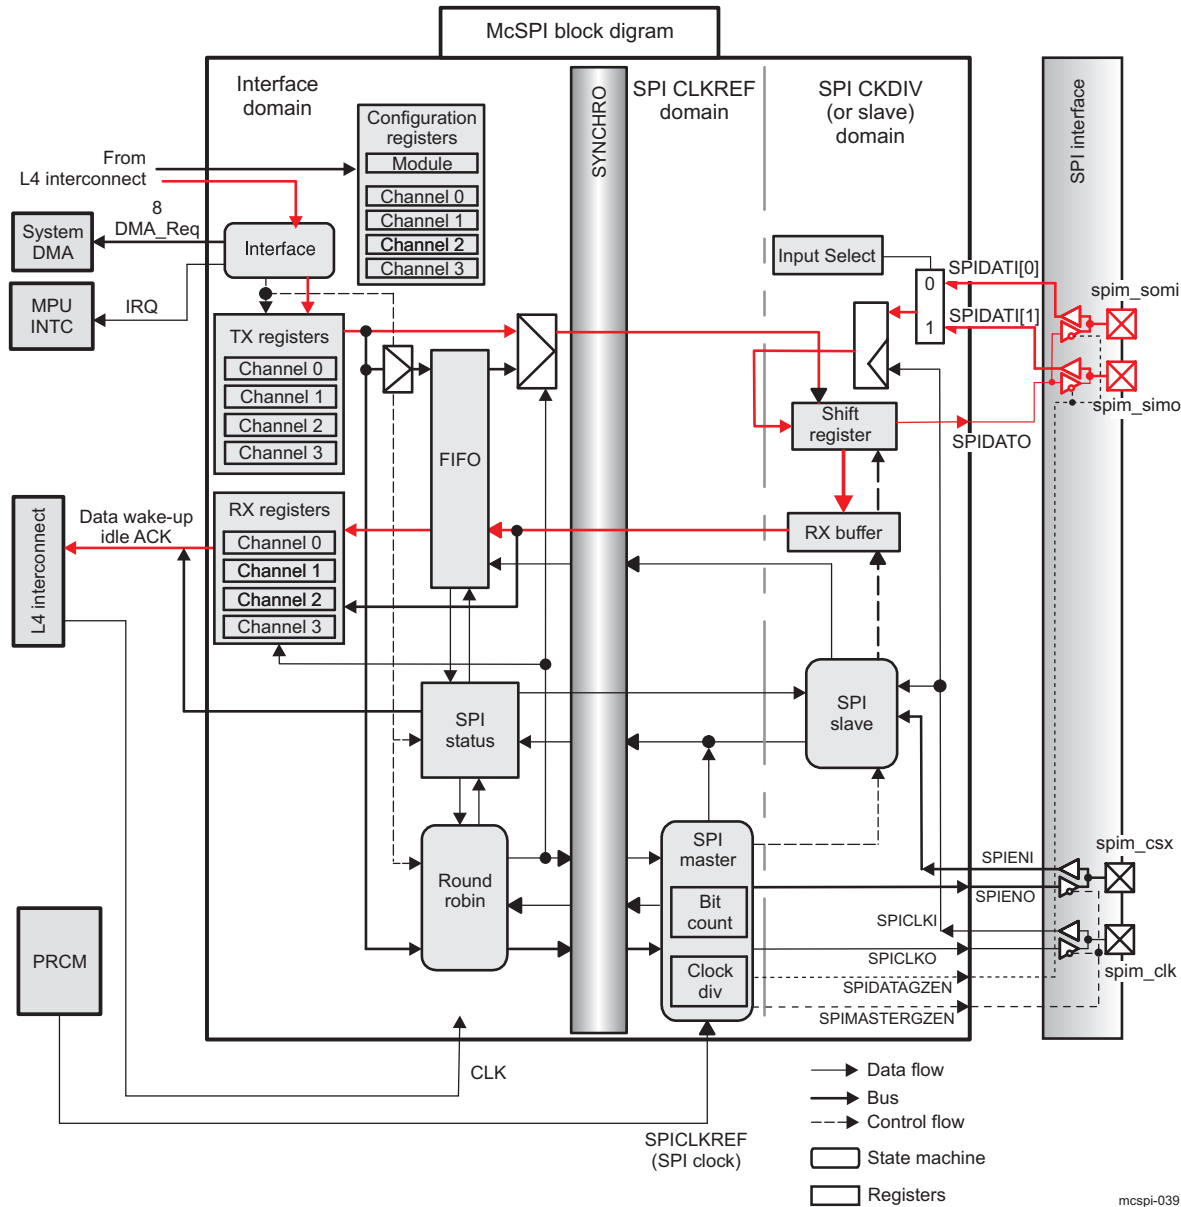

Figure 19-44. Environment

19.7.1.3 Data Path

In this use case, the McSPI2 manages the control path between the MPU subsystem and the EPSON VGA FlatLink™ 3G.

- Display configuration commands are transmitted via the channel 0 transmit register (TX Registers) and the shift register.
- A display status is read via the shift register, the receive buffer, and the channel 0 receive register (RX Registers).

Figure 19-45. McSPI Data Flow

19.7.1.4 Programming Flow

The initialization of the EPSON VGA is done in five steps:

1. McSPI module configuration
2. Send a 'SOFT RESET' command to the EPSON VGA
3. Send a 'SLEEP OUT' command
4. Send a 'DISPLAY ON' command
5. Send a 'READ DISPLAY STATUS' command and receive status data.

The four EPSON VGA commands needed in the EPSON VGA configuration are described in [Table 19-18](#).

Table 19-18. EPSON VGA Configuration Commands

	D/CX	D7	D6	D5	D4	D3	D2	D1	D0	Dummy bit
SOFT RESET (001h)	0	0	0	0	0	0	0	0	1	n/a
SLEEP OUT (011h)	0	0	0	0	1	0	0	0	1	n/a
DISPLAY ON (029h)	0	0	0	1	0	1	0	0	1	n/a
READ DISPLAY STATUS (009h and dummy bit '0')	0	0	0	0	0	1	0	0	1	0

The following subsections describe each of these initialization steps.

19.7.1.4.1 McSPI Module Configuration

Before configuring the external display VGA, the multi-channel serial port interface must be initialized as detailed in the following steps:

1. Enable the McSPI2 functional and interface clocks through the PRCM.CM_FCLKEN1_CORE[18] EN_MCSPi2 and PRCM.CM_ICLKEN1_CORE[18] EN_MCSPi2 fields.
2. Proceed to a McSPI software reset through the [MCSPi_SYSCONFIG\[1\]](#) SOFTRESET field. The SOFTRESET bit is automatically reset by hardware.
3. Poll the [MCSPi_SYSSTATUS\[0\]](#) RESETDONE field to check the software reset status.
4. Disable channel 0 through the [MCSPi_CHxCTRL\[0\]](#) EN field (with x=0).
5. Disable all interrupts ([MCSPi_IRQENABLE](#) register) then clear interrupt status register ([MCSPi_IRQSTATUS](#)). Interrupts are disabled once at this stage. Even if some interrupts of the [MCSPi_IRQSTATUS](#) register are set, no interrupt can go out to the MPU subsystem.
6. Set the module in Master mode and multichannel mode through the [MCSPi_MODULCTRL](#) register.
7. Configure channel 0 in transmit-only mode, with a word length of 9-bit through the [MCSPi_CHxCONF](#) register (with x=0). A word length of 9 bits is required to transmit the required command (SOFT RESET, SLEEP OUT, or DISPLAY ON) to the EPSON display, as detailed in [Table 19-18](#). Those 9 bits are serially transmitted on spi2_simo in the sequence D/CX, D7 to D0.

[Table 19-19](#) shows all registers to be configured with the required value for the McSPI module configuration and the use case values.

Table 19-19. McSPI Configuration Registers Print

Register Name (with x=0)	Physical Address	Value	Value Description
PRCM.CM_FCLKEN1_CORE[18]	0x4800 4A00	0x1	Enable McSPI2 functional clock
PRCM.CM_ICLKEN1_CORE[18]	0x4800 4A10	0x1	Enable McSPI2 interface clock
MCSPi_SYSCONFIG[1]	0x4809 A010	0x1	Initiate a software reset
MCSPi_SYSSTATUS	0x4809 A014	0x0000 0001	The RESETDONE field is set at 1 when the reset is complete
MCSPi_CHxCTRL	0x4809 A034	0x0000 0000	Disable channel 0
MCSPi_IRQENABLE	0x4809 A01C	0x0000 0000	Disable all interrupts
MCSPi_IRQSTATUS	0x4809 A018	0x0001 777F	Clear all interrupts
MCSPi_MODULCTRL	0x4809 A028	0x0000 0000	Master mode, multichannel

Table 19-19. McSPI Configuration Registers Print (continued)

MCSPI_CHxCONF	0x4809 A02C	0x0001 2453	CLKD = 4 (CLKSPIREF divided internally by 16) WL = 9-bit Transmit-only Receive on spi2_somi Transmit on spi2_simo
-------------------------------	-------------	-------------	---

19.7.1.4.2 'SOFT RESET', 'SLEEP OUT' and 'DISPLAY ON' Commands

Once the McSPI interface is configured, three commands must be send to the external display VGA: a software reset to reinitiate the external display, a 'SLEEP OUT' command to wake it up, and a 'DISPLAY ON' to turn on the display. Those three commands follow the same procedure, described here below, only the command opcode changes.

1. Enable channel 0 through the [MCSPI_CHxCTRL](#)[0] EN field (with x=0).
2. Write the command opcode to the [MCSPI_TXx](#) (with x=0) register so that it could be transmitted to the external display VGA. To transmit the SOFT RESET command, write 001h in the [MCSPI_TXx](#) (with x=0) register. To transmit a SLEEP OUT command write 011h and to transmit a DISPLAY ON command write 029h.
3. Poll the [MCSPI_CHxSTAT](#)[1] TXS field (with x=0) to check for transmit status. When the word has been transmitted, TXS is automatically set to 1.
4. Disable channel 0 through the [MCSPI_CHxCTRL](#)[0] EN field (with x=0).

[Table 19-20](#) shows all registers to be configured with the required value for the those commands and the use case values.

Table 19-20. Display Configuration Registers Print

Register Name (with x=0)	Physical Address	Value	Value Description
MCSPI_CHxCTRL	0x4809 A034	0x0000 0001	Enable channel 0
MCSPI_TXx	0x4809 A038	0x001 0x011 0x029	Transmit a 'SOFT RESET' command to the EPSON VGA display Transmit a 'SLEEP OUT' command Transmit a 'DISPLAY ON' command
MCSPI_CHxSTAT [1]	0x4809 A030	0x1	The word in MCSPI_TXx has been transmitted when the TXS flag is set to 1
MCSPI_CHxCTRL	0x4809 A034	0x0000 0000	Disable channel 0

19.7.1.4.3 'READ DISPLAY STATUS' Command

Once the EPSON VGA display is initialized, a 'READ DISPLAY STATUS' command is sent to the external display VGA to read and check the status of the component, such as Partial mode, Sleep In mode, Display status, Horizontal and Vertical Synchronization On or Off states.

The 'READ DISPLAY STATUS' command is not 9- but 10-bit long because the EPSON VGA display requires a dummy cycle between the transmission of the last command bit (D0 in [Table 19-18](#)) and the reception of the first data bit (the display status data is 32-bit long). In other words, a dummy bit is added as less significant bit of the command. Hence, those 10 bits are serially transmitted on spi2_simo in the sequence D/CX, D7 to D0, dummy bit.

1. Set the module in Master mode and single channel mode through the [MCSPI_MODULCTRL](#) register.
2. Configure channel 0 in transmit-only mode, with a word length of 10-bit through the [MCSPI_CHxCONF](#) register (with x=0).
3. Enable channel 0 through the [MCSPI_CHxCTRL](#)[0] EN field.

4. Shift left of one bit the command opcode 009h so that the required dummy bit ('0') can be sent after the D/CX and D7 to D0 bits to the EPSON VGA display. Refer to [Table 19-18](#) for more information. Then, write this command (012h) to the [MCSPI_TXx](#) (with x=0) register so that it could be transmitted to the EPSON VGA display.
5. Poll the [MCSPI_CHxSTAT\[1\]](#) TXS bit (with x=0) to check transmit status. When the word has been transmitted, TXS is automatically set to 1.
6. Read the [MCSPI_CHxSTAT\[1\]](#) RXS bit to check receive status. If data has already been received (RXS is set to 1) read the [MCSPI_RXx](#) (with x=0) receive register; this will automatically deactivate the RXS flag (RXS is automatically cleared).
7. Configure channel 0 in receive-only mode, with a word length of 32-bit through the [MCSPI_CHxCONF](#) register.
8. Poll the [MCSPI_CHxSTAT\[1\]](#) RXS bit to check receive status. When data has been received, RXS is automatically set to 1. The 32-bit display status information is available in the McSPI2 channel 0 receive register: [MCSPI_RXx](#) (with x=0).
9. Set channel 0 in transmit-only mode through the [MCSPI_CHxCONF](#) register.

[Table 19-21](#) shows all registers to be configured with the required value for the McSPI module configuration and the use case values.

Table 19-21. Display Status Check Registers Print

Register Name (with x=0)	Physical Address	Value	Value Description
MCSPI_MODULCTRL	0x4809 A028	0x0000 0001	Master mode, single channel
MCSPI_CHxCONF	0x4809 A02C	0x0011 24D3	CLKD = 4 (CLKSPIREF divided internally by 16) WL = 10-bit Transmit-only Receive on spi2_somi Transmit on spi2_simo
MCSPI_CHxCTRL	0x4809 A034	0x0000 0001	Enable channel 0
MCSPI_TXx	0x4809 A038	0x0000 0012	Send a 'READ DISPLAY STATUS' command. See Table 19-18 .
MCSPI_CHxSTAT[1] TXS	0x4809 A030	0x1	The word in MCSPI_TXx has been transmitted if the TXS flag is set to 1
MCSPI_CHxSTAT[0] RXS	0x4809 A030	-	Read RXS flag. Data has been received in MCSPI_RXx if the RXS flag is set to 1
MCSPI_RXx	0x4809 A03C	-	Read MCSPI_RXx only if the RXS bit is equal to 1 (this is a dummy read that will automatically clear the RXS flag)
MCSPI_CHxCONF	0x4809 A02C	0x0011 1FD0	CLKD = 4 (CLKSPIREF divided internally by 16) WL = 32-bit Receive-only Receive on spi2_somi Transmit on spi2_simo
MCSPI_CHxSTAT[0] RXS	0x4809 A030	0x0	Data has been received in MCSPI_RXx when the RXS flag is set to 1.
MCSPI_CHxCONF	0x4809 A02C	0x0011 2453	Back in transmit-only mode Receive on spi2_somi Transmit on spi2_simo

19.8 McSPI Registers

Table 19-22 lists the McSPI instances.

Table 19-22. Instance Summary

Module Name	Base Address	Size

19.8.2.6 MCSPI_SYST

Table 19-34. MCSPI_SYST

Address Offset	0x24		
Physical Address	0x4809 8024	Instance	MCSP11
	0x4809 A024		MCSP12
	0x480B 8024		MCSP13
	0x480B A024		MCSP14
Description	This register is used to check the correctness of the system interconnect either internally to peripheral bus, or externally to device IO pads, when the module is configured in system test (SYSTEST) mode.		
Type	RW		
Write Latency	Immediate		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0								
Reserved																SSB		SP1ENDIR		SP1DATDIR1		SP1DATDIR0		WAKD		SP1CLK		SP1DAT_1		SP1DAT_0		SP1EN_3		PIEN_2		SP1EN_1		SP1EN_0	

Bits	Field Name	Description	Type	Reset
31:12	Reserved	Reads returns 0	RW	0x00000
11	SSB	Set status bit 0x0: No action. Writing 0 does not clear already set status bits; This bit must be cleared prior attempting to clear a status bit of the MCSPI_ IRQSTATUS register. 0x1: Force to 1 all status bits of MCSPI_ IRQSTATUS register. Writing 1 into this bit sets to 1 all status bits contained in the MCSPI_IRQSTATUS register.	RW	0
10	SPIENDIR	Set the direction of the spim_cs lines and spim_clk line 0x0: Output (as in master mode) 0x1: Input (as in slave mode)	RW	0
9	SPIDATDIR1	Set the direction of the SPIDAT[1] (spim_simo) 0x0: Output 0x1: Input	RW	0
8	SPIDATDIR0	Set the direction of the SPIDAT[0] (spim_somi) 0x0: Output 0x1: Input	RW	0
7	WAKD	SWAKEUP output (signal data value of internal signal to system). The signal is driven high or low according to the value written into this register bit. 0x0: The pin is driven low. 0x1: The pin is driven high.	RW	0
6	SPICLK	spim_clk line (signal data value) If MCSPI_SYST [SPIENDIR] = 1 (input mode direction), this bit returns the value on the spim_clk line (high or low) and a write into this bit has no effect. If MCSPI_SYST [SPIENDIR] = 0 (output mode direction), the spim_clk line is driven high or low according to the value written into this register.	RW	0
5	SPIDAT_1	spim_somi line (signal data value) If MCSPI_SYST [SPIDATDIR1] = 0 (output mode direction), the spim_somi line is driven high or low according to the value written into this register. If MCSPI_SYST [SPIDATDIR1] = 1 (input mode direction), this bit returns the value on the spim_somi line (high or low) and a write into this bit has no effect.	RW	0
4	SPIDAT_0	spim_simo line (signal data value) If MCSPI_SYST [SPIDATDIR0] = 0 (output mode direction), the spim_simo line is driven high or low according to the value written into this register. If MCSPI_SYST [SPIDATDIR0] = 1 (input mode direction), this bit returns the value on the spim_simo line (high or low) and a write into this bit has no effect.	RW	0
3	SPIEN_3	spim_cs3 line (signal data value) If MCSPI_SYST [SPIENDIR] = 0 (output mode direction), the spim_cs3 line is driven high or low according to the value written into this register. If MCSPI_SYST [SPIENDIR] = 1 (input mode direction), this bit returns the value on the spim_cs3 line (high or low) and a write into this bit has no effect.	RW	0
2	PIEN_2	spim_cs2 line (signal data value) If MCSPI_SYST [SPIENDIR] = 0 (output mode direction), the spim_cs2 line is driven high or low according to the value written into this register.	RW	0

Bits	Field Name	Description	Type	Reset
		If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the spim_cs2 line (high or low) and a write into this bit has no effect.		
1	SPIEN_1	spim_cs1 line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the spim_cs1 line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the spim_cs1 line (high or low) and a write into this bit has no effect.	RW	0
0	SPIEN_0	spim_cs0 line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the spim_cs0 line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the spim_cs0 line (high or low) and a write into this bit has no effect.	RW	0

Table 19-38. MCSPI_CHxCONF

Address Offset	0x2C + (0x14 * x)	Index	x= 0 to 3 for MCSPI1. x= 0 to 1 for MCSPI2 and MCSPI3. x= 0 for MCSPI4.
Physical Address	0x4809 802C + (0x14 * x) 0x4809 A02C + (0x14 * x) 0x480B 802C + (0x14 * x) 0x480B A02C + (0x14 * x)	Instance	MCSPi1 MCSPi2 MCSPi3 MCSPi4
Description	This register is dedicated to the configuration of the channel x.		
Type	RW		
Write Latency	Immediate		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	CLKG	FFER	FFEW	TCS	SBPOL	SBE	SPIENSLV	FORCE	TURBO	IS	DPE1	DPE0	DMAR	DMAW	TRM	WL	EPOL	CLKD	POL	PHA											

Bits	Field Name	Description	Type	Reset
31:30	Reserved	Read returns 0s.	RW	0x00
29	CLKG	Clock divider granularity. This register defines the granularity of channel clock divider: power of two or one clock cycle granularity. When this bit is set, the MCSPI_CHxCTRL [15:8] EXTCLK bit field must be configured to reach a maximum of 4096 clock divider ratio. Then the clock divider ratio is a concatenation of MCSPI_CHxCONF [5:2] CLKD and EXTCLK values. 0x0: Clock granularity of power of two 0x1: One clock cycle granularity	RW	0x0
28	FFER	FIFO enabled for Receive. Only one channel can have this bit field set. 0x0: The buffer is not used to Receive data	RW	0x0

Bits	Field Name	Description	Type	Reset
		0x1: The buffer is used to Receive data		
27	FFEW	FIFO enabled for Transmit. Only one channel can have this bit field set. 0x0: The buffer is not used to Transmit data 0x1: The buffer is used to Transmit data	RW	0x0
26:25	TCS	Chip select time control Defines the number of interface clock cycles between CS toggling and first (or last) edge of SPI clock. 0x0: 0.5 clock cycle 0x1: 1.5 clock cycles 0x2: 2.5 clock cycles 0x3: 3.5 clock cycles	RW	0x0
24	SBPOL	Start bit polarity 0x0: Start bit polarity is held to 0 during SPI transfer. 0x1: Start bit polarity is held to 1 during SPI transfer.	RW	0x0
23	SBE	Start bit enable for SPI transfer 0x0: Default SPI transfer length as specified by WL bit field 0x1: Start bit D/CX added before SPI transfer. Polarity is defined by MCSPI_CHxCONF [SBPOL].	RW	0x0
22:21	SPIENSLV	Channel 0 only and slave mode only: SPI slave select signal detection. Reserved bits for MCSPI_CHxCONF where x= [1,2,3] 0x0: Detection enabled only on spim_cs0 0x1: Detection enabled only on spim_cs1 0x2: Detection enabled only on spim_cs2 0x3: Detection enabled only on spim_cs3	RW	0x0
20	FORCE	Manual SPIM_CSX assertion to keep SPIM_CSX for channel x active between SPI words (single channel master mode only). The MCSPI_MODULCTRL [0] SINGLE bit must be set to 1. 0x0: Writing 0 into this bit drives the spin_csx line low for channel x when MCSPI_CHxCONF [6] EPOL = 0, and drives it high when MCSPI_CHxCONF [6] EPOL = 1. 0x1: Writing 1 into this bit drives the SPIM_CSX line high for channel x when MCSPI_CHxCONF [6] EPOL = 0, and drives it low when MCSPI_CHxCONF [6] EPOL = 1.	RW	0x0
19	TURBO	Turbo mode 0x0: Turbo is deactivated (recommended for single SPI word transfer) 0x1: Turbo is activated to maximize the throughput for multi-SPI word transfers.	RW	0x0
18	IS	Input select 0x0: Data Line 0 (spim_somi) selected for reception 0x1: Data Line 1 (spim_simo) selected for reception	RW	0x1
17	DPE1	Transmission enable for data line 1 (spim_simo) 0x0: Data Line 1 (spim_simo) selected for transmission 0x1: No transmission on data Line 1 (spim_simo)	RW	0x1
16	DPE0	Transmission enable for data line 0 (spim_somi) 0x0: Data Line 0 (spim_somi) selected for transmission 0x1: No transmission on data Line 0 (spim_somi)	RW	0x0
15	DMAR	DMA Read request The DMA Read request line is asserted when the channel is enabled and a new data is available in the receive register of the channel.	RW	0x0

Bits	Field Name	Description	Type	Reset
		The DMA Read request line is deasserted on read completion of the receive register of the channel. 0x0: DMA read request disabled 0x1: DMA read request enabled		
14	DMAW	DMA Write request. The DMA write request line is asserted when the channel is enabled and the MCSPI_TXx register of the channel is empty. The DMA write request line is deasserted on load completion of the MCSPI_TXx register of the channel. 0x0: DMA write request disabled 0x1: DMA write request enabled	RW	0x0
13:12	TRM	Transmit/receive modes 0x0: Transmit and receive mode 0x1: Receive-only mode 0x2: Transmit-only mode 0x3: Reserved	RW	0x0
11:7	WL	SPI word length 0x0: Reserved 0x1: Reserved 0x2: Reserved 0x3: The SPI word is 4-bit long 0x4: The SPI word is 5-bit long 0x5: The SPI word is 6-bit long 0x6: The SPI word is 7-bit long 0x7: The SPI word is 8-bit long 0x8: The SPI word is 9-bit long 0x9: The SPI word is 10-bit long 0xA: The SPI word is 11-bit long 0xB: The SPI word is 12-bit long 0xC: The SPI word is 13-bit long 0xD: The SPI word is 14-bit long 0xE: The SPI word is 15-bit long 0xF: The SPI word is 16-bit long 0x10: The SPI word is 17-bit long 0x11: The SPI word is 18-bit long 0x12: The SPI word is 19-bit long 0x13: The SPI word is 20-bit long 0x14: The SPI word is 21-bit long 0x15: The SPI word is 22-bit long 0x16: The SPI word is 23-bit long 0x17: The SPI word is 24-bit long 0x18: The SPI word is 25-bit long 0x19: The SPI word is 26-bit long 0x1A: The SPI word is 27-bit long 0x1B: The SPI word is 28-bit long 0x1C: The SPI word is 29-bit long 0x1D: The SPI word is 30-bit long 0x1E: The SPI word is 31-bit long 0x1F: The SPI word is 32-bit long	RW	0x00
6	EPOL	SPIM_CSX polarity for channel x	RW	0x0

Bits	Field Name	Description	Type	Reset
		0x0: SPIM_CSX is held high during the active state. 0x1: SPIM_CSX is held low during the active state.		
5:2	CLKD	Frequency divider for spim_clk (for master device only) A programmable clock divider divides the SPI reference clock (CLKSPIREF) by a 4-bit value and results in a new spim_clk clock available to shift data in and out. 0x0: 1 0x1: 2 0x2: 4 0x3: 8 0x4: 16 0x5: 32 0x6: 64 0x7: 128 0x8: 256 0x9: 512 0xA: 1024 0xB: 2048 0xC: 4096 0xD: Division not supported 0xE: Division not supported 0xF: Division not supported	RW	0x0
1	POL	spim_clk polarity 0x0: spim_clk is held high during the active state. 0x1: spim_clk is held low during the active state.	RW	0x0
0	PHA	spim_clk phase 0x0: Data are latched on odd-numbered edges of spim_clk. 0x1: Data are latched on even-numbered edges of spim_clk.	RW	0x0

20.1 HDQ/1-Wire Overview

The HDQ/1-Wire module implements the hardware protocol of the master functions of the Benchmark HDQ and the Dallas Semiconductor 1-Wire® protocols. These protocols use a single wire for communication between the master (HDQ/1-Wire controller) and the slave (HDQ/1-Wire external compliant device).

Figure 20-1 shows the HDQ/1-Wire controller module.

Figure 20-1. HDQ/1-Wire Highlight

The HDQ and 1-Wire module has a generic L4 interface and is intended to be used in an interrupt-driven fashion. The one-pin interface is implemented as an open-drain output at the device level.

The HDQ operates from a fixed 12-MHz functional clock provided by the PRCM module.

Only the MPU subsystem uses the HDQ/1-Wire module.

The main features of the HDQ/1-Wire module support the following:

- Benchmark HDQ protocol
- Dallas Semiconductor 1-Wire® protocol
- Power-down mode

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

The HDQ/1-Wire module provides a communication rate of 5K bits/s over an address space of 128 bytes.

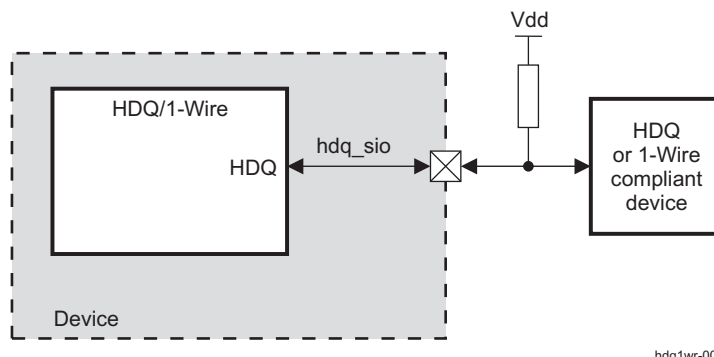

A typical application of the HDQ/1-Wire module is the communication with battery monitor (gas gauge) integrated circuits.

20.2 HDQ/1-Wire Environment

20.2.1 HDQ/1-Wire Functional Interface

Figure 20-2 shows a typical application using the HDQ/1-Wire connection.

Figure 20-2. HDQ/1-Wire Typical Application System Overview

hdq1wr-002

An external pullup is required, because the two protocols use a return-to-1 mechanism (that is, after any command, the line is pulled to a logical high level).

The HDQ/1-Wire module operates according to a command structure that is programmed into transmit command registers (as described in [Section 20.5](#)).

The 1-Wire mode runs at slower speeds than the capabilities of the mode.

[Table 20-1](#) describes the external pullup signal from an HDQ or 1-Wire compliant device.

Table 20-1. I/O Description

Signal Name	I/O	Description	Value at Reset
hdq_sio	Bidir	Serial data input/output	1

20.2.2 HDQ and 1-Wire (SDQ) Protocols

20.2.2.1 HDQ Protocol Initialization (Default)

In HDQ mode, the firmware does not require the host to create an initialization pulse to the slave. However, the slave can be reset by using an initialization pulse (also referred to as a break pulse). The initialization pulse is generated by setting the INITIALIZATION bit (HDQ.HDQ_CTRL_STATUS[2]). The slave does not respond with a presence pulse as it does in the 1-Wire protocol.

The HDQ is a command-based protocol in which the host sends a command byte to the slave. The command directs the slave either to store the next eight bits of data received to a register specified by the command byte (write operation) or to output the eight bits of data from a register specified by the command byte (read operation). The master implementation is a simple byte engine. The sending of the ID, command/address, and data is controlled by firmware. The master engine provides only a single HDQ.HDQ_TX_DATA register.

The command and data bytes consist of a stream of eight bits with a maximum transmission rate of 5K bits/s. The least significant bit (LSB) of a command or data byte is transmitted first. If a communication time-out occurs between the host and the slave (for example, if the host waits longer than the specified time for the slave to respond, or if this is the first access command), then the host must send an initialization pulse (BREAK pulse) before sending the command again.

The slave detects a break when the HDQ pin is driven to a logic-low state for a specified break time $t(B)$ or greater. The HDQ pin then returns to its normal ready-high logic state for a specified break-recovery time $t(BR)$. The slave is then ready for a command from the host processor. Figure 20-3 shows this behavior.

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out condition. Reading the interrupt status register clears all interrupt conditions. Only one interrupt signal is sent to the microcontroller, and only one overall mask bit can enable or disable the interrupt. The interrupt conditions cannot be individually masked.

Figure 20-3. HDQ Break-Pulse Timing Diagram

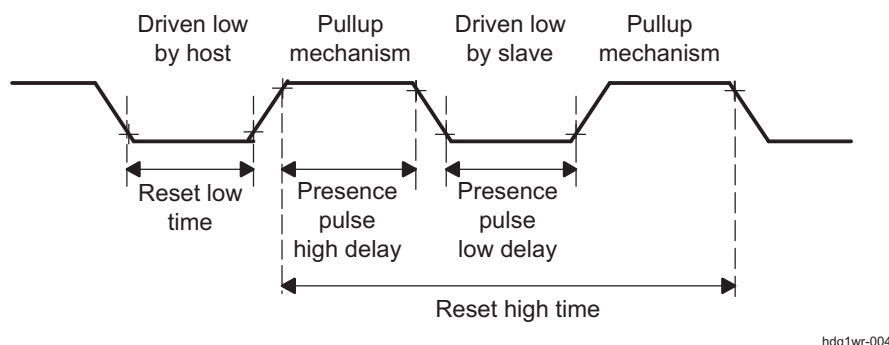

20.2.2.2 1-Wire (SDQ) Protocol Initialization

In 1-Wire (SDQ) protocol, the host first sends an initialization pulse (by pulling the line to a logic-low state) and then waits for the slave to respond with a presence pulse before enabling any communication sequence.

As for the initialization pulse, the presence pulse is a low-going edge on the line initiated by the slave. The timing diagram in Figure 20-4 shows the 1-Wire (SDQ) reset sequence.

Figure 20-4. 1-Wire (SDQ) Reset Timing Diagram

The host drives the line to a logic-low state for a minimum of reset low time. Once the slave detects this pulse, it must drive the line to a logic-low state within the presence pulse high delay for a minimum period of presence pulse low time.

If the slave does not respond within this interval of time, a time-out event occurs and no transaction can be initiated. The host must initiate the reset sequence again before sending any command to the slave.

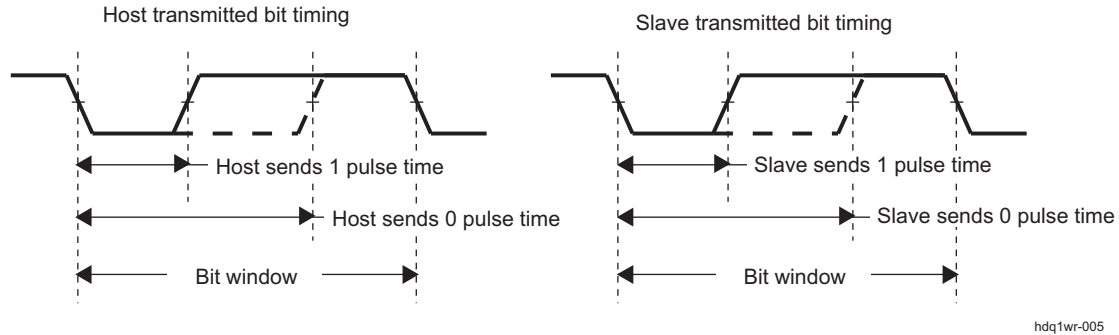

On the other hand, if the slave sends back its presence pulse within the specified interval of time, the communication can be enabled after the reset high time.

20.2.2.3 Communication Sequence (HDQ and 1-Wire Protocols)

This section describes the part common to both protocols.

After a successful break pulse (HDQ mode) or initialization sequence (1-Wire protocol), the host and slave are ready for bit transmission. Each bit to transmit (either from the host to the slave or from the slave to the host) is preceded by a low-going edge on the line, as shown in Figure 20-5.

Figure 20-5. HDQ/1-Wire Transmitted Bit Timing

The return-to-1 data-bit frame consists of three distinct sections. The first section starts the transmission when either the slave or the host takes the line to a logic-low state. The next section is the actual data transmission in which the data must be valid during a specified period of time after the negative edge that starts the communication. The final section stops the transmission by returning the HDQ/1-Wire line to a logic-high state. Communication with an HDQ/1-Wire slave always occurs with the LSB being transmitted first.

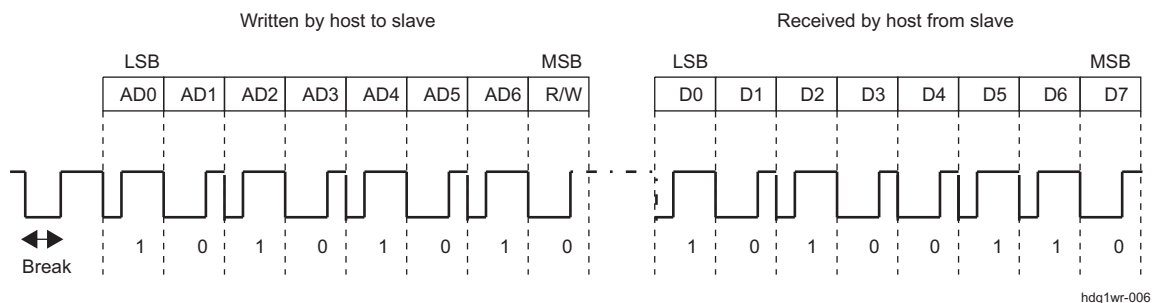

The command byte of the HDQ/1-Wire protocols consists of eight contiguous valid command bits. The command byte contains two fields: R/W command and address. The R/W bit of the command byte determines whether the command is a read or a write, and the address field containing bits AD6-AD0 indicates the address to be read or written. [Table 20-2](#) lists the command byte values.

Table 20-2. HDQ/1-Wire Command Byte

7	6	5	4	3	2	1	0
R/W	AD6	AD5	AD4	AD3	AD2	AD1	AD0

- R/W** Indicates whether the command byte is a read or a write. A 1 indicates a write command; the following eight bits must be written to the register specified by the address field of the command byte. A 0 indicates that the command is a read. On a read command, the slave outputs the requested register contents.
- AD6-AD0** Represent the seven bits labeled AD6-AD0 containing the address portion of the register to be accessed. The communication sequence example in [Figure 20-6](#) shows a read command at address 0x55; the received data is 0x65.

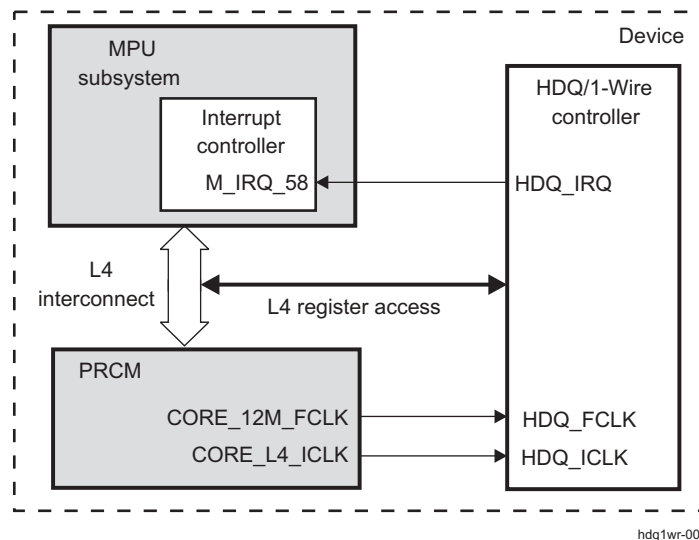

Figure 20-6. HDQ/1-Wire Communication Sequence

20.3 HDQ/1-Wire Integration

Figure 20-7 shows the HDQ/1-Wire module integration in the device.

Figure 20-7. HDQ/1-Wire Integration

20.3.1 Clocking, Reset, and Power Management Scheme

20.3.1.1 HDQ/1-Wire Clocks

There are two clock domains in the HDQ/1-Wire module: the functional clock domain and the interface clock domain.

- HDQ_FCLK belongs to the functional clock domain. It is a fixed 12-MHz clock provided by the PRCM. It is used to clock the internal module logic.

The HDQ_FCLK source is the CORE_12M_FCLK PRCM output, which is derived from the CORE_48M_FCLK clock signal (a 1/4 ratio is applied). The CORE_12M_FCLK clock is issued from the peripherals DPLL4. For more information about the clock, see the *Power, Reset, and Clock Management* chapter.

When the HDQ/1-Wire module no longer requires the HDQ_FCLK, the software can disable it at the PRCM level by setting the EN_HDQ bit (PRCM.CM_FCLKEN1_CORE[22]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it either.

For details about the PRCM register settings and DPLL4 configuration, see the *Power, Reset, and Clock Management* chapter.

- HDQ_ICLK is the interface clock. It runs at L4 interconnect clock speed and is used to trigger access to the HDQ/1-Wire L4 interface. Its source is the PRCM CORE_L4_ICLK signal. It typically runs at L3/2 frequency.

When the HDQ/1-Wire module no longer requires the HDQ_ICLK, the software can disable it at the PRCM level by setting the EN_HDQ bit (PRCM.CM_ICLKEN1_CORE[22]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it either.

It is also possible to activate an autoidle mode for this clock (AUTO_HDQ bit PRCM.CM_AUTOIDLE1_CORE[22] set to 1). In this case, HDQ_ICLK follows the CORE clock domain behavior. For more information, see the *Power, Reset, and Clock Management* chapter.

20.3.1.2 HDQ/1-Wire Reset Scheme

Global reset of the module is done either by activating the CORE_RST signal in the CORE_RST domain (for more information, see the *Power, Reset, and Clock Management* chapter) or by setting to 1 the SOFTRESET bit HDQ.HDQ_SYSCONFIG[1]. Setting this bit enables an active software reset functionality equivalent to a hardware reset.

20.3.1.3 HDQ/1-Wire Power Domain

The HDQ/1-Wire belongs to the CORE power domain. For more information about the CORE power domain, see the *Power, Reset, and Clock Management* chapter.

20.3.2 Hardware Requests

The HDQ/1-Wire can generate one interrupt:

- HDQ_IRQ: This is an interrupt to the MPU subsystem interrupt controller. It is mapped on M_IRQ_58.

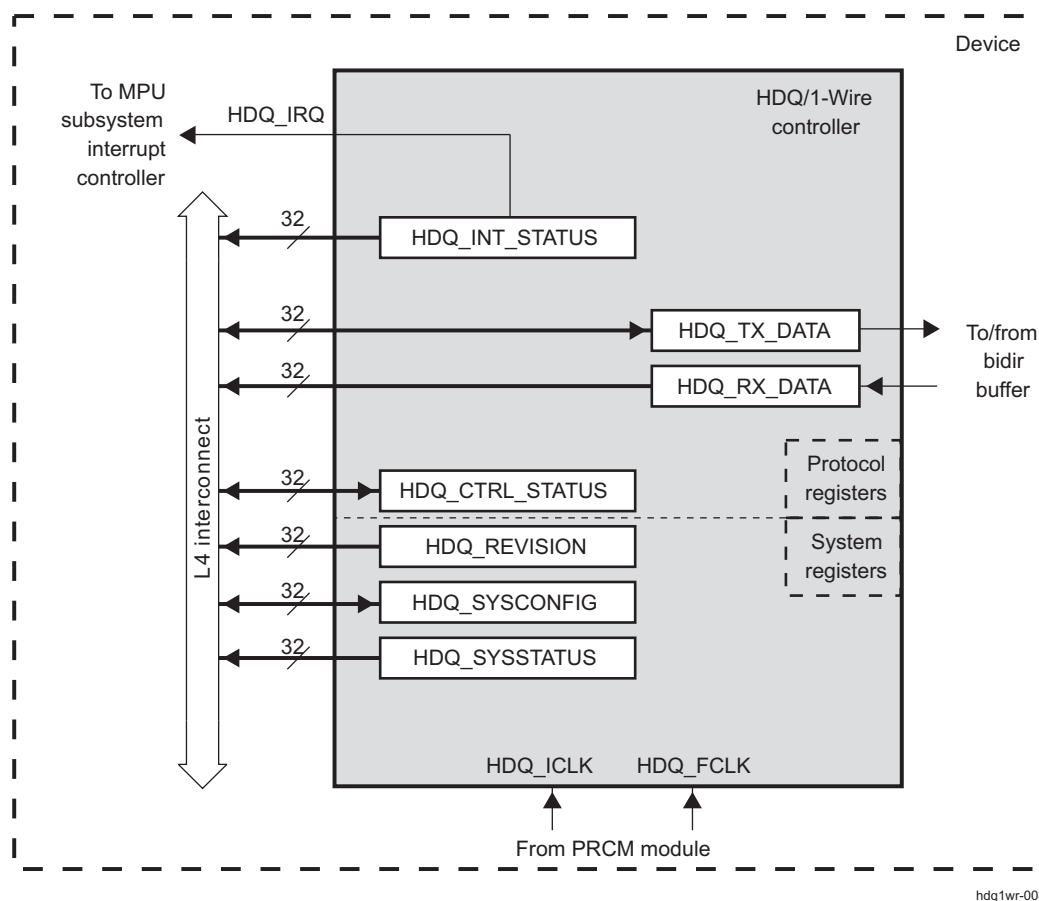

20.4 HDQ/1-Wire Functional Description

The HDQ/1-Wire module works with both the HDQ and 1-Wire protocols. The protocols use a single wire to establish communication between the master and the slave. Both protocols use a return-to-1 mechanism; that is, after any command is driven, the line is pulled to a high level. This mechanism requires an external pullup.

20.4.1 HDQ/1-Wire Block Diagram

Figure 20-8 shows the HDQ/1-Wire block diagram.

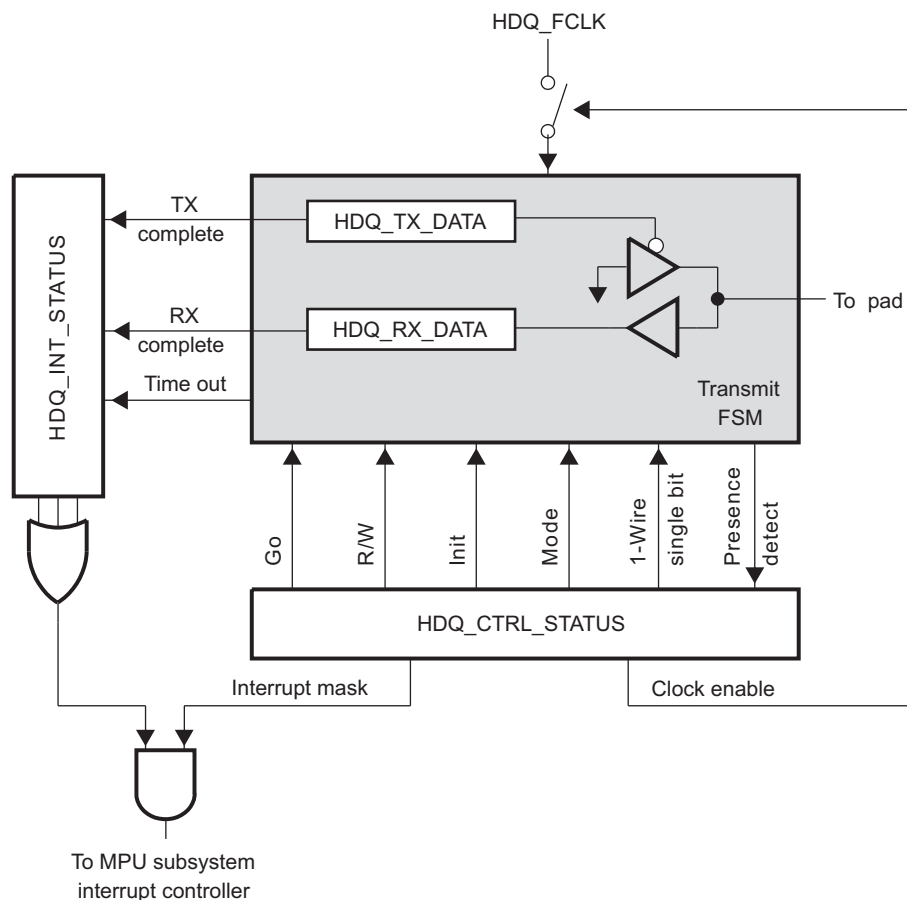

Figure 20-8. HDQ/1-Wire Block Diagram

The MODE bit HDQ.HDQ_CTRL_STATUS[0] allows selection between the HDQ and 1-Wire protocols. This bit is assumed static for design purposes. The configuration is in HDQ mode by default.

Figure 20-9 shows the protocol-dedicated register scheme.

Figure 20-9. Protocol Registers Description

hdq1wr-009

The receive and transmit operations are performed with respect to the HDQ protocol timing. The module is implemented once in the OMAP Applications Processor and is clocked with a single clock whether it runs HDQ or 1-Wire protocol. Although the data exchange is slower than the capabilities of the 1-Wire mode, this mode still meets the timing requirements and practical considerations. That is, the 1-Wire protocol runs at the HDQ protocol speed, which is slower (5K bits/s). The timing parameters and protocol are different in the two modes.

20.4.2 HDQ Mode (Default)

20.4.2.1 HDQ Mode Features

The HDQ mode supports the following:

- Benchmark HDQ protocol
- Power-down mode

20.4.2.2 Description

In the HDQ mode, there is no need for the host to create an initialization pulse to the slave. However, the host can reset the slave by using an initialization pulse (also known as a break pulse). Setting the INITIALIZATION bit HDQ.HDQ_CTRL_STATUS[2] creates this pulse by pulling the line down. When the slave receives the pulse, it is ready for communication but does not respond with a presence pulse.

In a typical write operation, two bytes are sent to the slave. The first byte corresponds to the command/address byte, and the second byte corresponds to the data to be written.

In a typical read operation, the host sends a command/address byte and the slave returns a byte of data.

The master is implemented to send and receive bytes. Sending the command/address and data is controlled by the firmware. The master provides only a single data TX register.

The HDQ protocol is a return-to-1 protocol. Consequently, after a byte is sent to the slave (either command/address + data for a write, or just command/address for a read), the host pulls the line up. The line is set to the high-impedance state in the device and an external pullup brings it to a logical high level.

In the case of a read operation, the slave also drives the line to a logic-low state before sending the requested data.

If the host initiates a read and does not receive data within a specified interval of time (that is, the slave does not drive the line low within this interval), the TIMEOUT bit HDQ.HDQ_INT_STATUS[0] is set, thereby indicating a read failure. The TIMEOUT bit remains set until the host reads the interrupt status register (HDQ.HDQ_INT_STATUS).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out on a transaction. The corresponding bit is set in the interrupt status register (HDQ.HDQ_INT_STATUS). This register is cleared as soon as it is read.

Only one interrupt signal is sent to the MPU, and only an overall mask can enable or disable the interrupts. These interrupts cannot be individually masked.

20.4.2.3 Single-Bit Mode

In HDQ mode, the single-bit mode (1_WIRE_SINGLE_BIT bit HDQ.HDQ_CTRL_STATUS[7] set to 1) has no effect because the HDQ protocol supports only byte transfers.

20.4.2.4 Interrupt Conditions

The HDQ/1-Wire module provides the following interrupt status:

1. Transmission complete:

A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in HDQ protocol. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).

2. Read complete:

In HDQ mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).

3. Presence detect/time-out:

In HDQ mode, the interrupt status indicates that after a read command initiated by the host, the slave did not pull the line low within the specified time. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).

In HDQ mode, a time-out condition is also used to indicate the successful completion of a break pulse. That is, if the master has sent the break pulse, it is indicated with a time-out instead of a TX-complete.

Only one interrupt is generated to the MPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all the interrupt status bits that were previously set.

20.4.3 1-Wire Mode

20.4.3.1 1-Wire Mode Features

The 1-Wire mode supports the following:

- Dallas Semiconductor 1-WireR protocol
- Power-down mode
- Single-bit mode

20.4.3.2 Description

The 1-Wire mode requires an initialization pulse to be sent to the slave(s) connected on the interface. If a slave is present, it responds with a presence pulse.

The initialization pulse is sent after **INITIALIZATION** bit [HDQ.HDQ_CTRL_STATUS\[2\]](#) is set. The firmware sends the initialization pulse depending on the value of this bit.

The slave presence on the line is detected by a presence bit in the control and status register. When the slave receives the initialization pulse, it sends back its presence pulse by pulling down the line. The module detects this low-going edge and sets the **PRESENCEDETECT** bit [HDQ.HDQ_CTRL_STATUS\[3\]](#).

In a similar way, if a presence pulse is not received from the slave after an initialization pulse is sent, the **PRESENCEDETECT** bit remains cleared.

Whether or not a presence pulse is detected after an initialization pulse is sent, the **TIMEOUT** bit [HDQ.HDQ_INT_STATUS\[0\]](#) is set and an interrupt condition is generated.

In 1-Wire mode, the generated interrupt condition means the maximum time allowed for receiving the response has elapsed and the software must check the **PRESENCEDETECT** bit to determine whether or not there was a presence pulse.

The **INITIALIZATION** bit is cleared at the end of the initialization pulse at the same time as the **TIMEOUT** bit is set. The **TIMEOUT** bit is cleared when the interrupt status register ([HDQ.HDQ_INT_STATUS](#)) is read.

For read operations, 1-Wire is a bit-by-bit protocol, which means the slave must be clocked by the host for each bit of the byte to read.

The line is pulled up at the end of the command/address byte. On the first read, the host creates a low-going edge to initiate a bit read. The line is then pulled up (pulled to the high-impedance state by the host and set to a high logical level by the external pullup) and the slave either drives the line low to transmit a 0 or does not drive the line to transmit a 1. This sequence is repeated for each bit to read.

The first bit the host receives is the LSB, and the last bit is the most significant bit (MSB) in the receive data register ([HDQ.HDQ_RX_DATA](#)).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out condition (that is, the time allowed for the slave to indicate its presence has elapsed). A read operation on the interrupt status register clears the interrupt conditions previously set. As in the HDQ mode, only one interrupt signal is sent to the MPU. Only an overall mask bit can enable or disable the interrupt (the interrupt conditions cannot be masked individually).

20.4.3.3 1-Wire Single-Bit Mode Operation

A single-bit mode can be entered by setting the appropriate bit in the control and status register (**1_WIRE_SINGLE_BIT** bit [HDQ.HDQ_CTRL_STATUS\[7\]](#)). In this mode, only one bit of data at a time is transferred between the master and the slave. After the bit is transferred, an interrupt is generated (that is, there is an RX-complete for a read operation and a TX-complete for a write operation). Bit 0 of the RX register ([HDQ.HDQ_RX_DATA](#)) is updated each time a bit is received from the slave; bit 0 of the TX register ([HDQ.HDQ_TX_DATA](#)) contains the bit to be sent.

20.4.3.4 Interrupt Conditions

The HDQ/1-Wire module provides the following interrupt status:

1. Transmission complete:
A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in 1-Wire protocol. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).
2. Read complete:
In 1-Wire mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).
3. Presence detect/time-out:
In 1-Wire mode, the interrupt status indicates that it is now valid to check the PRESENCEDETECT bit. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).

Only one interrupt is generated to the MPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all interrupt status bits that were previously set.

20.4.3.5 Status Flags

The presence-condition-detected status flag is contained in the PRESENCEDETECT bit HDQ.HDQ_CTRL_STATUS[3]. This is valid only in 1-Wire mode. The flag is updated when TIMEOUT bit HDQ.HDQ_INT_STATUS[0] is set. Therefore, its correct value shows only after the interrupt is generated. The firmware must wait for the time-out condition; otherwise, the flag keeps its previous value and is undefined.

20.4.4 Module Power Saving

20.4.4.1 Autoidle Mode

The HDQ/1-Wire module provides an autoidle function in its interconnect clock domain.

The interconnect clock autoidle power-saving mode is enabled or disabled through the AUTOIDLE bit HDQ.HDQ_SYSCONFIG[0]. When this mode is enabled and there is no activity on the interconnect interface, the interconnect clock (HDQ_ICLK) is disabled inside the module, thereby reducing power consumption. When there is new activity on the interconnect interface, the interconnect clock is restarted with no latency penalty. This mode is disabled by default after a reset.

This mode is recommended to reduce power consumption.

20.4.4.2 Power-Down Mode

The HDQ/1-Wire module also provides a power-saving function in its functional clock domain.

Setting the CLOCKENABLE bit in the control and status register (CLOCKENABLE bit HDQ.HDQ_CTRL_STATUS[5]) to 0 shuts off the functional clock (HDQ_FCLK) to the state-machine. The state-machine is reset when the functional clock is disabled; if any transaction is ongoing, it is aborted into the reset state.

The register values are not affected by disabling the functional clock.

Do not access the module registers after the software has put the module in power-down mode except to write to the CLOCKENABLE bit to take the module out of power-down mode.

20.4.5 System Power Management and Wakeup

As part of the system-wide power-management scheme, the HDQ/1-Wire module can go into idle state at the request of the PRCM module (for more information, see the *Power, Reset, and Clock Management* chapter). However, the HDQ/1-Wire module does not support handshake protocol with the PRCM. The HDQ/1-Wire module can go into idle mode only as part of the L4 interconnect clock domain (both CORE_L4_ICLK and CORE_12M_FCLK belong to the L4 interconnect clock domain).

When the AUTO_HDQ bit PRCM.CM_AUTOIDLE1_CORE[22] is set, the HDQ/1-Wire module behavior follows the L4 interconnect clock domain behavior. If the whole domain is put into idle, the HDQ/1-Wire is also put into idle.

Software must ensure correct clock management.

CAUTION

There is no hardware mechanism to prevent cutting off the HDQ/1-Wire clocks while the module is performing a transfer. The result would be a loss of data being transferred.

20.5 HDQ/1-Wire Basic Programming Model

The HDQ/1-Wire module can be considered a simple byte engine because it only implements the hardware interface layer for both HDQ and 1-Wire protocols. The correct sequencing is controlled by the firmware, which is described in this section.

20.5.1 Module Initialization Sequence

20.5.1.1 Mode Selection

MODE bit HDQ.HDQ_CTRL_STATUS[0] allows selection between the HDQ and 1-Wire protocols. When set to 0, the protocol is HDQ; when set to 1, the protocol is 1-Wire. The bit is assumed static for design purposes. The configuration is in HDQ mode by default.

Although this bit can be modified at any point, it is strongly recommended that it be modified only as part of the boot-up configuration.

20.5.1.2 Reset/Initialization

No slave presence test is required in HDQ mode; however, the slave can be reset by setting the INITIALIZATION bit HDQ.HDQ_CTRL_STATUS[2] and the GO bit HDQ.HDQ_CTRL_STATUS[4]. The line is then pulled down (break pulse) and the bit returns to 0 after the pulse is sent. Upon completion, a time-out interrupt is also generated. The slave does not respond to this pulse.

In 1-Wire mode, the slave returns a presence pulse when it receives the initialization pulse. The protocol for initialization is as follows:

1. Set the INITIALIZATION bit HDQ.HDQ_CTRL_STATUS[2] to 1 and the GO bit HDQ.HDQ_CTRL_STATUS[4] to 1 to send the pulse. When the pulse is sent, the bit is cleared in the register.
2. Wait for the presence detect flag (TIMEOUT bit HDQ.HDQ_INT_STATUS[0]) to generate an interrupt. This flag is set when the response time allowed to the slave has elapsed, whether it has sent a pulse or not.
3. Read the HDQ.HDQ_CTRL_STATUS register to check whether the presence pulse has been received before starting any transfer.

20.5.2 HDQ Protocol Basic Programming Model

20.5.2.1 Write Operation

The write operation sequence is as follows:

1. Write the command/address or data value to the TX write register (HDQ.HDQ_TX_DATA).

Note: Steps 2 and 3 can be performed simultaneously.

2. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to indicate a write.
3. Set GO bit HDQ.HDQ_CTRL_STATUS[4] to start the transmission.
 - a. The hardware sends the byte from the TX write register.
 - b. In a write operation, the TIMEOUT bit is always cleared, because there is no acknowledge mechanism from the slave.
 - c. When the write operation is completed, the TX-complete flag is set in the interrupt status register (TXCOMPLETE bit HDQ.HDQ_INT_STATUS[2]). If interrupts are masked (that is, the corresponding bit has been previously set in the control and status register), no interrupt signal is generated.
 - d. GO bit HDQ.HDQ_CTRL_STATUS[4] is cleared at the end of a write operation.
4. The software must read the interrupt status register to clear the interrupt.
5. Repeat step 1 through step 4 for each successive byte to write.

20.5.2.2 Read Operation

The read operation sequence is as follows:

1. Write the command value to the TX write register (HDQ.HDQ_TX_DATA).
2. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to 0 and GO bit HDQ.HDQ_CTRL_STATUS[4] to 1 and wait for the TX-complete interrupt.

Note: Steps 3 and 4 can be performed simultaneously.

3. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to 0 to indicate a read.
4. Write 1 to GO bit HDQ.HDQ_CTRL_STATUS[4] to initiate the read.
 - a. The hardware detects a low-going edge on the line (generated by the slave) and receives 8 bits of data in the RX receive buffer register (HDQ.HDQ_RX_DATA). The first bit received is the LSB and the last bit is the MSB. The master performs this step as soon as the slave sends the data, irrespective of the state of GO bit HDQ.HDQ_CTRL_STATUS[4]. However, an RX-complete interrupt is generated only when the software writes the GO bit.
 - b. If a time-out occurs, the TIMEOUT bit HDQ.HDQ_INT_STATUS[0] is set.
 - c. Completion of the operation is indicated by setting the RX-complete flag in the interrupt status register (RXCOMPLETE bit HDQ.HDQ_INT_STATUS[1]. If interrupts are masked (that is, the corresponding bit was previously set in the control and status register), no interrupt signal is generated.
 - d. At the end of the read operation, the GO bit HDQ.HDQ_CTRL_STATUS[4] is cleared. It is also cleared if a time-out is detected.
5. The software must read the interrupt status register (HDQ.HDQ_INT_STATUS) to determine whether an RX was successfully completed or a time-out occurred.
6. The software reads the RX receive buffer register (HDQ.HDQ_RX_DATA) to retrieve the read data from the slave.
7. Repeat step 1 through step 6 for each successive byte.

Note: In HDQ mode, the address/command is written only once to the slave. However, after the first byte is received, an RX-complete interrupt is set. Therefore, the software must initiate the read of the second byte by setting the GO bit in the control and status register. The first byte received is shadowed and provided to the software while the hardware is fetching the second byte of data.

20.5.3 1-Wire Mode (SDQ) Basic Programming Model

Note: TIMEOUT interrupt will be generated when Slave fails in sending PRESENCE pulse during protocol initialization.

20.5.3.1 Write Operation

The write operation sequence is as follows:

1. Write the ID, command, or data value to the TX write register (HDQ.HDQ_TX_DATA).

Note: Steps 2 and 3 can be performed simultaneously.

2. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to 1 to indicate a write operation.
3. Set GO bit HDQ.HDQ_CTRL_STATUS[4] to 1 to start the transmission.
 - a. The hardware sends the byte stored in the TX write register.
 - b. In a write operation, the TIMEOUT bit is always cleared.
 - c. When the operation is completed, the TX-complete flag is set in the interrupt status register.

- (TXCOMPLETE bit HDQ_INT_STATUS [2]). No interrupt signal is generated if interrupts are masked (that is, the corresponding bit was previously set in the control and status register).
- d. The GO bit of the control and status register is cleared at the end of a write operation.
 4. The software must read the interrupt status register (HDQ.HDQ_INT_STATUS) to clear the interrupt.
 5. Repeat step 1 through step 4 for each successive byte to write.

20.5.3.2 Read Operation

The read operation sequence is as follows:

1. Write the address to the TX write register (HDQ.HDQ_TX_DATA).
2. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to 0 and the GO bit HDQ.HDQ_CTRL_STATUS[4] to 1 and wait for the TX-complete interrupt flag.
3. Write the command value to the TX write register (HDQ.HDQ_TX_DATA).
4. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to 0 and GO bit HDQ.HDQ_CTRL_STATUS[4] to 1 and wait for the TX-complete interrupt flag.

Note: Steps 5 and 6 can be performed simultaneously.

5. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to 0 to indicate a read.
6. Set GO bit HDQ.HDQ_CTRL_STATUS[4] to 1 to start the transmission.
 - a. The hardware (master) generates a low-going edge and clocks 8 bits of data into the RX receive register (HDQ.HDQ_RX_DATA). The first bit received is the LSB and the last bit is the MSB.
 - b. TIMEOUT bit HDQ.HDQ_INT_STATUS[0] is always cleared in a read operation.
 - c. When the operation is complete, the RX-complete flag is set in the interrupt status register (RXCOMPLETE bit HDQ.HDQ_INT_STATUS[1]). No interrupt signal is generated if the interrupts are masked (that is, the corresponding bit was previously set in the control and status register).
 - d. GO bit HDQ.HDQ_CTRL_STATUS[4] is cleared at the end of the read. It is also cleared if a time-out occurs.
7. The software must read the interrupt status register to determine whether an RX was successfully completed or a time-out occurred.
8. The software reads the RX receive buffer register (HDQ.HDQ_RX_DATA) to retrieve the read data from the slave.
9. Repeat step 1 through step 8 for each successive byte.

20.5.3.3 1-Wire Bit Mode Operation

Select the single-bit mode by setting the 1_WIRE_SINGLE_BIT bit HDQ.HDQ_CTRL_STATUS[7] to 1. In this mode, only one bit of data at a time is transferred between the master and the slave. After the bit is transferred, the corresponding interrupt flag is set (that is, there is an RX-complete (RXCOMPLETE bit HDQ.HDQ_INT_STATUS[1]) for a read operation and a TX-complete (TXCOMPLETE bit HDQ.HDQ_INT_STATUS[2]) for a write operation). Bit 0 of the RX register (HDQ.HDQ_RX_DATA) is updated each time a bit is received; bit 0 of the TX register (HDQ.HDQ_TX_DATA) contains the bit of data to be sent.

20.5.4 Power Management

The software has independent control of the two clock domains (interconnect clock: HDQ_ICLK and functional clock: HDQ_FCLK). Because there is no acknowledge mechanism from the HDQ/1-Wire module to an idle request, the software must ensure that a clock is not shut off while a transfer is being processed (the data would be lost).

If the autoidle function (AUTOIDLE bit HDQ.HDQ_SYSCONFIG[0] set to 1) provides a transfer security (the module wakes up the HDQ_ICLK as soon as a transfer is initiated), the power-down mode and the PRCM idle requests (through the whole L4 clock domain idle request) must be handled carefully.

The following sections describe the steps to follow to use the power-down and idle modes.

20.5.4.1 Module Power-Down Mode

1. Before shutting off the HDQ_FCLK, wait for an RX-complete or a TX-complete interrupt.
 - In a read operation, the transfer is completed when the RX-complete flag (RXCOMPLETE bit HDQ.HDQ_INT_STATUS [1]) generates an interrupt.
 - In a write operation, the transfer is completed when the TX-complete flag (TXCOMPLETE bit HDQ.HDQ_INT_STATUS [2]) generates an interrupt. The software must check whether the interrupt was generated after the address/command byte was sent or after the data byte was sent. The clock must not be shut off after the command/ address byte is sent; otherwise, the data is not written to the slave.

HDQ.HDQ_INT_STATUS must be read to clear the interrupt condition.

2. Set the CLOCKSABLE bit HDQ.HDQ_CTRL_STATUS[5] to 0 to disable the clock.
Do not access the module registers after the software has put the module into power-down mode except to write to the clock-enable bit to take the module out of power-down mode.

20.5.4.2 System Idle Mode

This section describes the steps to follow at the module level before enabling the idle mode at the system level (for more information about the system power management scheme, see the *Power, Reset, and Clock Management* chapter).

As part of the L4 interconnect clock domain, the HDQ/1-Wire clocks can be cut at the PRCM level. HDQ_FCLK can be cut if the EN_HDQ bit PRCM.CM_FCLKEN1_CORE [22] is set to 0 and no other modules require CORE_12M_FCLK. The software must verify that no transfer is in progress.

In a read operation:

1. Wait for an RX-complete interrupt.
In a read operation, the transfer is completed when the RX-complete flag (RXCOMPLETE bit HDQ.HDQ_INT_STATUS [1]) generates an interrupt.
2. Read the HDQ.HDQ_INT_STATUS to clear the read-complete interrupt flag.
3. Read the HDQ.HDQ_RX_DATA to retrieve the read data.
4. The HDQ_ICLK can be shut off by entering the system idle mode.

In a write operation:

1. Wait for a TX-complete interrupt.
In a write operation, the transfer is completed when the TX-complete flag (TXCOMPLETE bit HDQ.HDQ_INT_STATUS[2]) generates an interrupt. The software must check whether the interrupt was generated after the address/command byte was sent or after the data byte was sent. The clock must not be shut off after the command/address byte is sent; otherwise, the data is not written to the slave.
2. Read the HDQ.HDQ_INT_STATUS to clear the TX-complete interrupt flag.
3. The HDQ_ICLK can be shut off by entering the system idle mode.

Concerning HDQ_ICLK, two situations can occur:

- The clock is no longer required and EN_HDQ bit PRCM.CM_ICLKEN1_CORE[22] is set by software. In this case, the clock is cut off, provided no other modules require it. Before setting the EN_HDQ bit, the software must follow the steps described in this section.
- AUTO_HDQ bit PRCM.CM_AUTOIDLE1_CORE[22] is set. In this case, the software must verify that all HDQ/1-Wire transfers are complete before enabling the L4 interconnect clock domain idle mode. Otherwise, the HDQ/1-Wire has no way to prevent the clock from being cut, because no hardware mechanism exists. The steps listed in this section must be verified before putting the L4 clock domain into idle state.

20.6 HDQ/1-Wire Use Cases and Tips

20.6.1 How to Configure the HDQ/1-Wire when Connected with a BQ27000 Gauge

20.6.1.1 Environment

Figure 20-10 details the OMAP device connections with the BQ27000 gauge.

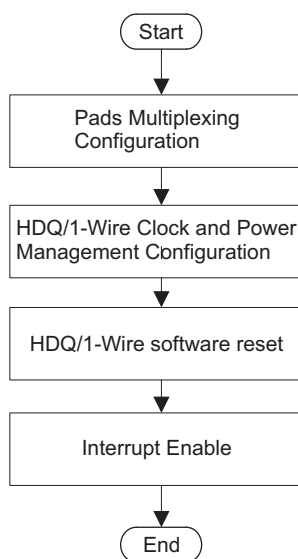

Figure 20-10. Environment

20.6.1.2 Programming Flow

This section details the programming flow of the HDQ/1-Wire. Figure 20-11 shows the main steps of this configuration. The BQ27000 gauge uses the HDQ mode.

Figure 20-11. HDQ/1-Wire Configuration in HDQ Mode

20.6.1.3 Pad Configuration and HDQ/1-Wire Clock and Power Management

Table 20-3 shows the pad multiplexing and the clock and power management configuration to select for the HDQ/1-Wire module.

Table 20-3. Registers Print for HDQ/1-Wire Configuration

Register Name	Address	Value	Value description
SCM.CONTROL_PA DCONF_I2C3_SDA	0x 4800 21C4	0x0118 0100	Configure hdq_sio pad in mode 0
PRCM.CM_FCLKEN 1_CORE	0x4800 4A00	0x0020 0000	Enable HDQ/1-Wire Functional clock
PRCM.CM_ICLKEN 1_CORE	0x4800 4A10	0x0020 0000	Enable HDQ/1-Wire Interface clock
HDQ_CTRL_STATU S	0x480B 200C	0x0000 0020	Enable clocks and select the HDQ mode
HDQ_SYSCONFIG	0x480B 2014	0x0000 0000	Module clock is free-running (Disable autoidle mode)

20.6.1.4 HDQ/1-Wire Software Reset

Perform a software reset as described in Figure 20-12.

Figure 20-12. Software Reset Flowchart

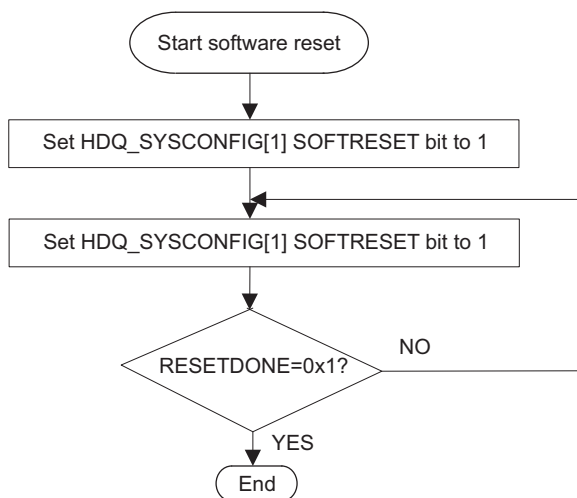

Table 20-4 describes the registers to be configured for the HDQ/1-Wire software reset step.

Table 20-4. Registers Print for HDQ/1-Wire Software Reset

Register Name	Address	Value	Value description
HDQ_SYSCONFIG	0x480B 2014	0x0000 0002	Initiate a software reset. The HDQ_SYSCONFIG[1] SOFTRESET is automatically reset by hardware.
HDQ_SYSSTATUS	0x480B 2018	0x0000 0001	The HDQ_SYSSTATUS[0] RESETDONE is set to 1 when the reset sequence is done.

20.6.1.5 Interrupts Enable

[Table 20-5](#) describes the registers to be configured for the interrupts enable step and the use case values.

Table 20-5. Registers Print for HDQ/1-Wire Interrupts Enable

Register Name	Address	Value	Value description
HDQ_CTRL_STATU S	0x480B 200C	0x0000 0060	Enable Interrupts

20.6.1.6 Read and Write Operations

The Read and Write operations in HDQ mode are described in [Section 20.5.2](#). Please, refer to this section to see how HDQ/1-Wire registers are configured for these operations.

Some write operations are needed to configure the BQ27000 gauge: for example, it is necessary to write a COMMAND KEY (0xA9 or 0x56) in the Device Control Register of the gauge. For more information, see the TI BQ27000 gauge specification.

20.7 HDQ/1-Wire Registers

Table 20-6 lists the HDQ/1-Wire instances.

Table 20-6. Instance Summary

Module Name	Base Address	Size
HDQ/1-Wire	0x480B 2000	4K bytes

CAUTION

All reserved bits must be written with 0. There is no synchronization between the register clock domain and the state-machine domain. Therefore, the following rules must be observed when accessing the module registers:

- A read from the interrupt status register or the receive buffer register is not allowed unless the processor has been interrupted by the module.
- After the release of the GO bit in the control and status register, no access to the TX data register or the control and status register is allowed until the processor has been interrupted by the module.
- Polling of the interrupt status register by software to determine whether an interrupt was generated is not allowed.
- No access to the module registers should be done after the software puts the module in power-down mode (by setting bit 5 of the control and status register to 0) except to re-enable the clock.

CAUTION

The HDQ/1-Wire registers are limited to 32-bit data accesses. 16-bit and 8-bit are not allowed and can corrupt register content.

20.7.1 HDQ/1-Wire Register Mapping Summary

Table 20-7 lists the HDQ/1-Wire registers.

Table 20-7. HDQ/1-Wire Registers

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address

Section 20.6	Added section and all subsections.

Multi-Channel Buffered Serial Port (McBSP)

This chapter introduces the multi-channel buffered serial port (McBSP) of the OMAP35x Applications Processor.

21.8 Revision History	2972

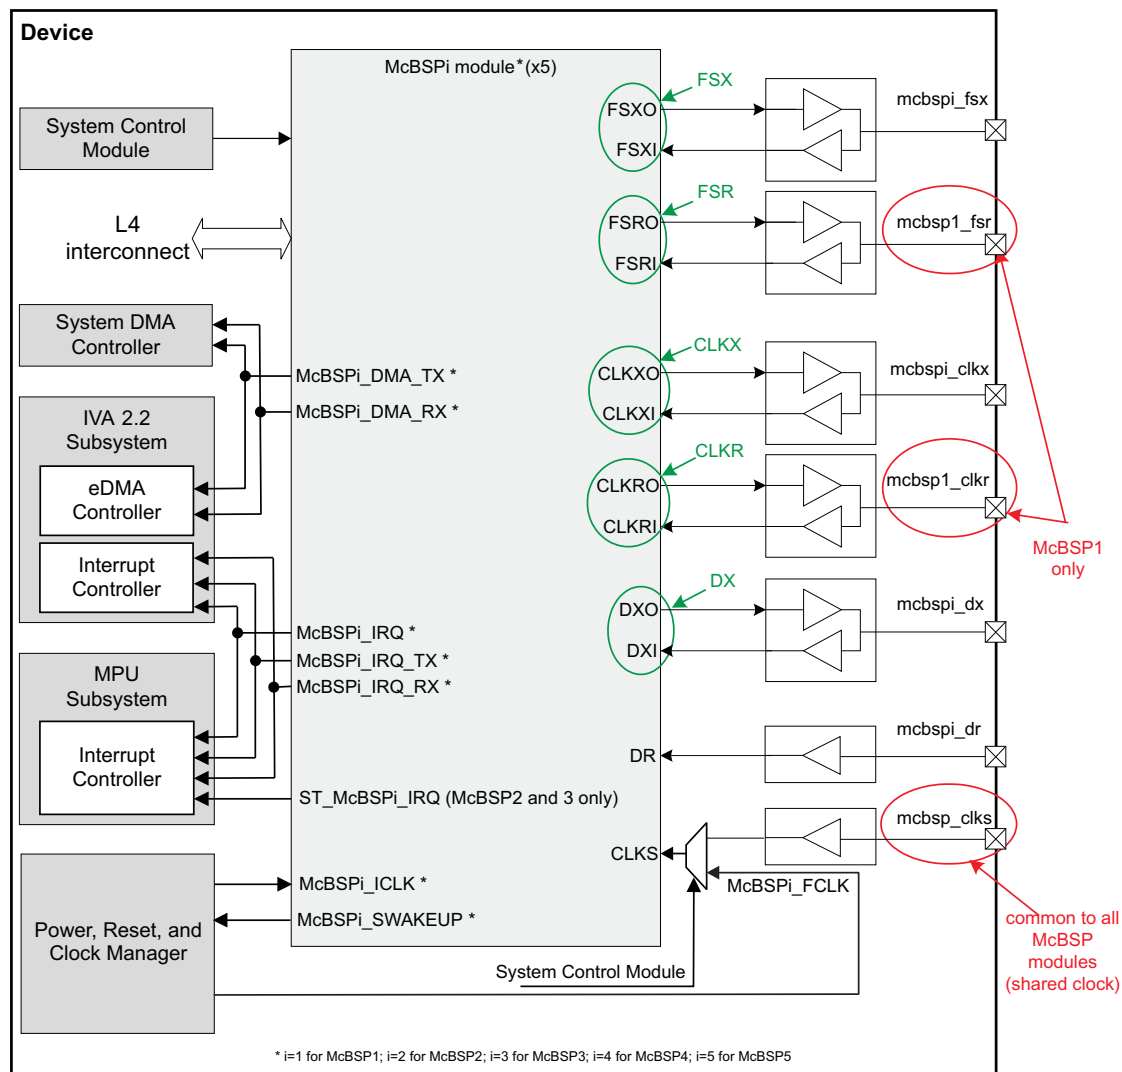

21.1 McBSP Overview

The multi-channel buffered serial port (McBSP) provides a full-duplex direct serial interface between the device and other devices in a system such as other application chips (digital base band), audio and voice codec (TPS65950 device), etc. Because of its high level of versatility, it can accommodate a wide range of peripherals and cFlocked frame oriented protocols (for details, see [Section 21.1.1](#)).

The device provides five instances of the McBSP module.

[Figure 21-1](#) shows the McBSP overview in the device.

Figure 21-1. McBSP Highlight

001

21.1.1 McBSP Features

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

The OMAP35x device provides five instances of the McBSP modules, called McBSP1, McBSP2, McBSP3, McBSP4, and McBSP5.

The main features of the McBSP modules are:

- L4 interconnect slave interface supports:
 - 32-bit data bus width
 - 32-bit access supported
 - 16-/8-bit access not supported
 - 10-bit address bus width
 - Burst mode not supported
 - Write nonposted transaction mode supported
- 128 x 32-bit words (512 bytes) for each buffer for transmit/receive operations (McBSP1, 3, 4, 5)
- 5K bytes (1024 x 32 bits for audio buffer + 256 x 32 bits for buffer) for each buffer for transmit/receive audio operations (McBSP2 only)
- Interrupts configurable in legacy mode (2 requests) or PRCM compliant (1 request)
- Transmit and receive DMA requests triggered with programmable FIFO thresholds
- SIDETONE core support: Audio loopback capability (McBSP2 and 3 only)
- Multidrop support
- Serial interface description
 - 6 pin configuration (McBSP 1 only)
 - 4 pin configuration (McBSP2, 3, 4, 5)
 - Full-duplex communication
 - Multichannel selection modes
 - Support to enable or block transfers in each of the channels
 - 128 channels for transmission and for reception
 - Direct interface to industry-standard codecs, analog interface chips (AICs), and other serially connected A/D and D/A devices:
 - Inter-IC sound (I2S) compliant devices
 - Pulse code modulation (PCM) devices
 - Time division multiplexed (TDM) bus devices

CAUTION

McBSP modules do not offer support for μ -law and A-law commanding, two partitions mode dynamic reassignment, AC'97, and SPI protocol.

- A wide selection of data sizes: 8, 12, 16, 20, 24, and 32 bits
- Bit reordering (send/receive least significant bit [LSB])
- Clock and frame-synchronization generation support:
 - Independent clocking and framing for reception and for transmission up to 48 MHz
 - Support for external generation of clock signals and frame-synchronization (frame-sync) signals
 - A programmable sample rate generator for internal generation and control of clock signals and frame-sync signals
 - Programmable polarity for frame-sync pulses and for clock signals

Notes:

- McBSP modules do not support features such as re-transmit or re-receive of an erroneous frame or word.
- McBSP modules support dual phase frames to provide I2S fully compliant capabilities. But, this dual phase mode is limited at one channel (or word) for each phase instead of 128 channels max for single phase mode.

21.1.2 SIDETONE Core

The purpose of this section is to present the SIDETONE core implemented in McBSP2 and 3 modules. It is required that two of the audio input channels to be looped back, filtered, and mixed to the two corresponding audio output channels.

Data to be processed comes on two separate paths (one for each channel) through a simple interface. After filtering the data, gain is applied and outputted through a similar interface. For more details, see [Figure 21-2](#).

Figure 21-2. SIDETONE Core Architecture

The SIDETONE core offers the following features:

- Filter coefficients are shared between the two channels (the filter coefficient is assumed to represent values in the range $-1...+1$)
- Gains are independent for the two channels (the gain coefficients are in the range $-2...+2$)
- The filter output is multiplied with the gain, and the result is rounded to output channel word width.
- The FIR filter length is 128 samples.
- Filtered loop back signals are added to the corresponding output signals, and saturation is applied if the result exceeds arithmetic range.
- Filter coefficients and gains are programmable:
 - Coefficients are changed while audio is stopped.
 - Gains are changed at any time (also during audio operation with SIDETONE enabled).

21.2 McBSP Environment

This section describes the intended functions for McBSP module from an environment point of view (that is, external connections). It presents the McBSP connectivity options, lists the possible interfaces, and details the protocol and data format used in each case.

21.2.1 McBSP Functions

The device provides five instances of the McBSP module, called McBSP1, McBSP2, McBSP3, McBSP4, and McBSP5.

List of recommended usage (non exhaustive) per McBSP modules in the device:

- McBSP1: Digital baseband (DBB) Data
- McBSP2: Audio data with audio buffer and SIDETONE feature
- McBSP3: Bluetooth voice data with SIDETONE feature
- McBSP4: DBB voice data
- McBSP5: Midi data

[Table 21-1](#) describes the functions and the corresponding application fields.

Table 21-1. Functions Description

Function	Application field	Recommended McBSP module	Description
Control and Data	Digital Base Band (DBB) Data	McBSP1	Serial interface to transfer data
Audio Data	Audio Data with Audio Buffer	McBSP2	Audio interface to transfer audio data with Inter-IC Sound codec (I2S)
	Audio Data with Audio Buffer and SIDETONE feature		
	Midi Data	McBSP5	
Voice Data	Bluetooth Voice Data	McBSP3	Voice interface to transfer voice data with Pulse Code Modulation codec (PCM)
	Bluetooth Voice Data with SIDETONE feature		
	DBB Voice Data	McBSP4	

21.2.2 McBSP Signals Descriptions

The five McBSP modules consist of a data-flow path and a control path connected to external devices by a serial interface with 6 pins configuration (McBSP 1 only) or 4 pins configuration (McBSP2, 3, 4, 5).

For a McBSP module with 6 pins configuration, an internal loop back capability between Transmitter and Receiver clock signals, and both frame synchronisation signals enables using the McBSP module with 4 pins configuration. The related internal multiplexers are controlled through the System Control Module on the device (see [Section 21.3](#)).

Table 21-2. Input/Output Description

Pin Name	I/O	Description	Internal Signal Name	Reset Value	Control and Data	Audio Data	Voice Data
mcbasp_clks	I	External clock (shared by all McBSP modules)	CLKS	-	ü	ü	ü
mcbspi_dr	I	Receive serial data	DR	-	ü	ü	ü
mcbspi_dx	(I)O see Note below	Transmit serial data	DX	0	ü	ü	ü
mcbasp1_clkx	I/O ⁽¹⁾	Transmit clock	CLKX	0	ü	ü	ü
mcbasp1_fsx	I/O ⁽¹⁾	Transmit frame synchronization	FSX	0	ü	ü	ü
mcbasp1_clkr	I/O ⁽¹⁾	Receive clock	CLKR	1	ü		
mcbasp1_fsr	I/O ⁽¹⁾	Receive frame synchronization	FSR	0	ü		

⁽¹⁾ For details of the input/output selection, see [Section 21.2.3.1](#).

Legend: I=1 to 5, I=Input, O=Output

- The mcbasp_clks pin can be used to inject an external clock. This clock is used to generate control signals depending on the module internal configuration (see [Section 21.4.3](#)). The CLKS signal of the McBSP modules is linked to an external signal through the mcbasp_clks pin, but the CLKS signal can also be linked to an internal clock provided by PRCM of the device. For more information, see [Section 21.3](#).
- Data are transmitted to external devices interfacing with McBSP modules via the mcbspi_dx pin. Data from those devices are received on the mcbspi_dr pin.

Note: The mcbspi_dx pin is an input/output signal to use the McBSP module in half-duplex mode.

- Control information is communicated via the following pins: mcbspi_clkx (transmit clock), mcbasp1_clkr (receive clock), mcbspi_fsx (transmit frame-sync), and mcbasp1_fsr (receive frame-sync).

CAUTION

External pins mcbasp1_clkr and mcbasp1_fsr are connected to pads only for McBSP1 module; other McBSP modules don't have these connections. For these modules, CLKR and FSR signals sources are mcbspi_clkx and mcbspi_fsx pins, respectively. Consequently, there is a light restriction on other McBSP modules when used in full-duplex mode. Both reception and transmission use the same clock signal and the same frame synchronization signal.

21.2.3 McBSP Functions Description

21.2.3.1 McBSP Modes

For all McBSP functions, McBSP modules can operate in master or slave mode. The difference between these modes is the definition of the source of McBSP clocks and McBSP frames synchronization:

- Master mode: McBSP module provides them to the external device
- Slave mode: McBSP module receives them from the external device

The choice between the two modes depends of technical data of the external device and the type of interface (protocols and data formats). For one McBSP module, there are four possible functions:

- Transmit and receive master mode

2. Transmit and receive slave mode
3. Transmit master mode and receive slave mode
4. Transmit slave mode and receive master mode

Note: If the McBSP module has a serial interface with 4 pins configuration (McBSP2, 3, 4, 5), only modes 1 or 2 are possible.

Figure 21-3 shows the connection between the McBSP1 module (6 pins configuration) and an external device in transmit master mode and receive slave mode.

Figure 21-3. Mode Overview of McBSP1 Module

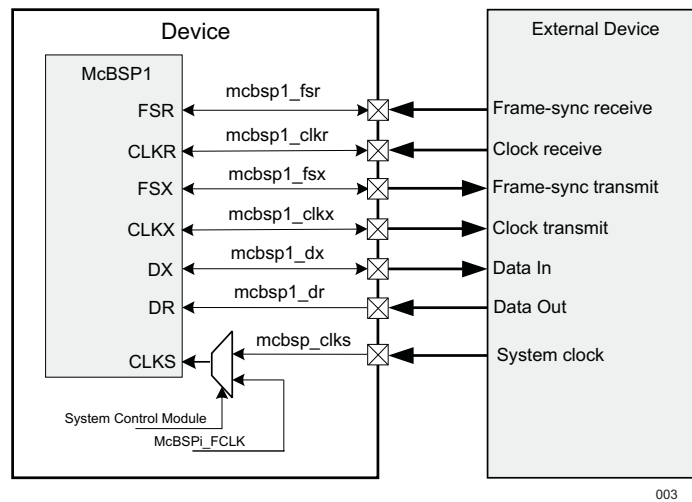

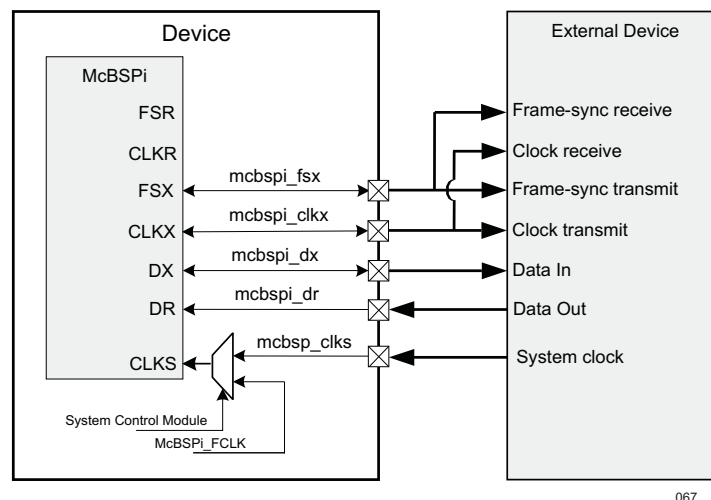

Figure 21-4 shows the connection between the McBSPi module, with I = 2, 3, 4 or 5 (4 pins configuration) and an external device in transmit and receive master mode.

Figure 21-4. Mode Overview of McBSPi Module

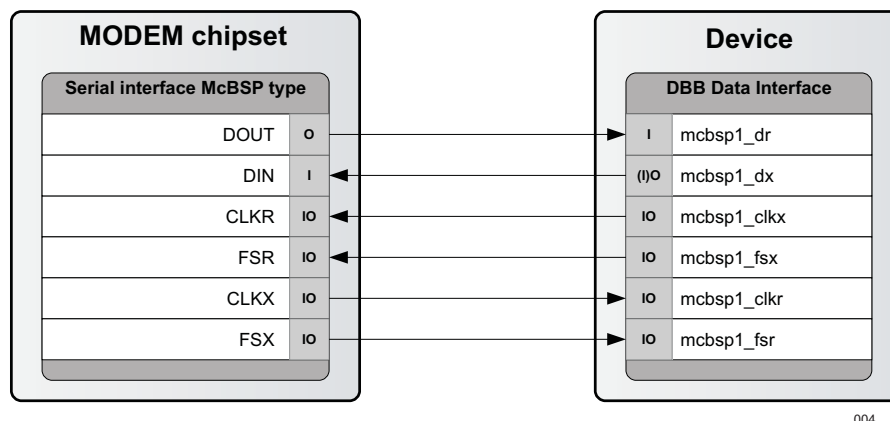

21.2.3.2 McBSP Functions

21.2.3.2.1 McBSP Function 1: Control and Data

In full-duplex mode (reception and transmission use independent clock signals and frame synchronization signals), the McBSP module can be used to exchange control and data with an external chipset, allowing the device to be interfaced with a modem device. Figure 21-5 shows typical connections between device and modem chipset to illustrate DBB data application.

Figure 21-5. DBB Data Application

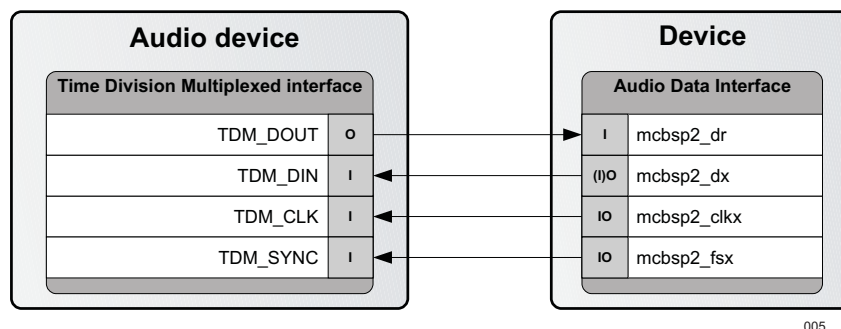

In Figure 21-5, the McBSP1 module is configured in transmit master mode and in receive slave mode.

21.2.3.2.2 McBSP Function 2: Audio Data

The McBSP module is connected to audio devices through the I2S interface. The I2S link serial interface is a TDM slot based serial interface that is used to transfer audio data. Those audio devices can be either AICs or other serially connected A/D and D/A devices.

Figure 21-6 shows typical connections between device and a typical device of analog audio interface (TPS65950 device) to illustrate Audio Data application. The typical device contains several audio analog inputs and outputs, as well as digital microphone inputs.

Figure 21-6. Audio Data Application

In Figure 21-6, the McBSP2 module is configured in transmit and receive master mode.

21.2.3.2.3 McBSP Function 3: Voice Data

The McBSP module is connected to a voice device through the PCM interface. The PCM link serial interface is a TDM slot based serial interface that is used to transfer voice data. The voice devices can be either modem chipsets, Bluetooth chipsets or others devices with voice data interface.

Figure 21-7 shows typical connections between device and Bluetooth chipset (TI BRF6300 or TI BRF6350) to illustrate voice data application.

Figure 21-7. Voice Data Application

In Figure 21-7, the McBSP3 module is configured in transmit and receive master mode.

21.2.4 McBSP Protocols and Data Formats

The McBSP module can use one of the three protocols with associated data formats:

- Serial protocol to exchange serial data
- Audio protocol to exchange the audio samples
- Voice protocol to exchange the voice samples

The McBSP modules offer the flexibility to modify the following parameters to adapt to the device features as described in the following subsections.

21.2.4.1 Words, Frames, and Phases Definitions

21.2.4.1.1 Words or Channels

The data bits are transferred (transmission or reception) in a group called a serial word or channel. The number of bits in a word (length) is programmable via bits field (McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 field and McBSPi.MCBSPLP_RCR2_REG[7:5] RWDLEN2 field, McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 field and McBSPi.MCBSPLP_XCR2_REG[7:5] XWDLEN2 field) and can be 8, 12, 16, 20, 24 or 32 bits (see Section 21.4.2.3). The McBSP module uses clock signals to control the time for each bit transfer. Data are sampled/driven on rising or falling edge of clock signals. This clock polarity is programmable via bits field of pin-control register (McBSPi.MCBSPLP_PCR_REG).

For more information, see Section 21.4.2.4.

21.2.4.1.2 Frames

One or more words (max 128) are transferred in a group called a frame. The McBSP module can transmit / receive a maximum of 128 words per frame, programmable via bits field of transmit and receive control registers (McBSPi.MCBSPLP_XCR1_REG/McBSPi.MCBSPLP_XCR2_REG and McBSPi.MCBSPLP_RCR1_REG/McBSPi.MCBSPLP_RCR2_REG). For more details, see Section 21.4.2.3.

All the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The McBSP module uses frame-synchronization signals to determine when each frame is received/transmitted. When a pulse occurs on a frame-synchronization signal, the McBSP module begins receiving/transmitting a frame of data. When the next pulse occurs, the McBSP module receives/transmits the next frame, and so on. Frame-synchronization pulse is active high or low. This pulse polarity is programmable via bits field of pin-control register (McBSPi.MCBSPLP_PCR_REG).

Each frame transfer can be delayed by 0, 1, or 2 clock cycles, depending on the value of bits for transmit and receive control registers (McBSPi.MCBSPLP_XCR2_REG and McBSPi.MCBSPLP_RCR2_REG). For more information, see Section 21.4.4.6.3 and Section 21.4.4.3.3.

21.2.4.1.3 Phases

The McBSP module allows configuring each frame to contain one or two phases. The McBSP module supports dual phase frames to provide I2S fully compliant capabilities. These two phases represent left and right channels of audio stereo signals.

The limitation on dual phase frame is that the number of words per phase must be set to one for both first and second phase. But, the number of bits per word can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers.

For example, software may define a frame composed of a first phase with one 12-bit word and a second phase with one 16-bit word. This configuration allows the software to compose frames for custom applications. For more details, see [Section 21.4.2.4](#).

Figure 21-8 shows signal activity for two possible reception/transmission scenarios.

Figure 21-8. McBSP Reception/Transmission Signal Activity

21.2.4.2 Serial Protocol and Data Formats

21.2.4.2.1 Protocol

The serial protocol is used to send and receive control data without specific formats. This allows McBSP module to accommodate all serial devices and their protocols.

21.2.4.2.2 Data Format

Figure 21-9 shows typical operation of the McBSP clock and frame sync signals. Serial clocks CLKR and CLKX define the boundaries between bits for receive and transmit, respectively. Similarly, frame-sync signals FSR and FSX define the beginning of an element and/or frame transfer. The McBSP module allows the configuration of the following parameters for data and frame synchronization:

- Polarity of FSR, FSX, CLKX, and CLKR
- The number of words per frame
- The number of bits per word
- Whether subsequent frame synchronization restarts the serial data stream or is ignored
- The data delay from frame synchronization to first data bit which can be 0-, 1-, or 2-bit delays

The configuration is independent for receive and transmit parts. For more details and configuration examples, see [Section 21.4](#) and [Section 21.5](#).

Figure 21-9. Serial Data Formats

009

21.2.4.3 Audio Protocol and Data Formats

21.2.4.3.1 Protocol

The I2S protocol is used to send and receive audio data from 8 KHz up to 48 KHz sampling rate (frame-sync frequency), with 16 bits or 32 bits per words (Supported frequencies are 8, 11.025, 12, 16, 22.05, 24, 32, 44.1 and 48 KHz).

The frame-synchronization signal defines the frame length in the I2S protocol. Each frame consists of a fixed number of words. In dual-phase frame, the frame-synchronization signal is low for the left phase time slot and is high for the right phase time slot. In addition, the frame-synchronization signal is synchronous to the falling edge of the clock signal.

21.2.4.3.2 Data Formats

The I2S protocol supports TDM, I2S, left justified, and right justified data formats.

Bits of each word (sample) are clocked using clock signal. For each word, MSB is first. LSBs are padded to 0 when the data length (8, 12, 16, 20, or 24 bits) is less than the sample word width (16 or 32 bits).

21.2.4.3.2.1 TDM Data Format

Figure 21-10 shows that each frame of TDM data format is composed of four words (or channels).

Figure 21-10. TDM Data Format; Word Width: 32 Bits; Data Length: 24 Bits

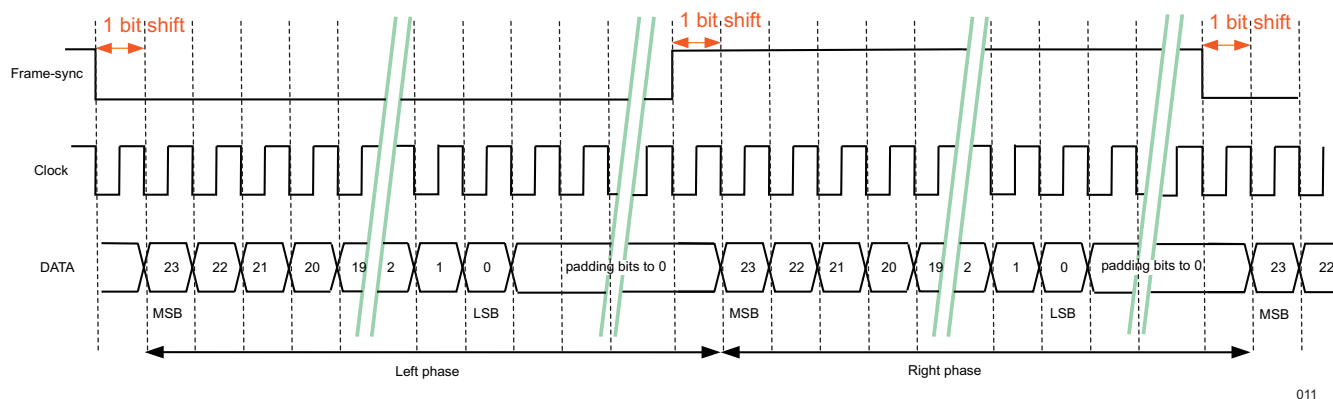

010

21.2.4.3.2.2 I2S Data Format

Figure 21-11 shows an example with 24 bits data (MSB first) and 8 padding bits at '0'.

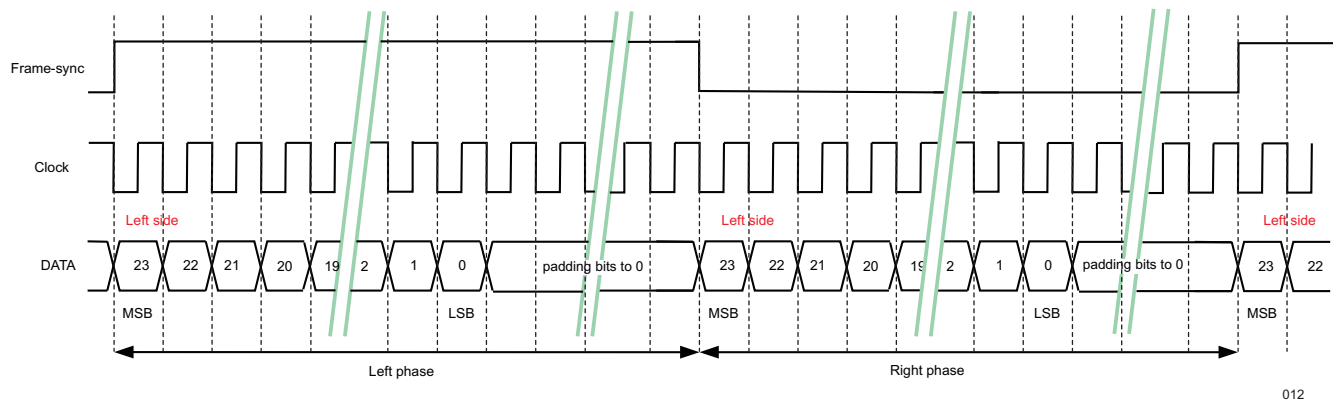

Figure 21-11. I2S Data Format; Word Width: 32 Bits; Data Length: 24 Bits

21.2.4.3.2.3 Left Justified Data Format

Figure 21-12 shows an example with 24 bits data (MSB first) and 8 padding bits at '0'.

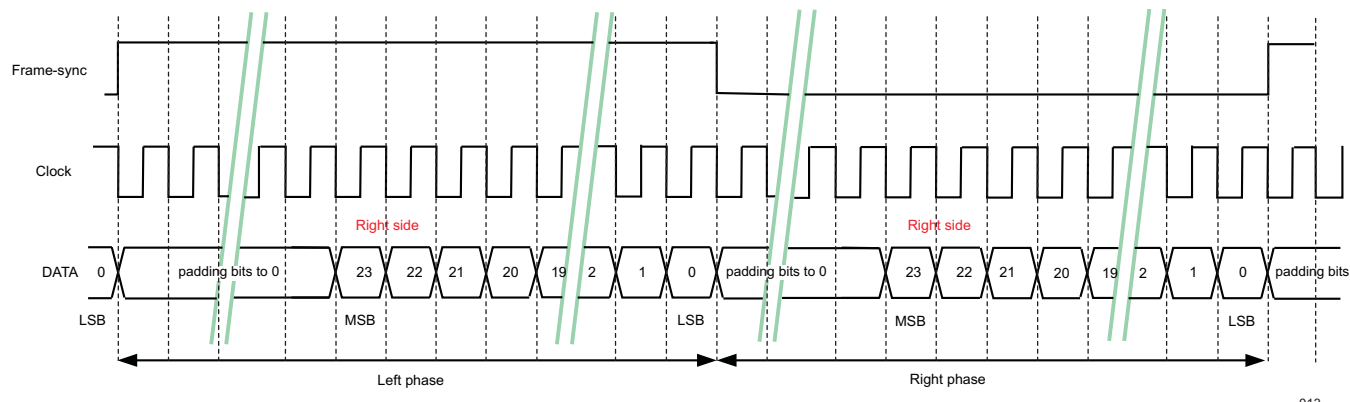

Figure 21-12. Left Justified Data Format; Word Width: 32 Bits; Data Length: 24 Bits

21.2.4.3.2.4 Right Justified Data Format

Figure 21-13 shows an example with 8 padding bits at '0' and 24 bits data (MSB first).

Figure 21-13. Right Justified Data Format; Word Width: 32 Bits; Data Length: 24 Bits

21.2.4.4 Voice Protocol and Data Formats

21.2.4.4.1 Protocol

The PCM protocol is intended to transfer voice data at 8 kHz (default narrowband mode) or 16 kHz (wideband mode) sample rates (frame-sync frequency). PCM protocol can act as a slave or master, and is used by the Bluetooth interface and the modem generic interface. The frame-synchronization defines the frame length in the PCM protocol. Bits are clocked using PCM clock signal, with MSB first.

21.2.4.4.2 Data Formats

Two modes are available for the PCM protocol: mode 1 and mode 2. For these both modes, it has two types of operations: Mono or stereo channels. The difference between PCM mode 1 and PCM mode 2 is in the way they use either the rising or the falling edge of clock signal, and the frame-synchronization polarity.

- PCM Mode 1: Input data is latched on the falling edge of the clock, and the transmitted data starts on the rising edge of the clock. Frame-synchronization pulse is active high.
- PCM Mode 2: Input data is latched on the falling edge of the clock, and the transmitted data starts on the falling edge of the clock. Frame-synchronization pulse is active low.

Figure 21-14 and Figure 21-15 shows an example of PCM protocol, mode 1 and mode 2, respectively, for a frame composed one word (width: 32 bits) with 16 bits data.

Figure 21-14. PCM Protocol - Mode 1 Data Format

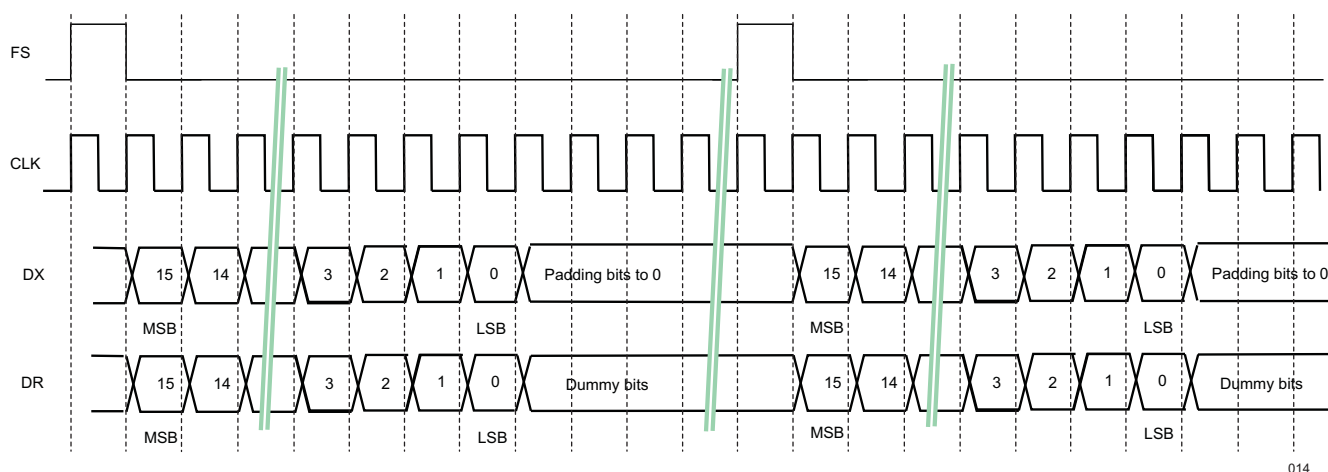

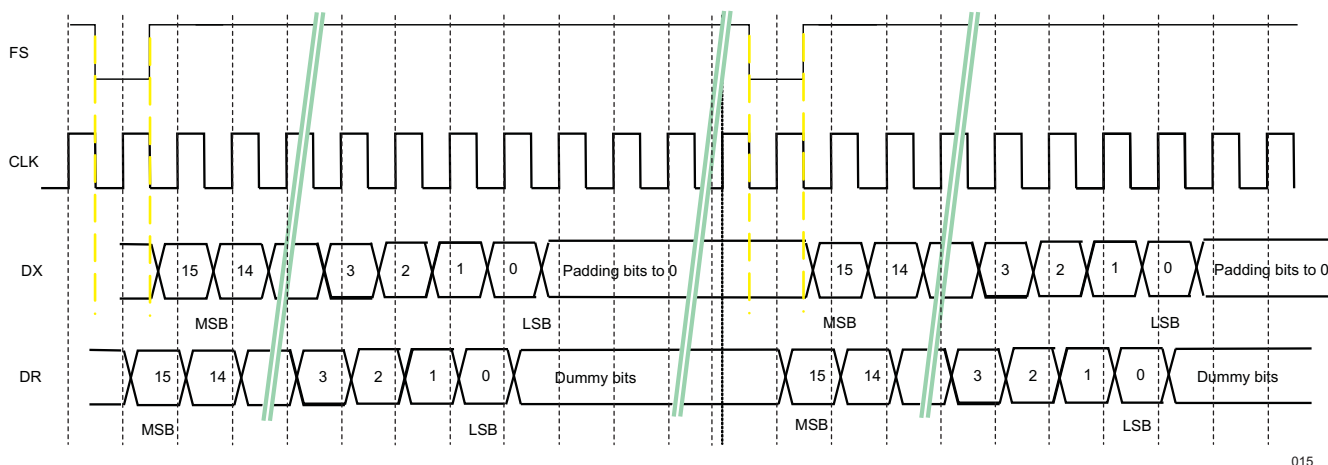

Figure 21-15. PCM Protocol - Mode 2 Data Format

21.3 McBSP Integration

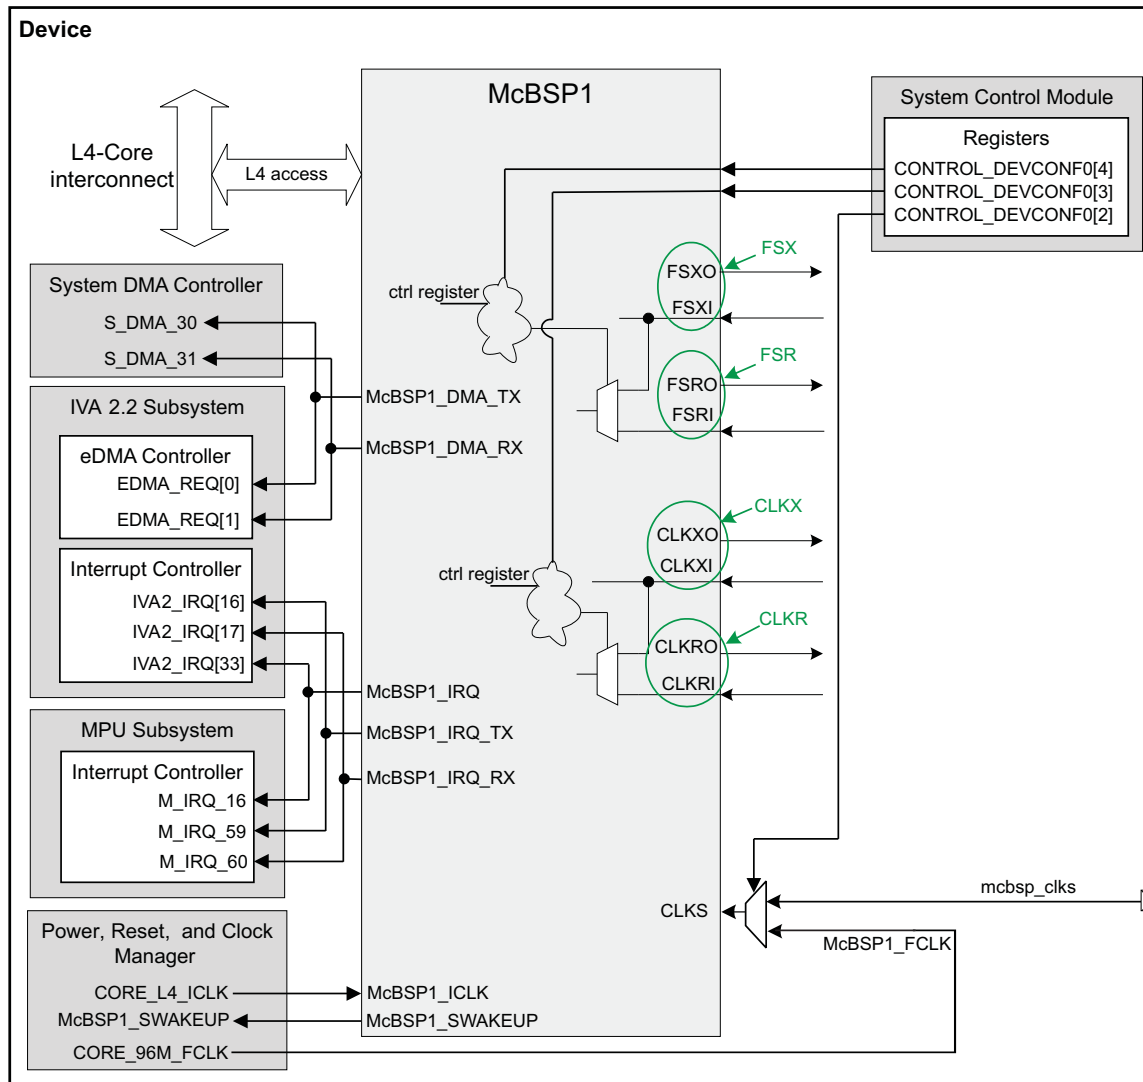

This section describes the McBSP modules integration inside the device and all the details about signal source controls, clocks, resets, power management, and hardware requests.

McBSP modules are divided into 2 families: McBSP modules that are gated in CORE domain (McBSP1 and 5), and McBSP modules that are gated in PER domain (McBSP2, 3, and 4).

For more details on CORE and PER domain, see the *Power, Reset and Clock Management* chapter.

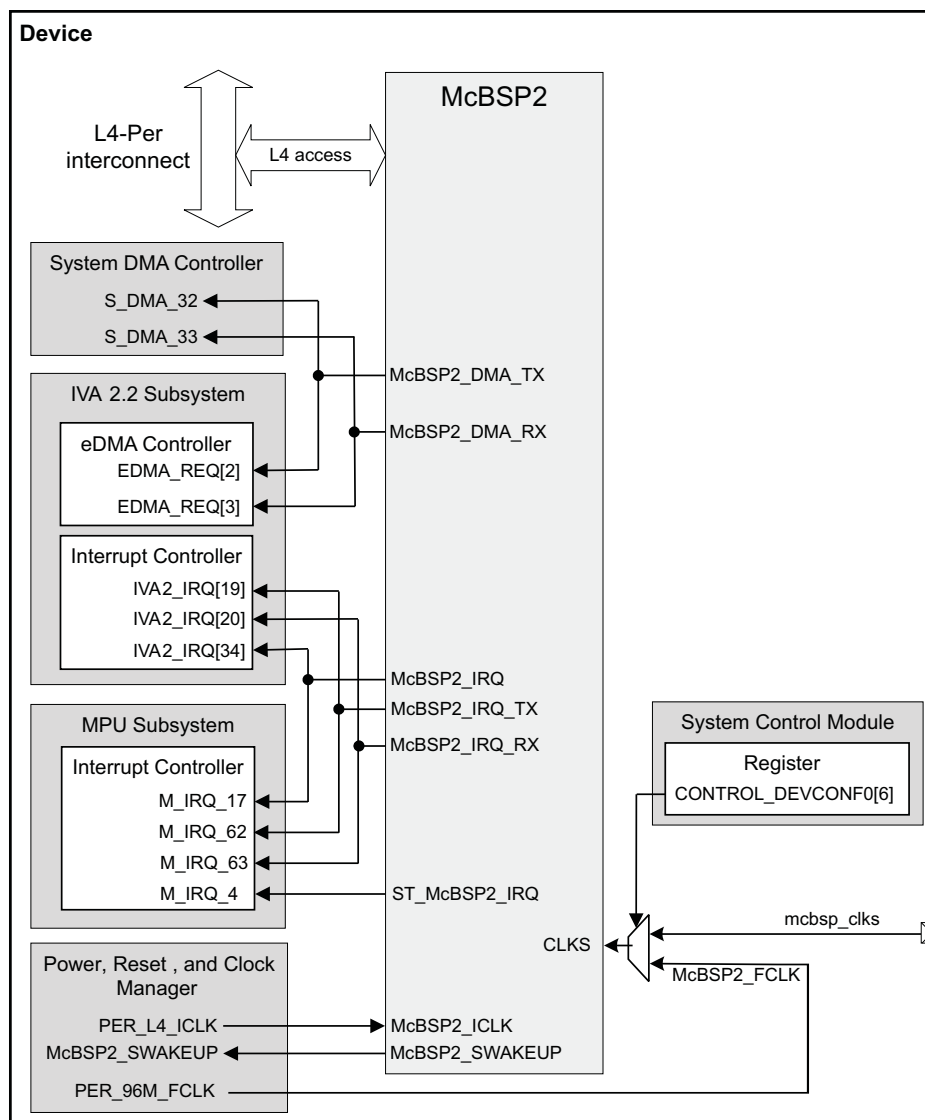

Figure 21-16 through Figure 21-20 highlight the integration of the McBSP modules in the device including interrupt handlers, DMA requests, clock generators, and interconnections.

21.3.1 Signal Source Control

The FSR, CLKR and CLKS signals sources are defined by the system control module. The control registers of the system control module are used to select these signals sources.

21.3.1.1 McBSP1 Module (6 Pins Configuration)

The MCBSP1_CLKS bit of the CONTROL.DEVCONF0[2] register is used to select the McBSP1 module CLKS signal source:

- When set to '0', the CLKS source is from the CORE_96M_FCLK
- When set to '1', the CLKS source is from the mcbasp_clks pin

The MCBSP1_CLKR bit of the CONTROL.DEVCONF0[3] register is used to select the McBSP1 module CLKR signal source:

- When set to '0', the CLKR source is from the CLKR input signal
- When set to '1', the CLKR source is from the CLKX input signal

The MCBSP1_FSR bit of the CONTROL.DEVCONF0[4] register is used to select the McBSP1 module FSR signal source:

- When set to '0', the FSR source is from the FSR input signal
- When set to '1', the FSR source is from the FSX input signal

21.3.1.2 McBSP2, 3, 4, and 5 modules (4 pins configuration)

For these McBSPi modules, there are no external mcbspi_clkr and mcbspi_fxr pins (i=2, 3, 4, and 5).

Consequently, the system control module controls only the internal connection of CLKS input signals. The settings are explained in [Section 21.3.2.2.2](#), [Section 21.3.2.2.3](#), [Section 21.3.2.2.4](#), and [Section 21.3.2.2.5](#).

21.3.2 Clocking, Reset, and Power Management Scheme

21.3.2.1 Power Domain

McBSP1 and McBSP5 modules belong to the CORE domain, whereas the McBSP2, McBSP3, and McBSP4 modules belong to the PER (peripheral) domain. This separation of McBSP modules in two power domain allows major part of the device to be switched off while keeping active McBSP2, 3, and 4.

For more information about these power domains, see the *Power Reset and Clock Management* chapter.

21.3.2.2 Clocks

There are two clock domains in the McBSP module:

- Functional clock domain
- Interface clock domain

Table 21-3. Clocking Signals Input to McBSP Module

Type	Name	Source	Description
Interface	McBSPi_ICLK	PER_L4_ICLK (McBSP2, 3, 4) ^{(1) (2)}	The L4 interface clock is used for the module internal L4 interconnect slave interface and all depending parts of the Interface clock domain.
		CORE_L4_ICLK (McBSP1, 5) ^{(1) (2)}	
Functional	CLKS	PER_96M_FCLK (McBSP2, 3, 4) ^{(1) (2)}	McBSP module is running using either a functional clock generated internally (master mode) or supplied from its serial interface (slave mode) for the internal logic. Internal registers select the source of the functional clock and the divider ratio to apply.
		CORE_96M_FCLK (McBSP1, 5) ^{(1) (2)}	
		mcbbsp_clks (external source common to all McBSP modules)	
Functional	CLKX	mcbbsp_clkx (external source)	Functional clock after division in any mode is limited to maximum frequency divided by 2.
Functional	CLKR (McBSP1 only)	mcbbsp1_clkr (external source)	

⁽¹⁾ For more information about these sources, see the *Power Reset and Clock Management* chapter.

⁽²⁾ Clock configurations depend on core voltage, please refer to your device-specific data manual for a description of the maximum clock frequencies.

21.3.2.2.1 McBSP1 Clocks

The McBSP1 module is clocked by a functional clock (CLKS, CLKX, or CLKR) and an interface clock (McBSP1_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 21.4](#)). For McBSP1 module, the functional clock comes from the CLKS signal, CLKX signal, or CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the McBSP1.MCBSPLP_PCR_REG[7] register and the CLKSM bit of the McBSP1.MCBSPLP_SRGR2_REG[13] register.

The CLKS signal of the McBSP1 module is linked to an internal clock (CORE_96M_FCLK) provided by PRCM, whereas the CLKS signal can also be linked to an external signal through the mcbbsp_clks pin of the device boundary. The McBSP1_CLKS bit of the CONTROL.CONTROL_DEVCONF0[2] register is used to select the McBSP1 module CLKS signal source:

- When set to '0', the CLKS source is from the CORE_96M_FCLK
 - When set to '1', the CLKS source is from the mcbasp_clks pin
- For more information on this register, see the *System Control Module* chapter.

Note: When the McBSP1 module does not require the PRCM functional clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP1 bit (PRCM.CM_FCLKEN1_CORE[9]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see the *Power Reset and Clock Management* chapter.

At PRCM level, when all the conditions to shut-off CORE_96M_FCLK clock are met the PRCM automatically launches a **Hardware** handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM asserts an IDLE request to McBSP module. For more details, see the *Power Reset and Clock Management* chapter.

The CLKX and CLKR signals are connected either by mcbasp1_clkx or mcbasp1_clkr pads. These signals are used like functional clocks by the intermediary of the sample rate generator (SRG).

- The McBSP1_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP1 L4 interface and McBSP1 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 21.4.3](#)). Its source is the CORE_L4_ICLK signal.

Note: When the McBSP1 module does not require the interface clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP1 bit (PRCM.CM_ICLKEN1_CORE[9]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see the *Power Reset and Clock Management* chapter.

At PRCM level, when all the conditions to shut-off CORE_L4_ICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM asserts an IDLE request to McBSP module. For more details, see the *Power Reset and Clock Management* chapter.

It is also possible to activate an autoidle mode for this clock (PRCM.CM_AUTOIDLE1_CORE[9] register AUTO_MCBSP1 bit set to 1). In this case, McBSP1_ICLK follows the CORE_L4 clock domain behavior on the device. For more information, see the *Power Reset and Clock Management* chapter.

21.3.2.2.2 McBSP2 Clocks

The McBSP2 module is clocked by a functional clock (CLKS, CLKX or CLKR) and an interface clock (McBSP2_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 21.4](#)). For McBSP2 module, the functional clock comes from the CLKS signal CLKX signal, or CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the MCBSP2.MCBSPLP_PCR_REG[7] register and the CLKSM bit of the MCBSP2.MCBSPLP_SRGR2_REG[13] register.

The CLKS signal of the McBSP2 module is linked to an internal clock (PER_96M_FCLK) provided by PRCM, whereas the CLKS signal can also be linked to an external signal through the mcbasp_clks pin of the device boundary. The MCBSP2_CLKS bit of the CONTROL.CONTROL_DEVCONF0[6] register is used to select the McBSP2 module CLKS signal source:

- When set to '0', the CLKS source is from the PER_96M_FCLK
- When set to '1', the CLKS source is from the mcbasp_clks pin

For more information, see the *System Control Module* chapter.

Note: When the McBSP2 module does not require the functional clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP2 bit (PRCM.CM_FCLKEN_PER[0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see the *Power Reset and Clock Management* chapter.

At PRCM level, when all the conditions to shut-off PER_96M_FCLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM asserts an IDLE request to McBSP module. For more details, see the *Power Reset and Clock Management* chapter.

Only, the CLKX signal is connected by mcbasp2_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of the SRG.

- The McBSP2_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP2 L4 interface and McBSP2 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 21.4.3](#)). Its source is either the PER_L4_ICLK signal.

Note: When the McBSP2 module does not require the interface clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP2 bit (PRCM.CM_ICLKEN_PER[0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see the *Power Reset and Clock Management* chapter.

At PRCM level, when all the conditions to shut-off PER_L4_ICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM asserts an IDLE request to McBSP module. For more details, see the *Power Reset and Clock Management* chapter.

It is also possible to activate an autoidle mode for this clock (PRCM.CM_AUTOIDLE_PER[0] register AUTO_MCBSP2 bit set to 1). In this case, McBSP2_ICLK follows the CORE_L4 clock domain behavior on the device. For more information, see the *Power Reset and Clock Management* chapter.

21.3.2.2.3 McBSP3 Clocks

The McBSP3 module is clocked by a functional clock (CLKS, CLKX or CLKR) and an interface clock (McBSP3_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 21.4](#)). For McBSP3 module, the functional clock comes from the CLKS signal CLKX signal, or CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the McBSP3.MCBSPLP_PCR_REG[7] register and the CLKSM bit of the McBSP3.MCBSPLP_SRGR2_REG[13] register.

The CLKS signal of the McBSP3 module is linked to an internal clock (PER_96M_FCLK) provided by PRCM, whereas the CLKS signal can also be linked to an external signal through the mcbasp_clks pin of the device boundary. The McBSP3_CLKS bit of the CONTROL.CONTROL_DEVCONF1[0] register is used to select the McBSP3 module CLKS signal source:

- When set to '0', the CLKS source is from the PER_96M_FCLK
- When set to '1', the CLKS source is from the mcbasp_clks pin

For more information, see the *System Control Module* chapter.

Note: When the McBSP3 module does not require the functional clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP3 bit (PRCM.CM_FCLKEN_PER[1]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see the *Power Reset and Clock Management* chapter.

At PRCM level, when all the conditions to shut-off PER_96M_FCLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM asserts an IDLE request to McBSP module. For more details, see the *Power Reset and Clock Management* chapter.

Only, the CLKX signal is connected by mcbasp3_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of SRG.

- The McBSP3_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP3 L4 interface and McBSP3 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 21.4.3](#)). Its source is either the PER_L4_ICLK signal.

Note: When the McBSP3 module does not require the interface clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP3 bit (PRCM.CM_ICLKEN_PER[1]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see the *Power Reset and Clock Management* chapter.

At PRCM level, when all the conditions to shut-off PER_L4_ICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM asserts an IDLE request to McBSP module. For more details, see the *Power Reset and Clock Management* chapter.

It is also possible to activate an autoidle mode for this clock (PRCM.CM_AUTOIDLE_PER[1] register AUTO_MCBSP3 bit set to 1). In this case, McBSP3_ICLK follows the PER_L4 clock domain behavior on the device. For more information, see the *Power Reset and Clock Management* chapter.

21.3.2.2.4 McBSP4 Clocks

The McBSP4 module is clocked by a functional clock (CLKS or CLKX) and an interface clock (McBSP4_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 21.4](#)). For McBSP4 module, the functional clock comes from the CLKS signal, the CLKX signal, or the CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the McBSP4.MCBSPLP_PCR_REG[7] register and the CLKSM bit of the McBSP4.MCBSPLP_SRGR2_REG[13] register.

The CLKS signal of the McBSP4 module is linked to an internal clock (PER_96M_FCLK) provided by PRCM, whereas the CLKS signal can also be linked to an external signal through the mcbasp_clks pin of the device boundary. The McBSP4_CLKS bit of the CONTROL.CONTROL_DEVCONF1[2] register is used to select the McBSP4 module CLKS signal source:

- When set to '0', the CLKS source is from the PER_96M_FCLK
- When set to '1', the CLKS source is from the mcbasp_clks pin

For more information, see the *System Control Module* chapter.

Note: When the McBSP4 module does not require the functional clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP4 bit (PRCM.CM_FCLKEN_PER[2]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see the *Power Reset and Clock Management* chapter.

At PRCM level, when all the conditions to shut-off PER_96M_FCLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM asserts an IDLE request to McBSP module. For more details, see the *Power Reset and Clock Management* chapter.

Only the CLKX signal is connected by mcbbsp4_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of SRG.

- The McBSP4_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP4 L4 interface and McBSP4 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 21.4.3](#)). Its source is either the PER_L4_ICLK signal.

Note: When the McBSP4 module does not require the interface clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP4 bit (PRCM.CM_ICLKEN_PER[2]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see the *Power Reset and Clock Management* chapter.

At PRCM level, when all the conditions to shut-off PER_L4_ICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM asserts an IDLE request to McBSP module. For more details, see the *Power Reset and Clock Management* chapter.

It is also possible to activate an autoidle mode for this clock (PRCM.CM_AUTOIDLE_PER[2] register AUTO_MCBSP4 bit set to 1). In this case, McBSP4_ICLK follows the PER_L4 clock domain behavior on the device. For more information, see the *Power Reset and Clock Management* chapter.

21.3.2.2.5 McBSP5 Clocks

The McBSP5 module is clocked by a functional clock (CLKS or CLKX) and an interface clock (McBSP5_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 21.4](#)). For McBSP5 module, the functional clock comes from the CLKS signal, the CLKX signal, or the CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the MCBSP5.MCBSPLP_PCR_REG[7] register and the CLKSM bit of the MCBSP5.MCBSPLP_SRGR2_REG[13] register.

The CLKS signal of the McBSP5 module is linked to an internal clock (CORE_96M_FCLK) provided by PRCM. The CLKS signal can also be linked to an external signal through the mcbbsp_clks pin of the device boundary. The MCBSP5_CLKS bit of the CONTROL.CONTROL_DEVCONF1[4] register is used to select the McBSP5 module CLKS signal source:

- When set to '0', the CLKS source is from the CORE_96M_FCLK
- When set to '1', the CLKS source is from the mcbbsp_clks pin

For more information, see the *System Control Module* chapter.

Note: When the McBSP5 module does not require the functional clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP5 bit (PRCM.CM_FCLKEN1_CORE[10]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see the *Power Reset and Clock Management* chapter.

At PRCM level, when all the conditions to shut-off CORE_96M_FCLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM asserts an IDLE request to McBSP module. For more details, see the *Power Reset and Clock Management* chapter.

Only, the CLKX signal is connected by mcbbsp5_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of SRG.

- The McBSP5_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP5 L4 interface and McBSP5 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 21.4.3](#)). Its source is either the CORE_L4_ICLK signal.

Note: When the McBSP5 module does not require the interface clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP5 bit (PRCM.CM_ICLKEN1_CORE[10]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see the *Power Reset and Clock Management* chapter.

At PRCM level, when all the conditions to shut-off CORE_L4_ICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM asserts an IDLE request to McBSP module. For more details, see the *Power Reset and Clock Management* chapter.

It is also possible to activate an autoidle mode for this clock (PRCM.CM_AUTOIDLE1_CORE[10] register AUTO_MCBSP5 bit set to 1). In this case, McBSP5_ICLK follows the CORE_L4 clock domain behavior on the device. For more information, see the *Power Reset and Clock Management* chapter.

21.3.2.2.6 SIDETONE Clock

The SIDETONE feature, in the McBSP2 and McBSP3 modules, is clocked only by an interface clock (McBSP2_ICLK or McBSP3_ICLK).

CAUTION

See [Section 21.3.2.2.2](#) and [Section 21.3.2.2.3](#) for information on McBSP2_ICLK and McBSP3_ICLK clocks.

When the SIDETONE feature does not require the clock anymore, the software can disable it at the SIDETONE level by setting the McBSPi.ST_SYSCONFIG_REG[0] AUTOIDLE bit in SIDETONE registers. To conserve power, when SIDETONE feature is not active or there is no activity on SIDETONE feature, the McBSPi_ICLK clock supports an automatic gating that is enabled or disabled by setting the McBSPi.ST_SYSCONFIG_REG[0] AUTOIDLE bit.

- When this bit is asserted (set to 1), the McBSPi_ICLK clock auto-gating is enabled and this clock is disabled internally to the SIDETONE feature, thus reducing power consumption, but not to the McBSP module that contains this feature.
After reset, the automatic clock gating is enabled; thus, this bit must be disabled by software for activated SIDETONE feature.
- When this bit is set to 0, the McBSPi_ICLK clock auto-gating is disabled and this clock is enabled. The SIDETONE feature can be used normally.

21.3.2.3 Hardware and Software Reset

McBSP1 and McBSP5 modules belong to the CORE domain and their reset signal is the CORE_RST signal from the PRCM module, whereas McBSP2, 3 and 4 modules belong to the PER domain and their reset signal is the PER_RST signal from the PRCM module.

For more details about these signals, see the *Power Reset and Clock Management* chapter.

Table 21-4. Software Reset Signals to All McBSP Modules

Type	Bit Field	Register Source	Activation	Description
Software	SOFTRESET	MCBSPi.MCBSPLP_SYSCONFIG_REG[1]	Active high	McBSP global software reset
	RRST	MCBSPi.MCBSPLP_SPCR1_REG[0]	Active low	This resets and disables the receiver
	XRST	MCBSPi.MCBSPLP_SPCR2_REG[0]		This resets and disables the transmitter
	GRST	MCBSPi.MCBSPLP_SPCR2_REG[6]		SRG is reset
	FRST	MCBSPi.MCBSPLP_SPCR2_REG[7]		Frame-sync logic is reset. Frame-sync generated signal is not generated by the SRG

For more details about these signals, see [Section 21.7](#). See [Section 21.5.1.1](#), for a complete description of the McBSP initialization procedure.

21.3.2.4 Power Management

21.3.2.4.1 McBSP Operating States

Two operating states are defined for all the McBSP modules:

- **ACTIVE** state: The module is running synchronously on the interface and functional clock, interrupts and DMA requests can be generated according to the configuration (register, master or slave mode, etc) and the external signals.
- **IDLE** state: As part of the system power management, the PRCM module can request the McBSP modules to enter IDLE state. Depending on the configured acknowledgment mode: Force Idle, No Idle and Smart Idle modes, a McBSP module will effectively enter IDLE state or not. As soon as a McBSP module enters IDLE state, it doesn't have anymore activities except those unrelated to clock activity (for example wakeup features) and its clocks are likely to be switched off at PRCM level.

Note: IDLE request and IDLE acknowledge are only internal signals, with no means to observe or to control. The signals generation and control is purely hardware (managed automatically by the PRCM and the McBSP module depending on the SIDLEMODE settings).

21.3.2.4.2 McBSP Acknowledgment Modes

During initialization or configuration of the McBSP module, the software must configure how the McBSP module will answer an IDLE solicitation from the PRCM module (that is, the way idle acknowledge will be asserted following an idle request assertion).

Each McBSP module can be configured via the MCBSPi.MCBSPLP_SYSCONFIG_REG[4:3] SIDLEMODE field as one of the following acknowledgment modes:

- **Force Idle mode** (SIDLEMODE bit = 0x0): An idle request is acknowledged unconditionally, regardless of the internal state of the module. The McBSP module immediately enters Idle state (no activity), interface and PRCM functional clock can be stopped, no interrupts and DMA requests can be generated. In this mode, the McBSP module freezes all the internal activity when the PRCM clocks are switched off by the PRCM module, leading to a potential loss of data.

CAUTION

In Force Idle mode, the wake-up feature is inhibited.

CAUTION

If the McBSP functional part, transmitter or receiver, is running within this period of time (the functional clock source is not the PRCM functional clock), the internal state of the McBSP module will not be idle (FSM states, processes, etc.), and when the McBSP module exits from the Force Idle state unexpected behavior may happen in both receiver and transmitter. To avoid this, both receive and transmit parts, must be disabled by software prior to idle request assertion (all functional clock external sources must be disabled).

- No Idle mode (SIDLEMODE bit = 0x1): An idle request is never acknowledged, meaning it will prevent the PRCM from switching off its related clocks and from putting in a lower power state than the power domain it belongs to. The McBSP module never enters Idle state (is active).
- Smart Idle mode (SIDLEMODE bit = 0x2): Acknowledgment to an idle request is given based on the internal activity of the McBSP module. The McBSP module is in a waiting state, interface / functional clocks can be stopped, no interrupt can be generated, a wake-up signal can be generated according to the configuration (See [Section 21.3.2.4.4](#)) and external signals.

Note: The value McBSPi.MCBSPLP_SYSCONFIG_REG[4:3] SIDLEMODE field = 0x3 must not be used.

When configured in Smart Idle mode, McBSP module also offers an additional granularity on McBSPi_FCLK and McBSPi_ICLK gating. McBSPi.MCBSPLP_SYSCONFIG_REG[9:8] CLOCKACTIVITY bit field is used to determine which clock will be shut down (McBSPi_FCLK, McBSPi_ICLK, none of them or both of them).

CLOCKACTIVITY setting is used in the McBSP module to determine on which part of the module the conditions to acknowledge the PRCM IDLE request will be tested. As an example, if McBSPi_FCLK is said not to be shut down upon a PRCM IDLE request, this means McBSP module will only consider McBSPi_ICLK and the associated pending activities before acknowledging the request.

Note: Some of McBSP features are associated to McBSPi_ICLK and others to McBSPi_FCLK. Using the CLOCKACTIVITY along with the Smart Idle mode ensures that the features associated with the clock that will remain active are always enabled, even if McBSP has acknowledged an IDLE request. For more information, see [Section 21.3.2.4.4](#).

[Table 21-5](#) lists the value of the bit field and indicates if the interface (McBSPi_ICLK) and PRCM functional (McBSPi_FCLK) clocks can be switched-off or not when an Idle request is received by McBSP module.

Table 21-5. State of Clocks When the Module is in Idle State

CLOCKACTIVITY Value	Interface Clock (McBSPi_ICLK)	PRCM Functional Clock (CORE_96M_FCLK or PER_96M_FCLK)
0b00	OFF	OFF
0b01	OFF	ON
0b10	ON	OFF
0b11	ON	ON

Note: OFF means this clock can be switched-off.
ON means this clock must be maintained during wake up period.

CAUTION

The PRCM module does not have any hardware mean to read CLOCKACTIVITY settings. It is thus software responsibility to ensure a consistent programming between McBSPi.MCBSPLP_SYSCONFIG_REG[9:8] CLOCKACTIVITY bit field and PRCM 96M_FCLK and L4_ICLK control bits (see Notes in previous [Section 21.3.2.2](#)). If McBSP module is disabled in both CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its IDLE request which will be acknowledged regardless of the features associated with the McBSP clocks. This may lead to unpredictable behaviors.

The software can disable all clocks at the McBSP module level by setting the IDLE_EN bit in McBSPi.MCBSPLP_PCR_REG[14] registers. The IDLE_EN bit allows stopping all the clocks in the McBSP module (legacy):

- When set to '0', the McBSP module is running
- When set to '1', the clocks in the McBSP module are shut off when both IDLE_EN =1 and his power domain is in idle mode.

21.3.2.4.3 Wake-Up Capability

When configured in Smart Idle mode, the sources for wake-up generation are a subset of the interrupt sources. The wake up sources are enabled by setting the McBSPi.MCBSPLP_SYSCONFIG_REG[2] ENAWAKEUP bit (wake up feature control):

- Set to '0', wake up capability is disabled
- Set to '1', wake up capability is enabled

The McBSPi_SWAKEUP signal is the McBSP module asynchronous wake-up signal sent to the PRCM module when a wake-up generation is requested.

The wake up configurations are defined by setting the corresponding bits in the McBSPi.MCBSPLP_WAKEUPEN_REG register.

21.3.2.4.3.1 Receive Wakeup

There are 4 receive possible wake up configurations:

- McBSPi.MCBSPLP_WAKEUPEN_REG[3] RRDYEN bit: The McBSP module asserts the McBSPi_SWAKEUP request when the receive buffer reaches the high threshold value (RTHRESHOLD value + 1) of the McBSPi.MCBSPLP_THRSH1_REG register. If the McBSPi.MCBSPLP_IRQENABLE_REG[3] RRDYEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode (interrupt will be asserted once the McBSPi.MCBSPLP_IRQSTATUS_REG[3] RRDY bit changes from '0' to '1', indicating that received data is ready to be read).
- McBSPi.MCBSPLP_WAKEUPEN_REG[2] REOFEN bit: The McBSP module asserts the McBSPi_SWAKEUP request at the end of the frame. If the McBSPi.MCBSPLP_IRQENABLE_REG[2] REOFEN bit is set to 1, theMcBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting idle mode.
- McBSPi.MCBSPLP_WAKEUPEN_REG[1] RFSREN bit: The McBSP module sends a McBSPi_SWAKEUP request to the PRCM module when a receive frame-sync pulse is detected while the McBSP module is in idle mode. If the McBSPi.MCBSPLP_IRQENABLE_REG[1] RFSREN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting idle mode.

- McBSPi.MCBSPLP_WAKEUPEN_REG[0] RSYNCERREN bit: The McBSP module asserts the McBSPi_SWAKEUP request when an unexpected receive frame-sync pulse is detected. If the McBSPi.MCBSPLP_IRQENABLE_REG[0] RSYNCERREN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode (interrupt is asserted once the McBSPi.MCBSPLP_IRQSTATUS_REG[0] RSYNCERR bit changes from '0' to '1', indicating that a receive error occurred).

21.3.2.4.3.2 Transmit Wakeup

For transmit, there are also 5 possible wakeup configuration scenarios:

- McBSPi.MCBSPLP_WAKEUPEN_REG[14] XEMPTYEOFEN bit: The McBSP module asserts the McBSPi_SWAKEUP request when a complete frame was transmitted and the transmit buffer is empty. If the McBSPi.MCBSPLP_IRQENABLE_REG[14] XEMPTYEOFEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode.
- McBSPi.MCBSPLP_WAKEUPEN_REG[10] XRDYEN bit: The McBSP module asserts the McBSPi_SWAKEUP request when the transmit buffer reaches the high threshold value (XTHRESHOLD value + 1) of the McBSPi.MCBSPLP_THRSH2_REG register. If the McBSPi.MCBSPLP_IRQENABLE_REG[10] XRDYEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode (interrupt is asserted once the McBSPi.MCBSPLP_IRQSTATUS_REG[10] XRDY bit changes from '0' to '1', indicating that transmit buffer data is ready to accept new data).
- McBSPi.MCBSPLP_WAKEUPEN_REG[9] XEOFEN bit: The McBSP module asserts the McBSPi_SWAKEUP request at the end of the frame. If the McBSPi.MCBSPLP_IRQENABLE_REG[9] XEOFEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode.
- McBSPi.MCBSPLP_WAKEUPEN_REG[8] XFSXEN bit: The McBSP module sends a McBSPi_SWAKEUP request when a transmit frame-sync pulse is detected while the module is in idle mode. If the McBSPi.MCBSPLP_IRQENABLE_REG[8] XFSXEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode.
- McBSPi.MCBSPLP_WAKEUPEN_REG[7] XSYNCERREN bit: The McBSP module asserts the McBSPi_SWAKEUP request when an unexpected transmits frame-sync pulse is detected. If the McBSPi.MCBSPLP_IRQENABLE_REG[7] XSYNCERREN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode (interrupt will be asserted once the McBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR bit changes from '0' to '1', indicating that a transmit error occurred).

21.3.2.4.3.3 Notes

When mcbbsp1_fsr/mcbbsp1_fsx pins is configured as an output, the FSR/FSX wakeup generation makes no sense (the module cannot be in Smart Idle mode).

Detection of RSYNCERR/XSYNCERR during idle mode can be used only when mcbbsp1_fsr/mcbbsp1_fsx pins is configured as an input and the remote system knows to assert such an error to trigger the wake up of the McBSP module.

The module does not implement interrupt request (IRQ) assertion when configured as (GPIO). Pins that can be used to accept input signals and/or send output signals but are not linked to specific uses); also a wake up capability in this mode is not available.

21.3.2.4.4 Analysis of the Receiver Smart Idle Behavior

The analysis of the power mode behavior is shown in [Table 21-6](#) :

In this table, the CLKRM bit is in the McBSPi.MCBSPLP_PCR_REG register on position 8, CLKXM bit in the McBSPi.MCBSPLP_PCR_REG[9] register, and CLOCKACTIVITY bit in the McBSPi.MCBSPLP_SYSCONFIG_REG[9:8] register.

The value X signifies that the bit value is not significant.

Table 21-6. McBSP Smart Idle Mode Configuration Behavior

CLKRM Bit	CLKXM Bit	McBSP Mode	Source of Functional Clock	CLOCKACTIVITY Bit	Behavior
0	0	Slave	outside	0bXX	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit buffer threshold synchronization (only when wake-up event is set on transmit threshold reached), regardless of the CLOCKACTIVITY settings or receive and transmit activity.
0	1	Transmit Master	McBSPi_ICLK	0b0X	The McBSP will not acknowledge the Idle request unless: <ul style="list-style-type: none"> The transmit part is disabled (XDISABLE) or under software reset (XRST) and the receive part is not using the transmit loop-back clock (CLKR is not connected to the CLKX input pin). Both transmit and receive parts are disabled (XDISABLE/RDISABLE) or under software reset (XRST/RRST) The idle acknowledge is asserted as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames were completed in case of transmit and/or receive disable.
			CLKS	0bX0	
			McBSPi_ICLK	0b1X	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached).
			CLKS	0bX1	
			CLKR (outside)	0bXX	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached), regardless of the CLOCKACTIVITY settings.
1	0	Receive master	McBSPi_ICLK	0b0X	The McBSP will not acknowledge the idle request unless: The receive part is disabled (RDISABLE) or under software reset (RRST) The Idle acknowledge is asserted as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames where completed in case of transmit and/or receive disable.
			CLKS	0bX0	
			McBSPi_ICLK	0b1X	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached).
			CLKS	0bX1	
			CLKX	0bXX	When CLKX is used as source (functional clock is provided from outside) then the module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached), regardless of the CLOCKACTIVITY settings.

Table 21-6. McBSP Smart Idle Mode Configuration Behavior (continued)

CLKRM Bit	CLKXM Bit	McBSP Mode	Source of Functional Clock	CLOCKACTIVITY Bit	Behavior
1	1	Transmit and Receive Master	McBSPi_ICLK	0b0X	The McBSP will not acknowledge the idle request unless: Both transmit and receive parts are disabled (XDISABLE/RDISABLE) or under software reset (XRST/RRST) The idle acknowledge is asserted as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames were completed in case of transmit and/or receive disable. Note that no wake-up event is available in this mode since the entire McBSP and remote device activity is frozen.
			CLKS	0bX0	
			McBSPi_ICLK	0b1X	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached).
			CLKS	0bX1	

Note: The RFSREN/XFSXEN mode is suitable for wakeup generation when both clocks (PRCM functional and interface) are switched off and mcbasp1_fsr/mcbspi_fsx pins is configured as input. The frame-sync pulse is asynchronously detected during idle.

The RSYNCERREN/XSYNCERREN mode can be used to wakeup the McBSP module only by a remote module implementing such a feature, to trigger a wake up. This mode requires functional clock to be active.

21.3.3 Hardware Requests

21.3.3.1 DMA Requests

The DMA requests are shared between the IVA2.2 subsystem DMA controller (eDMA) and system DMA controller (sDMA). Each of the five McBSP modules can generate two DMA events:

- McBSPi_DMA_TX : McBSPi module transmit request
- McBSPi_DMA_RX : McBSPi module receive request

The following table summaries the DMA events with the mapping on both DMA controllers.

Table 21-7. McBSP DMA Requests

Request Name	Mapping	Destination	Description
McBSP1_DMA_TX	EDMA_REQ[0] S_DMA_30	IVA2.2 subsystem DMA controller system DMA controller	write (or transmit) request
McBSP1_DMA_RX	EDMA_REQ[1] S_DMA_31	IVA2.2 subsystem DMA controller system DMA controller	read (or receive) request
McBSP2_DMA_TX	EDMA_REQ[2] S_DMA_32	IVA2.2 subsystem DMA controller system DMA controller	write (or transmit) request
McBSP2_DMA_RX	EDMA_REQ[3] S_DMA_33	IVA2.2 subsystem DMA controller system DMA controller	read (or receive) request
McBSP3_DMA_TX	EDMA_REQ[4] S_DMA_16	IVA2.2 subsystem DMA controller system DMA controller	write (or transmit) request
McBSP3_DMA_RX	EDMA_REQ[5] S_DMA_17	IVA2.2 subsystem DMA controller system DMA controller	read (or receive) request
McBSP4_DMA_TX	EDMA_REQ[6] S_DMA_18	IVA2.2 subsystem DMA controller system DMA controller	write (or transmit) request
McBSP4_DMA_RX	EDMA_REQ[7] S_DMA_19	IVA2.2 subsystem DMA controller system DMA controller	read (or receive) request
McBSP5_DMA_TX	EDMA_REQ[8] S_DMA_20	IVA2.2 subsystem DMA controller system DMA controller	write (or transmit) request
McBSP5_DMA_RX	EDMA_REQ[9] S_DMA_21	IVA2.2 subsystem DMA controller system DMA controller	read (or receive) request

21.3.3.2 Interrupt Requests

21.3.3.2.1 McBSP Interrupt Requests

Each of the five McBSP modules can generate three interrupts, shared between the MPU subsystem and IVA2.2 subsystem interrupt controllers:

- McBSPi_IRQ: McBSPi module common interrupt request
- McBSPi_IRQ_TX: McBSPi module transmit interrupt request
- McBSPi_IRQ_RX: McBSPi module receive interrupt request

The following tables list the interrupt requests with the mapping.

Table 21-8. McBSP Common Interrupt Requests

Request Name	Mapping	Destination
McBSP1_IRQ	IVA2_IRQ[33] M_IRQ_16	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP2_IRQ	IVA2_IRQ[34] M_IRQ_17	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP3_IRQ	IVA2_IRQ[35] M_IRQ_22	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP4_IRQ	IVA2_IRQ[36] M_IRQ_23	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller

Table 21-8. McBSP Common Interrupt Requests (continued)

Request Name	Mapping	Destination
McBSP5_IRQ	IVA2_IRQ[37] M_IRQ_27	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller

Table 21-9. McBSP Transmit Interrupt Requests

Request Name	Mapping	Destination
McBSP1_IRQ_TX	IVA2_IRQ[16] M_IRQ_59	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP2_IRQ_TX	IVA2_IRQ[19] M_IRQ_62	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP3_IRQ_TX	IVA2_IRQ[21] M_IRQ_89	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP4_IRQ_TX	IVA2_IRQ[23] M_IRQ_54	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP5_IRQ_TX	IVA2_IRQ[25] M_IRQ_81	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller

Table 21-10. McBSP Receive Interrupt Requests

Request Name	Mapping	Destination
McBSP1_IRQ_RX	IVA2_IRQ[17] M_IRQ_60	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP2_IRQ_RX	IVA2_IRQ[20] M_IRQ_63	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP3_IRQ_RX	IVA2_IRQ[22] M_IRQ_90	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP4_IRQ_RX	IVA2_IRQ[24] M_IRQ_55	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP5_IRQ_RX	IVA2_IRQ[26] M_IRQ_82	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller

An event can generate an interrupt request when the corresponding mask bit in the McBSPi.MCBSPLP_IRQENABLE_REG register is set to '1'.

Table 21-11 and Table 21-12 summarize the events causing the generation of an interrupt request.

Table 21-11. McBSP Transmit Interrupt Events

Event Name	Status Bit	Mask Bit	Description
Transmit buffer empty at end of frame	McBSPi.MCBSPLP_IRQSTATUS_REG[14] XEMPTYEOF	McBSPi.MCBSPLP_IRQENABLE_REG [14] XEMPTYEOFEN	This event happens when a complete frame was transmitted and the transmit buffer is empty .
Overflow	McBSPi.MCBSPLP_IRQSTATUS_REG[12] XOVFLSTAT	McBSPi.MCBSPLP_IRQENABLE_REG [12] XOVFLEN	This event happens when transmit data buffer is full and a new data is written in this buffer. The new data written is discarded.
Underflow	McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT	McBSPi.MCBSPLP_IRQENABLE_REG [11] XUNDFLEN	This event happens when transmit data buffer is empty and a new data is required to be transmitted.
Threshold reached	McBSPi.MCBSPLP_IRQSTATUS_REG[10] XRDY	McBSPi.MCBSPLP_IRQENABLE_REG [10] XRDYEN	This event happens when the transmit buffer free locations are equal or above the THRSH2_REG value.
End of Frame	McBSPi.MCBSPLP_IRQSTATUS_REG[9] XEOF	McBSPi.MCBSPLP_IRQENABLE_REG [9] XEOFLEN	This event happens when a complete frame was transmitted.
Frame-sync	McBSPi.MCBSPLP_IRQSTATUS_REG[8] XFSX	McBSPi.MCBSPLP_IRQENABLE_REG [8] XFSXEN	This event happens when a new transmit frame synchronization is asserted.

Table 21-11. McBSP Transmit Interrupt Events (continued)

Event Name	Status Bit	Mask Bit	Description
Frame-sync error	McBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR	McBSPi.MCBSPLP_IRQENABLE_REG [7] XSYNCERREN	This event happens when a transmit frame synchronization error is detected.

Table 21-12. McBSP Receive Interrupt Events

Event Name	Status bit	Mask bit	Description
Overflow	McBSPi.MCBSPLP_IRQS TATUS_REG[5] ROVFLSTAT	McBSPi.MCBSPLP_IRQENABLE_ REG[5] ROVFLEN	This event happens when receive data buffer is full and a new data is written in this buffer. The new data written is discarded.
Underflow	McBSPi.MCBSPLP_IRQS TATUS_REG[4] XUNDFLSTAT	McBSPi.MCBSPLP_IRQENABLE_ REG[4] RUNDFLEN	This event happens when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined.
Threshold reached	McBSPi.MCBSPLP_RQS TATUS_REG[3] RRDY	McBSPi.MCBSPLP_IRQENABLE_ REG[3] RRDYEN	This event happens when the receive buffer occupied locations are equal or above the THRSH1_REG value.
End of Frame	McBSPi.MCBSPLP_IRQS TATUS_REG[2] REOF	McBSPi.MCBSPLP_IRQENABLE_ REG[2] REOFLEN	This event happens when a complete frame was received.
Frame-sync	McBSPi.MCBSPLP_IRQS TATUS_REG[1] RFSR	McBSPi.MCBSPLP_IRQENABLE_ REG[1] RFSREN	This event happens when a new receive frame synchronization is asserted.
Frame-sync error	McBSPi.MCBSPLP_IRQS TATUS_REG[0] RSYNCERR	McBSPi.MCBSPLP_IRQENABLE_ REG[0] RSYNCERREN	This event happens when a receive frame synchronization error is detected.

Once an interrupt request is generated, the software must read the McBSPi.MCBSPLP_IRQSTATUS_REG register to check what event has caused the interrupt request generation, and acknowledge each processed event by writing a 1 to the corresponding bit in the McBSPi.MCBSPLP_IRQSTATUS_REG register.

Note: All Status bits can be cleared in two ways:

- If the corresponding mask bit is set to '1' (interrupt generation enabled), the status bit is cleared by writing a '1'.
- If the corresponding mask bit is cleared to '0' (interrupt generation disabled), the status bit is cleared when a new start or stop condition is detected on the receiver/transmitter.

21.3.3.2.2 SIDETONE_McBSP Interrupt Requests

The McBSP2 and McBSP3 can generate another interrupt to the MPU subsystem interrupt controller:

- **ST_McBSPi_IRQ:** SIDETONE interrupt request for McBSPi module (where I = 2, 3).

Table 21-13. SIDETONE_McBSP Interrupt Requests

Request Name	Mapping	Destination
ST_McBSP2_IRQ	M_IRQ_4	MPU subsystem interrupt controller
ST_McBSP3_IRQ	M_IRQ_5	MPU subsystem interrupt controller

Table 21-14. SIDETONE_McBSP Interrupt Events

Event Name	Status Bit	Mask Bit	Description
Over-run	McBSPi.ST_IRQSTATUS_REG[0] OVRERROR	McBSPi.ST_IRQENABLE_REG[0] OVRERROREN	This event happens when a new data to be processed arrives before the previous one has ended.

Once an interrupt request has been generated, the software must read the McBSPi.ST_IRQSTATUS_REG register to check what event caused the interrupt request generation, and acknowledge each processed event by writing a 1 to the corresponding bit in the McBSPi.ST_IRQSTATUS_REG register.

-
- Note:** The McBSPi.ST_IRQSTATUS_REG[0] OVRRError status bit can be cleared in two ways:
- If the McBSPi.ST_IRQENABLE_REG[0] OVRRErrorEN mask bit is set to '1' (interrupt generation enabled), the status bit is cleared by writing a '1'.
 - If the McBSPi.ST_IRQENABLE_REG[0] OVRRErrorEN mask bit is cleared to '0' (interrupt generation disabled), the status bit is cleared when a new start or stop condition is detected on the SIDETONE channels.
-

21.4 McBSP Functional Description

This section is a functional description of the McBSP module.

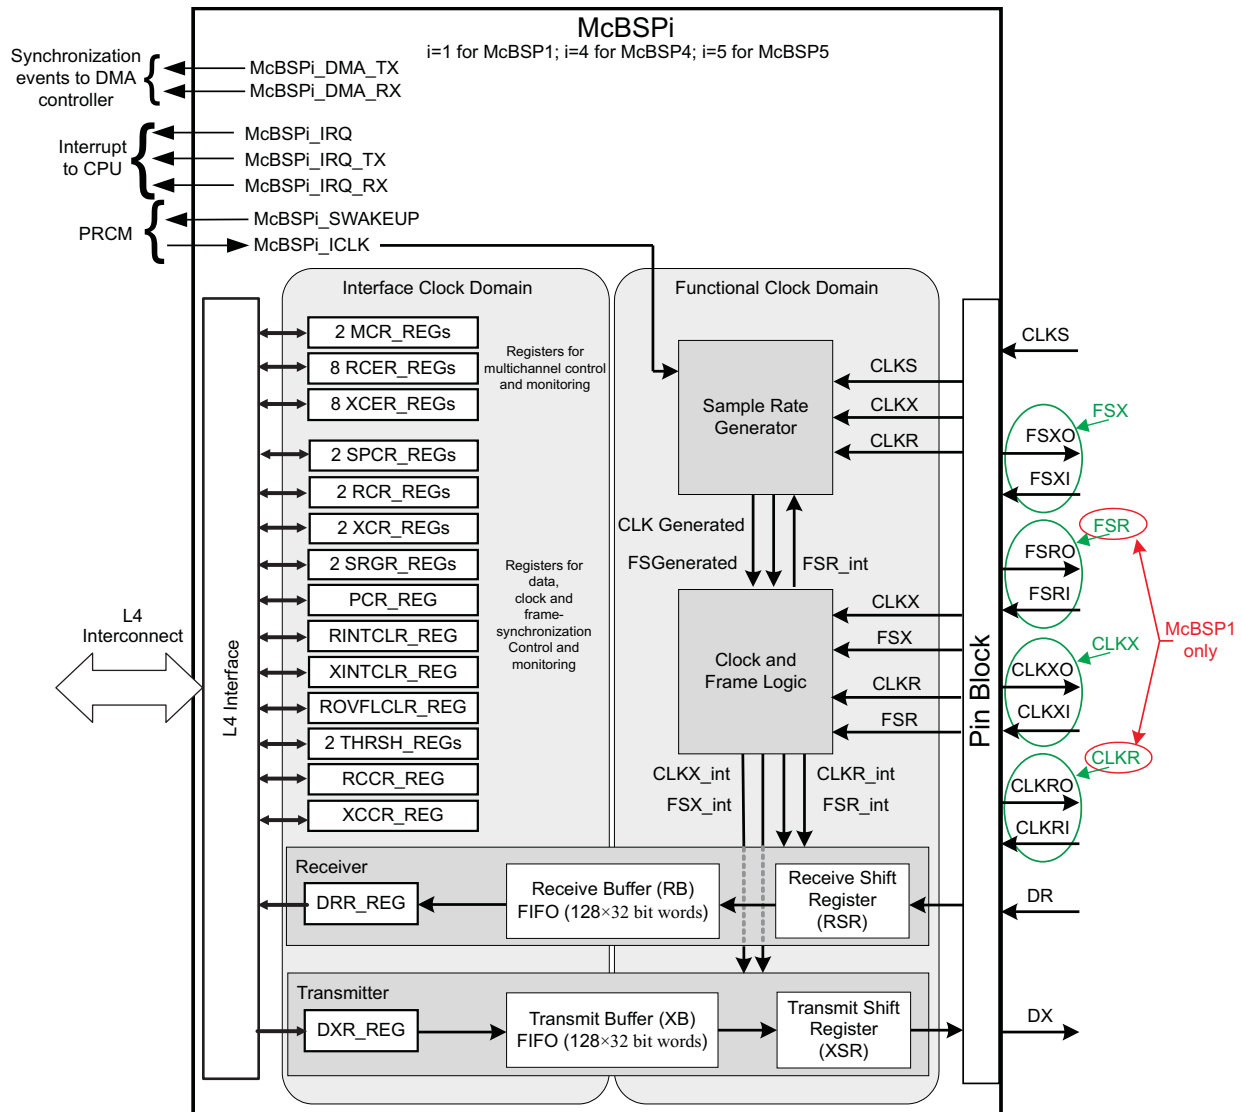

21.4.1 Block Diagram

Figure 21-21, Figure 21-22, and Figure 21-23 show functional block diagrams of the five instances of the McBSP modules.

These figures regroup the McBSP modules by categories:

- McBSP module without audio buffer and SIDETONE core: McBSP1, McBSP4 and McBSP5
- McBSP module with audio buffer and SIDETONE core: McBSP2
- McBSP module without audio buffer, but with SIDETONE core: McBSP3

022

Figure 21-23. McBSP3 Block Diagram

023

21.4.2 McBSP Data Transfer Process

For McBSP1, McBSP3, McBSP4, and McBSP5 modules, receive and transmit operations are triple-buffered (512 bytes buffers organized in 32-bit words are used).

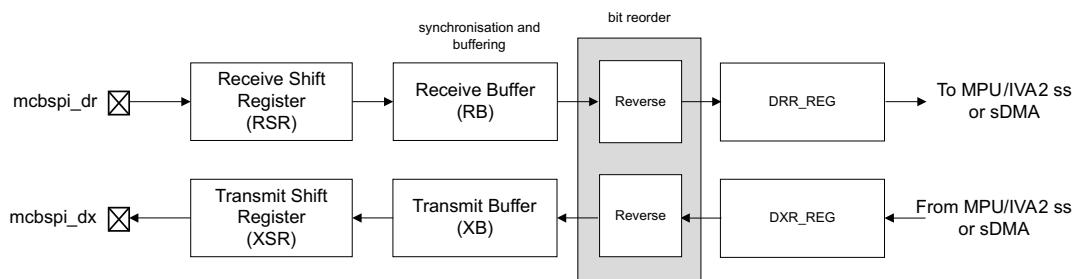

For the McBSP2 module, receive and transmit operations are quadruple-buffered (5K bytes buffers organized in 32-bit words are used). Receive and transmit buffers are separated in two memories: The same buffer as the others McBSP modules (1K bytes) and an audio buffer (4K bytes). The audio buffer is the largest one and is clocked by the interface clock, while the other buffer is used for synchronizing data to/from the audio buffer with the functional transmit/receive clock domains. Figure 21-25 shows this implementation in the McBSP2 data transfer paths.

All registers of McBSP data transfer paths are 32-bits wide. [Figure 21-24](#) and [Figure 21-25](#) illustrate the McBSP data transfer paths.

CAUTION

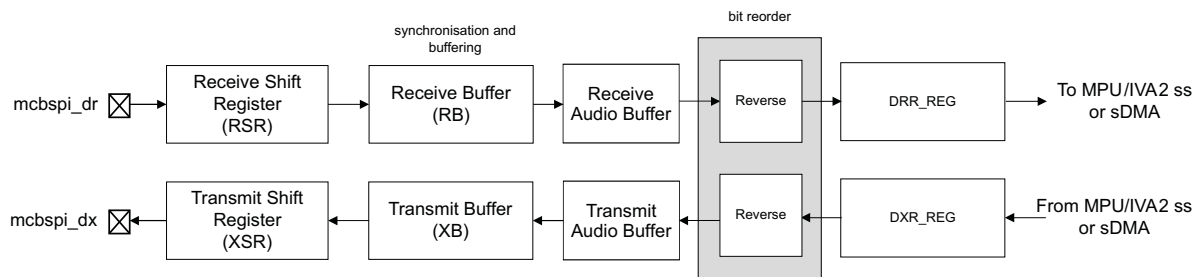

The McBSP registers (DRR_REG and DXR_REG) are limited to 32-bit data accesses (L4 Interconnect). 16-bit and 8-bit is not allowed and can corrupt register content.

Figure 21-24. McBSP Data Transfer Paths

024

Figure 21-25. McBSP2 Data Transfer Paths

068

21.4.2.1 Data Transfer Process for 8- / 12- / 16- / 20- / 24- / 32-bits Long Words

CAUTION

For each data word length, one data occupies one 32-bit buffer word.

Receive data arrives on the mcbspi_dr pin and is shifted into the receive shift register (RSR). When a full word (depending on the data length configuration) is received, the content of the shift register is copied into the receive buffer (RB) if it is not full. When the RB threshold is reached the McBSP module asserts DMA or interrupt request and the RB content is then transferred (the sDMA or the eDMA controller reads the data receive register McBSPi.MCBSPLP_DRR_REG).

Transmit data is written by the MPU subsystem, the IVA2.2 subsystem or the DMA controller to data transmit register (McBSPi.MCBSPLP_DXR_REG) using the McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit enable input (when a byte is not enabled, the byte value in the memory will contain the previous written value). If there is no previous data in transmit shift register (XSR), the value from the transmit buffer (XB) is copied to XSR; otherwise, the content is copied to the XSR when the last bit of the previous data is shifted out on the mcbspi_dx pin.

21.4.2.2 Bit Reordering (Option to Transfer LSB First)

Generally, the McBSP module transmits or receives all data with the MSB first. However, some data protocols require the LSB to be transferred first.

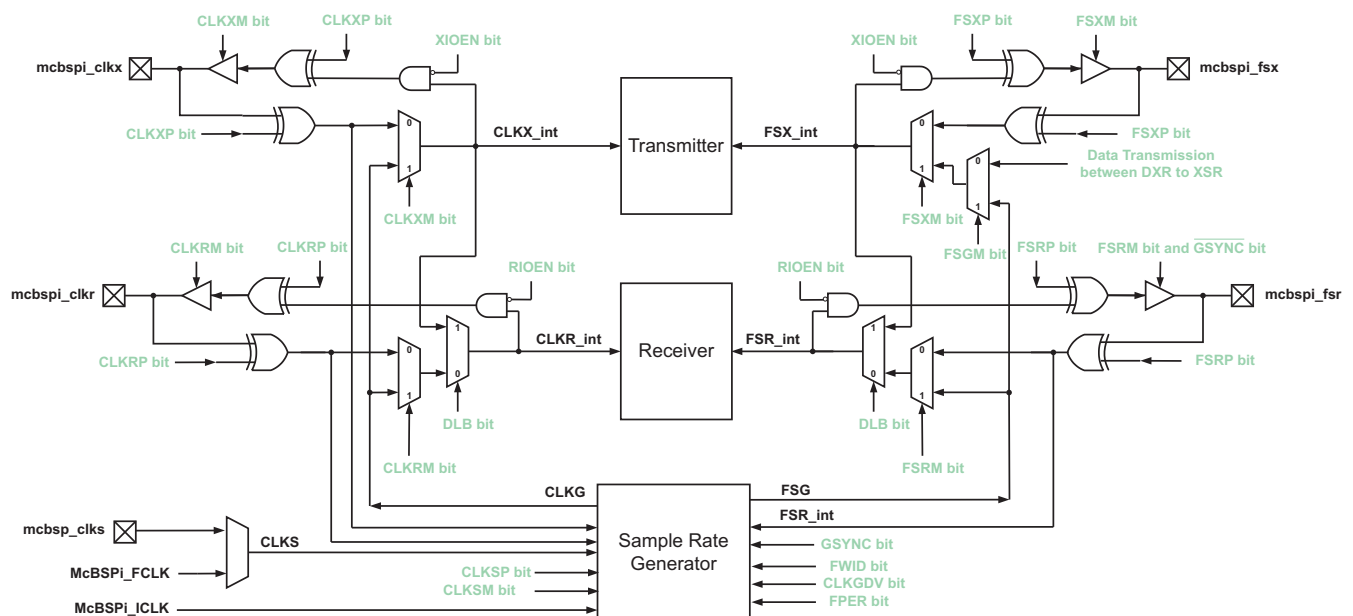

If you set McBSPi.MCBSPLP_XCR2_REG[4:3] XREVERSE=0b01, the bit ordering of the data words is reversed (LSB first) before being sent to the serial port. If you set McBSPi.MCBSPLP_RCR2_REG[4:3] RREVERSE=0b01, the bit ordering of the data words is reversed during reception (LSB first).

This feature is available for all the data formats from 8 up to 32-bit data length.

21.4.2.3 Clocking and Framing Data

This section explains basic concepts and terminology important for understanding how McBSP data transfers are timed and delimited.

Figure 21-26. Conceptual Block Diagram for Clock and Frame Generation

MCBSP_025

21.4.2.3.1 Clocking

Data is shifted one bit at a time from the mcbspi_dr pin to the RSRs or from the XSRs to the mcbspi_dx pin. The time for each bit transfer is controlled by the rising or falling edge of a clock signal.

The receive clock signal (CLKR_int) controls bit transfers from the mcbspi_dr pin to the RSRs. The transmit clock signal (CLKX_int) controls bit transfers from the XSRs to the mcbspi_dx pin. CLKR_int or CLKX_int signals can be derived from a pin at the boundary of the McBSP module (mcbspi_clkr and mcbspi_clkx respectively) or derived from inside the McBSP module (see Figure 21-26). The clocks source is selected by programming the McBSPi.MCBSPLP_PCR_REG[9] CLKXM bit and the McBSPi.MCBSPLP_PCR_REG[8] CLKRM bit respectively.

When the McBSPi.MCBSPLP_PCR_REG[9] CLKXM bit (transmitter clock mode) is set to:

- '0', CLKX_int is driven by an external clock and mcbspi_clkx is an input pin.
- '1', CLKX_int is driven by the internal sample rate generator and mcbspi_clkx is an output pin.

For the McBSPi.MCBSPLP_PCR_REG[8] CLKRM bit (receiver clock mode), see Table 21-15.

Table 21-15. Receiver Clock Mode

Value	Digital loop back mode	mcbspi_clkr pin	Description
0x0	McBSPi.MCBSPLP_XCCR_REG[5] DLB bit =0	input	CLKR_int is driven by an external clock
	McBSPi.MCBSPLP_XCCR_REG[5] DLB bit =1	High-impedance	CLKR_int is driven by CLKX_int. The CLKX_int is derived based on the CLKXM value.
0x1	McBSPi.MCBSPLP_XCCR_REG[5] DLB bit =0	output	CLKR_int is driven by the internal sample rate generator
	McBSPi.MCBSPLP_XCCR_REG[5] DLB bit =1	output	CLKR_int is driven by CLKX_int. The CLKX_int is derived based on the CLKXM value.

The polarities of CLKR and CLKX signals are configured in McBSPi.MCBSPLP_PCR_REG register.

The McBSPi.MCBSPLP_PCR_REG[1] CLKXP defines the transmit clock polarity:

- When set to 0, transmit data driven on rising edge of CLKX signal
- When set to 1, transmit data driven on falling edge of CLKX signal

The McBSPi.MCBSPLP_PCR_REG[0] CLKRP defines the receive clock polarity:

- When set to 0, receive data sampled on falling edge of CLKX signal
- When set to 1, transmit data sampled on rising edge of CLKX signal

Figure 21-27 gives an example where the clock signal controls the timing of each bit transfer on the pin.

Figure 21-27. Clock Signal Control of Bit Transfer Timing

Note: The McBSP module is constrained to operate at an internal functional frequency of up to L4 interface frequency divided by 2. When driving CLKX or CLKR at the pin, choose an appropriate input clock frequency. When using the internal sample rate generator for CLKX/CLKR/CLKS, choose an appropriate input clock frequency (up to L4 interface frequency) and divide down value by programming the McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV bit field.

21.4.2.3.2 Serial Words

Bits traveling between a shift register (RSR or XSR) and a data pin (mcbspi_dr or mcbspi_dx) are transferred in a group called a serial word. The software defines how many bits are in a word by programming:

- For the receiver: the McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 field and the McBSPi.MCBSPLP_RCR2_REG[7:5] RWDLEN2 field.
- For the transmitter: the McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 field and the McBSPi.MCBSPLP_XCR2_REG[7:5] XWDLEN2 field.

The difference of use is explained to [Section 21.4.2.4.1](#).

The various possibilities of word length are 8, 12, 16, 20, 24, and 32 bits (for field values, see [Section 21.7](#))

Bits coming from the mcbspi_dr pin are held in the RSR until it holds a full serial word, then the word is passed to the RB and to the McBSPi.MCBSPLP_DRR_REG register.

During transmission, XSR accepts new data from XB after a full serial word has been passed from XSR to the mcbspi_dx pin.

In the example in [Figure 21-26](#), an 8-bit word size was defined (see the transfer of the 8-bit word B).

21.4.2.3.3 Frames and Frame Synchronization

One or more words (up to 128) are transferred in a group called a frame. The software defines how many words are in a frame by programming:

- For the receiver: The McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1 field and the McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLEN2 field.
- For the transmitter: The McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 field and the McBSPi.MCBSPLP_XCR2_REG[14:8] XFRLEN2 field.

The difference between these registers is explained to [Section 21.4.2.4.1](#). For the corresponding between field value and words number, see [Section 21.7](#).

All the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The McBSP module uses frame-synchronization signals (FSG) to determine when each frame is received/transmitted. When a pulse occurs on a frame-synchronization signal, the McBSP module begins receiving/transmitting a frame of data. When the next pulse occurs, the McBSP module receives/transmits the next frame, and so on.

Pulses on the receive frame-synchronization (FSR_int) signal initiate frame transfers on mcbspi_dr. Pulses on the transmit frame-sync (FSX_int) signal initiate frame transfers on mcbspi_dx. FSR_int or FSX_int signals can be derived from a pin at the boundary of the McBSP module (mcbspi_fsr and mcbspi_fsx respectively) or derived from inside the McBSP module (see [Figure 21-25](#)). The frame-sync source is selected by programming the McBSPi.MCBSPLP_PCR_REG[11] FSXM bit and the McBSPi.MCBSPLP_PCR_REG[10] FSRM bit respectively.

When the McBSPi.MCBSPLP_PCR_REG[11] FSXM bit (transmitter frame-sync mode) is set to:

- '0', FSX_int is derived from an external source and mcbspi_fsx is an input pin.
- '1', FSX_int is determined by the McBSPi.MCBSPLP_SRGR2_REG[12] FSGM bit and mcbspi_fsx is an output pin.

For the McBSPi.MCBSPLP_PCR_REG[10] FSRM bit (receiver frame-sync mode), is set to:

- '0', FSR_int is generated by an external source and mcbspi_fsr is an input pin
- '1', FSR_int is generated internally by sample rate generator. The mcbspi_fsx is an output pin except when McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit = 0x1

In the example in [Figure 21-26](#), a one-word frame is transferred when a frame-synchronization pulse occurs. The polarities of FSR and FSX signals are programmable by bits on McBSPi.MCBSPLP_PCR_REG register.

The McBSPi.MCBSPLP_PCR_REG[3] FSXP defines the transmit frame-sync polarity:

- When set to '0', frame-sync pulse FSX is active high
- When set to '1', frame-sync pulse FSX is active low

The McBSPi.MCBSPLP_PCR_REG[2] FSRP defines the receive frame-sync polarity:

- When set to '0', frame-sync pulse FSR is active high
- When set to '1', frame-sync pulse FSR is active low

In McBSP operation, the inactive-to-active transition of the frame-synchronization signal indicates the start of the next frame. For this reason, the frame-synchronization signal may be high for an arbitrary number of clock cycles. Only after the signal is recognized to have gone inactive, and then active again, does the next frame synchronization occur.

21.4.2.3.4 Detecting Frame-Synchronization Pulses, Even in Reset State

The McBSP module can generate receive and transmit interrupts to the MPU/IVA2.2 subsystems to indicate specific events in the McBSP module. To facilitate detection of frame synchronization, these interrupts can be sent in response to frame-synchronization pulses (see [Section 21.5](#) for further details).

Unlike other serial port interrupt modes, this mode can operate while the associated portion of the serial port is in reset (such as activating receive interrupt when the receiver is in reset). In this case, McBSPi.MCBSPLP_PCR_REG[0] FSRM bit/McBSPi.MCBSPLP_PCR_REG[1] FSXM bit and McBSPi.MCBSPLP_PCR_REG[2] FSRP bit/McBSPi.MCBSPLP_PCR_REG[3] FSXP bit still select the appropriate source and polarity of frame synchronization. Thus, even when the serial port is in the reset state, these signals are synchronized to the interface clock (McBSPi_ICLK) and then sent to the MPU/IVA2.2 subsystem in the form of receive interrupt and transmit interrupt at the point where they feed the receiver and transmitter of the serial port. Consequently, a new frame-synchronization pulse can be detected, and then, the MPU/IVA2.2 subsystem can take the serial port out of reset safely.

21.4.2.3.5 Ignoring Frame-Synchronization Pulses

The McBSP module ignores transmit and/or receive frame-synchronization pulses if the frame transfer was started by a previous frame-synchronization pulse (unexpected frame-synchronization pulses). The McBSP module does not support features like retransmit or re-receive of an erroneous frame or word. The receiver or transmitter ignores frame-synchronization pulses until the desired frame length or number of words is reached. For more details on unexpected frame-synchronization pulses, see [Section 21.4.4.3](#), or [Section 21.4.4.6](#)

21.4.2.3.6 Frame Frequency

The frame frequency is determined by the period between frame-synchronization pulses and is defined as shown in the following equation:

Frame frequency = Clock frequency / (Number of clock cycles between two rising edges [or falling edges] of two consecutive frame synchronization pulses)

The frame frequency can be increased by decreasing the time between frame-synchronization pulses (limited only by the number of bits per frame). As the frame transmit frequency increases, the inactivity period between the data packets for adjacent transfers decreases to zero.

21.4.2.3.7 Maximum Frame Frequency

The minimum number of clock cycles between frame synchronization pulses is equal to the number of bits transferred per frame. The maximum frame frequency is defined as shown in the following equation:

Maximum frame frequency = clock frequency / Number of bits per frame

[Figure 21-28](#) below shows the McBSP operating at maximum packet frequency. At maximum packet frequency, the data bits in consecutive packets are transmitted contiguously with no inactivity between bits.

Figure 21-28. McBSP Operating at Maximum Packet Frequency

027

If there is a 1-bit data delay as shown in [Figure 21-28](#), the frame-synchronization pulse overlaps the last bit transmitted in the previous frame. Effectively, this permits a continuous stream of data, back-to-back transfers.

Note: For McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY = 0x0 (0-bit data delay), the first bit of data is transmitted asynchronously to the internal transmit clock signal (CLKX_int). For more details, see [Section 21.5.1.6.2.2.5](#).

21.4.2.4 Frame Phases (Dual-Phase Frame I2S Support)

The McBSP module allows you to configure each frame to contain one or two phases. The support for dual-phase frames is required to provide I2S fully compliant capabilities (audio left and right channels—stereo audio stream).

CAUTION

The limitation on dual-phase frame support is that the number of words per phase must be set to 1 for both first and second phase. It is the only possible value for word per frame when using the dual phase frame.

The number of bits per word can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers. For example, a user might define a frame as consisting of one phase containing one word of 16 bits, followed by a second phase consisting of one word of 32 bits. This configuration allows the user to compose frames for custom applications such as I2S protocol.

21.4.2.4.1 Number of Phases, Words, and Bits per Frame

Table 21-16 below shows which bit fields in the receive control registers (McBSPi.MCBSPLP_RCR1_REG and McBSPi.MCBSPLP_RCR2_REG) and in the transmit control registers (McBSPi.MCBSPLP_XCR1_REG and McBSPi.MCBSPLP_XCR2_REG) determine the number of phases per frame, the number of words per frame, and the number of bits per word for each phase, for both receiver and transmitter. The maximum number of words per frame is limited to 2 when using dual-phase frames (one word for each phase), and to 128 for a single-phase frame. The number of bits per word can be 8, 12, 16, 20, 24, or 32 bits.

The following legend applies to the table:

- RPHASE => McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit
- XPHASE => McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit
- RFRLEN1 => McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1 field
- RFRLEN2 => McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLEN2 field
- XFRLEN1 => McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 field
- XFRLEN2 => McBSPi.MCBSPLP_XCR2_REG[14:8] XFRLEN2 field
- RWDLEN1 => McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 field
- RWDLEN2 => McBSPi.MCBSPLP_RCR2_REG[7:5] RWDLEN2 field
- XWDLEN1 => McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 field
- XWDLEN2 => McBSPi.MCBSPLP_XCR2_REG[7:5] XWDLEN2 field

Table 21-16. Phases, Words and Bits per Frame Control Bit

Operation	Number of phases	Words per frame set with	Bits per word set with
Reception	1 (RPHASE=0)	RFRLEN1	RWDLEN1
Reception	2 (RPHASE=1)	RFRLEN1=0x0 and RFRLEN2=0x0	RWDLEN1 for phase 1 RWDLEN2 for phase 2
Transmission	1 (XPHASE=0)	XFRLEN1	XWDLEN1
Transmission	2 (XPHASE=1)	XFRLEN1=0x0 and XFRLEN2=0x0	XWDLEN1 for phase 1 XWDLEN2 for phase 2

21.4.2.4.2 Single-Phase Frame Example

Figure 21-29 below shows an example of a single-phase data frame containing one 8-bit word. Because the transfer is configured for one data bit delay, the data on the mcbspi_dx and mcbspi_dr pins are available one clock cycle after FS(R/X) goes active. The following table shows the assumptions used in the example of this figure.

Table 21-17. Assumptions for the Single-Phase Frame Example

Assumption	Value	Bit or Field Name
Single-phase frame	'0'	McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit
		McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit
One word per frame	0x0	McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLLEN1 field
		McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLLEN1 field
8-bit word length	0x0	McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 field
		McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 field
word length in register2	ignored	McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLLEN2 field
		McBSPi.MCBSPLP_XCR2_REG[14:8] XWDLEN2 field
Receive data clocked on falling edge	'0'	McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit
Transmit data clocked on rising edge		McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit
Active-high frame-sync signals	'0'	McBSPi.MCBSPLP_PCR_REG[2] FSRP bit
		McBSPi.MCBSPLP_PCR_REG[3] FSXP bit
1-bit data delay	01b	McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY field
		McBSPi.MCBSPLP_XCR2_REG[1:0] XDARDLY field

Figure 21-29. Single-Phase Frame for a McBSP Data Transfer

21.4.2.4.3 Dual-Phase Frame Example

Figure 21-30 below shows an example of a frame. The first phase consists of one word of 16 bits, followed by a second phase of one word of 8 bits. The entire bit stream in the frame is contiguous. There are no gaps between words/phases. Table 21-18 shows the assumptions used to the example in Figure 21-30.

Table 21-18. Assumptions for the Dual-Phase Frame Example

Assumption	Value	Bit or Field name
Single-phase frame	'1'	McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit
		McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit
One word per frame	0x0	McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLLEN1 field
		McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLLEN1 field
16-bit word length	0x0	McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 field
		McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 field
8-bit word length	0x2	McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLLEN2 field
		McBSPi.MCBSPLP_XCR2_REG[14:8] XWDLEN2 field
Receive data clocked on falling edge	'0'	McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit
Transmit data clocked on rising edge		McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit
Active-high frame-sync signals	'0'	McBSPi.MCBSPLP_PCR_REG[2] FSRP bit
		McBSPi.MCBSPLP_PCR_REG[3] FSXP bit
0-bit data delay	00b	McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY field
		McBSPi.MCBSPLP_XCR2_REG[1:0] XDARDLY field

21.4.2.5 McBSP Reception

This section explains the fundamental process of reception in the McBSP module. For details about how to program the McBSP receiver, see [Section 21.5](#), [Section 21.5.1.4](#), and [Section 21.5.1.5](#).

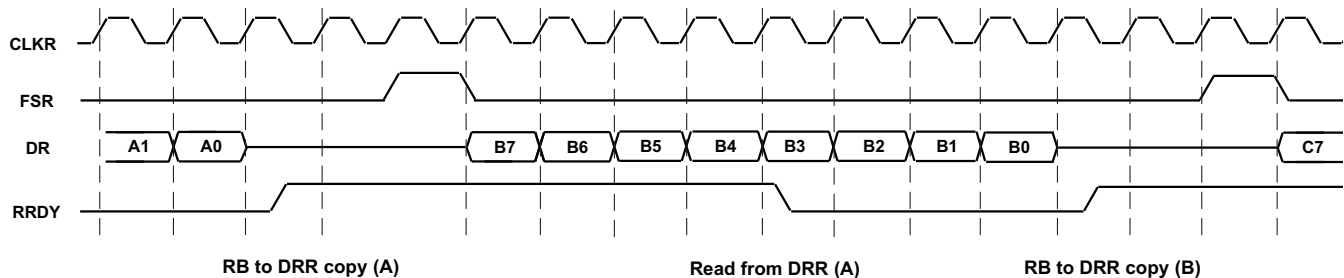

[Figure 21-31](#) and [Figure 21-32](#) below show how reception occurs in the McBSP module. A description of the process follows the figures. [Figure 21-31](#) shows the physical path for the data.

Figure 21-31. McBSP Reception Physical Data Path

[Figure 21-32](#) is a timing diagram showing signal activity for one possible reception scenario.

Figure 21-32. McBSP Reception Signal Activity

RRDY: Status of receiver ready bit (high is 1)

The following process describes how data travels from the mcbspi_dr pin to the MPU/IVA2.2 subsystem or to the sDMA controller:

1. The McBSP module waits for a receive frame-synchronization pulse on FSR_int.
2. When the pulse arrives, the McBSP module inserts the appropriate data delay that is selected with the McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY bits. In the preceding timing diagram a 1-bit data delay is selected.
3. The McBSP module accepts data bits on the mcbspi_dr pin and shifts them into the RSR. For details on choosing a word length, see [Section 21.5.1.5.2.2.2](#).
4. When a full word is received, the McBSP module copies the contents of the RSR to the RB, provided that RB is not full.
5. When the programmed receive threshold is reached (McBSPi.MCBSPLP_THRSH1_REG[11:0] RTHRESHOLD field), the McBSP module asserts the receiver ready bit (McBSPi.MCBSPLP_SPCR1_REG[1] RRDY bit). This indicates that receive data is ready to be read by the MPU/IVA2.2 subsystem or the sDMA controller by accessing McBSPi.MCBSPLP_DRR_REG register.

The data copied from RB to McBSPi.MCBSPLP_DRR_REG is justified and bit filled according to the

McBSPi.MCBSPLP_SPCR1_REG[14:13] RJUST field.

6. The MPU/IVA2.2 subsystem or the sDMA controller reads the data from the data receive register. When the RB is empty, McBSPi.MCBSPLP_SPCR1_REG[1] RRDY bit is cleared.

21.4.2.6 McBSP Transmission

This section explains the fundamental process of transmission in the McBSP module. For details about how to program the McBSP transmitter, see [Section 21.5](#), and [Section 21.5.1.6](#).

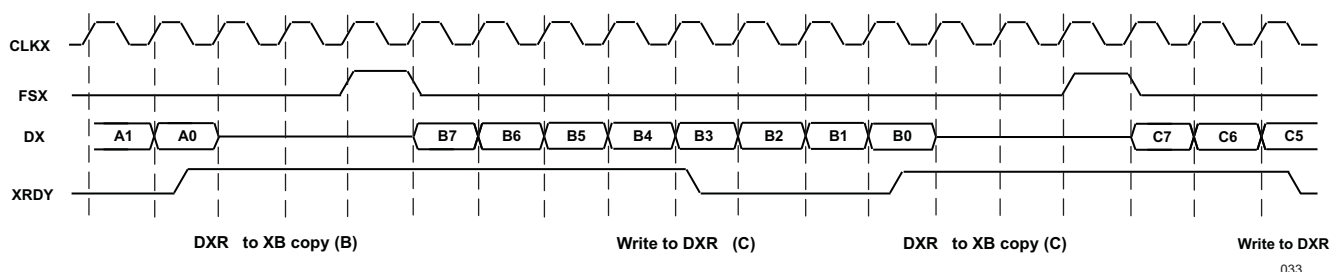

Figures below show how transmission occurs in the McBSP module. A description of the process follows the figures. [Figure 21-33](#) shows the physical path for the data.

Figure 21-33. McBSP Transmission Physical Data Path

[Figure 21-34](#) is a timing diagram showing signal activity for one possible transmission scenario.

Figure 21-34. McBSP Transmission Signal Activity

XRDY: Status of transmitter ready bit (high is 1)

1. The MPU/IVA2.2 subsystem or the sDMA controller writes data to the data transmit register (McBSPi.MCBSPLP_DXR_REG). When the XB is reached the transmitter ready bit (McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit) is cleared to indicate that the transmitter is not ready for new data. For details on choosing a word length, see [Section 21.5.1.6.2.2.2](#).
2. When new data arrives in McBSPi.MCBSPLP_DXR_REG register, the McBSP module copies the content of the data transmit register to the XB. In addition, the transmit ready bit (McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit) is set as long as the buffer contains at least the transmit threshold number of free locations (McBSPi.MCBSPLP_THRSH2_REG[11:0] XTHRESHOLD field). This indicates that the transmitter is ready to accept new data from the MPU/IVA2.2 subsystem or the sDMA controller.
3. The McBSP module waits for a transmit frame-synchronization pulse on FSX_int.
4. When the pulse arrives, the McBSP module inserts the appropriate data delay that is selected with the McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY field.
In the preceding timing diagram, a 1-bit data delay is selected.
5. The McBSP module shifts data bits from the XSR to the mcbspi_dx pin.

21.4.2.7 Enable/Disable the Transmit and Receive Processes

The McBSP module has the option to stop-resume the transmit/receive process while the module is in functional mode (out of transmit/receive reset).

When the transmit/receive disable bit (McBSPi.MCBSPLP_XCCR_REG[0] XDISABLE/McBSPi.MCBSPLP_RCCR_REG[0] RDISABLE) is set, the McBSP module stops the transmit/receive operation at the next frame boundary (frame corruption avoided).

During the receive disable state, the frames that are sent (when FSR signal is asserted while receive disable) by the remote device are lost, and receive buffer overflow status bit (McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT) is not set. Also, the frames received by the remote device while McBSPi.MCBSPLP_XCCR_REG[0] XDISABLE bit is set (when FSX signal is asserted while transmit disable) are meaningless undefined data frames, and transmit buffer underflow status bit (McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT) is not set. The presence of the frame synchronization, while transmit/receive process is disabled, can be checked by reading the transmit/receive Frame-sync interrupt status: McBSPi.MCBSPLP_IRQSTATUS_REG[8] XFSX / McBSPi.MCBSPLP_IRQSTATUS_REG[1] RFSR bits.

As soon as the McBSPi.MCBSPLP_XCCR_REG[0] XDISABLE/McBSPi.MCBSPLP_RCCR_REG[0] RDISABLE bit is cleared, the transmit/receive process resumes at the next frame boundary.

Note: It is not recommended to use this mechanism together with the possibility to interrogate the transmit/receive buffer status register (McBSPi.MCBSPLP_XBUFFSTAT_REG[7:0] XBUFFSTAT/McBSPi.MCBSPLP_RBUFFSTAT_REG[7:0] RBUFFSTAT field indicating the occupied/available buffer locations), since this register is an interface clock (McBSPi_ICLK) synchronous register and does not reflect the exact number of occupied/free locations available on the functional clock domain.

21.4.2.8 McBSP Data Transfert Mode

Note: For all examples in this section, the configured CLKX edge is the rising edge (McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit=0x0) and the configured CLKR edge is the falling edge (McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit=0x0). There are the reset values.

In timing diagrams below, a 1-bit data delay is selected (McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY field=0x01 and McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY field=0x01), because data often follows a 1-cycle active frame-synchronisation.

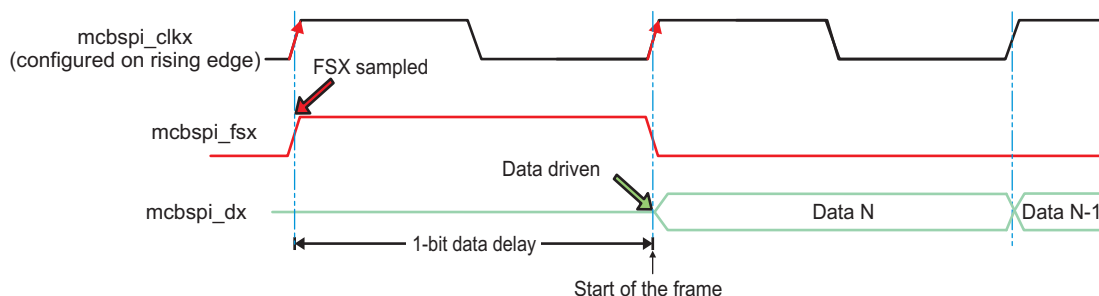

McBSP modules can support 2 edge selection modes for transmit and receive data transfer at the system level:

- The full cycle mode, for which one clock period is used to transfer the data, generated on one edge and captured on the same edge (one clock period later).
- The half cycle mode, for which one half clock period is used to transfer the data, generated on one edge and captured on the opposite edge (one half clock period later). Note that a new data is generated only every clock period, which permits to secure the required hold time.

21.4.2.8.1 Transmit Full Cycle Mode

When configured in full cycle mode (McBSPi.MCBSPLP_XCCR_REG[11] XFULL_CYCLE bit = 0x1), the FSX signal is sampled on the configured CLKX edge and the data is driven on the same configured edge. See Figure 21-35.

Figure 21-35. Transmit Full Cycle Timing Diagram

069

21.4.2.8.2 Transmit Half Cycle Mode

When configured in half cycle mode (McBSPi.MCBSPLP_XCCR_REG[11] XFULL_CYCLE bit = 0x0, reset value), the FSX signal is sampled on the opposite configured CLKX edge and the data is driven on the next configured edge. See Figure 21-36.

Figure 21-36. Transmit Half Cycle Timing Diagram

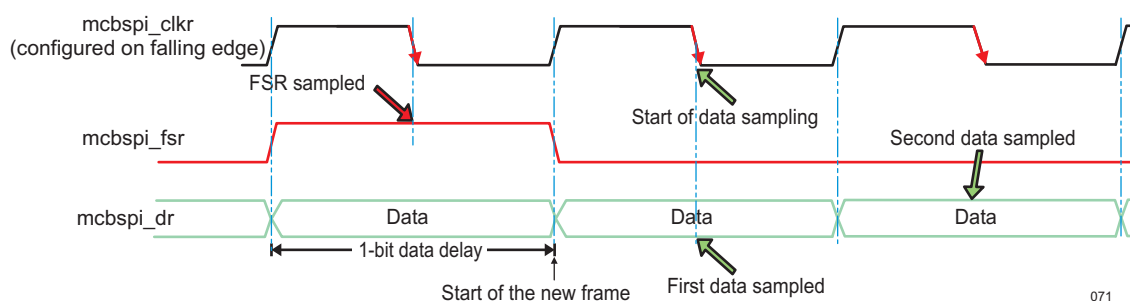

070

21.4.2.8.3 Receive Full Cycle Mode

When configured in full cycle mode (McBSPi.MCBSPLP_RCCR_REG[11] RFULL_CYCLE bit = 0x1, reset value), the FSR signal is sampled on the configured CLKR edge and the data is driven on the same configured edge. See Figure 21-37.

Figure 21-37. Receive Full Cycle Timing Diagram

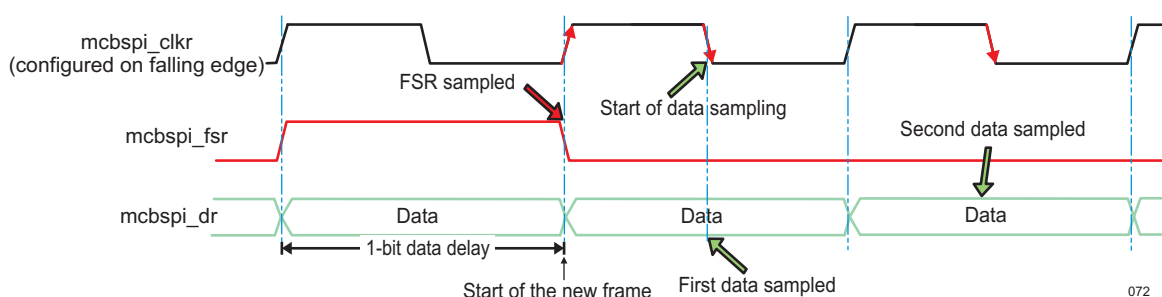

071

21.4.2.8.4 Receive Half Cycle Mode

When configured in half cycle mode (McBSPi.MCBSPLP_RCCR_REG[11] RFULL_CYCLE bit = 0x0), the FSR signal is sampled on the opposite configured CLKR edge and the data is driven on the next configured edge. See Figure 21-38.

Figure 21-38. Receive Half Cycle Timing Diagram

072

For timing information on the both cycle mode, see your device-specific data manual.

21.4.3 McBSP SRG

The McBSP module contains an internal SRG that can be used to generate an internal data clock (CLKG) and an internal frame-synchronization signal (FSG). CLKG can be used for bit shifting on the data receive pin (mcbspi_dr) and/or the data transmit pin (mcbspi_dx). FSG can be used to initiate frame transfers on mcbspi_dr pin and/or mcbspi_dx pin. Figure 21-39 is a conceptual block diagram of the SRG.

Figure 21-39. Conceptual Block Diagram of the Sample Rate Generator

The source clock for the SRG (labeled CLKSRG in the diagram) can be supplied by either the interface clock (McBSPi_ICLK), or the functional clock (CLKS input), or by an external pin (mcbspi_clkx, or mcbspi_clkr). The source is selected with the McBSPi.MCBSPLP_PCR_REG[7] SCLKME bit and the McBSPi.MCBSPLP_SRGR2_REG[13] CLKSM bit.

If a pin or CLKS signal is used, the polarity of the incoming signal can be inverted with the appropriate polarity bit (McBSPi.MCBSPLP_SRGR2_REG[14] CLKSP bit, McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit, or McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit).

The SRG has a three-stage clock divider that gives CLKG and FSG programmability.

The three stages provide:

- Clock divide-down: The source clock (CLKSRG) is divided according to the McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV field to produce CLKG signal
- Frame period divide-down: CLKG is divided according to the McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER field to control the period from the start of a frame-pulse to the start of the next pulse
- Frame-synchronization pulse-width countdown: CLKG cycles are counted according to the McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID field to control the width of each frame-synchronization pulse

Note: The McBSP module cannot operate at an internal functional frequency faster than L4 interface frequency divided by 2. Choose an input clock frequency and a McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV value such that CLKG is less than or equal to L4 interface frequency divided by 2.

In addition to the three-stage clock divider, the sample rate generator has a frame-synchronization pulse detection and clock synchronization module that allows synchronization of the clock divide down with an incoming frame-synchronization pulse on the mcbspi_fsr pin. This feature is enabled or disabled with the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit.

CLKG is used as source to generate the output clocks CLKX/CLKR when the McBSPi.MCBSPLP_PCR_REG[9] CLKXM / McBSPi.MCBSPLP_PCR_REG[8] CLKRM bit indicates that the clock is an output. The output CLKX/CLKR is generated according to the clock polarity setting (see Figure 21-26).

For details on getting the sample rate generator ready for operation, see Section 21.5.

21.4.3.1 Clock Generation in the SRG

The SRG can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both. Use of the SRG to drive clocking is controlled by the clock mode bits (McBSPi.MCBSPLP_PCR_REG[9] CLKXM and McBSPi.MCBSPLP_PCR_REG[8] CLKRM) and polarity mode bits (McBSPi.MCBSPLP_PCR_REG[1] CLKXP and McBSPi.MCBSPLP_PCR_REG[0] CLKRP).

When a clock mode bit is set to 1 (CLKRM=1 for reception, CLKXM=1 for transmission), the corresponding data clock (CLKR for reception, CLKX for transmission) is driven by the internal SRG output clock (CLKG) according to the polarity setting.

The effects of this setting on the McBSP module are partially affected by the use of the digital loopback (DLB) mode, the analog loop back (ALB) mode and by the synchronous receive/transmit setting, respectively, as described in Table 21-19. The ALB mode is selected with the McBSPi.MCBSPLP_SPCR1_REG[15] ALB bit. The DLB mode is selected with the McBSPi.MCBSPLP_XCCR_REG[5] DLB bit. The synchronous setting is controlled by input signals. These signals are defined by the control registers of the System Control Module (more details, refer Section 21.3.1)

When using the SRG as a clock source, make sure the SRG is enabled (McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit =1).

Table 21-19. Effects of DLB and ALB Bits on Clock Modes

	Mode Bit Settings	Effect
CLKRM=1	DLB=0 and ALB = 0 (Digital and analog loop back mode disabled)	mcbbsp1_clkr is an output pin driven by the SRG output clock (CLKG).
	DLB=0 and ALB = 1 (Digital loop back mode disabled and Analog loop back mode enabled)	mcbbsp1_clkr is an output pin driven by the SRG output clock (CLKG). The receiver functional part internal clock is driven by CLKX input signal provided by mcbbspi_clkx pin. The source of CLKX depends on the CLKXM bit. The receive frame synchronization is driven by FSX input signal provided by mcbbspi_fsx pin. The receive data is driven by the DX input loop-back pin (mcbbspi_dx).
	DLB=1 & ALB = 0 (Digital loop back mode enabled and Analog loop back mode disabled)	The SRG and the frame synchronization generator must be enabled. The internal transmit and receive clocks are driven by the SRG (CLKG having the appropriate CLKXP polarity). The transmit and receive frame synchronization signals are driven by FSG (having the appropriate FSXP polarity). The transmit data is connected to the DR input data. Note that in digital loop back mode no serial link activity will be seen by the remote device.
	DLB=1 & ALB = 1 (reserved mode)	Undefined functionality.
CLKXM = 1	DLB=0 & ALB = 0 (Digital & analog loop back mode disabled)	mcbbspi_clkx is an output pin driven by the SRG output clock (CLKG).
	DLB=0 & ALB = 1 (Digital loop back mode disabled and Analog loop back mode enabled)	mcbbspi_clkx is an output pin driven by the SRG output clock (CLKG).
	DLB=1 & ALB = 0 (Digital loop back mode enabled and Analog loop back mode disabled)	The SRG and the frame synchronization generator need to be enabled. The internal transmit and receive clocks are driven by the SRG (CLKG having the appropriate CLKXP polarity). The transmit and receive frame synchronization signals are driven by FSG (having the appropriate FSXP polarity). The transmit data is connected to the DR input data. Note that in digital loop back mode no serial link activity will be seen by the remote device.
	DLB=1 & ALB = 1 (reserved mode)	Undefined functionality.
	SCM.CONTROL_DEVCONF0[3] MCBSP1_CLKR bit =1 (synchronous setting and DLB = 0 & ALB = 0)	CLKX is an output pin driven by the SRG output clock (CLKG). CLKR is connected to the CLKX.

21.4.3.2 Frame Sync Generation in the SRG

The SRG can produce a frame-synchronization signal (FSG) for use by the receiver, the transmitter, or both.

If you want the receiver to use FSG for frame synchronization, make sure McBSPi.MCBSPLP_PCR_REG[10] FSRMbit =1. (When FSRM=0, receive frame synchronization is supplied via the mcbbspi_fsr pin.)

If you want the transmitter to use FSG for frame synchronization, you must set:

- McBSPi.MCBSPLP_PCR_REG[11] FSXM = 1: This indicates that transmit frame synchronization is supplied by the McBSP module itself rather than from the mcbbspi_fsx pin.
- MCBSPi.MCBSPLP_SRGR2_REG[12] FSGM=1: This indicates that when FSXM=1, transmit frame synchronization is supplied by the SRG.

Note: When FSGM=0 and FSXM=1, the transmit frame-sync signal (FSX) is generated when XB is not empty. When FSGM = 0, McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER and McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID field are used to determine the frame synchronization period and width (external FSX is gated by the buffer empty condition).

In either case, the SRG must be enabled (McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit=1) and the frame-synchronization logic in the SRG must be enabled (McBSPi.MCBSPLP_SPCR2_REG[7] FRST bit=0).

21.4.3.2.1 Choosing the Width of the Frame-sync Pulse

Each pulse on FSG has a programmable width. You program the McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID field, and the resulting pulse width is (FWID+1)CLKGcycles, where CLKG is the output clock of the SRG. The range is from 1 to 256 clock periods.

21.4.3.2.2 Controlling the Period Between the Starting Edges of Frame Sync Pulses

You can control the amount of time from the starting edge of one FSG pulse to the starting edge of the next FSG pulse. This period is controlled in one of two ways, depending on the configuration of the SRG:

- If the SRG is using an external input clock and McBSPi.MCBSPLP_SRGR2_REG[15] GSYNCbit =1, FSG pulses in response to an inactive-to-active transition on the mcbspi_fsr pin. Thus, an external device controls the frame-synchronization period.
- Otherwise, the software program the McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER field, and the resulting frame-synchronization period is (FPER+1)CLKGcycles, where CLKG is the output clock of the SRG. The range is from 1 to 4096 clock periods.

21.4.3.2.3 Keeping FSG Synchronized to an External Clock

When an external signal is selected to drive the SRG, the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit and the mcbspi_fsr pin can be used to configure the timing of FSG pulses.

McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC=1 ensures that the McBSP module and an external device are dividing down the input clock with the same phase relationship.

If McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC=1, an inactive-to-active transition on the mcbspi_fsr pin triggers a resynchronization of CLKG and generation of FSG.

21.4.3.3 Synchronizing SRG Outputs to an External Clock

The SRG can produce a clock signal (CLKG) and a FSG based on an input clock signal that is either the interface clock signal (McBSPi_ICLK), or the CLKS signal (PRCM functional clock or mcbbsp_clks), or a signal at the mcbspi_clkr, or mcbspi_clkx pin. When an external clock (mcbbsp_clks, or mcbspi_clkr, or mcbspi_clkx) is selected to drive the SRG, the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit and the mcbspi_fsr pin can be used to control the timing of CLKG and the pulsing of FSG relative to the chosen input clock. Make GSYNC=1 so that the McBSP module and an external device divide down the input clock with the same phase relationship.

If the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit=1:

- An inactive-to-active transition on the mcbspi_fsr pin triggers a resynchronization of CLKG signal and a pulsing of FSG signal.
- CLKG signal always begins with a high state after synchronization.
- FSR signal is always detected at the same edge of the input clock signal that generates CLKG signal, no matter how long the FSR pulse is.
- The McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER field are ignored because the frame-synchronization period on FSG is determined by the arrival of the next frame-synchronization pulse on the mcbspi_fsr pin.

If the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit=0, CLKG signal runs freely and is not resynchronized, and the frame-synchronization period on FSG signal is determined by McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER field.

21.4.3.3.1 Operating the Transmitter Synchronously with the Receiver

When the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit=1, the transmitter can operate synchronously with the receiver, provided that the FSX signal is programmed to be driven by FSG signal (McBSPi.MCBSPLP_SRGR2_REG[12] FSGM=1 and McBSPi.MCBSPLP_PCR_REG[11] FSXM="1"). If the FSR input signal has appropriate timing so that it can be sampled by the falling edge of CLKG signal, it can be used, instead, by setting McBSPi.MCBSPLP_PCR_REG[11] FSXM=0 and connecting FSR signal to FSX externally.

The SRG clock drives the transmit and receive clocking (McBSPi.MCBSPLP_PCR_REG[8] CLKRMbit and McBSPi.MCBSPLP_PCR_REG[9] CLKXM bit are set to '1'). Therefore, the CLK(R/X) pin must not be driven by any other driving source.

21.4.3.3.2 Synchronization Examples

Figure 21-40 and Figure 21-41 show the clock and frame-synchronization operation with various polarities of CLKS (the chosen input clock) and FSR signals. These figures assume McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID = 0x0, for an FSG pulse that is oneCLKGcycle wide. The McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER field are not programmed; the period from the start of a frame-synchronization pulse to the start of the next pulse is determined by the arrival of the next inactive-to-active transition on the mcbspi_fsr pin.

Each figure shows what happens to CLKG signal when the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit = 1 and if it is initially synchronized or if it is not initially synchronized. Figure 21-41 has a slower CLKG frequency (it has a larger divide-down value in the McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV field).

Figure 21-40. CLKG Synchronization and FSG Generation (GSYNC = 1 and CLKGDV = 0x1)

21.4.4 McBSP Exception/Error Conditions

21.4.4.1 Introduction

There are several serial port events that can constitute a system error. Any error conditions can be a source of an interrupt:

- Receiver overrun (McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT bit is set to '1', and legacy mode McBSPi.MCBSPLP_SPCR1_REG[2] RFULLbit is set to '1')
This occurs when RB is full and RSR are full with another new word shifted in from mcbspi_dr. Therefore, McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT (McBSPi.MCBSPLP_SPCR1_REG[2] RFULL) indicates an error condition wherein any new data that can arrive at this time on mcbspi_dr replaces the contents of the RSR, and the previous word is lost. The RSR continues to be overwritten as long as new data arrives on mcbspi_dr and McBSPi.MCBSPLP_DRR_REG register is not read. For more details about overrun in the receiver, see [Section 21.4.4.2](#).
- Unexpected receive frame-synchronization pulse (McBSPi.MCBSPLP_IRQSTATUS_REG[0] RSYNCERRbit is set to '1', and legacy mode McBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR bit is set to '1')
This occurs during reception when an unexpected frame-synchronization pulse arrives. An unexpected frame-synchronization pulse is one that is supposed to begin the next frame transfer before all the bits of the current frame have been received. Such a pulse is ignored by the receiver, but sets the McBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR bit. For more details about receive frame-synchronization errors, see [Section 21.4.4.3, Unexpected Receive Frame-Sync Pulse](#).
- Receiver underflow (McBSPi.MCBSPLP_IRQSTATUS_REG[4] RUNDFLSTAT bit is set to '1')
This occurs when sDMA controller or MPU/IVA2.2 subsystem reads data from an empty receive buffer. For more details about underflow in the receiver, see [Section 21.4.4.4](#).
- Transmitter underflow (McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT bit is set to '1', and legacy mode McBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY bit is set to '0')
If a new frame-synchronization signal arrives when XB is empty, the previous data in the XSR is sent again. This procedure continues for every new frame-synchronization pulse that arrives until McBSPi.MCBSPLP_DXR_REG register is loaded with new data (and the XB is no longer empty). For more details about underflow in the transmitter, see [Section 21.4.4.5](#).
- Unexpected transmit frame-synchronization pulse (McBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERRbit is set to '1', and legacy mode McBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERRbit is set to '1')
This occurs during transmission when an unexpected frame-synchronization pulse arrives. An

unexpected frame-synchronization pulse is one that is supposed to begin the next frame transfer before all the bits of the current frame have been transferred. Such a pulse is ignored by the transmitter, but sets the McBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR bit. For more details see [Section 21.4.4.6](#).

- Transmitter overflow (McBSPi.MCBSPLP_IRQSTATUS_REG[12] XOVLSTAT bit is set to '1')
This occurs when sDMA controller or MPU/IVA2.2 subsystem writes data to a full XB. For more details about underflow in the receiver, see [Section 21.4.4.7](#).

21.4.4.2 Overrun in the Receiver

When McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT bit set to '1', and McBSPi.MCBSPLP_SPCR1_REG[2] RFULL bit set to '1' (legacy mode) indicates that the receiver has experienced overrun and is in an error condition. Receive overrun is set when all of the following conditions are met:

1. McBSPi.MCBSPLP_DRR_REG is not read even if the McBSPi.MCBSPLP_IRQSTATUS_REG[3] RRDY bit is set (legacy mode) and DMA or interrupt request has been asserted.
2. RB is full
3. RSR is full

As previously described, data arriving on mcbspi_dr is continuously shifted into the Receive Shift Register (RSR). Once a complete word is shifted into the RSR, an RSR-to-RB copy can occur only if the RB is not full.

Either of the following events clears the legacy mode McBSPi.MCBSPLP_SPCR1_REG[2] RFULL bit and allows subsequent transfers to be read properly:

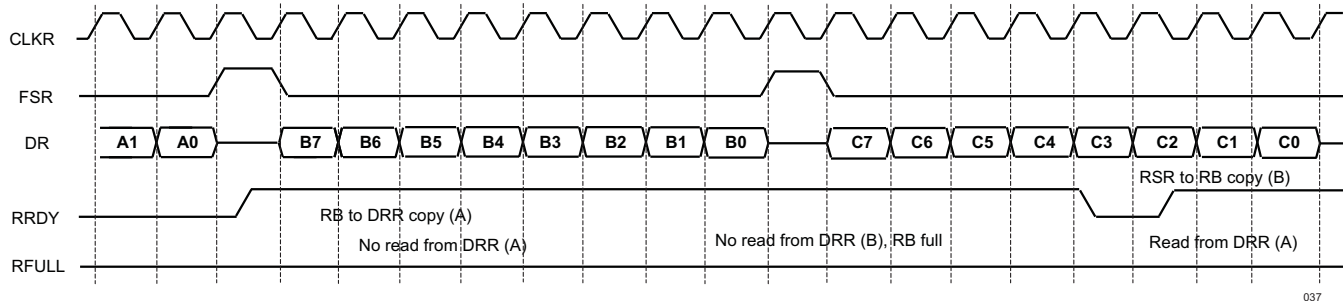

- The MPU/IVA2.2 subsystems or sDMA controller reads McBSPi.MCBSPLP_DRR_REG.
- The receiver is reset individually (McBSPi.MCBSPLP_SPCR1_REG[0] RRSTbit =0) or as part of a global reset.

Another frame-synchronization pulse is required to restart the receiver.

According to the McBSPi.MCBSPLP_IRQENABLE_REG register setting, this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in McBSPi.MCBSPLP_IRQSTATUS_REG register clears the interrupt.

[Figure 21-42](#) shows the receive overrun condition.

Figure 21-42. Overrun in the McBSP Receiver

037

21.4.4.3 Unexpected Receive Frame-sync Pulse

21.4.4.3.1 Possible Responses to Receive Frame-sync Pulses

If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully received, this pulse is treated as an unexpected frame-synchronization pulse, and the receiver sets the receive frame-synchronization error bit McBSPi.MCBSPLP_IRQSTATUS_REG[0] RSYNCERR (and the legacy McBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR bit).

According to the McBSPi.MCBSPLP_IRQENABLE_REG register settings this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in McBSPi.MCBSPLP_IRQSTATUS_REG register clears the interrupt.

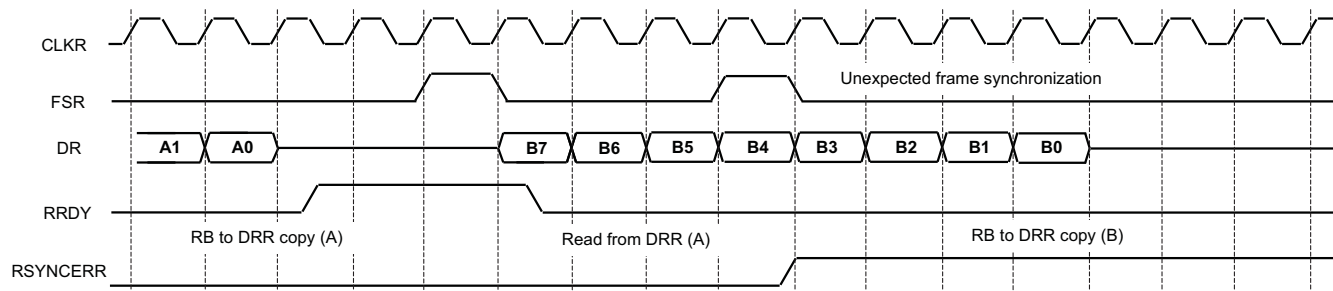

Using the legacy mode, McBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR bit can be cleared only by a receiver reset or by writing 0 to this bit. If you want the McBSP module to notify the MPU/IVA2.2 subsystem of receive frame-synchronization errors, set the legacy mode receive interrupt with the McBSPi.MCBSPLP_SPCR1_REG[5:4] RINTM field. When RINTM=0b11, the McBSP module sends a receive interrupt (legacy mode) request to the MPU/IVA2.2 subsystems each time that RSYNCERR is set.

21.4.4.3.2 Example of an Unexpected Receive Frame-sync Pulse

Figure 21-43 shows an unexpected receive frame-synchronization pulse during normal operation of the serial port, with time intervals between data packets.

Note: The unexpected receive frame-synchronization pulse does not influence the data receive process, being ignored by the data receive state-machine.

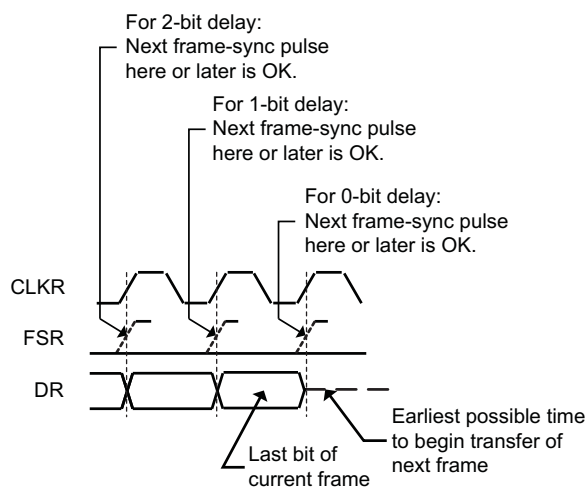

Figure 21-43. Unexpected Frame-sync Pulse During a McBSP Reception

21.4.4.3.3 Preventing Unexpected Receive Frame-sync Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKR cycles, depending on the value of the McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY field. For each possible data delay, Figure 21-44 shows when a new frame-synchronization pulse on FSR can safely occur relative to the last bit of the current frame.

Figure 21-44. Proper Positioning of Receive Frame-sync Pulses

039

21.4.4.4 Underflow in the Receiver

The McBSP module indicates a receiver underflow condition by setting the McBSPi.MCBSPLP_IRQSTATUS_REG[4] RUNDLSTAT bit. This error occurs when sDMA controller or MPU/IVA2.2 subsystem reads data from an empty RB this happens only if the MPU/IVA2.2 subsystem or sDMA controller does not respect the DMA length, does not wait for DMA request, or does not check the buffer status before reading data. According to the McBSPi.MCBSPLP_IRQENABLE_REG register settings this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in McBSPi.MCBSPLP_IRQSTATUS_REG register clears the interrupt.

21.4.4.5 Underflow in the Transmitter

The McBSP module indicates a transmitter empty (or underflow) condition by setting the McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDLSTAT bit. Also the legacy mode McBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY bit is cleared. Either of the following events activates XEMPTY bit (XEMPTY = 0):

- McBSPi.MCBSPLP_DXR_REG has not been loaded and XB is empty, and all bits of the data word in the XSR have been shifted out on the mcbspi_dx pin.
- The transmitter is reset (by forcing McBSPi.MCBSPLP_SPCR2_REG[0] XRST=0, or by an global reset) and is then restarted.

XEMPTY bit is deactivated (XEMPTY=1) when a new word in McBSPi.MCBSPLP_DXR_REG is transferred to Transmit Buffer (XB). If McBSPi.MCBSPLP_PCR_REG[11] FSXM=1 and McBSPi.MCBSPLP_SRGR2_REG[12] FSGM=0, the transmit frame-sync signal (FSX) is generated when Transmit Buffer (XB) is not empty. When McBSPi.MCBSPLP_SRGR2_REG[12] FSGM=0, McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER and McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID are used to determine the frame synchronization period and width (external FSX is gated by the buffer empty condition). Otherwise, the transmitter waits for the next frame-synchronization pulse before sending out the next frame on mcbspi_dx.

When the transmitter is taken out of reset (McBSPi.MCBSPLP_SPCR2_REG[0] XRST=1), it is in a transmitter ready state (McBSPi.MCBSPLP_SPCR2_REG[1] XRDYbit =1) and transmitter empty (McBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY=0) state. If McBSPi.MCBSPLP_DXR_REG is loaded by the MPU/IVA2.2 subsystem or the sDMA controller before internal FSX goes active high, a valid XB-to-XSR transfer occurs. This allows for the first word of the first frame to be valid even before the transmit frame-synchronization pulse is generated or detected. Alternatively, if a transmit frame-synchronization pulse is detected before McBSPi.MCBSPLP_DXR_REG is loaded, zeros are output on mcbspi_dx.

The McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDLSTAT bit indicates a real underflow condition, in which the frame is corrupted due to lack of data availability during transmit process. According to the McBSPi.MCBSPLP_IRQENABLE_REG register settings this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in McBSPi.MCBSPLP_IRQSTATUS_REG register clears the interrupt.

21.4.4.6 Unexpected Transmit Frame-sync Pulse

21.4.4.6.1 Possible Responses to Transmit Frame-sync Pulses

If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully transmitted, this pulse is treated as an unexpected frame-synchronization pulse, and the transmitter sets the transmit frame-synchronization error bit McBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR (and the legacy McBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR bit).

According to the McBSPi.MCBSPLP_IRQENABLE_REG register settings, this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in status register clears the interrupt.

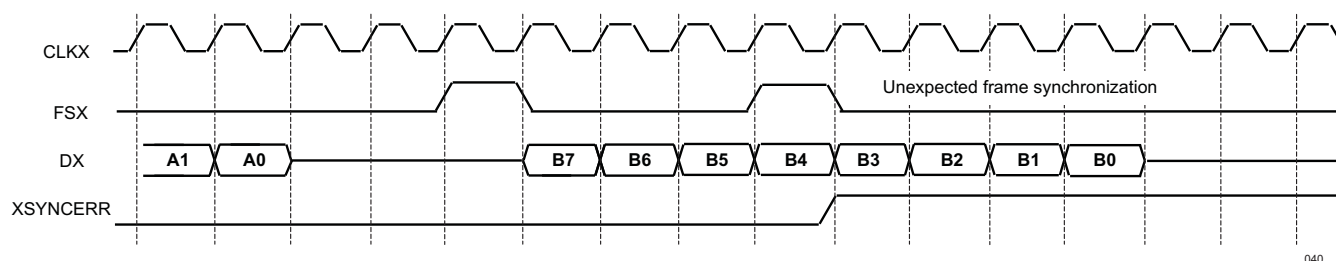

Using the legacy mode, McBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR bit can be cleared only by a transmitter reset or by a write of 0 to this bit. If you want the McBSP module to notify the MPU/IVA2.2 subsystem of frame-synchronization errors, you can set a special transmit interrupt mode with the McBSPi.MCBSPLP_SPCR2_REG[5:4] XINTM field. When XINTM=0b11, the McBSP module sends a transmit interrupt request to the MPU/IVA2.2 subsystem each time that XSYNCERR is set.

21.4.4.6.2 Example of Unexpected Transmit Frame-Synchronization Pulse

Figure 21-45 shows an unexpected transmit frame-synchronization pulse during normal operation of the serial port with intervals between the data packets.

Note: The unexpected transmit frame-synchronization pulse does not influence the data transmit process, being ignored by the data transmit state-machine.

Figure 21-45. Unexpected Frame-sync Pulse During a McBSP Transmission

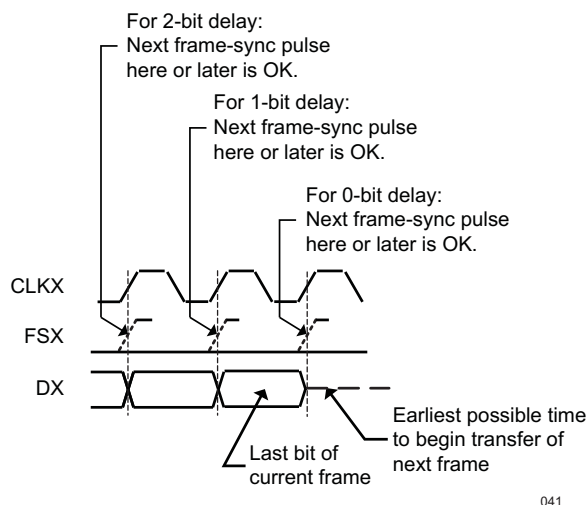

040

21.4.4.6.3 Preventing Unexpected Transmit Frame-sync Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKX cycles, depending on the value in the McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY field. For each possible data delay, Figure 21-46 shows when a new frame-synchronization pulse on FSX can safely occur relative to the last bit of the current frame.

Figure 21-46. Proper Positioning of Transmit Frame-sync Pulses

041

21.4.4.7 Overflow in the Transmitter

The McBSP module indicates a transmitter overflow condition by setting the McBSPi.MCBSPLP_IRQSTATUS_REG[12] XOVLSTAT bit. This error occurs when sDMA controller or MPU/IVA2.2 subsystem write data to a full XB (this may happen only if the MPU/IVA2.2 subsystem or sDMA controller does not respect the DMA length, does not wait for DMA request or does not check the buffer status before writing data). According to the McBSPi.MCBSPLP_IRQENABLE_REG register settings this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in status register clears the interrupt.

21.4.5 McBSP DMA Configuration

The McBSP receive and transmit data DMA requests are active after the receive McBSPi.MCBSPLP_SPCR1_REG[0] RRST and transmit McBSPi.MCBSPLP_SPCR2_REG[0] XRST are released. After reset the default DMA threshold (and length) is one.

The receive and transmit DMA requests can be individually disabled by setting the McBSPi.MCBSPLP_RCCR_REG[3] RDMAEN, McBSPi.MCBSPLP_XCCR_REG[3] XDMAEN bits to 0. When disabling the DMA, the DMA request line is de-asserted even if a DMA transfer is pending and the DMA state-machine is not reset.

The DMA threshold and length configuration is done through McBSPi.MCBSPLP_THRSH1_REG and McBSPi.MCBSPLP_THRSH2_REG registers as follows:

- (THRSH1_REG + 1) value represents the required receive DMA request length (the length of the transfer is the same as the threshold value plus one). As long as the RB occupied locations level is above or equal to the THRSH1_REG value + 1, the DMA request is asserted. After transferring the configured (THRSH1_REG + 1) number of words, the receive DMA request is de-asserted and reasserted as soon as the conditions are met again.
- (THRSH2_REG + 1) value represents the required transmit DMA request length (the length of the transfer is the same as the threshold value plus one). As long as the XB free locations level is above or equal to the THRSH2_REG value + 1, the DMA request is asserted. After transferring the configured (THRSH2_REG + 1) number of words, the transmit DMA request is de-asserted and reasserted as soon as the conditions are met again.

Note: The MPU/IVA2.2 subsystem can decide not to use the DMA to transfer the data. In this case, the DMA must be disabled (or the DMA request can be ignored by MPU/IVA2.2 subsystem) and the common interrupt line (McBSPi_IRQ) can be used. The McBSPi.MCBSPLP_SPCR1_REG[1] RRDY bit for receive and McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit for transmit will indicate when the threshold values are reached. Also, by reading the receive buffer status McBSPi.MCBSPLP_RBUFFSTAT_REG register and transmit buffer status McBSPi.MCBSPLP_XBUFFSTAT_REG register, the MPU/IVA2.2 subsystem can decide to transfer data even if the threshold is not reached. This mechanism is useful on the last transfer on receive side when the threshold value is bigger than the occupied locations inside the receive buffer and the MPU/IVA2.2 subsystem needs to read this data. Since no interrupt or DMA request is asserted the only option in this case is to read the RB status register value and to transfer the remaining data without using the DMA or interrupt indication.

21.4.6 Multi-channel Selection Modes

21.4.6.1 Channels, Blocks and Partitions

A McBSP channel is a time slot for shifting in/out the bits of one serial word. The McBSP module supports up to 128 channels for reception and 128 channels for transmission. In the receiver and in the transmitter, the 128 available channels are divided into eight blocks that contain 16 contiguous channels each (see [Table 21-20](#)):

Table 21-20. McBSP Channels

Block 0: Channels 0–15	Block 4: Channels 64–79
Block 1: Channels 16–31	Block 5: Channels 80–95
Block 2: Channels 32–47	Block 6: Channels 96–111

The blocks are assigned to partitions according to the selected partition mode. In the two-partition mode described in [Section 21.4.6.6](#), you assign one even-numbered block (0, 2, 4, or 6) to partition A and one odd-numbered block (1, 3, 5, or 7) to partition B. In the 8-partition mode [Section 21.4.6.4](#), blocks 0 through 7 are automatically assigned to partitions A through H, respectively.

The number of partitions for reception and the number of partitions for transmission are independent of each other. For example, it is possible to use two receive partitions (A and B) and eight transmit partitions (A–H).

21.4.6.2 Multi-channel Selection

When a McBSP module uses a time-division multiplexed (TDM) data stream while communicating with other McBSP modules or serial devices, the McBSP module may need to receive and/or transmit on only a few channels. To save memory and bus bandwidth, you can use a multi-channel selection mode to prevent data flow in some of the channels.

Each channel partition has a dedicated channel enable register. If the appropriate multi-channel selection mode is on, each bit in the register controls whether data flow is allowed or prevented in one of the channels that is assigned to that partition.

The McBSP module has one receive multi-channel selection mode [Section 21.4.6.5](#), and three transmit multi-channel selection modes [Section 21.4.6.7](#).

21.4.6.3 Configuring a Frame for Multi-channel Selection

Before enabling a multi-channel selection mode, make sure you properly configure the data frame:

- Select a single-phase frame (McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit and McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit=0). Each frame represents a TDM data stream.
- Set a frame length (in McBSPi.MCBSPLP_RCR1_REG[14:8] RFLEN1 field and in McBSPi.MCBSPLP_XCR1_REG[14:8] XFLEN1 field) that includes the highest-numbered channel to be used. For example, if you plan to use channels 0, 15, and 39 for reception, the receive frame length must be at least 40 (RFLEN1=39). If XFLEN1=39 in this case, the receiver creates 40 time slots per frame but only receives data during time slots 0, 15, and 39 of each frame.

21.4.6.4 Using Eight Partitions

For multi-channel selection operation in the receiver and/or the transmitter, you can use eight partitions or two partitions (as previously described). If you choose the 8-partition mode (McBSPi.MCBSPLP_MCR1_REG[9] RMCME=1 for reception, McBSPi.MCBSPLP_MCR2_REG[9] XMCME=1 for transmission), McBSP channels are activated in the following order: A, B, C, D, E, F, G, H.

In response to a frame-synchronization pulse, the receiver or transmitter begins with the channels in partition A and then continues with the other partitions in order until the complete frame has been transferred. When the next frame-synchronization pulse occurs, the next frame is transferred, beginning with the channels in partition A.

In the 8-partition mode, the McBSPi.MCBSPLP_MCR1_REG[6:5] RPABLK/McBSPi.MCBSPLP_MCR2_REG[6:5] XPABLK and McBSPi.MCBSPLP_MCR1_REG[8:7] RPBBLK/McBSPi.MCBSPLP_MCR2_REG[8:7] XPBBLK bits are ignored and the 16-channel blocks are assigned to the partitions as shown in [Table 21-21](#) through [Table 21-22](#). These assignments cannot be changed. The tables also show the registers used to control the channels in the partitions.

Table 21-21. Eight Partitions – Receive Channel Assignment and Control

Receive Partition	Assigned Block of Receive Channels	Register Used for Channel Control
A	Block 0: channels 0 through 15	McBSPi.MCBSPLP_RCERA_REG
B	Block 1: channels 16 through 31	McBSPi.MCBSPLP_RCERB_REG
C	Block 2: channels 32 through 47	McBSPi.MCBSPLP_RCERC_REG
D	Block 3: channels 48 through 63	McBSPi.MCBSPLP_RCERD_REG
E	Block 4: channels 64 through 79	McBSPi.MCBSPLP_RCERE_REG
F	Block 5: channels 80 through 95	McBSPi.MCBSPLP_RCERF_REG
G	Block 6: channels 96 through 111	McBSPi.MCBSPLP_RCERG_REG
H	Block 7: channels 112 through 127	McBSPi.MCBSPLP_RCERH_REG

Table 21-22. Eight Partitions – Transmit Channel Assignment and Control

Transmit Partition	Assigned Block of Receive Channels	Register Used for Channel Control
A	Block 0: channels 0 through 15	McBSPi.MCBSPLP_XCERA_REG
B	Block 1: channels 16 through 31	McBSPi.MCBSPLP_XCERB_REG
C	Block 2: channels 32 through 47	McBSPi.MCBSPLP_XCERC_REG
D	Block 3: channels 48 through 63	McBSPi.MCBSPLP_XCERD_REG
E	Block 4: channels 64 through 79	McBSPi.MCBSPLP_XCERE_REG
F	Block 5: channels 80 through 95	McBSPi.MCBSPLP_XCERF_REG
G	Block 6: channels 96 through 111	McBSPi.MCBSPLP_XCERG_REG
H	Block 7: channels 112 through 127	McBSPi.MCBSPLP_XCERH_REG

Figure 21-47 shows an example of the McBSP using the 8-partition mode. In response to a frame-synchronization pulse, the McBSP module begins a frame transfer with partition A and then activates B, C, D, E, F, G, and H to complete a 128-word frame.

Figure 21-47. McBSP Data Transfer in the 8-partition Mode

21.4.6.5 Receive Multi-channel Selection Mode

The McBSPi.MCBSPLP_MCR1_REG[0] RMCM bit determines whether all channels or only selected channels are enabled for reception.

- When RMCM=0, all 128 receive channels are enabled and cannot be disabled.
- When RMCM=1, the receive multi-channel selection mode is enabled. In this mode:
 - Channels can be individually enabled or disabled. The enabled channels are those selected in the appropriate receive channel enable registers (McBSPi.MCBSPLP_RCERA_REG/McBSPi.MCBSPLP_RCERH_REG). The channels are assigned to the McBSPi.MCBSPLP_RCERA_REG/McBSPi.MCBSPLP_RCERH_REG registers depends on the number of receive channel partitions (2 or 8), as defined by the McBSPi.MCBSPLP_MCR1_REG[9] RMCME bit.
 - If a receive channel is disabled, any bits received in that channel are not transferred to the RB, and as a result, the receiver ready bit (RRDY) is not set. Therefore, no DMA synchronization event is generated and, if the receiver interrupt mode depends on RRDY (McBSPi.MCBSPLP_SPCR1_REG[5:4] RINTM=0b00), no interrupt is generated.

As an example of how the McBSP module behaves in the receive multi-channel selection mode, suppose you enable only channels 0, 15, and 39 and that the frame length is 40. The McBSP module:

1. Accepts bits shifted in from the mcbspi_dr pin in channel 0
2. Ignores bits received in channels 1–14
3. Accepts bits shifted in from the mcbspi_dr pin in channel 15
4. Ignores bits received in channels 16–38
5. Accepts bits shifted in from the mcbspi_dr pin in channel 39

21.4.6.6 Using Two Partitions (Legacy Only)

For multi-channel selection operation in the receiver and/or the transmitter, you can use two partitions or eight partitions. If you choose the 2-partition mode (McBSPi.MCBSPLP_MCR1_REG[9] RMCME=0 for reception, McBSPi.MCBSPLP_MCR2_REG[9] XMCME=0 for transmission), McBSP channels are activated using an alternating scheme. In response to a frame-synchronization pulse, the receiver or transmitter begins with the channels in partition A and then alternates between partitions B and A until the complete frame has been transferred. When the next frame-synchronization pulse occurs, the next frame is transferred beginning with the channels in partition A.

For reception, any two of the eight receive-channel blocks can be assigned to receive partitions A and B, which means up to 32 receive channels can be enabled at any given point. Similarly, any two of the eight transmit-channel blocks (up to 32 enabled transmit channels) can be assigned to transmit partitions A and B.

For reception:

- Assign an even-numbered channel block (0, 2, 4, or 6) to receive partition A by writing to the McBSPi.MCBSPLP_MCR1_REG[6:5] RPABLK field. In the receive multi-channel selection mode, the channels in this partition are controlled by receive channel enable register A (McBSPi.MCBSPLP_RCERA_REG).
- Assign an odd-numbered block (1, 3, 5, or 7) to receive partition B with the McBSPi.MCBSPLP_MCR1_REG[8:7] RPBBLK field. In the receive multi-channel selection mode, the channels in this partition are controlled by receive channel enable register B (McBSPi.MCBSPLP_RCERB_REG).

For transmission:

- Assign an even-numbered channel block (0, 2, 4, or 6) to transmit partition A by writing to the McBSPi.MCBSPLP_MCR2_REG[6:5] XPABLK fields. In one of the transmit multi-channel selection modes, the channels in this partition are controlled by transmit channel enable register A (McBSPi.MCBSPLP_XCERA_REG).
- Assign an odd-numbered block (1, 3, 5, or 7) to transmit partition B with the McBSPi.MCBSPLP_MCR1_REG[8:7] XPBBLK field. In one of the transmit multi-channel selection modes, the channels in this partition are controlled by transmit channel enable register B (McBSPi.MCBSPLP_XCERB_REG).

Figure 21-48 shows an example of alternating between the channels of partition A and the channels of partition B. Channels 0–15 have been assigned to partition A, and channels 16–31 have been assigned to partition B. In response to a frame-synchronization pulse, the McBSP module begins a frame transfer with partition A and then alternates between partitions B and A until the complete frame is transferred.

Figure 21-48. Alternating Between Partitions A and B Channels

043

21.4.6.7 Transmit Multi-channel Selection Modes

The McBSPi.MCBSPLP_MCR2_REG[1:0] XMCM field determine whether all channels or only selected channels are enabled and unmasked for transmission. The McBSP module has three transmit multi-channel selection modes (XMCM=0b01, XMCM=0b10, and XMCM=0b11), which are described in Table 21-23.

Table 21-23. Selecting a Transmit Multi-Channel Selection Mode with the XMCM Bit Field

XMCM	Transmit Multi-Channel Selection Mode
0b00	No transmit multi-channel selection mode is on. All channels are enabled and unmasked. No channels can be disabled or masked.
0b01	All channels are disabled unless they are selected in the appropriate transmit channel enable registers (McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG). If enabled, a channel in this mode is also unmasked. The McBSPi.MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 channels or 128 channels are selectable in the McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG registers.
0b10	All channels are enabled, but they are masked unless they are selected in the appropriate transmit channel enable registers (McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG). The McBSPi.MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 channels or 128 channels are selectable in the McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG registers.
0b11	This mode is used for symmetric transmission and reception. All channels are disabled for transmission unless they are enabled for reception in the appropriate receive channel enable registers (McBSPi.MCBSPLP_RCERA_REG/McBSPi.MCBSPLP_RCERH_REG). Once enabled, they are masked unless they are also selected in the appropriate transmit channel enable registers (McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG). The McBSPi.MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 channels or 128 channels are selectable in McBSPi.MCBSPLP_RCERA_REG/McBSPi.MCBSPLP_RCERH_REG registers and McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG registers.

As an example of how the McBSP module behaves in a transmit multi-channel selection mode, suppose that XMCM=0b01 (all channels disabled unless individually enabled) and that you have enabled only channels 0, 15, and 39. Suppose also that the frame length is 40. The McBSP module:

1. Shifts data to the mcbspi_dx pin in channel 0
2. Places the mcbspi_dx pin in the high impedance state in channels 1–14
3. Shifts data to the mcbspi_dx pin in channel 15
4. Places the mcbspi_dx pin in the high impedance state in channels 16–38
5. Shifts data to the mcbspi_dx pin in channel 39

21.4.6.7.1 Disabling/Enabling Versus Masking/Unmasking

For transmission, a channel can be:

- Enabled and unmasked (transmission can begin and can be completed)
- Enabled but masked (transmission can begin but cannot be completed)
- Disabled (transmission cannot occur)

The definitions in Table 21-24 explain the channel control options:

Table 21-24. McBSP Channel Control Options

Enabled channel	A channel that can begin transmission by passing data from the data transmit register (McBSPi.MCBSPLP_DXR_REG) to the XSR through XB.
Masked channel	A channel that cannot complete transmission. The mcbspi_dx pin is held in the high impedance state; data cannot be shifted out on the mcbspi_dx pin. In systems where symmetric transmit and receive provide software benefits, this feature allows transmit channels to be disabled on a shared serial bus. A similar feature is not needed for reception because multiple receptions cannot cause serial bus contention.
Disabled channel	A channel that is not enabled. A disabled channel is also masked. Because no DXR-to-XB copy occurs, the McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit is not set. Therefore, no DMA synchronization event is generated, and if the transmit interrupt mode depends on XRDY (McBSPi.MCBSPLP_SPCR2_REG[5:4] XINTM=00b), no interrupt is generated. The McBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY bit is not affected.
Unmasked channel	A channel that is not masked. Data in the XSR(s) is shifted out on the mcbspi_dx pin.

21.4.6.7.2 Activity on McBSP Pins for Different Values of XMCM

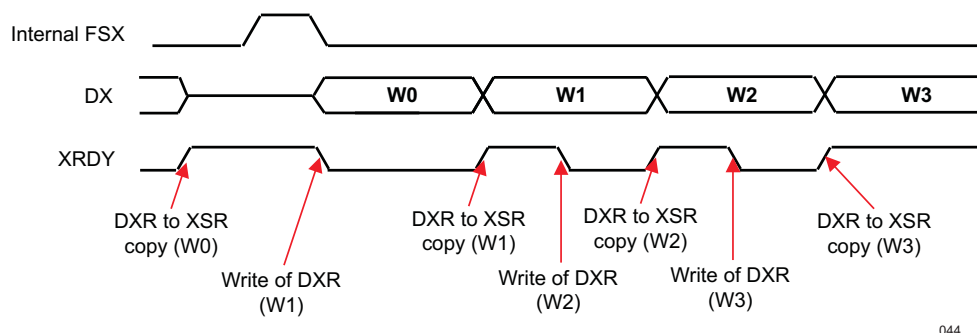

Figure 21-49 shows the activity on the McBSP pins for the various McBSPi.MCBSPLP_MCR2_REG[1:0] XMCM values. In all cases, the transmit frame is configured as follows:

- XPHASE=0: Single-phase frame (required for multi-channel selection modes)
- XFRLN1=0b0000011: 4 words per frame
- XWDLEN1=0b000: 8 bits per word
- XMCME=0: 2-partition mode (only partitions A and B used)

In the case where McBSPi.MCBSPLP_MCR2_REG[1:0] XMCM=0b11, transmission and reception are symmetric, which means the corresponding bits for the receiver (RPHASE, RFRLN1, RWDLEN1, and RMCME) must have the same values as XPHASE, XFRLN1, and XWDLEN1, respectively.

In Figure 21-49, the arrows showing where the various events occur are only sample indications. Wherever possible, there is a time window in which these events can occur.

Figure 21-49. Activity on McBSP Pins When XMCM=0b00

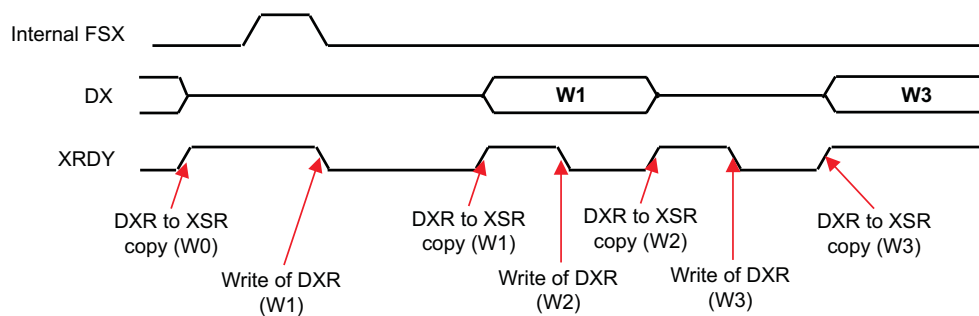

If XMCM = 0b00, all channels are enabled and unmasked. Words W0, W1, W2, and W3 are written to the XB, then, from the XB, there are transferred by mcbspi_dx.

Figure 21-50. Activity on McBSP Pins When XMCM=0b01

In Figure 21-50 if XMCM = 0b01, XPABLK = 0b00, and XCERA = 0b1010, only channels 1 and 3 are enabled and unmasked. Words W1 and W3 are written to the XB, then, from the XB, there are transferred by mcbspi_dx.

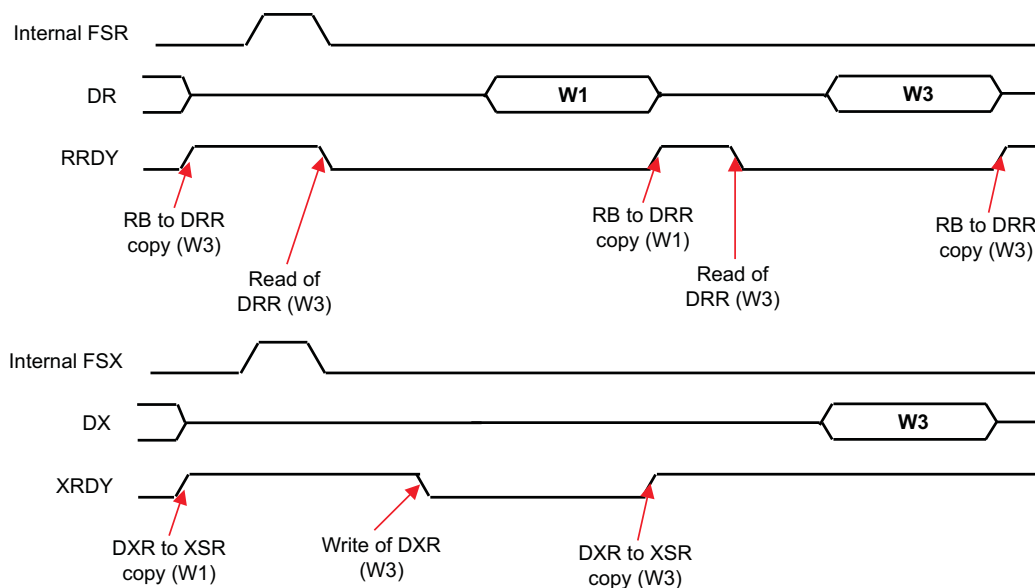

Figure 21-51. Activity on McBSP Pins When XMCM=0b10

046

In [Figure 21-51](#) if XMCM = 0b10, XPABLK = 0b00, and XCERA = 0b1010, all channels are enabled, only 1 and 3 unmasked. Words W0, W1, W2, and W3 are written to the XB, but only W1 and W3, from the XB, there are transferred by mcbspi_dx.

Figure 21-52. Activity on McBSP Pins When XMCM=0b11

047

In [Figure 21-52](#) if XMCM = 0b11, RPABLK = 0b00, XPABLK = 0bX, RCERA = 0b1010 and XCERA = 0b1000, channels 1 and 3 are enabled in receive and transmit mode, but only 3 unmasked. Words W1 and W3 are written to the XB, but only W3, from the XB, there are transferred by mcbspi_dx.

21.4.7 SIDETONE Mode (ALP)

21.4.7.1 Introduction

In multimedia-rich mobile communication devices, loopback signals from audio inputs to audio outputs are renamed. A traditional example is the telephone SIDETONE (that is, the telephone user expects to also hear his own voice in the earpiece).

Some of the features using the loopback have strict delay requirements.

It is required that two of the audio input channels be looped back, filtered, and mixed to the corresponding two audio output channels. The SIDETONE mode filters and applies gain to each sample received.

21.4.7.2 SIDETONE Interface

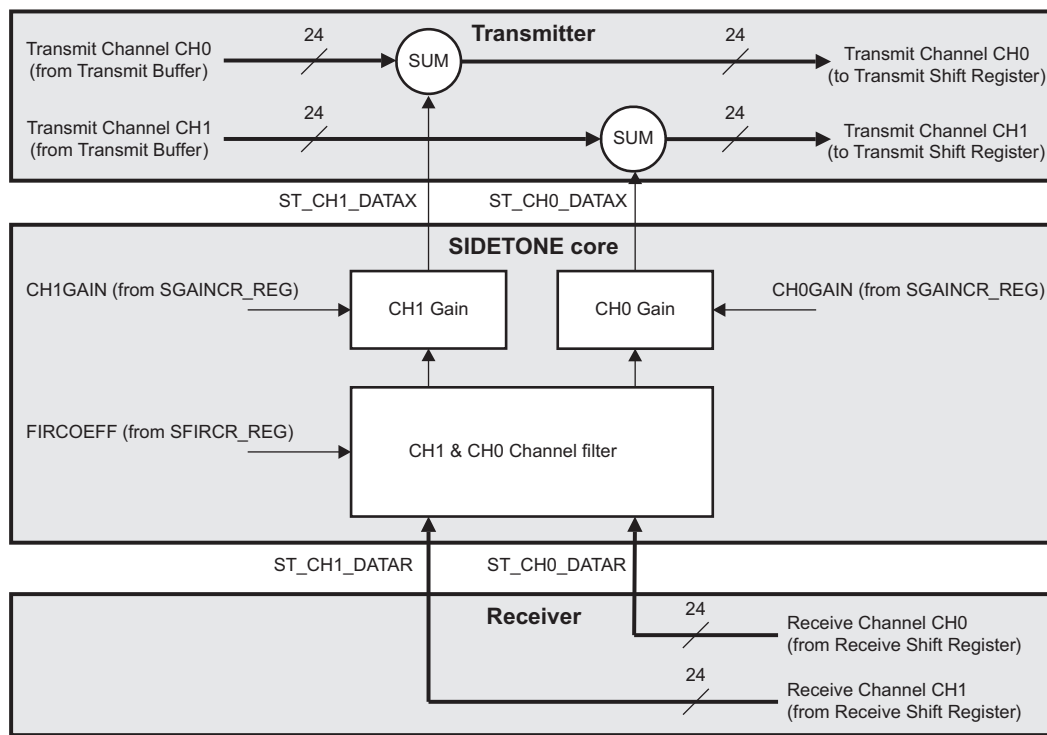

The data from digital microphone, two (out of four) channels, can be configured to be input in the external SIDETONE core. After filtering, the data from digital microphone data is mixed and sent out to the speaker output channels using two (out of eight) configured output channels (separate configuration bits are used). The McBSP module synchronizes the incoming data (filtered by the external SIDETONE core). The transmit and receive part of the McBSP module are not required to operate on the same functional frequency.

The SIDETONE interface offers the following features:

- Send out two 24-bit data channels for the configured SIDETONE received channels (channels can be the same)
- Send out two control signals to indicate to the SIDETONE module that the data is valid (toggle signals which are changing the value from 0 to 1 or 1 to 0 each time a new data is available)
- Receive two 24-bit filtered data channels from the external SIDETONE module and send these channels to the configured transmit channels after mixing the data with the incoming data (from the L4 interface). The sum between the incoming data and SIDETONE loopback data is a saturated sum.
- Receive two control signals to indicate that the SIDETONE module filtered data is available (toggle signals which are changing the value from 0 to 1 or 1 to 0 each time a new data is available).

Figure 21-53 shows the SIDETONE external module data path:

Figure 21-53. SIDETONE Data Path

MCBSP_048

Before you enable a SIDETONE selection mode, make sure you properly configure the data frame for multi-channel and SIDETONE mode:

- Select a single-phase frame (McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit and McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit=0). Each frame represents a TDM data stream.
- Set McBSPi.MCBSPLP_MCR1_REG[0] RMCM=1 to select multi-channel mode enable.
- Set a frame length (in McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1 bit field and in McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 bit field) that includes the highest-numbered channel to be used (a maximum of 4 channels can be used in this configuration).
- Set a word length (in McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 bit field and in

McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 bit field) to be either 16, 24 or 32 (see note).

- Select the input/output channels configured as SIDETONE channels and enable SIDETONE by setting the McBSPi.MCBSPLP_SSELCR_REG[1:0] ICH0ASSIGN/McBSPi.MCBSPLP_SSELCR_REG[6:4] OCH0ASSIGN, McBSPi.MCBSPLP_SSELCR_REG[3:2] ICH1ASSIGN/McBSPi.MCBSPLP_SSELCR_REG[9:7] OCH1ASSIGN fields (2 out of 4 channels external SIDETONE assignment) and McBSPi.MCBSPLP_SSELCR_REG[10] SIDETONEEN bit to 1.

Note: Word width in the loop is 24 bits. If input channel word width is less than 24 bits, LSBs of the samples are zero padded. If input channel word width is more than 24 bits, samples are truncated.

Figure 21-54 describes the data exchange protocol between McBSP module and SIDETONE core:

Figure 21-54. McBSP to SIDETONE Data Exchange

049

Figure 21-55 describes the data exchange protocol between SIDETONE core and McBSP module:

Figure 21-55. SIDETONE to McBSP Data Exchange

050

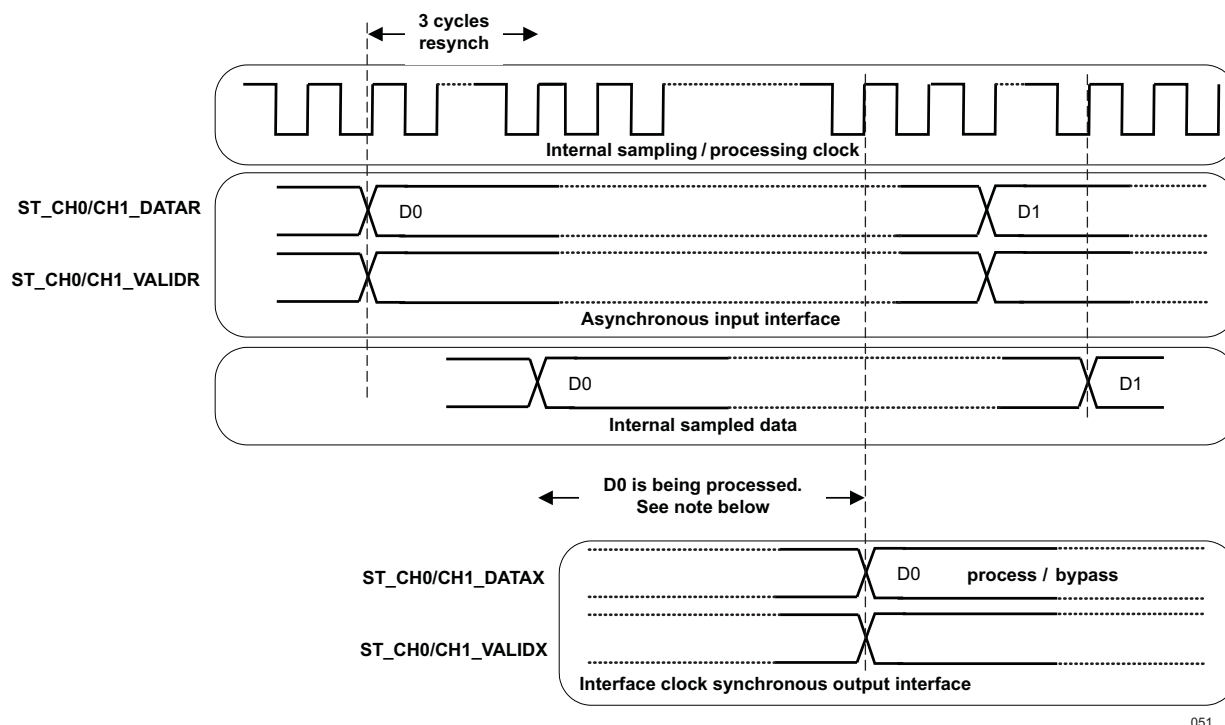

Note: To use the same input channel as source for both SIDETONE output channels the McBSPi.MCBSPLP_SSELCR_REG[1:0] ICH0ASSIGN should be equal to McBSPi.MCBSPLP_SSELCR_REG[3:2] ICH1ASSIGN. The McBSP module does not support two input channels to be assigned to only one SIDETONE output channel.

21.4.7.3 Data Processing Path

The SIDETONE core receives the data to be processed through two 24-bits parallel data interfaces, one for each audio channel. When enabled through McBSPi.ST_SSELCR_REG[0] SIDETONEEN bit-field, the module applies the filtering and gain functions to each data item (frame) and outputs it through two similar 24-bits parallel data interfaces.

Figure 21-56 below describes how the data is sampled and output through the dedicated data interfaces.

Figure 21-56. SIDETONE Processed Data Interfaces

051

Note: The processing time needed is 132 clock cycles (SIDETONE enabled). The total number of cycles needed for outputting the new processed data upon arrival of a sample is maximum 135 (including synchronizations). When not enabled, the data response takes maximum 5 clock cycles.

The `ST_CH0_VALIDR` and `ST_CH1_VALIDR` are 1 bit inputs and their toggling information is used to signal that new data is valid for sampling from `ST_CH0_DATAR` / `ST_CH1_DATAR`.

The `ST_CH0_VALIDX` and `ST_CH1_VALIDX` are 1 bit outputs and their toggling information is used to signal that new data is valid on the output data bus `ST_CH0_DATAX` / `ST_CH1_DATAX`.

21.4.7.4 Data Processing

The processing consists in 2 stages filtering and applying gain to signal. The whole process takes 132 clock cycles.

If a new frame comes too early causing the interrupt assertion, the current frame will be completely processed and this new frame will be ignored. Consequent frames will also be ignored until the current frame processing has ended.

21.4.7.4.1 Filtering

A 128 length FIR filter scheme is used. The module must process the two channels in parallel so two instances of filter will work in parallel sharing only the same coefficients.

Samples data are signed values in interval (-1..1) in Q23 format, negative values are expressed in 2's complement. Coefficients are also signed values in interval (-1..1) in Q15 format, negative values are expressed in 2's complement too.

The module handles overflows in the sums of the product but the user should choose the coefficients with the sum of magnitudes in absolute value is smaller than 1, otherwise the user must ensure that gain applying brings the samples value below |1|, to avoid saturation.

$$|C0| + |C1| + \dots + |C127| < 1$$

CAUTION

The coefficients cannot be loaded while the filtering is active (SIDETONE enabled).

21.4.7.4.2 Applying Gain

Each output sample will be multiplied with the gain value specified in the McBSPi.ST_SGAINCR_REG. The gain is independent for each channel and can be modified anytime through L4-interface with immediate effect. Gain values are in the interval (-2..2) in Q1.14 format, negative values are expressed in 2's complement.

The user must choose the gain's value according to the magnitude of the samples to avoid overflow in the final product between the FIR data and gain value. If an overflow occurs, the output data is saturated.

21.4.7.4.3 Enabling SIDETONE

When the SIDETONE operation is enabled (McBSPi.ST_SSELCR_REG[0] SIDETONEEN is 1), the module starts collecting samples received through the data interface without returning any sample or toggling any of the ST_CH0/CH1_VALIDX outputs. The first 127 samples for each channel are only accumulated, no processed data is provided. The first processed frame comes after receiving the 128th sample (with the specific delay).

When the SIDETONE operation is disabled, data is output through the data interface as it comes on the data input interface with the resynchronization latency of maximum 5 clock cycles. Re-enabling it requires waiting another 128 samples before providing new processed samples (each transition of McBSPi.ST_SSELCR_REG[0] SIDETONEEN from 0 to 1 triggers this initialization process).

Note: After reset, the McBSPi.ST_SSELCR_REG[0] SIDETONEEN bit is 0.

21.4.7.4.4 FIR Accuracy

All the arithmetic inside the module is performed without any truncation/saturation until the last stage – the gain applying, where the result of the product between gain and FIR value is saturated to +/-1 if overflow occurs and the last significant bits are truncated.

21.4.7.5 Interrupt Operation

The SIDETONE core has a single interrupt line and a single event that may trigger the interrupt. The event (an error one) occurs when the input interface data rate overflows the processing ability of the module. As described in the data processing path section, the SIDETONE core completes a frame processing in 132 cycles. If the input frame rate for any channel exceeds 1 frame/132 x interface clock period while SIDETONE is enabled, the McBSPi.ST_IRQSTATUS_REG[0] OVRERROR bit is set and, if McBSPi.ST_IRQENABLE_REG[0] OVRERRORREN bit is set to 1, the interrupt line is asserted.

21.5 McBSP Basic Programming Model

This section describes the programming model of typical McBSP module and SIDETONE core applications.

21.5.1 McBSP Core

CAUTION

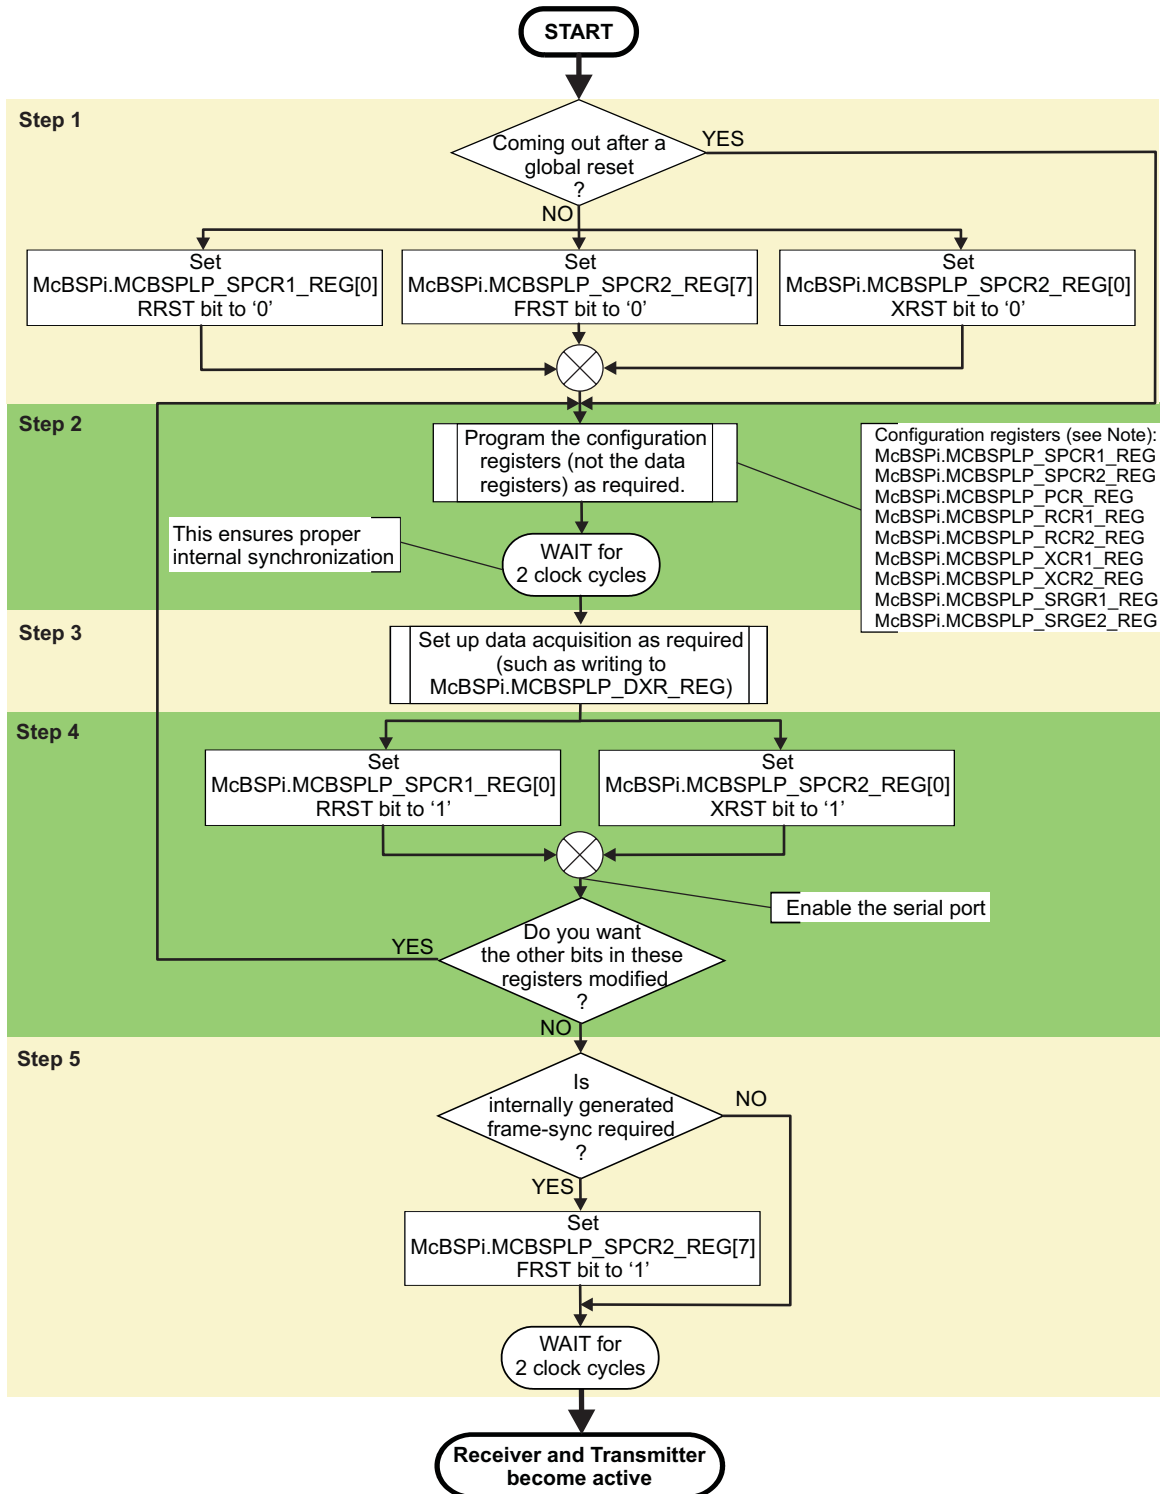

For all descriptions in this section, the McBSPi.MCBSPLP_XCCR_REG[11] XFULL_CYCLE bit and the McBSPi.MCBSPLP_RCCR_REG[11] RFULL_CYCLE bit are their reset value (XFULL_CYCLE bit=0 and RFULL_CYCLE bit=1).

21.5.1.1 McBSP Initialization Procedure

This procedure for reset/initialization can be applied in general when the Receiver or Transmitter has to be reset during its normal operation, and also when the Sample Rate Generator is not used for either operation.

[Figure 21-57](#) presents the serial port initialization procedure.

Figure 21-57. Flow Diagram of McBSP Initialization Procedure

062

Alternatively, on write (step 1 or 4), the transmitter and receiver can be placed in or taken out of reset by modifying the McBSPi.MCBSPLP_SPCR2_REG[0] XRST bit and the McBSPi.MCBSPLP_SPCR1_REG[0] RRST bit, respectively.

Notes:

- The necessary duration of the active-low period of XRST or RST is at least two CLKR/CLKX cycles.
- The appropriate bits in serial port configuration registers (McBSPi.MCBSPLP_SPCR1_REG, McBSPi.MCBSPLP_SPCR2_REG, McBSPi.MCBSPLP_PCR_REG, McBSPi.MCBSPLP_RCR1_REG, McBSPi.MCBSPLP_RCR2_REG, McBSPi.MCBSPLP_XCR1_REG, McBSPi.MCBSPLP_XCR2_REG, McBSPi.MCBSPLP_SRGR1_REG and McBSPi.MCBSPLP_SRGR2_REG) should only be modified when the affected portion of the serial port is in its reset state.
- In most cases, the data transmit register (McBSPi.MCBSPLP_DXR_REG) should be loaded by the MPU/IVA2 subsystem or the sDMA controller only when the transmitter is enabled (McBSPi.MCBSPLP_SPCR2_REG[0] XRST = 1). An exception to this rule is when these registers are used for loopback internal data.
- The bits of the channel control registers (McBSPi.MCBSPLP_MCR1_REG, McBSPi.MCBSPLP_MCR2_REG, McBSPi.MCBSPLP_RCER{A-H}_REG and McBSPi.MCBSPLP_XCER{A-H}_REG) can be modified at any time as long as they are not being used by the current reception/transmission in a multichannel selection mode.
- The SRG is reset by setting McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit to 0.

21.5.1.2 Reset and Initialization Procedure for the Sample Rate Generator

To reset and initialize the Sample Rate Generator:

- Place the McBSP Sample Rate Generator in RESET.
During a Global RESET, the Sample Rate Generator, the Receiver, and the Transmitter reset bits (GRST, RST, and XRST) are automatically forced to '0'. Otherwise, during normal operation, the Sample Rate Generator can be reset by making McBSPi.MCBSPLP_SPCR2_REG[6] GRST=0, provided that CLKG and/or FSG internal signal is not used by any portion of the McBSP module. Depending on the system needs, the software may also to reset the Receiver (McBSPi.MCBSPLP_SPCR1_REG[0] RST=0) and reset the Transmitter (McBSPi.MCBSPLP_SPCR2_REG[0] XRST bit =0).

- Program the registers that affect the Sample Rate Generator.

Program the Sample Rate Generator registers (McBSPi.MCBSPLP_SPCR1_REG and McBSPi.MCBSPLP_SPCR2_REG) as required for your application. Refer to [Figure 21-58](#).

If necessary, other control registers can be loaded with desired values provided the respective portion of the McBSP module (the Receiver or Transmitter) is in reset. [Table 21-25](#) presents the McBSP configuration when one of the clock sources is selected, but others registers can be impacted in function of the user application.

Table 21-25. McBSP Configuration in Function of the SRG Clock Source Selected

SRG Clock Source Selected	Module Configuration	McBSPi.MCBSPLP_PCR_REG Configuration			
		CLKRM bit ⁽¹⁾	CLKXM bit	FSRM bit ⁽¹⁾	FSXM bit
McBSPi_ICLK or CLKS	Master Transmitter and Slave Receiver	0	1	0	1
	Master Receiver and Slave Transmitter	1	0	1	0
	Master Transmitter and Receiver	1	1	1	1
CLKR	Master Transmitter and Slave Receiver	0	1	0	1
CLKX	Master Receiver and Slave Transmitter	1	0	1	0

⁽¹⁾ This configuration is correct if McBSPi.MCBSPLP_XCCR_REG[5] DLB bit=0x0. When the DLB bit is set to 1, the CLKR clock (not the mcbspi_clk pin) is driven by the CLKX clock, which is based on the CLKXM bit.

After the Sample Rate Generator registers are programmed, wait for 2 CLKSRG cycles. This ensures proper synchronization internally.

- Enable the Sample Rate Generator (take it out of reset).

Set McBSPi.MCBSPLP_SPCR2_REG[6] GRSTbit to 1 to enable the Sample Rate Generator.

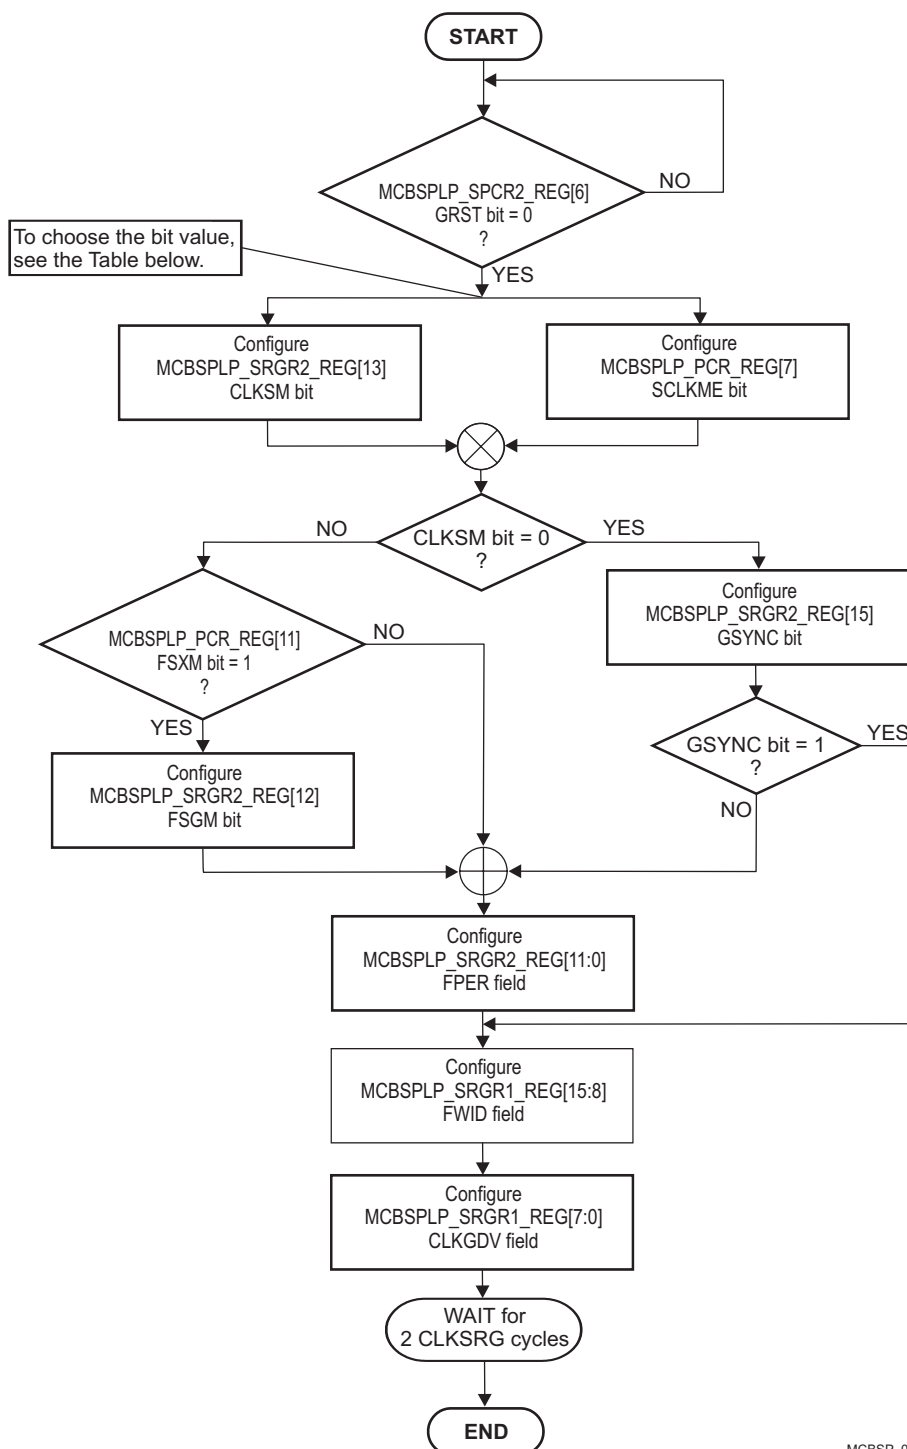

After the Sample Rate Generator is enabled, wait for 2 CLKG cycles for the Sample Rate Generator logic to stabilize.

On the next rising edge of CLKSRG, the CLKG signal transitions to '1' and starts clocking with a frequency equal to (input clock frequency)/(CLKGDV + 1).

- If necessary, enable the receiver and/or the transmitter.

If necessary, remove the receiver and/or transmitter from reset by setting

McBSPi.MCBSPLP_SPCR1_REG[0] RRST bit and/or McBSPi.MCBSPLP_SPCR2_REG[0] XRST = 1.

Figure 21-58. Flow Diagram for the SRG Registers Programming

The input clock is selected with the McBSPi.MCBSPLP_PCR_REG[7] SCLKME bit and the McBSPi.MCBSPLP_SRGR2_REG[13] CLKSM bit in one of the following configurations (see Table 21-26):

Table 21-26. Input Clock Selection for Sample Rate Generator

SCLKME bit	CLKSM bit	Input Clock for Sample Rate Generator
0	0	Signal on mcbbsp_clks pin
0	1	McBSPi_ICLK clock
1	0	Signal on mcbbsp_clkr pin
1	1	Signal on mcbbsp_clkx pin

21.5.1.3 Data Transfer DMA Request Configuration

To configure the McBSP receive/transmit data DMA requests (McBSPi_DMA_RX and McBSPi_DMA_TX), perform the following procedure:

- Write the receive McBSPi.MCBSPLP_THRSH1_REG register with the required receive DMA request length (the length of the transfer is the same as the threshold value + 1). As long as the RB occupied locations level is above or equal to the THRSH1_REG value + 1, the DMA request will be asserted. After transferring the configured THRSH1_REG value + 1 number of words, the receive DMA request will be de-asserted and reasserted as soon as the conditions are met again.

Note: In case of a number of transfers that exceed the number of the programmed DMA length the McBSP module will respond to the command, and will perform the transfer regardless of the receive buffer empty condition. When the receive buffer is empty a data transfer access will trigger a receive underflow interrupt, if enabled by McBSPi.MCBSPLP_IRQENABLE_REG[4] RUNDLEN bit.

- Write the transmit McBSPi.MCBSPLP_THRSH2_REG register with the required transmit DMA request length (the length of the transfer is the same as the threshold value + 1). As long as the XB free locations level is above or equal to the THRSH2_REG value + 1, the DMA request will be asserted. After transferring the configured THRSH2_REG value + 1 number of words, the transmit DMA request will be de-asserted and reasserted as soon as the conditions are met again.

Note: In case of a number of transfers that exceed the number of the programmed DMA length the McBSP module will respond to the command, and will perform the transfer regardless of the transmit buffer full condition. When the transmit buffer is full a data transfer access will trigger a transmit overflow interrupt, if enabled by McBSPi.MCBSPLP_IRQENABLE_REG[12] XOVLEN bit.

21.5.1.4 Interrupt Configuration

The McBSP module offers two interrupt schemes:

- L4 compliant interrupt request scheme using a common receive/transmit interrupt request line
- The legacy interrupt compliant scheme using 3 interrupt lines: one for receive, one for transmit and the common interrupt line.

21.5.1.4.1 L4-Compliant Interrupt Line

The L4-compliant interrupt line can be configured by using the McBSPi.MCBSPLP_IRQENABLE_REG register. When the McBSPi.MCBSPLP_IRQSTATUS_REG bit is set and the corresponding McBSPi.MCBSPLP_IRQENABLE_REG bit is set to one, the interrupt line is asserted. Writing one to a bit in McBSPi.MCBSPLP_IRQSTATUS_REG register clears the bit.

There are several conditions, which can be configured to generate an interrupt as follows:

- Transmit buffer empty at end of frame (McBSPi.MCBSPLP_IRQSTATUS_REG[14] XEMPTYEOF bit is set to one when a complete frame was transmitted and the transmit buffer is empty).
- Transmit buffer overflow (McBSPi.MCBSPLP_IRQSTATUS_REG[12] XOVFLSTAT bit is set to one when transmit buffer overflow; the data written while overflow condition is discarded).
- Transmit buffer underflow (McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT bit is set to one when the transmit data buffer is empty, new data needs to be transmitted).

4. Transmit buffer threshold reached (McBSPi.MCBSPLP_IRQSTATUS_REG[10] XRDY bit is set to one when the transmit buffer free locations are equal or above the [THRSH2_REG + 1] value).
5. Transmit end of frame (McBSPi.MCBSPLP_IRQSTATUS_REG[9] XEOF is set to one when a complete frame was transmitted).
6. Transmit frame synchronization (McBSPi.MCBSPLP_IRQSTATUS_REG[8] XFSX bit is set to one when a new transmit frame synchronization is asserted).
7. Transmit frame synchronization Error (McBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR is set to one when a transmit frame synchronization error is detected).
8. Receive buffer overflow (McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT bit is set to one when receive buffer overflow; the data which is written while overflow condition is discarded).
9. Receive buffer underflow (McBSPi.MCBSPLP_IRQSTATUS_REG[4] RUNDLSTAT bit is set to one when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined).
10. Receive buffer threshold Reached (McBSPi.MCBSPLP_IRQSTATUS_REG[3] RRDY bit is set to one when the receive buffer occupied locations are equal or above the [THRSH1_REG + 1] value).
11. Receive end of frame (McBSPi.MCBSPLP_IRQSTATUS_REG[2] REOF is set to one when a complete frame was received).
12. Receive frame synchronization (McBSPi.MCBSPLP_IRQSTATUS_REG[1] RFSR bit is set to one when a new receive frame synchronization is asserted).
13. Receive frame synchronization error (McBSPi.MCBSPLP_IRQSTATUS_REG[0] RSYNCERR is set to one when a receive frame synchronization error is detected).

21.5.1.4.2 Legacy Interrupt Line

McBSPi_IRQ_TX and McBSPi_IRQ_RX are legacy interrupt. Not to be used for new development. McBSPi_IRQ (common interrupt line) should be preferred.

21.5.1.4.2.1 Set the receive interrupt line (legacy only)

The McBSPi.MCBSPLP_SPCR1_REG[5:4] RINTM bit field determines which event generates a receive interrupt request, McBSPi_IRGQ_RX, to the MPU/IVA2.2 subsystem.

The receive interrupt informs the MPU/IVA2.2 subsystem of changes to the serial port status. Four options exist for configuring this interrupt.

- RINTM=0b00: The receive interrupt generated when the McBSPi.MCBSPLP_SPCR1_REG[1] RRDY bit changes from 0 to 1. Interrupt on every serial word by tracking the McBSPi.MCBSPLP_SPCR1_REG[1] RRDY bit. Regardless of the value of RINTM, RRDY bit can be read to detect the RRDY=1 condition.
- RINTM = 0b01: The receive interrupt generated by an end-of-frame condition in the receive multi-channel selection mode. In any other serial transfer case, this setting is not applicable and, therefore, no interrupts are generated.
- RINTM = 0b10: The receive interrupt generated by a new receive frame-synchronization pulse. Interrupt on detection of receive frame-synchronization pulses. This generates an interrupt even when the receiver is in its reset state. This is done by synchronizing the incoming frame-synchronization pulse to the McBSPi_ICLK clock and sending it to the MPU/IVA2.2 subsystem via the receive interrupt .
- RINTM = 0b11: The receive interrupt generated when McBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR is set. Interrupt on frame-synchronization error. Regardless of the value of RINTM, RSYNCERR can be read to detect this condition. For information on using RSYNCERR, see [Section 21.4.4.3](#).

The McBSP module also provides a common interrupt line McBSPi_IRQ, which can be used by setting the McBSPi.MCBSPLP_IRQENABLE register. All the above settings have equivalent enable bits in the McBSPi.MCBSPLP_IRQENABLE register to enable the common interrupt line:

- RRDYEN is equivalent with RINTM = 0 setting
- REOFEN is equivalent with RINTM = 0b01setting (the interrupt is generated by an end-of-frame condition regardless of the multi-channel selection mode)
- RFSREN is equivalent with RINTM = 0b10 setting

- RSYNCERREN is equivalent with RINTM = 0b11 setting

This interrupt line has its own status register, McBSPi.MCBSPLP_IRQSTATUS_REG.

21.5.1.4.2.2 Set the transmit interrupt line (legacy only)

The McBSPi.MCBSPLP_SPCR2_REG[5:4] XINTM bit field determines which event generates a transmit interrupt request (McBSPi_IRQ_TX) to the MPU/IVA2.2 subsystem.

The transmit interrupt informs the MPU/IVA2.2 subsystem of changes to the serial port status. Four options exist for configuring this interrupt.

- XINTM = 0b00: The transmit interrupt generated when the McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit changes from 0 to 1. Interrupt on every serial word by tracking the XRDY bit. Regardless of the value of XINTM, XRDY bit can be read to detect the XRDY=1 condition.
- XINTM = 0b01: The transmit interrupt generated by an end-of-frame condition in the transmit multi-channel selection mode. In any other serial transfer case, this setting is not applicable and, therefore, no interrupts are generated.
- XINTM = 0b10: The transmit interrupt generated by a new transmit frame-synchronization pulse. Interrupt on detection of transmit frame-synchronization pulses. This generates an interrupt even when the transmitter is in its reset state. This is done by synchronizing the incoming frame-synchronization pulse to the McBSPi_ICLK clock and sending it to the MPU/IVA2.2 subsystem via transmit interrupt.
- XINTM = 0b11: The transmit interrupt generated when McBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR is set. Interrupt on frame-synchronization error. Regardless of the value of XINTM, XSYNCERR bit can be read to detect this condition. For information on using XSYNCERR bit, see [Section 21.4.4.6](#).

The McBSP module provides also a common interrupt line McBSPi_IRQ, which can be used by setting the McBSPi.MCBSPLP_IRQENABLE register. All the above settings have equivalent enable bits in the McBSPi.MCBSPLP_IRQENABLE register to enable the common interrupt line:

- XDYEN is equivalent with XINTM = 0b00 setting
- XEOFEN is equivalent with XINTM = 0b01 setting (the interrupt is generated by an end-of-frame condition regardless of the multi-channel selection mode)
- XFSXEN is equivalent with XINTM = 0b10 setting
- XSYNCERREN is equivalent with XINTM = 0b11 setting

This interrupt line has its own status register, McBSPi.MCBSPLP_IRQSTATUS_REG.

21.5.1.5 Receiver Configuration

To configure the McBSP receiver, perform the following procedure:

1. Place the McBSP receiver in reset .
2. Program the McBSP registers for the desired receiver operation.
3. Take the receiver out of reset.

These 3 steps are detailed in the following subsections.

21.5.1.5.1 Resetting (Step 1) and Enabling (Step 3) the Receiver

The first step of the receiver configuration procedure is to reset the receiver, and the last step is to enable the receiver (to take it out of reset).

The serial port can be reset in the following 2 ways:

1. A global reset places the receiver, transmitter, and SRG in reset. When the device reset is removed, McBSPi.MCBSPLP_SPCR2_REG[6] GRST, McBSPi.MCBSPLP_SPCR2_REG[7] FRST, McBSPi.MCBSPLP_SPCR1_REG[0] RRST and McBSPi.MCBSPLP_SPCR2_REG[0] XRST bits = 0, which keeps the entire serial port in the reset state.

2. The serial port receiver can be reset directly using the McBSPi.MCBSPLP_SPCR1_REG[0] RRST bit. If the SRG needs to be used, SRG must be reset directly using the McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit. Similar operations with frame synchronization generator also require using the McBSPi.MCBSPLP_SPCR2_REG[7] FRST bit when the frame-sync signal must be generated.

To enable the receiver, the preceding bits, cleared to 0, must be set to 1.

21.5.1.5.2 Programming the McBSP Registers for the Desired Receiver Configuration (Step 2)

Figure 21-59 and Figure 21-60 lists important tasks to be performed when the software is configuring the McBSP receiver. Each task corresponds to one or more McBSP register bit fields.

Figure 21-59. Important Tasks to Configure the McBSP Receiver (Part 1)

063

Figure 21-60. Important Tasks to Configure the McBSP Receiver (Part 2)

064

21.5.1.5.2.1 Global Behavior

21.5.1.5.2.1.1 Set the Receiver Pins to Operate as McBSP Pins

The McBSPi.MCBSPLP_PCR_REG[12] RIOEN bit determines whether the receiver pins are McBSP pins (RIOEN bit=0) or general-purpose I/O pins (RIOEN bit=1).

Please refer to [Section 21.5.1.7](#) which describes how to use McBSP pins as GPIO pins.

21.5.1.5.2.1.2 Enable/Disable the Digital Loop Back Mode

The McBSPi.MCBSPLP_XCCR_REG[5] DLB bit determines whether the digital loopback mode is on or off.

In the digital loopback mode, the receive signals are connected internally through multiplexers to the corresponding transmit signals:

- DR signal is connected on DX signal to receive the transmitted data
- FSR is connected to FRX output signal
- CLKR is connected to the CLKX output signal

This mode allows testing of serial port; the McBSP module receives the data it transmits. This loopback mode is not done through pads, all output signals being disabled.

Note: That in digital loopback mode the SRG and the frame synchronization generator need to be enabled to generate the CLKX and FSX signals.

21.5.1.5.2.1.3 Enable/Disable the Analog Loopback Mode

The McBSPi.MCBSPLP_SPCR1_REG[15] ALB bit determines whether the analog loopback mode is on or off.

In the analog loopback mode, the receive signals are connected internally through multiplexers to the corresponding transmit loop back signals:

- DR is connected to transmit loop back data on DX input pin
- FSR is connected to FRX input pin
- CLKR is connected to the CLKX input pin

This Analog Loopback mode is also done to test the Input/Output buffers, through pads.

21.5.1.5.2.1.4 Enable/disable the synchronous transmit-receive mode (McBSP1 only)

The control registers of the System Control Module is used to configure the synchronous transmit-receive mode.

The MCBSP1_CLKR bit of the CONTROL_DEVCONF0[3] register is used to select the McBSP1 module CLKR signal source:

- When set to '0', the CLKR source is from the CLKR input signal
- When set to '1', the CLKR source is from the CLKX input signal

The MCBSP1_FSR bit of the CONTROL_DEVCONF0[4] register is used to select the McBSP1 module FSR signal source:

- When set to '0', the FSR source is from the FSR input signal
- When set to '1', the FSR source is from the FSX input signal

21.5.1.5.2.1.5 Enable/Disable the Receive Multi-channel Selection Mode

The McBSPi.MCBSPLP_MCR1_REG[0] RMCM bit determines whether the receive multi-channel selection mode is on or off.

For further details, see [Section 21.4.6.5](#).

21.5.1.5.2.2 Data Behavior

21.5.1.5.2.2.1 Choose 1 or 2 Phases for the Receive Frame

The McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit determines whether the receive data frame has one (Single phase) or two phases (Dual phase). When dual-phase is selected the number of words per phase must be set to one.

21.5.1.5.2.2.2 Set the Receive Word Length(s)

The McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 and McBSPi.MCBSPLP_RCR2_REG[7:5] RWDLEN2 bit fields determine how many bits are in each serial word in phase 1 and in phase 2, respectively, of the receive data frame.

If a single-phase frame is selected, RWDLEN1 selects the length for every serial word received in the frame.

If a dual-phase frame is selected, RWDLEN1 and RWDLEN2 must be set to select the both length. These both bits can have values different.

21.5.1.5.2.2.3 Set the Receive Frame Length

The receive frame length is the number of serial words in the receive frame.

The McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLLEN1 and McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLLEN2 bit fields determine how many serial words are in phase 1 and in phase 2, respectively, of the receive data frame.

If a dual-phase frame is selected (RPHASE=1), the frame length must be two words (one word for phase 1 plus the one word for phase 2). Others values must not be used.

The 7-bit RFRLN1 field allows up to 128 words per phase when single-phase frame. See [Table 21-27](#) below for a summary of how to calculate the frame length. This length corresponds to the number of words or logical time slots or channels per frame—synchronization pulse.

Program the RFRLN fields with [W - 1], where W represents the number of words per phase. For example, to get a phase length of 128 words in phase 1, load 127 words into RFRLN1.

Table 21-27. How to Calculate the Length of the Receive Frame

RPHASE	RFRLN1	RFRLN2	Frame Length
0	$0 \leq \text{RFRLN1} \leq 127$	Don't care	(RFRLN1value + 1) words
1	RFRLN1 = 0	RFRLN2 = 0	2 words

21.5.1.5.2.2.4 Set the Receive Reverse Mode

The McBSPi.MCBSPLP_RCR2_REG[4:3] RREVERSE bit field determines whether reverse (LSB first) data transfer option is chosen for McBSP reception.

For further information about reverse mode, see [Section 21.4.2.2](#).

21.5.1.5.2.2.5 Set the Receive Data Delay

The McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY bit field determines the length of the data delay for the receive frame.

The start of a frame is defined by the first clock cycle in which frame synchronization is active. The beginning of actual data reception or transmission with respect to the start of the frame can be delayed if required. This delay is called data delay.

McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY specifies the data delay for reception. The range of programmable data delay is zero to two bit-clocks (RDATDLY=0b00–0b10), as shown in [Figure 21-61](#) below. In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on. Typically a 1-bit delay is selected, because data often follows a 1-cycle active frame—synchronization pulse.

Figure 21-61. Range of Programmable Data Delay

21.5.1.5.2.2.5.1 0-Bit Data Delay

Normally, a frame—synchronization pulse is detected or sampled with respect to an edge of internal serial clock CLK(R/X). Thus, on the following cycle or later (depending on the data delay value), data may be received or transmitted. However, in the case of 0-bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle.

For reception, this problem is solved because receive data is sampled on the first falling edge of CLKR

where an active-high internal FSR is detected. However, data transmission must begin on the rising edge of the internal CLKX clock that generated the frame synchronization. Therefore, the first data bit is assumed to be present in XSR, and thus on mcbasp_dx. The transmitter then asynchronously detects the frame-synchronization signal (FSX) going active high and immediately starts driving the first bit to be transmitted on the mcbasp_dx pin.

21.5.1.5.2.2.5.2 2-Bit Data Delay

A data delay of two bit periods allows the serial port to interface to different types of T1 framing devices where the data stream is preceded by a framing bit. During reception of such a stream with data delay of two bits (framing bit appears after a 1-bit delay and data appears after a 2-bit delay), the serial port essentially discards the framing bit from the data stream, as shown in Figure 21-62. In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on.

Figure 21-62. 2-Bit Data Delay Used to Skip a Framing Bit

053

21.5.1.5.2.2.6 Set the Receive Sign-Extension and Justification Mode

The McBSPi.MCBSPLP_SPCR1_REG[14:13] RJUST bit field determines whether data received by the McBSP module is sign-extended or not and how it is justified.

RJUST bit selects whether data in RB is right- or left-justified (with respect to the MSB) in McBSPi.MCBSPLP_DRR_REG register and whether unused bits in McBSPi.MCBSPLP_DRR_REG are filled with zeroes or with sign bits.

Table 21-28 and Table 21-29 show the effects of various RJUST values; the effect on an example 12-bit receive-data value 0xABC, and the effect on an example 20-bit receive-data value 0xABCDE, respectively.

Table 21-28. Example: Use of RJUST Bit Field with 12-bit Data Value 0xABC

RJUST	Justification	Extension	Value in DRR_REG
0b00	Right	Zero fill MSBs	0x0000 0ABC
0b01	Right	Sign extend data into MSBs	0xFFFF FABC
0b10	Left	Zero fill LSBs	0xABC0 0000
0b11	Reserved	Reserved	Reserved

Table 21-29. Example: Use of RJUST Bit Field with 20-bit Data Value 0xABCDE

RJUST	Justification	Extension	Value in DRR_REG
0b00	Right	Zero fill MSBs	0x000A BCDE
0b01	Right	Sign extend data into MSBs	0xFFFF BCDE
0b10	Left	Zero fill LSBs	0xABCD E000
0b11	Reserved	Reserved	Reserved

21.5.1.5.2.2.7 Set the Receive Interrupt Mode

Please refer to Section 21.5.1.4.2.1.

21.5.1.5.2.2.8 Set the Receive DMA Mode

The McBSP receive-data DMA requests (McBSPi_DMA_RX) are active after the McBSPi.MCBSPLP_SPCR1_REG [0] RST bit is released. After reset, the default DMA threshold (and length) is 1.

The receive DMA requests can be disabled by setting the McBSPi.MCBSPLP_RCCR_REG[3] RDMAEN bit to 0. When disabling the DMA, the DMA request line is deasserted even if a DMA transfer is pending, and the DMA state-machine is not reset.

To configure the McBSP receive data DMA requests, perform the following:

- Write the receive McBSPi.MCBSPLP_THRSH1_REG register with the required receive DMA request length (the length of the transfer is the same as the threshold value + 1).
- As long as the occupied locations level in the RB is above or equal to the THRSH1_REG value + 1, the DMA request is asserted.
- After transferring the configured (THRSH1_REG value + 1) number of words, the receive DMA request is deasserted, and then reasserted as soon as the conditions are met again.

21.5.1.5.2.3 Frame-Sync Behavior

21.5.1.5.2.3.1 Set the Receive Frame-Sync Mode

McBSPi.MCBSPLP_PCR_REG[10] FSRM bit, McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit, McBSPi.MCBSPLP_SPCR1_REG[15] ALB bit and McBSPi.MCBSPLP_XCCR_REG[5] DLB bit field are used to determine the source for receive frame synchronization and the function of the mcbasp_fsr pin.

Table 21-30 below shows how you can select various sources to provide the receive frame-synchronization signal and the effect on the mcbasp_fsr pin. The polarity of the signal on the mcbasp_fsr pin is determined by the McBSPi.MCBSPLP_PCR_REG[2] FSRP bit.

Table 21-30. FSRM and GSYNC Effects on Frame-Sync Signal and mcbasp_fsr Pin

FSRM	GSYNC	Source of Receive FrameSynchronization	MCBSPLP.FSR Pin Status
0	0 or 1	An external frame synchronization signal enters the McBSP module through the mcbasp_fsr pin. The signal is then inverted as determined by FSRP bit before being used as internal FSR.	Input
1	0	Internal FSR is driven by the SRG frame-synchronization signal (FSG).	Output. FSG is inverted as determined by FSRP bit before being driven out on the mcbasp_fsr pin.
1	1	Internal FSR is driven by the SRG frame-synchronization signal (FSG).	Input. The external frame-synchronization input on the mcbasp_fsr pin is used to synchronize CLKG and generate FSG pulses.

In digital loop-back mode (DLB=1), the transmit frame-synchronization signal is used as the receive frame-synchronization signal.

Also in the analog loop back mode (ALB=1), the internal receive clock signal (CLKR), and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX.

For more details on clock and frame-sync configuration, see [Section 21.4.3](#).

21.5.1.5.2.3.2 Set the Receive Frame-Sync Polarity

The McBSPi.MCBSPLP_PCR_REG[2] FSRP bit determines whether frame-synchronization pulses are active high or active low on the mcbasp_fsr pin.

Receive frame-synchronization pulses can be generated internally by the SRG or driven by an external source. The source of frame synchronization is selected by programming the McBSPi.MCBSPLP_PCR_REG[10] FSRM bit. FSR is also affected by the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit. For information about the effects of FSRM and GSYNC, see [Section 21.4.3.2](#).

When FSR and FSX are inputs (FSXM=FSRM=0, external frame-synchronization pulses), the McBSP module detects them on the internal falling edge of clock, internal CLKR, and internal CLKX, respectively. The receive data arriving at the mcbspi_dr pin is also sampled on the falling edge of internal CLKR. These internal clock signals are either derived from an external source via CLK(R/X) pins or driven by the SRG clock (CLKG) internal to the McBSP module.

When FSR and FSX are outputs, implying that they are driven by the SRG, they are generated (transition to their active state) on the rising edge of the internal clock, CLK(R/X). Similarly, data on the mcbbsp_dx pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP bit fields in the pin control register (McBSPi.MCBSPLP_PCR_REG) configure the polarities of the FSR, FSX, CLKR, and CLKX signals, respectively. All frame-synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP), and FSRP=FSXP=1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC=0) is selected, the internal active-high frame-synchronization signals are inverted, if the polarity bit FS(R/X)P=1, before being sent to the FS(R/X) pin.

Figure 21-63 below shows how data clocked by an external serial device using a rising edge can be sampled by the McBSP receiver on the falling edge of the same clock.

Figure 21-63. Data Externally Clocked on a Rising Edge and Sampled on a Falling Edge

21.5.1.5.2.3.3 Set the SRG Frame-Sync Period and Pulse Width

The SRG can produce a clock signal, CLKG, and FSG. If the SRG is supplying receive or transmit frame synchronization, you must program the bit fields FPER and FWID.

McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER bit field is used to set the SRG frame-sync period and McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID bit field is used to set the SRG pulse width.

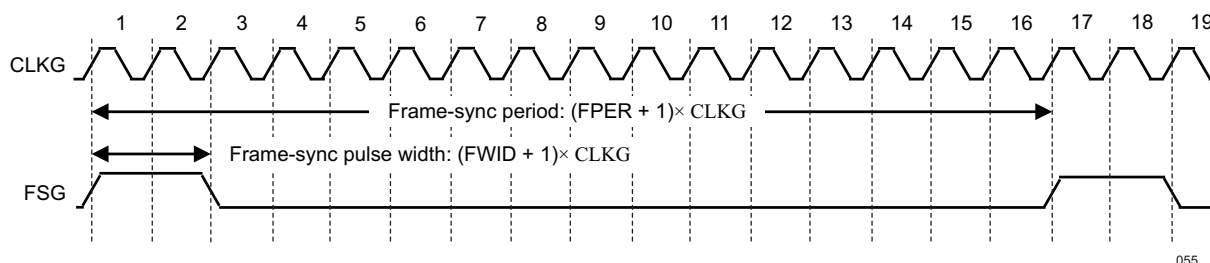

On FSG, the period from the start of a frame-synchronization pulse to the start of the next pulse is (FPER+1) CLKG cycles. The 12 bits of FPER allow a frame-synchronization period of 1 to 4096 CLKG cycles, which allows up to 4096 data bits per frame. When GSYNC=1, FPER is a don't care value.

Each pulse on FSG has a width of (FWID+1) CLKG cycles. The eight bits of FWID allow a pulse width of 1 to 256 CLKG cycles. It is recommended that FWID be programmed to a value less than the programmed word length.

The values in FPER and FWID are loaded into separate down-counters. The 12-bit FPER counter counts down the generated clock cycles from the programmed value (4095 maximum) to 0. The 8-bit FWID counter counts down from the programmed value (255 maximum) to 0.

Figure 21-64 shows a frame-synchronization period of 16 CLKG periods (FPER=15 or 00001111b) and a frame-synchronization pulse with an active width of 2 CLKG periods (FWID=1).

Figure 21-64. Frame of Period 16 CLKG Periods and Active Width of 2 CLKG Periods

When the SRG comes out of reset, FSG is in its inactive state. Then, when GRST=1 and FSGM=1, a frame-synchronization pulse is generated. The frame width value (FWID+1) is counted down on every CLKG cycle until it reaches 0, at which time FSG goes low. At the same time, the frame period value (FPER+1) is also counting down. When this value reaches 0, FSG goes high, indicating a new frame.

21.5.1.5.2.4 Clock Behavior

21.5.1.5.2.4.1 Set the receive clock mode

McBSPi.MCBSPLP_PCR_REG[8] CLKRM bit, McBSPi.MCBSPLP_SPCR1_REG[15] ALB bit and McBSPi.MCBSPLP_XCCR_REG[5] DLB bit are used to set the receive clock mode.

Table 21-31 shows how to select various sources to provide the receive clock signal and affect the mcbssp_clkr pin. The McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit determines the polarity of the signal on the mcbssp_clkr pin.

Table 21-31. CLKRM Effect on Receive Clock Signal and mcbssp_clkr Pin

CLKRM	Source of Receive Clock	mcbssp_clkr Pin Status
0	The mcbssp_clkr pin is an input driven by an external clock. The external clock signal is inverted as determined by CLKRP bit before being used.	Input
1	The SRG clock (CLKG) drives internal CLKR.	Output. CLKG, inverted as determined by CLKRP, is driven out on the mcbssp_clkr pin.

In the digital loop-back mode (DLB=1) or analog loop-back mode (ALB = 1), the transmit clock signal is used as the receive clock signal. For more details on clock configuration, see [Section 21.4.3.1](#).

21.5.1.5.2.4.2 Set the Receive Clock Polarity

McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit is used to set the receive clock polarity.

The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal CLKR. Therefore, if CLKRP=1 and external clocking is selected (CLKRM=0 and CLKR is an input pin), the external rising-edge triggered input clock on CLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP=1 and internal clocking is selected (CLKRM=1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the mcbssp_clkr pin.

Note: CLKRP=CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

21.5.1.5.2.4.3 Set the SRG Clock Divide-Down Value

McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV bit field is used to set the SRG clock divide-down value.

The first divider stage generates the serial data bit clock from the input clock. This divider stage utilizes a counter, preloaded by CLKGDV, that contains the divide ratio value.

The output of the first divider stage is the data bit clock, which is output as CLKG and which serves as the input for the second and third stages of the divider.

CLKG has a frequency equal to $1/(\text{CLKGDV}+1)$ of SRG input clock. Thus, the sample generator input clock frequency is divided by a value between 1 and 256. The CLKG duty cycle is 50%.

21.5.1.5.2.4.4 Set the SRG Clock Synchronization Mode

McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit is used to set the SRG clock synchronization mode.

For more information about the clock synchronization feature, see [Section 21.4.3](#).

21.5.1.5.2.4.5 Set the SRG Clock Mode (Choose an Input Clock)

McBSPi.MCBSPLP_PCR_REG[7] SCLKME bit and McBSPi.MCBSPLP_SRGR2_REG[13] CLKSM bit are used to set the SRG clock mode.

The SRG can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both, but CLKG is derived from an input clock.

For further details about the clock synchronization feature, see [Section 21.4.3](#).

21.5.1.5.2.4.6 Set the SRG Input Clock Polarity

McBSPi.MCBSPLP_SRGR2_REG[14] CLKSP bit, McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit and McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit are used to set the SRG input clock polarity.

The SRG can produce a clock signal (CLKG) and a frame-synchronization signal (FSG) for use by the receiver, the transmitter, or both. To produce CLKG and FSG, the SRG must be driven by an input clock signal derived from the McBSP_FCLK clock or from an external clock on the mcbasp_clks, mcbasp_clxx, or mcbasp_clkr pin. If you use a pin, choose a polarity for that pin by using the appropriate polarity bit (CLKSP for the mcbasp_clks pin, CLKXP for the mcbasp_clxx pin, CLKRP for the mcbasp_clkr pin). The polarity determines whether the rising or falling edge of the input clock generates transitions on CLKG and FSG.

21.5.1.6 Transmitter Configuration

To configure the McBSP transmitter, perform the following procedure:

1. Place the McBSP transmitter in reset
2. Program the McBSP registers for the desired transmitter operation
3. Take the transmitter out of reset

These 3 steps are described in more details in the sub-sections below.

21.5.1.6.1 Resetting (Step 1) and Enabling (Step 3) the Transmitter

The first step of the transmitter configuration procedure is to reset the transmitter, and the last step is to enable the transmitter (to take it out of reset).

The serial port can be reset in the following two ways:

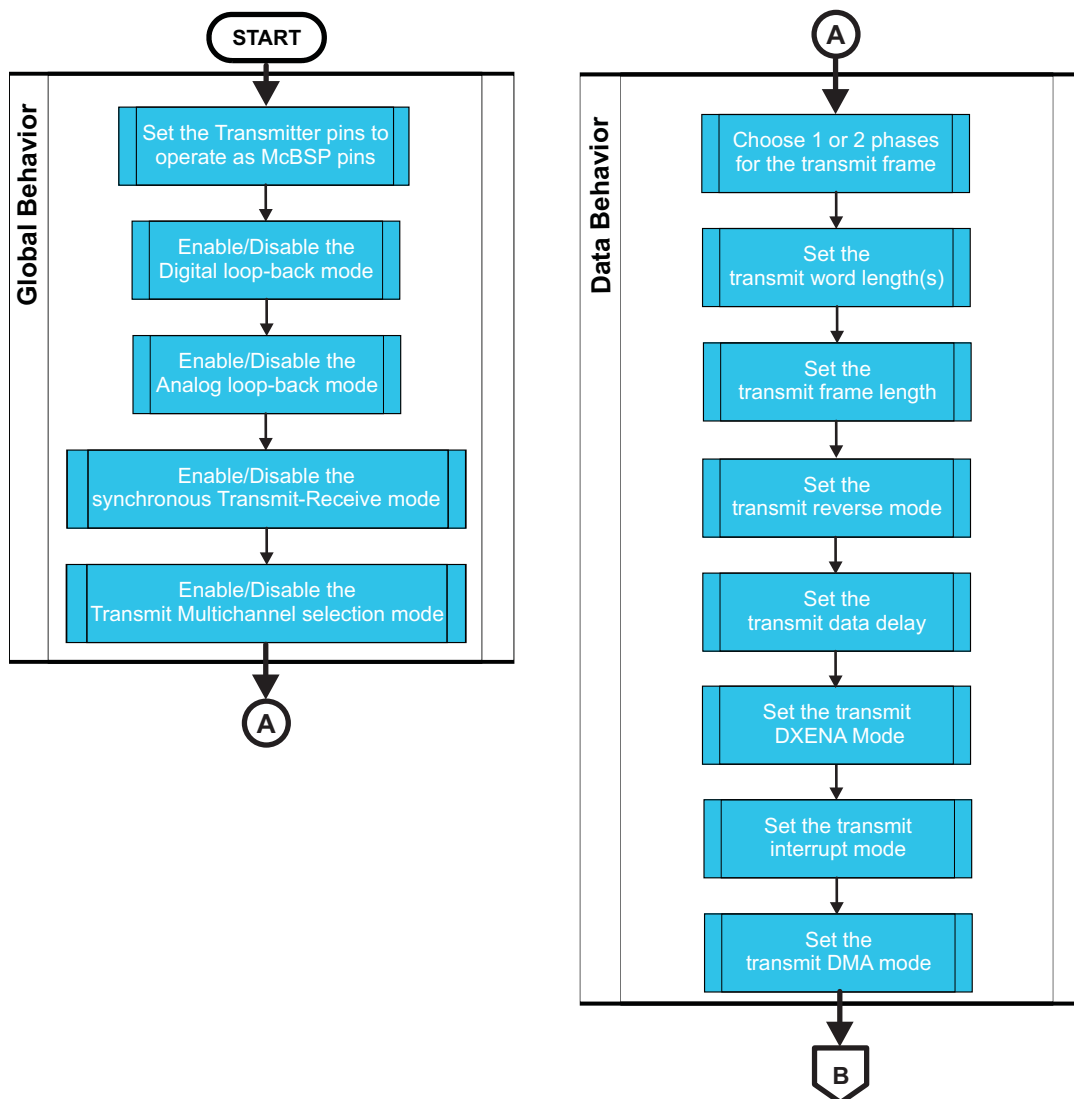

1. A global reset places the receiver, transmitter, and SRG in reset. When the device reset is removed, McBSPi.MCBSPLP_SPCR2_REG[6] GRST, McBSPi.MCBSPLP_SPCR2_REG[7] FRST, McBSPi.MCBSPLP_SPCR1_REG[0] RST and McBSPi.MCBSPLP_SPCR2_REG[0] XRST bits = 0, which keeps the entire serial port in the reset state.
2. The serial port receiver can be reset directly using the McBSPi.MCBSPLP_SPCR2_REG[0] XRST bit. If the SRG needs to be used, SRG must be reset directly using the McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit. Similar operation with the Frame Synchronization Generator also requires using the McBSPi.MCBSPLP_SPCR2_REG[7] FRST bit when the frame-sync signal must be generated.

To enable the transmitter, the preceding bits, cleared to 0, must be set to 1.

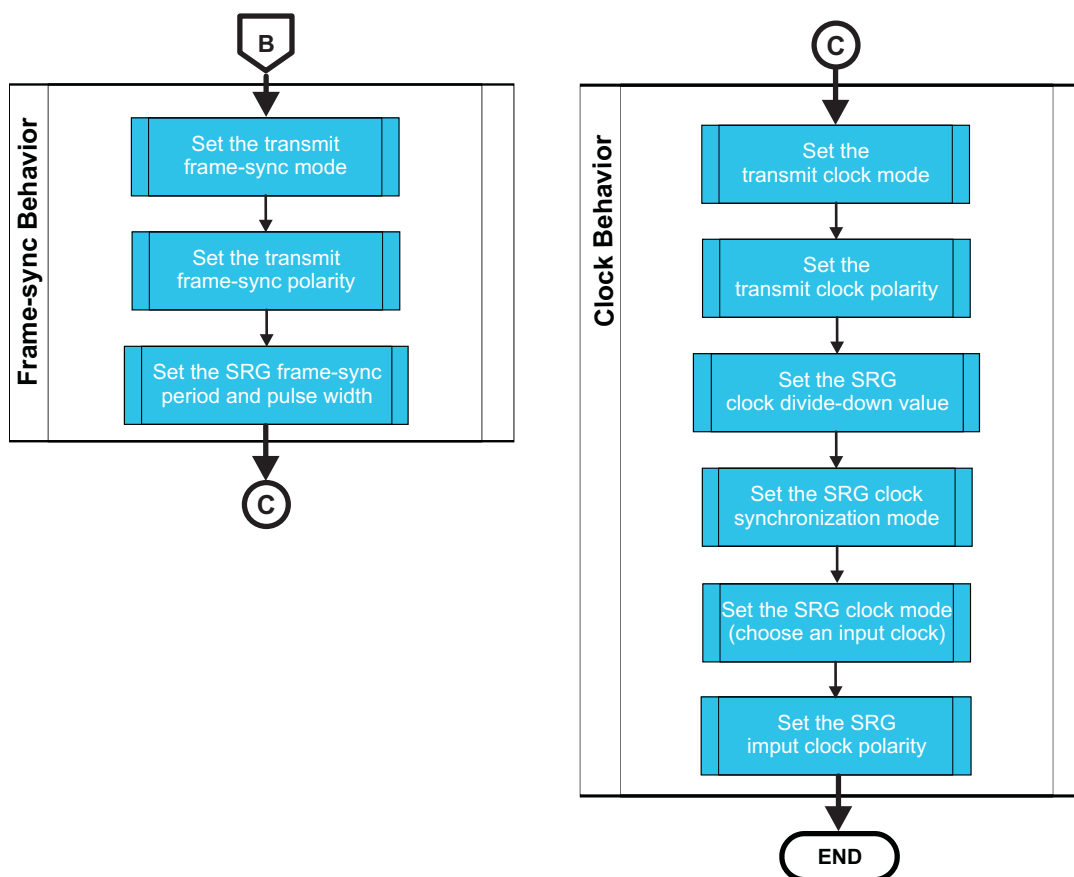

21.5.1.6.2 Programming the McBSP Registers for the Desired Transmitter Operation (Step 2)

Figure 21-65 and Figure 21-66 list important tasks to be performed when configuring the McBSP transmitter. Each task corresponds to one or more McBSP register bit fields.

Figure 21-65. Important Tasks to Configure the McBSP Transmitter (Part 1)

065

Figure 21-66. Important Tasks to Configure the McBSP Transmitter (Part 2)

066

21.5.1.6.2.1 Global Behavior

21.5.1.6.2.1.1 Set the Transmitter Pins to Operate as McBSP Pins

McBSPi.MCBSPLP_PCR_REG[13] XIOEN bit determines whether the transmitter pins are McBSP pins (XIOEN=0) or general-purpose I/O pins (XIOEN=1).

Refer to [Section 21.5.1.7](#) which describes how to use McBSP pins as GPIO pins.

21.5.1.6.2.1.2 Enable/Disable the Digital Loop-Back Mode

Refer to it, [Section 21.5.1.5.2.1.2](#).

21.5.1.6.2.1.3 Enable/Disable the Analog Loop-Back Mode

Refer to it, [Section 21.5.1.5.2.1.3](#).

21.5.1.6.2.1.4 Enable/Disable the Synchronous Transmit-Receive Mode (McBSP1 only)

Refer to it, [Section 21.5.1.5.2.1.4](#).

21.5.1.6.2.1.5 Enable/Disable the Transmit Multi-Channel Selection

McBSPi.MCBSPLP_MCR2_REG[1:0] XMCM bit field determines whether the transmit multi-channel selection mode is on or off.

Refer to [Section 21.4.6.7](#).

21.5.1.6.2.2 Data Behavior

21.5.1.6.2.2.1 Choose 1 or 2 Phases for the Transmit Frame

McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit determines whether the transmit data frame has one (Single phase) or two phases (Dual phase). When dual-phase is selected the number of words per phase must be set to one.

21.5.1.6.2.2.2 Set the Transmit Word Length(s)

McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 and McBSPi.MCBSPLP_XCR2_REG[7:5] XWDLEN2 bit fields determine how many bits are in each serial word in phase 1 and in phase 2, respectively, of the transmit data frame.

If a single-phase frame is selected, XWDLEN1 selects the length for every serial word received in the frame.

If a dual-phase frame is selected, XWDLEN1 and XWDLEN2 must be set to select the both length. These both bits can have values different.

21.5.1.6.2.2.3 Set the Transmit Frame Length

The transmit frame length is the number of serial words in the transmit frame.

McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 and McBSPi.MCBSPLP_XCR2_REG[14:8] XFRLEN2 bit fields determine how many serial words are in phase 1 and in phase 2, respectively, of the transmit data frame.

If a dual-phase frame is selected (XPHASE=1), the frame length is 2 words, the length of phase 1 (one word) plus the length of phase 2 (one word). Others values must not be used.

The 7-bit XFRLEN fields allow up to 128 words per phase. See [Table 21-32](#) for a summary of how to calculate the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization pulse.

Program the XFRLEN fields with [W minus 1], where W represents the number of words per phase. For the example, if you want a phase length of 128 words in phase 1, load 127 into XFRLEN1.

Table 21-32. How to Calculate the Length of the Transmit Frame

XPHASE	XFRLEN1	XFRLEN2	Frame Length
0	$0 \leq \text{XFRLEN1} \leq 127$	Don't care	(XFRLEN1value +1) words
1	XFRLEN1= 0	XFRLEN2 = 0	2 words

21.5.1.6.2.2.4 Set the Transmit Reverse Mode

McBSPi.MCBSPLP_XCR2_REG[4:3] XREVERSE bit field determines whether reverse (LSB first) data transfer option is chosen for McBSP reception.

For additional information about reverse mode, see [Section 21.4.2.2](#).

21.5.1.6.2.2.5 Set the Transmit Data Delay

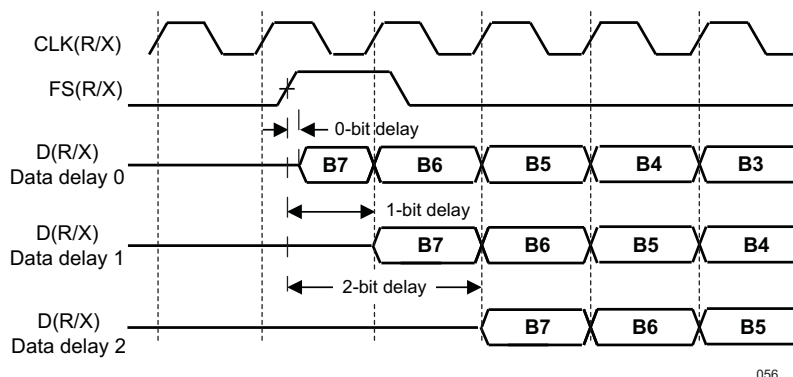

McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY bit field determines the length of the data delay for the transmit frame.

The start of a frame is defined by the first clock cycle in which frame synchronization is found to be active. The beginning of actual data transmission with respect to the start of the frame can be delayed if required. This delay is called data delay.

XDATDLY specifies the data delay for reception. The range of programmable data delay is zero to two bit-clocks (XDATDLY=00b–10b), as shown in [Figure 21-67](#). In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on.

Note: Typically a 1-bit delay is selected, because data often follows a 1-cycle active frame-synchronization pulse.

Figure 21-67. Range of Programmable Data Delay

21.5.1.6.2.2.5.1 0-Bit Data Delay:

Normally, a frame-synchronization pulse is detected or sampled with respect to an edge of internal serial clock CLK(R/X). Thus, on the following cycle or later (depending on the data delay value), data may be received or transmitted. However, in the case of 0-bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle.

For reception, this problem is solved because receive data is sampled on the first falling edge of CLKR where an active-high internal FSR is detected. However, data transmission must begin on the rising edge of the internal CLKX clock that generated the frame synchronization. Therefore, the first data bit is assumed to be present in XSR1, and thus on mcbspi_dx. The transmitter then asynchronously detects the frame-synchronization signal (FSX) going active high and immediately starts driving the first bit to be transmitted on the mcbbsp_dx pin.

21.5.1.6.2.2.5.2 2-Bit Data Delay:

A data delay of two bit periods allows the serial port to interface to different types of T1 framing devices where the data stream is preceded by a framing bit. During reception of such a stream with data delay of two bits (framing bit appears after a 1-bit delay and data appears after a 2-bit delay), the serial port essentially discards the framing bit from the data stream, as shown in Figure 21-68. The data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on.

Figure 21-68. 2-Bit Data Delay Used to Skip a Framing Bit

21.5.1.6.2.2.6 Set the Transmit DXENA Mode

McBSPi.MCBSPLP_SPCR1_REG[7] DXENA bit is used to set the transmit DXENA (DX delay enable) mode.

The DXENA bit controls the delay enabler on the mcbbsp_dx pin. Set DXENA to enable an extra delay for

turn-on time. This bit does not control the data itself, so only the first bit is delayed (the delay is given by a combinatorial delay buffer). The inserted delay: 7 ns, 14 ns (default), 20 ns or 28 ns can be set using the McBSPi.MCBSPLP_XCCR_REG[13:12] DXENDLY field. If you tie together the mcbasp_dx pins of multiple McBSP modules, make sure DXENA=1, to avoid having more than one McBSP transmitting on the data line at one time.

21.5.1.6.2.2.7 Set the Transmit Interrupt Mode

Refer to [Section 21.5.1.4.2.2](#).

21.5.1.6.2.2.8 Set the Transmit DMA Mode

The McBSP transmit data DMA requests (McBSPi_DMA_TX) are active after the transmit McBSPi.MCBSPLP_SPCR2_REG[0] XRST bit is released. After reset, the default DMA threshold (and length) is 1.

The transmit DMA requests can be disabled by setting the McBSPi.MCBSPLP_XCCR_REG[3] XDMAEN bit to 0. When disabling the DMA, the DMA request line is deasserted even if a DMA transfer is pending, and the DMA state-machine is not reset.

To configure the McBSP transmit data DMA requests, follow this procedure:

- Write the transmit McBSPi.MCBSPLP_THRSH2_REG register with the required transmit DMA request length (the length of the transfer is the same as the threshold value + 1).
- As long as the free locations level in XB is above or equal to the THRSH2_REG value + 1, the DMA request is asserted.
- After transferring the configured (THRSH2_REG value + 1) number of words, the transmit DMA request is deasserted, and then reasserted as soon as the conditions are met again.

21.5.1.6.2.3 Frame-Synchronization Behavior

21.5.1.6.2.3.1 Set the Transmit Frame-Sync Mode

McBSPi.MCBSPLP_PCR_REG[11] FSXM bit and McBSPi.MCBSPLP_SRGR2_REG[12] FSGM bit are used to set the transmit frame-sync mode.

[Table 21-33](#) shows how FSXM and FSGM select the source of transmit frame-synchronization pulses. The three choices are:

1. External frame-synchronization input
2. Sample rate generator frame-synchronization signal (FSG)
3. Sample rate generator frame-synchronization signal (FSG) gated by the transmit buffer XB empty condition.

[Table 21-33](#) also shows the effect of each bit setting on the mcbasp_fsx pin. The FSXP bit determines the polarity of the signal on the mcbasp_fsx pin.

Table 21-33. How FSXM and FSGM Select the Source of Transmit Frame-Sync Pulses

FSXM	FSGM	Source of Transmit FrameSynchronization	mcbasp_fsx Pin Status
0	0 or 1	An external FSG enters the McBSP through the mcbasp_fsx pin. The signal is then inverted by FSXP bit before being used as internal FSX.	Input
1	1	Internal FSX is driven by the SRG FSG.	Output. FSG is inverted by FSXP bit before being driven out on mcbasp_fsx pin.
1	0	A XB empty condition causes the McBSP not to generate a transmit frame-synchronization pulse. The frame synchronization is generated taking into account the FWID and FPER bits as long as the transmit buffer is not empty. When the buffer is empty the generated frame synchronization signal is gated.	Output. The generated frame-synchronization pulse is inverted as determined by FSXP bit before being driven out on mcbasp_fsx pin.

If the SRG creates a frame-synchronization signal (FSG) that is derived from an external input clock, the GSYNC bit determines whether FSG is kept synchronized with pulses on the mcbasp_fsr pin. For more details, see [Section 21.4.3.3](#).

In the digital loopback mode (DLB=1) or analog loopback mode (ALB = 1), the transmit frame synchronization signal is used as the receive frame synchronization signal. For more details on frame-sync configuration, see [Section 21.4.3.2](#).

21.5.1.6.2.3.2 Set the Transmit Frame-Sync Polarity

McBSPi.MCBSPLP_PCR_REG[3] FSXP bit determines whether frame-synchronization pulses are active high or active low on the mcbasp_fsx pin.

Transmit frame-synchronization pulses can be generated internally by the SRG or driven by an external source. The source of frame synchronization is selected by programming the McBSPi.MCBSPLP_PCR_REG[11] FSXM bit. FSX is also affected by the McBSPi.MCBSPLP_SRGR2_REG[12] FSGM bit. For information about the effects of FSXM and FSGM, see [Section 21.5.1.6.2.3.1](#).

When FSR and FSX are inputs (FSXM=FSRM=0, external frame-synchronization pulses), the McBSP module detects them on the internal falling edge of clock, internal CLKR, and internal CLKX, respectively. The receive data arriving at the mcbasp_dr pin is also sampled on the falling edge of internal CLKR. These internal clock signals are either derived from external source via CLK(R/X) pins or driven by the SRG clock (CLKG) internal to the McBSP module.

When FSR and FSX are outputs, implying that they are driven by the SRG, they are generated (transition to their active state) on the rising edge of internal clock, CLK(R/X). Similarly, data on the mcbasp_dx pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR_REG) configure the polarities of the FSR, FSX, CLKR, and CLKX signals, respectively. All FSG (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP) and FSRP=FSXP=1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC=0) is selected and the polarity bit FS(R/X)P=1, the internal active-high FSG are inverted before being sent to the FS(R/X) pin.

21.5.1.6.2.3.3 Set the SRG Frame-Sync Period and Pulse Width

See [Section 21.5.1.5.2.3.3](#).

21.5.1.6.2.4 Clock Behavior

21.5.1.6.2.4.1 Set the Transmit Clock Mode

The McBSPi.MCBSPLP_PCR_REG[9] CLKXM bit is used to set the transmit clock mode.

[Table 21-34](#) shows how the CLKXM bit selects the transmit clock and the corresponding status of the mcbasp_clkx pin. The CLKXP bit determines the polarity of the signal on the mcbasp_clkx pin.

Table 21-34. CLKXM Bit Effect on Transmit Clock and MCBSPLP.CLKX Pin

CLKXM	Source of Transmit Clock	mcbasp_clkx Pin Status
0	Internal CLKX is driven by an external clock on the mcbasp_clkx pin. CLKX is inverted as determined by CLKXP before being used.	Input
1	Internal CLKX is driven by the SRG clock, CLKG.	Output. CLKG, inverted as determined by CLKXP, is driven out on mcbasp_clkx.

If the SRG creates a clock signal (CLKG) that is derived from an external input clock, the GSYNC bit determines whether CLKG is kept synchronized with pulses on the mcbasp_fsr pin.

In the digital loopback mode (DLB=1) or analog loopback mode (ALB = 1), the transmit frame synchronization signal is used as the receive frame synchronization signal. For more details on clock configuration, see [Section 21.4.3.1](#).

21.5.1.6.2.4.2 Set the Transmit Clock Polarity

The McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit is used to set the transmit clock polarity.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP=1 and external clocking is selected (CLKXM=0 and CLKX is an input), the external falling-edge triggered input clock on CLKX is inverted to a rising-edge triggered clock before being sent to the transmitter. If CLKXP=1 and internal clocking is selected (CLKXM=1 and CLKX is an output pin), the internal (rising-edge triggered) clock, internal CLKX, is inverted before being sent out on the mcbasp_clkx pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal CLKR. Therefore, if CLKRP=1 and external clocking is selected (CLKRM=0 and CLKR is an input pin), the external rising-edge triggered input clock on CLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP=1 and internal clocking is selected (CLKRM=1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the mcbasp_clkr pin.

Note: CLKRP=CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

21.5.1.6.2.4.3 Set the SRG Clock Divide-Down Value

See [Section 21.5.1.5.2.4.3](#).

21.5.1.6.2.4.4 Set the SRG Clock Synchronization Mode

See [Section 21.5.1.5.2.4.4](#).

21.5.1.6.2.4.5 Set the SRG Clock Mode (Choose an Input Clock)

See [Section 21.5.1.5.2.4.5](#).

21.5.1.6.2.4.6 Set the SRG Input Clock Polarity

See [Section 21.5.1.5.2.4.6](#).

21.5.1.7 General-Purpose I/O on the McBSP Pins (Legacy Only)

[Table 21-35](#) summarizes how to use the McBSP pins as general-purpose I/O pins. All the bits mentioned in the table except XRST and RREST bits are in the pin control register (McBSPi.MCBSPLP_PCR_REG). McBSPi.MCBSPLP_SPCR2_REG[0] XRST bit and McBSPi.MCBSPLP_SPCR1_REG[0] RREST bit are in the serial port control registers.

To use receiver pins mcbasp_clkr, mcbasp_fsr, and mcbasp_dr as general-purpose I/O pins rather than as serial port pins, you must set two conditions:

1. The receiver of the serial port is in reset (McBSPi.MCBSPLP_SPCR1_REG[0] RRESTbit =0).
2. General-purpose I/O is enabled for the serial port receiver (McBSPi.MCBSPLP_PCR_REG[12] RIOEN=1).

The mcbasp_clkr and mcbasp_fsr pins can be individually configured as either input or output pins with the CLKRM and FSRM bits, respectively. The mcbasp_dr pin can only be an input pin. Table 21-35 shows, which bits in McBSPi.MCBSPLP_PCR_REG are used to read from/write to these pins.

For the transmitter pins mcbasp_clkx, mcbasp_fsx, and mcbasp_dx, you must meet two conditions:

1. The transmitter of the serial port is in reset (McBSPi.MCBSPLP_SPCR2_REG[0] XRST=0).
2. General-purpose I/O is enabled for the serial port transmitter (McBSPi.MCBSPLP_PCR_REG[12] XIOEN=1).

The mcbasp_clkx and mcbasp_fsx pins can be individually configured as input or output pins with the CLKXM and FSXM bits, respectively. The mcbasp_dx pin can only be an output pin. Table 21-35 shows the bits in McBSPi.MCBSPLP_PCR_REG used to read from/write to these pins.

For the mcbasp_clks pin (common to all McBSP modules), all of the reset and I/O enable conditions must be met:

1. Both the receiver and transmitter of the serial port are in reset (RRST=0 and XRST=0).
2. General-purpose I/O is enabled for both the receiver and the transmitter (RIOEN=1 and XIOEN=1).

The mcbasp_clks pin can only be an input pin. To read the status of the signal on the mcbasp_clks pin, read the McBSPi.MCBSPLP_PCR_REG[6] CLKS_STAT bit.

Table 21-35. Using McBSP Pins for General-Purpose I/O

Pin	General-Purpose use enabled by this bit combination	Selected as output when	Output value driven from this bit	Selected as input when	Input value read from this bit
mcbasp_clkx	XRST = 0 XIOEN = 1	CLKXM = 1	CLKXP	CLKXM = 0	CLKXP
mcbasp_fsx	XRST = 0 XIOEN = 1	FSXM = 1	FSXP	FSXM = 0	FSXP
mcbasp_dx	XRST = 0 XIOEN = 1	Always	DX_STAT	Never	Does not apply
mcbasp_clkr	RRST = 0 RIOEN = 1	CLKRM = 1	CLKRP	CLKRM = 0	CLKRP
mcbasp_fsr	RRST = 0 RIOEN = 1	FSRM = 1	FSRP	FSRM = 0	FSRP
mcbasp_dr	RRST = 0 RIOEN = 1	Never	Does not apply	Always	DR_STAT
mcbasp_clks	RRST = XRST = 0 RIOEN = XIOEN = 1	Never	Does not apply	Always	CLKS_STAT

21.5.1.8 Data Packing Examples

This section describes two ways to implement data packing in the McBSP: Using frame length and word length, and using word length and ignoring frame sync pulses.

21.5.1.8.1 Data Packing Using Frame Length and Word Length

Frame length and word length can be manipulated to pack data effectively. For example, four 8-bit words are transferred in a single-phase frame, as shown in Figure 21-69. In this case:

- (R/X)PHASE = 0: Single-phase frame
- (R/X)FRLLEN1 = 00011b: 4-word frame
- (R/X)WDLEN1 = 101b: 32-bit words

Four 8-bit data words are transferred to and from the McBSP by the MPU/IVA2.2 subsystems or the sDMA controller. Thus, four reads from McBSPi.MCBSPLP_DRR_REG and four writes to McBSPi.MCBSPLP_DXR_REG are necessary for each frame.

Figure 21-69. Four 8-bit Data Words Transferred To/From McBSP Module

This data can also be treated as a single-phase frame consisting of one 32-bit data word, as shown in [Figure 21-70](#). In this case:

- (R/X)PHASE = 0: Single-phase frame
- (R/X)FRLLEN1 = 0000000b: 1-word frame
- (R/X)WDLEN1 = 000b: 8-bit words

Two 16-bit data words are transferred to and from the McBSP by the MPU/IVA2.2 subsystems or the sDMA controller. Thus, two reads from McBSPi.MCBSPLP_DRR_REG and two writes to McBSPi.MCBSPLP_DXR_REG are necessary for each frame. This results in only half the number of transfers, as compared to the previous case. This manipulation reduces the percentage of bus time required for serial port data movement.

Figure 21-70. One 32-bit Data Word Transferred To/From McBSP Module

21.5.1.8.2 Data Packing Using Word Length and the Frame-Sync Ignore Function

When there are multiple words per frame, data can be packed by increasing the word length (defining a serial word with more bits) and by ignoring frame-sync pulses. [Figure 21-71](#) shows the McBSP operating at the maximum packet frequency. Here, each frame has only one 8-bit word. Notice the frame-sync pulse that initiates each frame transfer for reception and for transmission. For reception, this configuration requires one read operation for each word. For transmission, this configuration requires one write operation for each word.

Figure 21-71. 8-bit Data Words Transferred at Maximum Packet Frequency

Figure 21-72 shows the McBSP configured to treat this data stream as a continuous 32-bit word. In this example, the McBSP responds to an initial frame-sync pulse. However, the McBSP ignores subsequent pulses. Only one read transfer or one write transfer is required every 32 bits. This configuration effectively reduces the required bus bandwidth to one-fourth the bandwidth needed to transfer four 8-bit words.

Figure 21-72. Configuring the Data Stream as a Continuous 32-bit Word

21.5.2 SIDETONE Feature

21.5.2.1 SIDETONE Activation Procedure

Before you enable a SIDETONE selection mode, make sure you properly configure the data frame for multi-channel mode of the McBSP module:

- Select a single-phase frame (McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit and McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit=0). Each frame represents a TDM data stream.
- Set to 1 the McBSPi.MCBSPLP_MCR1_REG[0] RMCMBit, to select multi-channel mode enable.
- Set a frame length (McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLN1 bit field and McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLN1 bit field) that includes the highest-numbered channel to be used (a maximum of 4 channels can be used in this configuration).
- Set a word length (McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 bit field and McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 bit field) to be either 16, 24 or 32 (see the note

below).

- Select the input/output channels configured as SIDETONE channels by setting the following bit fields listed in [Table 21-36](#):

Table 21-36. Selection of the SIDETONE Input and Output Channels

Bit field	Description
McBSPi.MCBSPLP_SSELCR_REG[9:7] OCH1ASSIGN	Map the CH1 data for the speaker out channels to one of the McBSP channels (1 out of 8 channels)
McBSPi.MCBSPLP_SSELCR_REG[6:4] OCH0ASSIGN	Map the CH0 data for the speaker out channels to one of the McBSP channels (1 out of 8 channels)
McBSPi.MCBSPLP_SSELCR_REG[3:2] ICH1ASSIGN	Map the CH1 data from the digital microphone channels to one of the McBSP channels (1 out of 4 channels)
McBSPi.MCBSPLP_SSELCR_REG[1:0] ICH0ASSIGN	Map the CH0 data from the digital microphone channels to one of the McBSP channels (1 out of 4 channels)

- Enable SIDETONE by setting 2 bits to 1:
 1. In McBSP module, the McBSPi.MCBSPLP_SSELCR_REG[10] SIDETONEEN bit
 2. In SIDETONE core, the McBSPi.ST_SSELCR_REG[0] SIDETONEEN bit

Note: Word width in the loop is 24 bits. If input channel word width is less than 24 bits, LSBs of the samples are zero padded. If input channel word width is more than 24 bits, samples are truncated.

21.5.2.2 SIDETONE Initialization Procedure

The SIDETONE core initialization procedure is as follows:

1. Write 1 in McBSPi.ST_SSELCR_REG[1] COEFFWREN bit to enable loading of the FIR coefficients.
2. Load one by one the FIR coefficients performing 128 write accesses to McBSPi.ST_SFIRCR_REG[15:0] FIRCOEFF bit field, the McBSPi.ST_SFIRCR_REG[0] FIRCOEFF bit is loaded first. To ensure the completion of loading, check the status bit-field, McBSPi.ST_SSELCR_REG[2] COEFFWRDONE bit.
3. Set-up gain values for both channels writing desired values inside McBSPi.ST_SGAINCR_REG[31:16] CH1GAIN bit field for the second sidetone channel and McBSPi.ST_SGAINCR_REG[15:0] CH0GAIN bit field for the first sidetone channel.

21.5.2.3 SIDETONE FIR Coefficients Writing

Writing the coefficients is only possible when the SIDETONE is disabled.

1. Write 1 in McBSPi.ST_SSELCR_REG[1] COEFFWREN bit to enable writing of the FIR coefficients or write 0 followed by 1 write in COEFFWREN bit to reset the write process.
2. Perform 128 write accesses in 32/16 LSB bit mode on McBSPi.ST_SFIRCR_REG[15:0] FIRCOEFF bit field. The first write action following the previous step sets the coefficient index 0.
3. Check that the write is done by reading McBSPi.ST_SSELCR_REG[2] COEFFWRDONE bit (it becomes '1' after the 128th coefficient is written).

21.5.2.4 SIDETONE FIR Coefficients Reading

Reading the coefficients is only possible when the SIDETONE is disabled.

- Write 0 in McBSPi.ST_SSELCR_REG[1] COEFFWREN bit to enable reading of the FIR coefficients or write 1 followed by 0 write in COEFFWREN bit to reset the read process.
- Perform 128 read accesses from McBSPi.ST_SFIRCR_REG[15:0] FIRCOEFF bit field. Each read returns coefficients one by one. The first read following previous step returns coefficient index 0.

21.6 McBSP Use Case and Tips

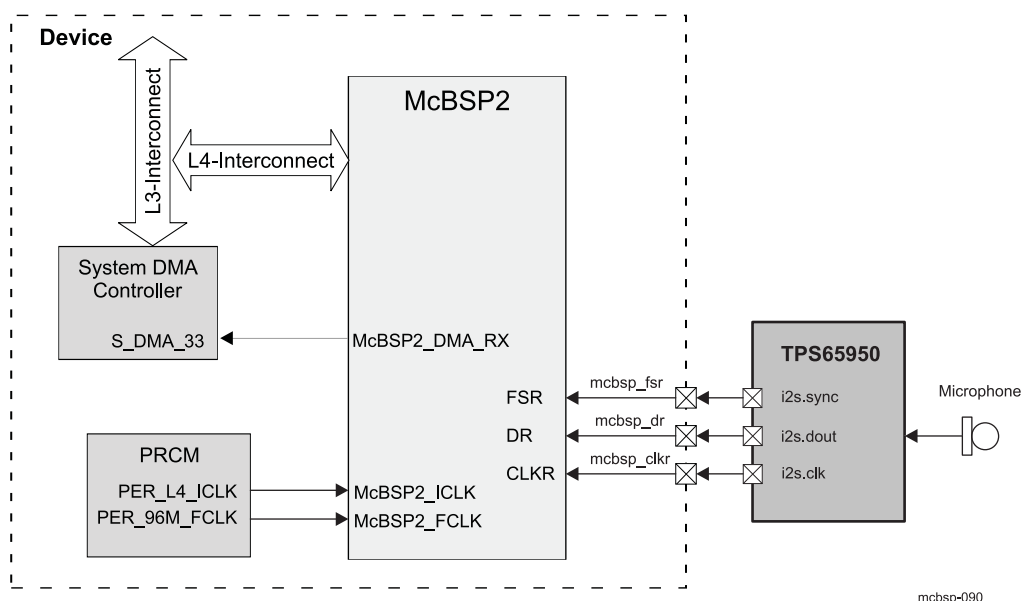

21.6.1 Camcorder Use Case: How to Configure the McBSP2 to Receive Voice Stream From the TPS65950 Device

21.6.1.1 Overview

In the camcorder use case, the McBSP2 is used to transfer voice from the TPS65950 device to external DRAM through the sDMA controller. The McBSP2 module is directly connected to the TPS65950 device in slave mode (that is, the TPS65950 generates clock and FSR signals to manage data).

Figure 21-73 is an overview of the voice path.

Figure 21-73. Overview

mcbasp-090

The TPS65950 device samples audio data at 16 kHz/16 bits in stereo. In the camcorder user case, a monophonic microphone is plugged on one channel of the TPS65950 device. Although only one channel is used, both left and right audio channels are transmitted to the McBSP. Moreover, the 16-bit channels are transmitted on two 32-bit words for this use case. The result is an I2S format with the following properties:

- Word width = 16 bits
- Sample length = 2 x 32 bits (two channels at 16 bits over 32 bits)
- Right-justified data format (zero-fill MSBs)

The TPS65950 device transmits two 32-bit frames that correspond to the two channels of a stereo signal, one on the low level of the frame synchronization signal, and the other on the high level. The microphone is monophonic; therefore, the McBSP2 is configured to receive only the right channel. Figure 21-74 shows the input data, CLKR, and FSR signal from the TPS65950 device.

Figure 21-74. I2S Format

mcbasp-091

21.6.1.2 Programming Flow

The McBSP2 is configured as a slave receiver device driven by the TPS65950 device. It is configured to receive input data (see [Figure 21-74](#)). When the configuration is complete, the sDMA controller can transfer data from [MCBSPLP_DRR_REG](#) to the external DRAM.

First, the correct functional clock must be selected in the system control module. The MCBSP2_CLKS bit of the CONTROL.CONTROL_DEVCONF0[6] register is set to 0 to make PER_96M_FCLK the functional clock of the module (CLKS).

Next, the McBSP2 clocks are enabled on the PRCM:

- Enable the functional clock: PRCM.CM_FLCKEN_PER[0] = 1
- Enable the interface clock: PRCM.CM_ILCKEN_PER[0] = 1

Then, the initialization procedure is followed (see [Figure 21-57](#)):

1. Put the receiver and frame-sync generator under reset:
 - [MCBSPLP_SPCR1_REG](#)[0] RRST = 0
 - [MCBSPLP_SPCR2_REG](#)[7] FRST = 0
2. Program the configuration registers as required:
 - a. Set one phase for the receive frame (only one channel is taken in account):
[MCBSPLP_RCR2_REG](#)[15] RPHASE = 0
 - b. Set the receive data delay to 0-bit data delay:
[MCBSPLP_RCR2_REG](#)[1:0] RDATDLY = 0
 - c. Set Receive Word Length to 32 bits:
[MCBSPLP_RCR1_REG](#)[7:5] RWDLEN1 = 5
 - d. Set the number of words per frame to 1:
[MCBSPLP_RCR1_REG](#)[14:8] RFRLN1 = 0
 - e. Set the threshold to one-half of the FIFO size (that is, 127):
[MCBSPLP_THRSH1_REG](#)[6:0] RTHRESHOLD = 0x7F
 - f. Set the receive sign-extension and justification mode to right-justify and zero-fill MSBs in [MCBSPLP_DRR_REG](#):
[MCBSPLP_SPCR1_REG](#)[14:13] RJUST = 0
 - g. Set the receive frame-synchronization mode, frame-synchronization pulses generated by an external device. FSR is an input pin.
[MCBSPLP_PCR_REG](#)[10] FSRM = 0
 - h. Set the receive frame-synchronization polarity to active high: The channel on the high level of FSR will be received.
[MCBSPLP_PCR_REG](#)[2] FSRP = 0
 - i. Set the receive clock mode: Receive clock is an input driven by an external clock with CLKR as an input pin.
[MCBSPLP_PCR_REG](#)[8] CLKR = 0
 - j. Set the receive clock polarity: Receive data sampled on the falling edge of CLKR.
[MCBSPLP_PCR_REG](#)[0] CLKRP = 0
 - k. Wait for two clock cycles.
3. Not applicable in receiver mode.
4. Release the receiver reset:
[MCBSPLP_SPCR1_REG](#)[0] RRST = 1
5. Internally generated frame-sync is not required:
 - a. The frame-sync generator reset is not released.
 - b. Wait for two clock cycles.

[Table 21-37](#) lists the registers involved during a transfer.

Table 21-37. McBSP2 Registers Print

Register Name	Address	Value	Value Description
MCBSPLP_SPCR1_REG	0x4902 2014	0x0000 0001	Receiver started
MCBSPLP_SPCR2_REG	0x4902 2010	0x0000 0000	Frame-synch generator under reset
MCBSPLP_RCR1_REG	0x4902 201C	0x0000 00a0	32-bit word length and 1 word per frame
MCBSPLP_RCR2_REG	0x4902 2018	0x0000 0000	0-bit data delay
MCBSPLP_THRSH1_REG	0x4902 2094	0x0000 007f	FIFO threshold
MCBSPLP_PCR_REG	0x4902 2048	0x0000 0000	Pin configuration

21.7 McBSP Registers

Table 21-38 shows the base address and address space for the OMAP35x module instances.

Table 21-38. Instance Summary

Module Name	Base Address (hex)	Size
McBSP1	0x4807 4000	4K bytes
McBSP5	0x4809 6000	4K bytes
McBSP2	0x4902 2000	4K bytes
McBSP3	0x4902 4000	4K bytes
McBSP4	0x4902 6000	4K bytes
SIDETONE_McBSP2	0x4902 8000	4K bytes
SIDETONE_McBSP3	0x4902 A000	4K bytes

21.7.1 McBSP Register Mapping Summary

CAUTION

The McBSP registers are limited to 32-bit data accesses. 16-bit and 8-bit are not allowed and can corrupt register content.

Table 21-39. McBSP1 Register Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address

Description	McBSPLP serial port control register 2		
Type	RW		

SPRUF98B—September 2008
[Submit Documentation Feedback](#)

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Read return 0x0 value	R	0x000000
9	FREE	Free Running Mode (When this bit is set, the module ignores the Msuspend input) 0x0: Free running mode is disabled 0x1: Free running mode is enabled	RW	0x0
8	SOFT	Soft Bit 0x0: SOFT Mode is disabled: the McBSP module stops its activity immediately following MSuspend assertion. 0x1: SOFT Mode is enabled: the McBSP module freezes its state after completion of the current operation when MSuspend is asserted.	RW	0x0
7	FRST	Frame-Sync Generator Reset 0x0: Frame-synchronization logic is reset. Frame-sync signal FSG is not generated by the sample-rate generator 0x1: Frame-sync signal FSG is generated after (FPER+1) number of CLKG clocks; i.e., all frame counters are loaded with their programmed values	RW	0x0
6	GRST	Sample-Rate Generator Reset 0x0: SRG is reset 0x1: SRG is pulled out of reset. CLKG is driven as per programmed value in SRG registers (SRGR[1,2])	RW	0x0
5:4	XINTM	Transmit Interrupt Mode (legacy) 0x0: Transmit interrupt is driven by XRDY 0x1: Transmit interrupt generated by end-of-frame 0x2: Transmit interrupt generated by a new frame synchronization 0x3: Transmit interrupt generated by XSYNCERR	RW	0x0
3	XSYNCERR	Transmit Synchronization Error (writing 0 to this bit clear the legacy transmit interrupt if asserted due to XSYNCERROR condition) 0x0: No synchronization error 0x1: Synchronization error detected by McBSP	RW	0x0
2	XEMPTY	Transmit Shift Register XSR Empty 0x0: XSR is empty 0x1: XSR is not empty	R	0x0
1	XRDY	Transmitter ready 0x0: Transmitter is not ready. 0x1: Transmitter is ready for new data in DXR	R	0x0
0	XRST	Transmitter reset. This resets and enables the transmitter. 0x0: The serial port transmitter is disabled and in reset state. 0x1: The serial port transmitter is enabled.	RW	0x0

Table 21-51. Register Call Summary for Register MCBSP_LP_SPCR2_REG

McBSP Integration

- [Hardware and Software Reset: \[0\] \[1\] \[2\]](#)

Bits	Field Name	Description	Type	Reset
14:13	RJUST	Receive Sign-Extension and Justification Mode 0x0: Right-justify and zero-fill MSBs in DRR 0x1: Right-justify and sign-extend MSBs in DRR 0x2: Left-justify and zero-fill LSBs in DRR 0x3: Reserved	RW	0x0
12:8	RESERVED	Read return 0x0 value	R	0x00
7	DXENA	DX Enabler 0x0: DX enabler is off 0x1: DX enabler is on	RW	0x0
6	RESERVED	Read return 0x0 value	R	0x0
5:4	RINTM	Receive Interrupt Mode (legacy) 0x0: Receive Interrupt driven by RRDY (i.e. end of word) and end of frame in A-bis mode 0x1: Receive Interrupt generated by end-of-block or end-of-frame in multichannel operation 0x2: Receive Interrupt generated by a new frame synchronization 0x3: Receive Interrupt generated by RSYNCERR	RW	0x0
3	RSYNCERR	Receive Synchronization Error (writing 0 to this bit clear the legacy receive interrupt if asserted due to RSYNCERROR condition) 0x0: No synchronization error 0x1: Synchronization error detected by McBSP	RW	0x0
2	RFULL	Receive Shift Register (RSR) Full 0x0: DRR is not read, RB is full and RSR is also full with new word 0x1: RB is not in overrun condition	R	0x0
1	RRDY	Receiver Ready 0x0: Receiver is not ready 0x1: Receiver is ready with data to be read from DRR	R	0x0
0	RRST	Receiver reset. This resets and enables the receiver. 0x0: The serial port receiver is disabled and in reset state. 0x1: The serial port receiver is enabled.	RW	0x0

Description	McBSPLP SRG register 2		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																GSYNC	CLKSP	CLKSM	FSGM	FPER											

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Read return 0x0 value	R	0x0000
15	GSYNC	<p>Sample Rate Generator Synchronization</p> <p>Only used when the external clock (CLKS) drives the SRG clock (CLKSM=0)</p> <p>0x0: The SRG clock (CLKG) is free running.</p> <p>0x1: The SRG clock (CLKG) is running. But CLKG is resynchronized and frame-sync signal (FSG) is generated only after detecting the receive frame-synchronization signal (FSR). Also, frame period, FPER,is a don't care because the period is dictated by the external frame-sync pulse.</p>	RW	0x0
14	CLKSP	<p>CLKS Polarity Clock Edge Select</p> <p>Only used when the external clock CLKS drives the SRG clock (CLKSM=0).</p> <p>0x0: Rising edge of CLKG and FSG.</p> <p>0x1: Falling edge of CLKG and FSG.</p>	RW	0x0

Bits	Field Name	Description	Type	Reset
13	CLKSM	McBSP SRG Clock Mode 0x0: SCLKME=0: SRG clock derived from the CLKS pin. SCLKME=1: SRG clock derived from the CLKR input pin. 0x1: SCLKME=0: SRG clock derived from the McBSPi_ICLK clock. SCLKME=1: SRG clock derived from the CLKX input pin.	RW	0x1
12	FSGM	Sample Rate Generator Transmit Frame-Synchronization Mode Used when FSXM=1 in the PCR. 0x0: Transmit frame-sync signal (FSX) is generated when transmit buffer is not empty. When FSGM=0, FPER and FWID are used to determine the frame synchronization period and width (external FSX is gated by the buffer empty condition). 0x1: Transmit frame-sync signal driven by the SRG frame-sync signal, FSG.	RW	0x0
11:0	FPER	Frame Period. This value + 1 determines when the next frame-sync signal becomes active. Range: 1 to 4096 CLKG periods	RW	0x000

14	IDLE_EN	Idle enable. This bit allows stopping all the clocks in the McBSP module. (legacy) 0x0: The McBSP is running 0x1: The clocks in the McBSP are shut off when both IDLE_EN=1 and his power domain is in idle mode (Force idle or Smart idle)	RW	0x0
13	XIOEN	Transmit General Purpose I/O Mode only when XRST=0 in SPCR[1,2] (legacy) 0x0: DX, FSX and CLKX are configured as serial port pins and do not function as general-purpose I/Os. 0x1: DX pin is a general purpose output. FSX and CLKX are general purpose I/Os. These serial port pins do not perform serial port operation.	RW	0x0
12	RIOEN	Receive General Purpose I/O Mode when RRST=0 in SPCR[1,2] (legacy) 0x0: DR, FSR, CLKR and CLKS are configured as serial port pins and do not function as general-purpose I/Os. 0x1: DR and CLKS pins are general purpose inputs; FSR and CLKR are general purpose I/Os. These serial port pins do not perform serial port operation. The CLKS pin is affected by a combination of RRST and RIOEN signals of the receiver.	RW	0x0
11	FSXM	Transmit Frame-Synchronization Mode 0x0: Frame-synchronization signal derived from an external source 0x1: Frame synchronization is determined by the SRG frame-synchronization mode bit FSGM in SRGR2.	RW	0x0
10	FSRM	Receive Frame-Synchronization Mode 0x0: Frame-Synchronization pulses generated by an external device. FSR is an input pin. 0x1: Frame synchronization generated internally by SRG. FSR is an output pin except when GSYNC=1 in SRGR.	RW	0x0

Bits	Field Name	Description	Type	Reset
9	CLKXM	<p>Transmitter Clock Mode</p> <p>When digital loop-back mode set (McBSPi.MCBSPLP_XCCR_REG[5] DLB=1), CLKXM bit is ignored. The internal transmit clock (not the mcbspi_clkx pin) is driven by the internal SRG and mcbspi_clkx pin is in high-impedance.</p> <p>0x0: Transmitter clock is driven by an external clock with CLKX as an input pin.</p> <p>0x1: CLKX is an output pin and is driven by the internal SRG.</p>	RW	0x0
8	CLKRM	<p>Receiver Clock Mode</p> <p>When digital loop-back mode set (McBSPi.MCBSPLP_XCCR_REG[5] DLB=1), CLKRM bit is ignored. The internal receive lock (not the mcbbsp1_clkr pin) is driven by the internal SRG and mcbbsp1_clkr pin is in high-impedance.</p> <p>0x0: Receive clock is an input driven by an external clock with CLKR as an input pin.</p> <p>0x1: CLKR is an output pin and is driven by the internal SRG.</p>	RW	0x0
7	SCLKME	<p>The frequency of CLKG is: $CLKG \text{ frequency} = (\text{Input clock frequency}) / (CLKGDV + 1)$</p> <p>SCLKME is used in conjunction with the CLKSM bit to select the input clock:</p> <p>0x0: CLKSM = 0: Signal on CLKS pin CLKSM = 1: McBSPi_ICLK clock</p> <p>0x1: CLKSM = 0: Signal on CLKR pin CLKSM = 1: Signal on CLKX pin</p>	RW	0x0
6	CLKS_STAT	<p>CLKS pin status. Reflects value on CLKS pin when selected as a general purpose input. (legacy)</p> <p>0x0: The signal on the CLKS pin is low</p> <p>0x1: The signal on the CLKS pin is high</p>	R	0x0
5	DX_STAT	<p>DX pin status. Reflects value driven on to DX pin when selected as a general purpose output. (legacy)</p> <p>0x0: Drive the signal on the DX pin low</p> <p>0x1: Drive the signal on the DX pin high</p>	RW	0x0
4	DR_STAT	<p>DR pin status. Reflects value on DR pin when selected as a general purpose input. (legacy)</p> <p>0x0: The signal on DR pin is low</p> <p>0x1: The signal on DR pin is high</p>	R	0x0
3	FSXP	<p>Transmit Frame-Synchronization Polarity</p> <p>0x0: Frame-synchronization pulse FSX is active high</p> <p>0x1: FFrame-synchronization pulse FSX is active low</p>	RW	0x0
2	FSRP	<p>Receive Frame-Synchronization Polarity</p> <p>0x0: Frame-synchronization pulse FSR is active high</p> <p>0x1: Frame-synchronization pulse FSR is active low</p>	RW	0x0
1	CLKXP	<p>Transmit Clock Polarity</p> <p>0x0: Transmit data driven on rising edge of CLKX</p> <p>0x1: Transmit data driven on falling edge of CLKX</p>	RW	0x0

Bits	Field Name	Description	Type	Reset
0	CLKRP	Receive Clock Polarity 0x0: Receive data sampled on falling edge of CLKR 0x1: Receive data sampled on rising edge of CLKR	RW	0x0

RESERVED																XEMPTYEOF	RESERVED	XOVFLSTAT	XUNDFLSTAT	XRDY	XEOF	XFSX	XSYNCERR	RESERVED	XOVFLSTAT	XUNDFLSTAT	XRDY	XEOF	XFSX	XSYNCERR	

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Read return 0x0 value	R	0x000000
14	XEMPTYEOF	Transmit Buffer Empty at end of frame (XEMPTYEOF is set to one when a complete frame was transmitted and the transmit buffer is empty). Writing 1 to this bit clears the bit. 0x0: Transmit buffer NOT Empty at end of frame 0x1: Transmit buffer Empty at end of frame; Writing 1 to this bit clears the bit.	RW	0x0
13	RESERVED	Read return 0x0 value	R	0x0
12	XOVFLSTAT	Transmit Buffer Overflow (XOVFLSTAT bit is set to one when transmit buffer overflow; the data which is written while overflow condition is discarded). Writing 1 to this bit clears the bit. 0x0: Transmit buffer NOT overflow 0x1: Transmit buffer overflow; Writing 1 to this bit clears the bit.	RW	0x0
11	XUNDFLSTAT	Transmit Buffer Underflow (XUNDFLSTAT bit is set to one when the transmit data buffer is empty new data is required to be transmitted). Writing 1 to this bit clears the bit. 0x0: the transmit data buffer is NOT empty new data is required to be transmitted. 0x1: the transmit data buffer is empty new data is required to be transmitted. Writing 1 to this bit clears the bit.	RW	0x0
10	XRDY	Transmit Buffer Threshold Reached (XRDY bit is set to one when the transmit buffer free locations are equal or above the THRSH2_REG value). Writing 1 to this bit clears the bit. 0x0: Transmit buffer occupied locations are below the THRSH2_REG value). 0x1: Transmit buffer occupied locations are equal or above the THRSH2_REG value). Writing 1 to this bit clears the bit.	RW	0x0
9	XEOF	Transmit End Of Frame (XEOF is set to one when a complete frame was transmitted). Writing 1 to this bit clears the bit. 0x0: complete frame was NOT transmitted 0x1: complete frame was transmitted; Writing 1 to this bit clears the bit.	RW	0x0

Bits	Field Name	Description	Type	Reset
8	XFSX	Transmit Frame Synchronization (XFSX bit is set to one when a new transmit frame synchronization is asserted). Writing 1 to this bit clears the bit. 0x0: new transmit frame synchronization is NOT asserted 0x1: new transmit frame synchronization is asserted; Writing 1 to this bit clears the bit.	RW	0x0
7	XSYNCERR	Transmit Frame Synchronization Error (XSYNCERR is set to one when a transmit frame synchronization error is detected). Writing 1 to this bit clears the bit. 0x0: Transmit frame synchronization error is NOT detected 0x1: Transmit frame synchronization error is detected. Writing 1 to this bit clears the bit.	RW	0x0
6	RESERVED	Read return 0x0 value	R	0x0
5	ROVFLSTAT	Receive Buffer Overflow (ROVFLSTAT bit is set to one when receive buffer overflow; the data which is written while overflow condition is discarded). Writing 1 to this bit clears the bit. 0x0: receive buffer NOT overflow 0x1: receive buffer overflow; Writing 1 to this bit clears the bit.	RW	0x0
4	RUNDFLSTAT	Receive Buffer Underflow (RUNDFLSTAT bit is set to one when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined). Writing 1 to this bit clears the bit. 0x0: read operation is performed to the receive data register while receive buffer is NOT empty 0x1: read operation is performed to the receive data register while receive buffer is empty; Writing 1 to this bit clears the bit.	RW	0x0
3	RRDY	Receive Buffer Threshold Reached (RRDY bit is set to one when the receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit clears the bit. 0x0: receive buffer occupied locations are below the THRSH1_REG value). 0x1: receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit clears the bit.	RW	0x0
2	REOF	Receive End Of Frame (REOF is set to one when a complete frame was received). Writing 1 to this bit clears the bit. 0x0: complete frame was NOT received 0x1: complete frame was received; Writing 1 to this bit clears the bit.	RW	0x0
1	RFSR	Receive Frame Synchronization (RFSR bit is set to one when a new receive frame synchronization is asserted). Writing 1 to this bit clears the bit. 0x0: new receive frame synchronization is NOT asserted 0x1: new receive frame synchronization is asserted; Writing 1 to this bit clears the bit.	RW	0x0
0	RSYNCERR	Receive Frame Synchronization Error (RSYNCERR is set to one when a receive frame synchronization error is detected). Writing 1 to this bit clears the bit. 0x0: receive frame synchronization error is NOT detected 0x1: receive frame synchronization error is detected. Writing 1 to this bit clears the bit.	RW	0x0

RESERVED																RBUFFSTAT															

Bits	Field Name	Description	Type	Reset
31:11	RESERVED	Read return 0x0 value	R	0x000000
10:0 ⁽¹⁾	RBUFFSTAT	Receive Buffer Status (indicates the number of occupied locations inside receive buffer). The RBUFFSTAT value reflects the buffer status on the L4 clock domain and it can be smaller than the real number of the occupied locations which are seen by the receive state machine.	R	0x00

⁽¹⁾ RBUFFSTAT is an 11-bit field in McBSP2. For other McBSPs, RBUFFSTAT is an 8-bit field (bits 7 to 10 are reserved).

RESERVED																FIRCOEFF															

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Read return 0x0 value	R	0x0000
15:0	FIRCOEFF	FIR coefficients control register (the coefficients are programmed by successive write sequence of all 128 FIR coefficients) The write sequence should start with the coefficient 0. In order to enable the write to this register the COEFFWREN bit in SSELCR_REG should be set to one. When this bit is set the read operation will return only the last written value. After a complete FIR coefficients write sequence the COEFFWREN should be set to zero. A read sequence from SFIRCR_REG while COEFFWREN is set to zero will return the coefficients values starting from 0 to 127. The write coefficient address is set to 0 by the change of COEFFWREN from 0 to 1. The read coefficient address is set to 0 by the change of COEFFWREN from 1 to 0	RW	0x0000

Multimedia Card/Secure Digital/ Secure Digital I/O (MMC/SD/SDIO) Card Interface

This chapter describes the features and functions of the multimedia card/secure digital/secure digital I/O (MMC/SD/SDIO) card interface for the OMAP35x Applications Processor.

Topic	Page
22.1 MMC/SD/SDIO Overview	2974
22.2 MMC/SD/SDIO Environment	2978
22.3 MMC/SD/SDIO Integration	2986

22.7 MMC/SD/SDIO Registers	3033
22.8 Revision History	3070

22.1 MMC/SD/SDIO Overview

The OMAP35x Applications Processor contains three multimedia card high-speed/secure data/secure digital I/O (MMC/SD/SDIO) host controller which provides an interface between a local host (LH) such as a microprocessor unit (MPU) or digital signal processor (DSP) and either MMC, SD memory cards, or SDIO cards and handles MMC/SD/SDIO transactions with minimal LH intervention.

The application interface manages transaction semantics. The MMC/SD/SDIO host controller deals with MMC/SD/SDIO protocol at transmission level, data packing, adding cyclic redundancy checks (CRC), start/end bit, and checking for syntactical correctness.

The application interface can send every MMC/SD/SDIO command and either poll for the status of the adapter or wait for an interrupt request, which is sent back in case of exceptions or to warn of end of operation.

The application interface can read card responses or flag registers. It can also mask individual interrupt sources. All these operations can be performed by reading and writing control registers. The MMC/SD/SDIO host controller also supports two DMA channels.

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

There are three MMC/SD/SDIO host controllers inside the device: [Figure 22-1](#) gives an overview of the MMC/SD/SDIO controller instances 1 and 3, and [Figure 22-2](#) gives an overview of the MMC/SD/SDIO2 controller instance.

Figure 22-1. MMC/SD/SDIO1 and 3 Overview

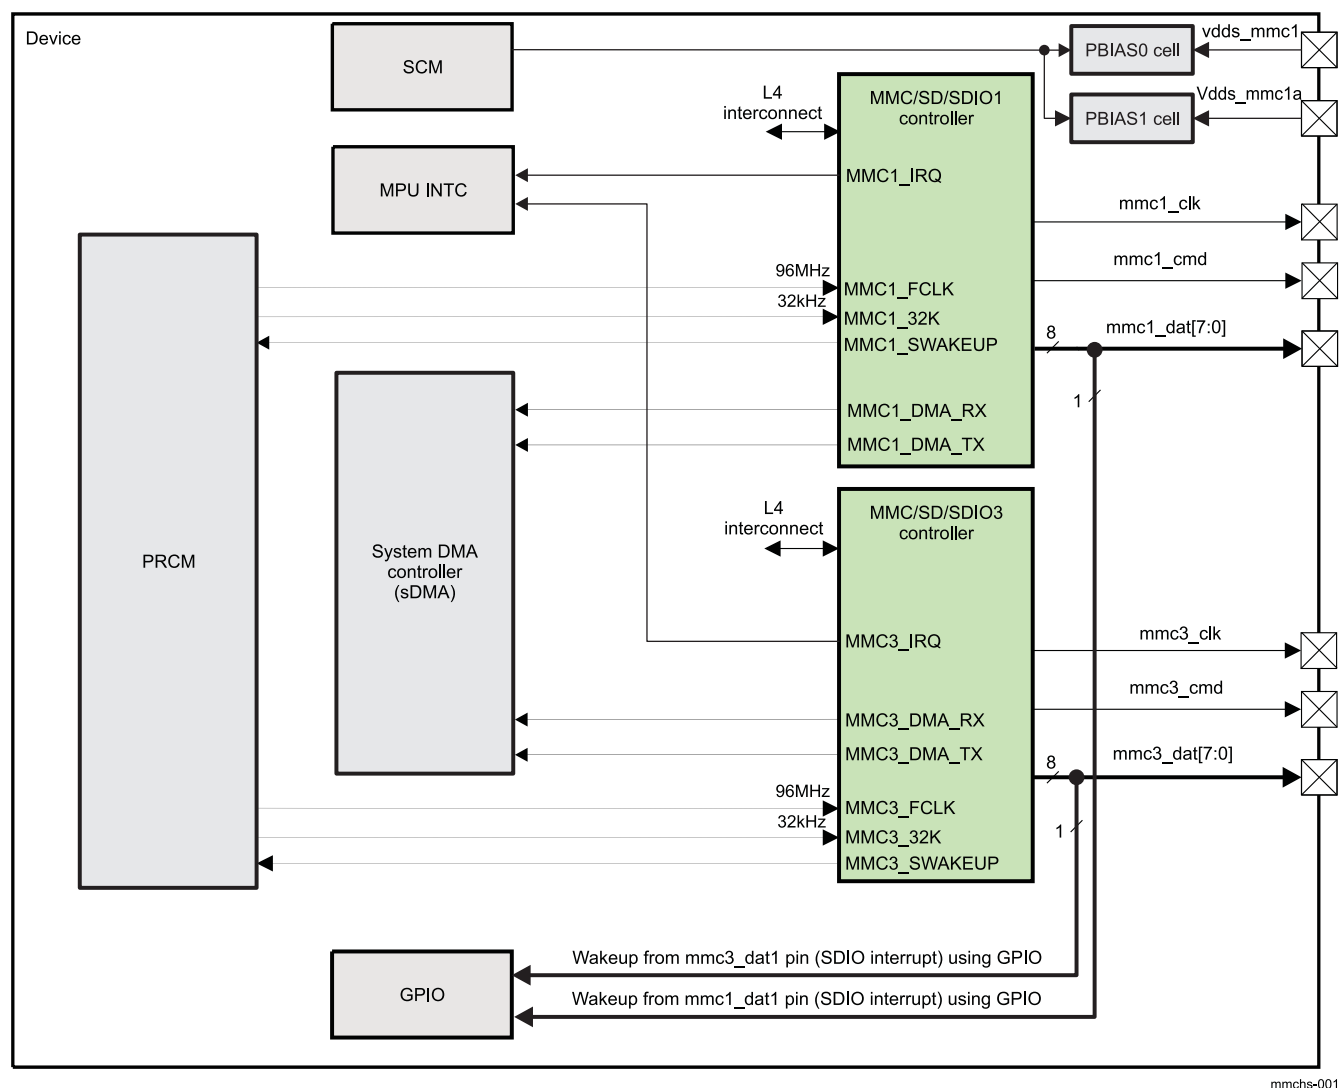

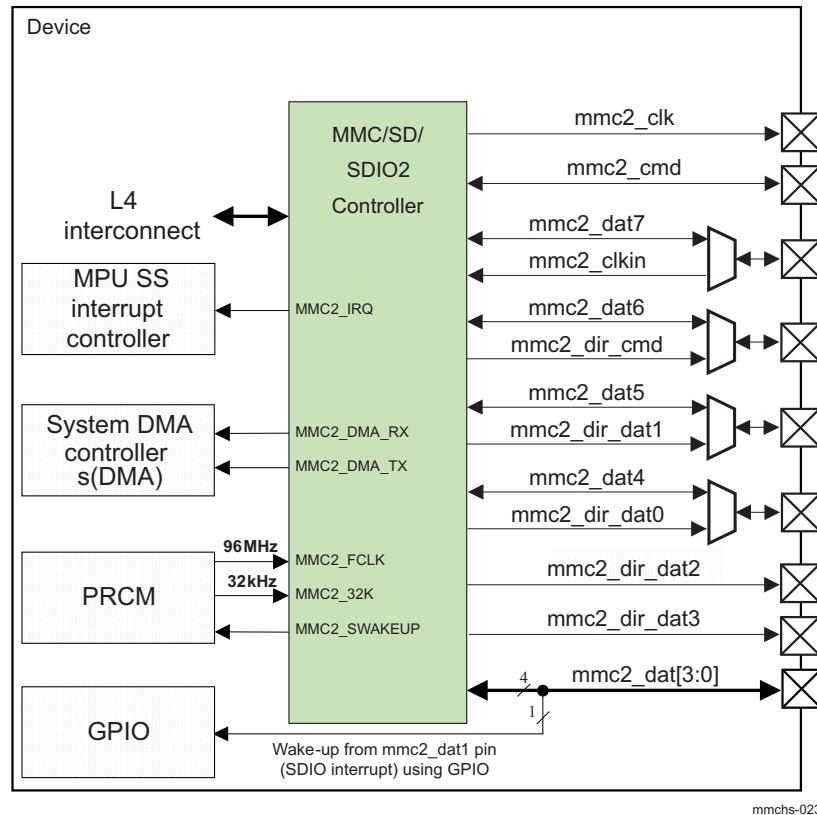

Figure 22-2. MMC/SD/SDIO2 Overview

22.1.1 MMC/SD/SDIO Features

The main features of the MMC/SD/SDIO host controller are:

- Full compliance with MMC command/response sets as defined in the *Multimedia Card System Specification*, v4.2. Including high-capacity (size >2GB) cards HC MMC.
- Full compliance with SD command/response sets as defined in the *SD Memory Card Specifications*, v2.0. Including high-capacity cards SDHC up to 32 GB.
- Full compliance with SDIO command/response sets and interrupt/read-wait mode as defined in the *SDIO Card Specification, Part E1*, v1.10
- Compliance with sets as defined in the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v1.00
- Full compliance with MMC bus testing procedure as defined in the *Multimedia Card System Specification*, v4.2
- Full compliance with CE-ATA command/response sets as defined in the *CE-ATA Standard Specification*
- Full compliance with ATA for MMCA specification
- Flexible architecture allowing support for new command structure
- Support:
 - 1-bit or 4-bit transfer mode specifications for SD and SDIO cards
 - 1-bit, 4-bit, or 8-bit transfer mode specifications for MMC cards
- Built-in 1024-byte buffer for read or write
- 32-bit-wide access bus to maximize bus throughput
- Single interrupt line for multiple interrupt source events
- Two slave DMA channels (1 for TX, 1 for RX)
- Designed for low power

- Programmable clock generation
- Support SDIO Read Wait and Suspend/Resume functions
- Support Stop at block gap
- Support command completion signal (CCS) and command completion signal disable (CCSD) management as specified in the *CE-ATA Standard Specification*

The known limitations are as follows:

- No built-in hardware support for error correction codes (ECC). See the *Multimedia Card System Specification*, v4.2, and the *SD Memory Card Specifications*, v2.0, for details about ECC.
- The maximum block size defined in the *SD Memory Card Specifications*, v2.0, that the host driver can read and write to the buffer in the host controller is 2048 bytes. MMC supports a maximum block size of 1024 bytes. Up to 512 byte transfers, the buffer in MMC is considered as a double buffering with ping-pong management; half of the buffer can be written while the other part is read. For 512 to 1024 byte transfers, the entire buffer is dedicated to the transfer (read only or write only).

Note: For more information about timing limitations, refer to your device-specific data manual.

The differences between the MMC/SD/SDIO host controllers and a Standard SD host controller are defined by the *SD Card Specification, Part A2*, *SD Host Controller Standard Specification*, v1.00, as follows:

- The MMC/SD/SDIO host controllers support MMC cards.
- The MMC/SD/SDIO host controller is defined as a DMA slave device. Standard SD host controller is defined as DMA master controller that can start and stop a DMA transfer. MMC/SD/SDIO host controllers support DMA transfers through slave DMA requests.
- The clock divider in MMC/SD/SDIO host controller supports a wider range of frequency than specified in the *SD Memory Card Specifications*, v2.0. The MMC/SD/SDIO host controller supports odd and even clock ratio.
- The MMC/SD/SDIO host controller supports configurable busy timeout.

22.2 MMC/SD/SDIO Environment

One MMC/SD/SDIO host controller can support one MMC memory card, one SD memory card, or one SDIO card.

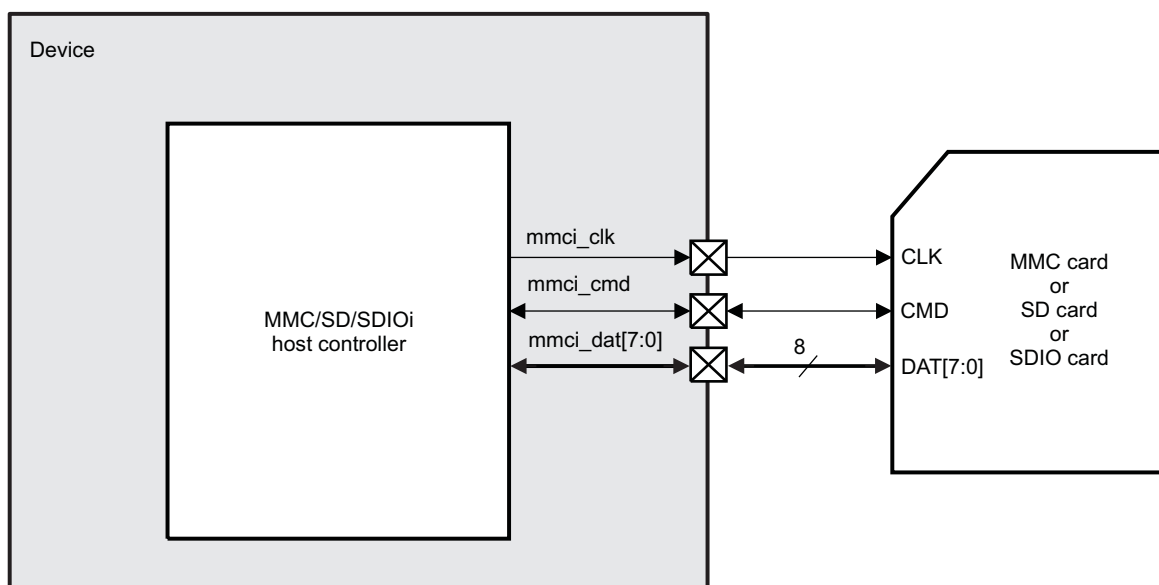

Other combinations (for example, two SD cards, one MMC card, and one SD card) are not supported through a single controller.

- The first controller (MMC/SD/SDIO1) integrates an internal transceiver that allows a direct connection to the MMC/SD/SDIO card (1.8 and 3V), without external transceiver.
- The second controller (MMC/SD/SDIO2) allows connecting MMC/SD/SDIO cards (only 1.8V cards) or an external device that uses the MMC/SD/SDIO interface (WLAN device for example). The second instance also supports an external transceiver and provides direction signals for data and command.
- The third controller (MMC/SD/SDIO3) allows connecting MMC/SD/SDIO cards (only 1.8V cards) or an external device that uses the MMC/SD/SDIO interface (Wireless USB card for example). This interface is used without external transceiver.

22.2.1 MMC/SD/SDIO Connected to an MMC, an SD, or an SDIO Card

Figure 22-3 shows MMC/SD/SDIOi host controller, instance 1, 2 or 3, connected to an MMC, an SD, or an SDIO card and its related external connections.

Figure 22-3. MMC/SD/SDIO Connected to an MMC, an SD, or an SDIO Card Without External Transceiver

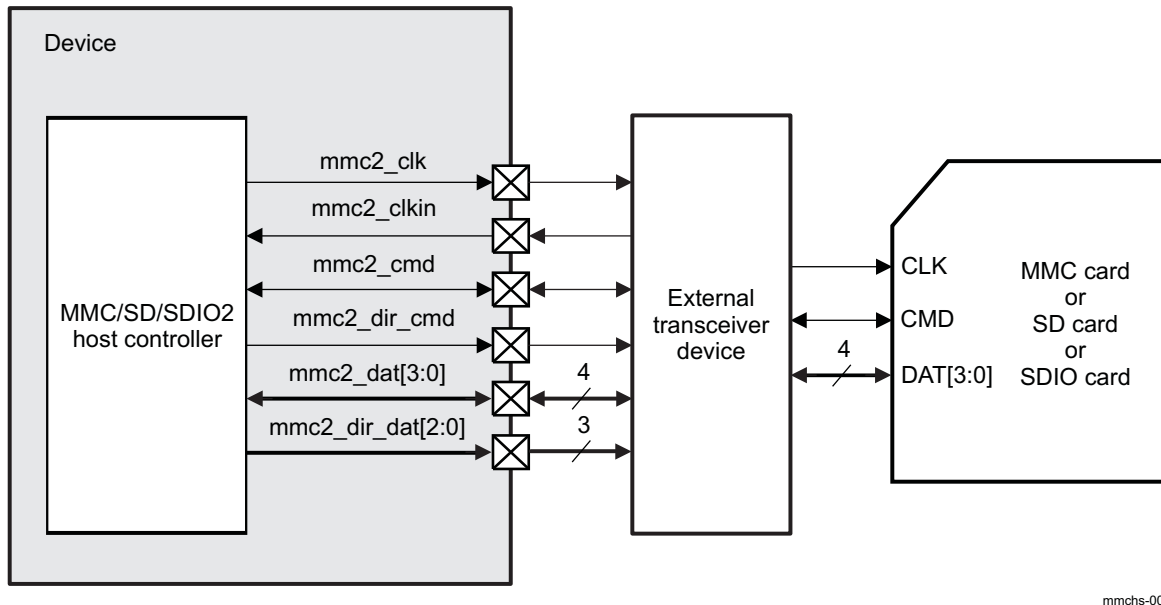

mmchs-002

22.2.2 MMC/SD/SDIO Connected to an MMC, an SD, or an SDIO Card Through an External Transceiver Device

This connection is supported only by the MMC/SD/SDIO2 host controller. Figure 22-4 shows the MMC/SD/SDIO2 host controller connected to an MMC, an SD, or an SDIO card through an external transceiver device.

Figure 22-4. MMC/SD/SDIO2 Connected to an MMC, an SD, or an SDIO Card with External Transceiver

22.2.3 MMC/SD/SDIO Functional Interfaces

22.2.3.1 Basic MMC/SD/SDIOi Pins Without External Transceiver

Figure 22-5 shows the MMC/SD/SDIOi host controller interface signals (instance 1, 2 or 3).

Figure 22-5. MMC/SD/SDIOi Interface Signals

Table 22-1 describes the MMC/SD/SDIOi inputs/outputs.

Table 22-1. MMC/SD/SDIOi I/O Description

Signal Name	I/O	Description	Reset Value
<code>mmci_clk</code>	O	External clock for MMC/SD/SDIO card	0
<code>mmci_cmd</code>	I/O	Command signal	0
<code>mmci_dat[7:0]</code>	I/O	Data signals	0

22.2.3.2 Basic MMC/SD/SDIO2 Pins with External Transceiver

Figure 22-6 shows the MMC/SD/SDIO2 host controller interface signals.

Figure 22-6. MMC/SD/SDIO2 Interface Signals

Table 22-2 describes the MMC/SD/SDIO2 inputs/outputs.

Table 22-2. MMC/SD/SDIO2 I/O Description

Signal Name	I/O	Description	Reset Value
mmc2_clk	O	External clock for MMC/SD/SDIO card	0
mmc2_clkin	I	Input clock from MMC/SD/SDIO card	0
mmc2_cmd	I/O	Command signal	0
mmc2_dir_cmd	O	Direction control for mmc2_cmd signal case an external transceiver is used (high when transmit, low when receive)	0
mmc2_dat[3:0]	I/O	Data signals	0
mmc2_dir_dat0	O	Direction control for mmc2_dat0 signal when an external transceiver is used (high when transmit, low when receive)	0
mmc2_dir_dat1	O	Direction control for mmc2_dat1 and mmc2_dat3 signal when an external transceiver is used (high when transmit, low when receive)	0
mmc2_dir_dat2	O	Direction control for mmc2_dat2 signal when an external transceiver is used (high when transmit, low when receive)	0
mmc2_dir_dat3	O	Direction control for mmc2_dat[7:4] signal when an external transceiver is used (high when transmit, low when receive). Unusable on the device because mmci_dat[7:4] are muxed with other direction control signals. See the <i>System Control Module</i> chapter for further details on the pin multiplexing.	0

22.2.3.3 MMC/SD/SDIO Protocol and Data Format

The bus protocol between the MMC/SD/SDIOi host controller and the card is message-based. Each message is represented by one of the following parts:

Command: a command starts an operation. The command is transferred serially from the MMC/SD/SDIO host controller to the card on the mmci_cmd line.

Response: a response is an answer to a command. The response is sent from the card to the MMC/SD/SDIO host controller. It is transferred serially on the mmci_cmd line.

Data: data are transferred from the MMC/SD/SDIOi host controller to the card or from a card to the MMC/SD/SDIO host controller using the DATA lines.

Busy: the mmci_dat0 signal is maintained low by the card as far as it is programming the data received.

CRC status: CRC result is sent by the card through the mmci_dat0 line when executing a write transfer. In the case of transmission error, occurring on any of the active data lines, the card sends a negative CRC status on mmci_dat0. In the case of successful transmission, over all active data lines, the card sends a positive CRC status on mmci_dat0 and starts the data programming procedure.

22.2.3.3.1 Protocol

There are two types of data transfer:

- Sequential operation
- Block-oriented operation

There are specific commands for each type of operation (sequential or block-oriented).

See the *Multimedia Card System Specification*, v4.2, the *SD Memory Card Specifications*, v2.0, and the *SDIO Card Specification, Part E1*, August 2004, for details about commands and programming sequences supported by the MMC, SD, and SDIO cards.

Figure 22-7 and Figure 22-8 show how sequential operations are defined. Sequential operation is only for 1-bit transfer and initiates a continuous data stream. The transfer terminates when a stop command follows on the mmci_cmd line.

CAUTION

Stream commands are supported only by MMC cards.

Figure 22-7. Sequential Read Operation (MMC Cards Only)

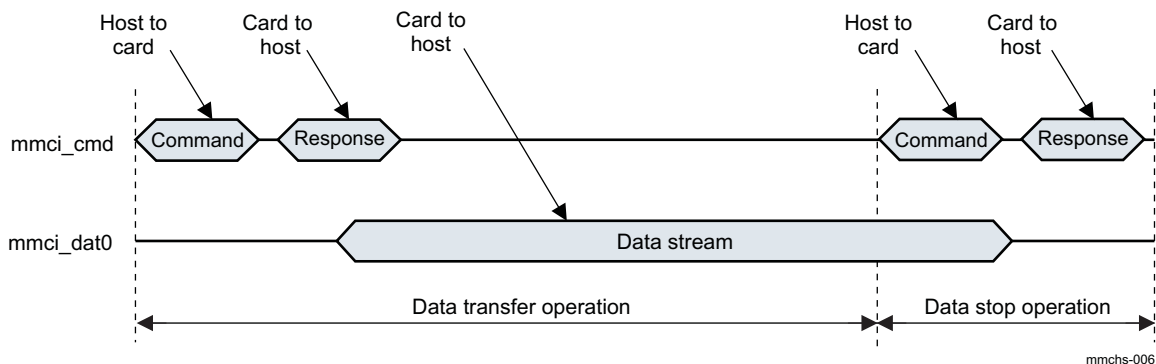

Figure 22-8. Sequential Write Operation (MMC Cards Only)

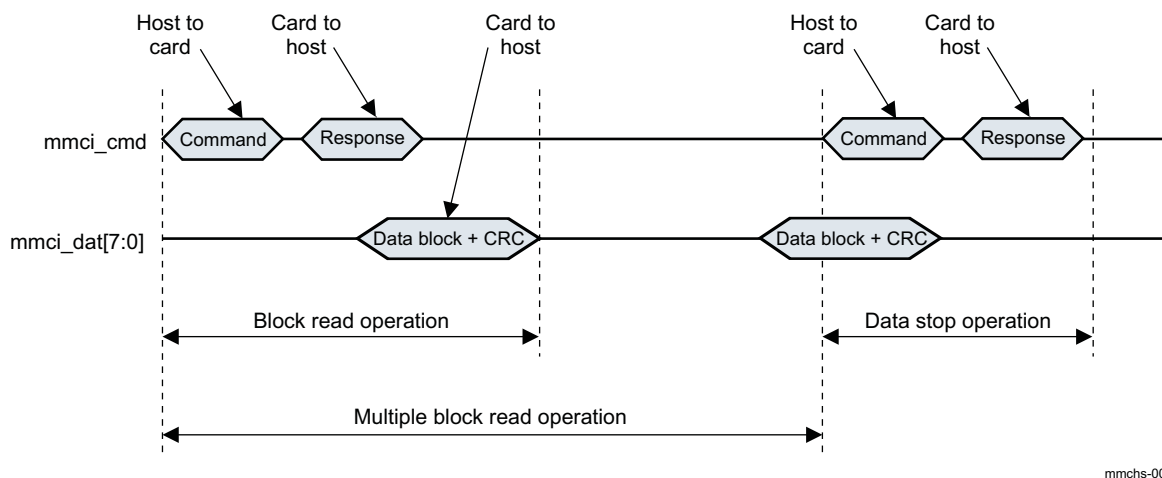

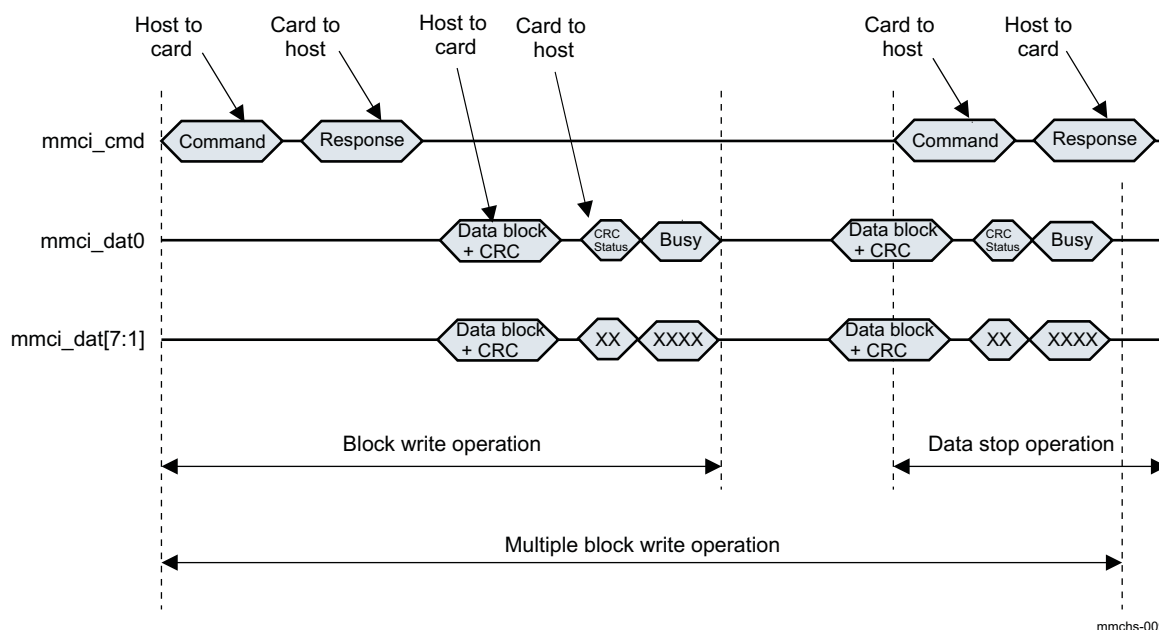

Figure 22-9 and Figure 22-10 show how multiple block-oriented operations are defined. A multiple block-oriented operation sends a data block plus CRC bits. The transfer terminates when a stop command follows on the mmci_cmd line. These operations are available for all kinds of cards.

Figure 22-9. Multiple Block Read Operation

Figure 22-10. Multiple Block Write Operation with Card Busy Signal

Notes:

1. The card busy signal is not always generated by the card; the previous examples show a particular case.
2. It is software responsibility to do a software reset (set MMCI_MMCHS_SYSCTL[26] SRD bit to 0x1) after data timeout to ensure mmci_clk is stopped
3. For multiblock transfer, and especially for MMC cards, you can abort a transfer without using a stop command. Use a CMD23 before data transfer to define the number of blocks that will be transferred, then the transfer stops automatically after the last block (if the MMC card supports this feature).

22.2.3.3.2 Data Format

Coding Scheme for Command Token

Command tokens always start with 0 and end with 1. The second bit is a transmitter bit: 1 for a host command. The content is the command index (coded by 6 bits) and an argument (for example, an address), coded by 32 bits. The content is protected by 7-bit CRC checksum (see [Figure 22-11](#)).

Figure 22-11. Command Token Format

Coding Scheme for Response Token

Response tokens always start with 0 and end with a 1. The second bit is a transmitter bit: 0 for a card response. The content is different for each type of response (R1, R2, R3, R4, and R5 R6 [for SDIO]) and the content is protected by 7-bit CRC checksum (see [Figure 22-12](#) and [Figure 22-13](#)). Depending on the type of commands sent to the card, the [MMCHS_CMD](#) register must be configured differently to avoid false CRC or index errors to be flagged on command response (see [Table 22-3](#)). For more details about response types, see the *Multimedia Card System Specification*, v4.2, the *SD Memory Card Specifications*, v2.0, or the *SDIO Card Specification, Part E1*, v1.10.

Figure 22-12. Response Token Format (R1, R3, R4, R5, R6)

Figure 22-13. Response Token Format (R2)

Table 22-3. Relation Between Configuration and Name of Response Type⁽¹⁾

Response Type MMCI.MMCHS_CMD[17:16] RSP_TYPE	Index Check Enable MMCI.MMCHS_CMD[20] CICE	CRC Check Enable MMCI.MMCHS_CMD[19] CCCE	Name of Response Type
00	0	0	No Response
01	0	1	R2
10	0	0	R3 (R4 for SD cards)
10	1	1	R1, R6, R5
11	1	1	R1b, R5b

⁽¹⁾ The MMC/SD/SDIO host controller assumes that both clocks may be switched off, whatever the value set in the MMCI.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY bit.

Coding Scheme for Data Token

Data tokens always start with 0 and end with 1 (see Figure 22-14, Figure 22-15, and Figure 22-16).

22.3 MMC/SD/SDIO Integration

Figure 22-17 shows the internal connections between the three instances of the MMC/SD/SDIO host controller and the other modules

Figure 22-17. MMC/SD/SDIO1 Integration

mmchs-016

22.3.1 Clocking, Reset, and PowerManagement Scheme

22.3.1.1 Clocks

22.3.1.1.1 Module Clocks

The MMC/SD/SDIO receives three clocks:

- A fixed functional clock of 96 MHz (the MMCi_FCLK) independent of the device external clock frequency
- An interface clock (the MMCi_ICLK) for interfacing with L4 interconnects (register accesses)
- A debounce clock, the MMCi_32K for reset process only

All these clocks are generated and controlled by the power, reset, and clock manager (PRCM) module (see the *Power Reset and Clock Management* chapter for more information).

22.3.1.1.2 Power Management

The MMC/SD/SDIO host controller can enter into different modes and save power:

- Normal mode
- Idle mode

The two modes are mutually exclusive (the module can be in normal mode or in idle mode). The MMC/SD/SDIO host controller is compliant with the PRCM module handshake protocol.

Normal Mode

The autogating of interface and functional clocks occurs when the following conditions are met:

- The MMCI.MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1 (1 = 1 for MMC/SD/SDIO1, 2 for MMC/SD/SDIO2 and 3 for MMC/SD/SDIO3 instances).
- There is no transaction on the MMC interface.

The autogating of interface and functional clocks stops when the following conditions are met:

- A register access occurs through the L4 interconnect.
- A wake-up event occurs (an interrupt from a SDIO card).
- A transaction on the MMC/SD/SIO interface starts.

Then the MMC/SD/SDIO host controller enters in low-power state (MMCI_ICLK clock autogated) even if MMCI.MMCHS_SYSCONFIG[0] AUTOIDLE is set to 0.

The functional clock is internally switched off and only interconnect read and write accesses are allowed.

Idle Mode

The MMCI_ICLK and MMCI_FCLK clocks provided to MMC/SD/SDIO are switched off upon a PRCM module request. They are switched back upon module request.

The MMC/SD/SDIO host controller complies with the PRCM module handshaking protocol:

- Idle request from the system power manager
- Idle acknowledgment from the MMC/SD/SDIO host controller
- Wake-up request from the MMC/SD/SDIO host controller

The idle acknowledgment varies according to the MMCI.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field:

- 0x0: Force-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request unconditionally.
- 0x1: No-idle mode. The MMC/SD/SDIO host controller ignores the system power manager request and behaves normally as if the request was not asserted.
- 0x2: Smart-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state.

During the smart-idle mode period, the MMC/SD/SDIO host controller acknowledges that the MMCI_ICLK and MMCI_FCLK clocks may be switched off whatever the value set in the MMCI.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY field.

Transition from Normal Mode to Smart-Idle Mode

Smart-idle mode is enabled when the MMCI.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x2.

The MMC/SD/SDIOi host controller goes into idle mode when the PRCM issues an idle request, according to its internal activity.

During normal to idle mode transition, any access to the registers of the MMC/SD/SDIOi host controller generates an error as long as the MMCI_ICLK clock is alive. The PRCM.CM_IDLEST1_CORE[25] ST_MMC2 and (respectively the PRCM.CM_IDLEST1_CORE[24] ST_MMC1 bit) is set to 0x0 when the MMC/SD/SDIO2 module (respectively the MMC/SD/SDIO1 module) can be accessed.

The MMC/SD/SDIO host controller acknowledges the idle request from the PRCM after ensuring the following:

- The current multi/single-block transfer is completed.
- Any interrupt or DMA request is asserted.
- There is no card interrupt on mmci_dat[1] signal.

As long as the MMC/SD/SDIOi controller do not acknowledge the idle request, if an event occurs, the MMC/SD/SDIOi host controller can still generate an interrupt or a DMA request. In this case, the module ignores the idle request from the PRCM.

As soon as the MMC/SD/SDIOi controller acknowledges the idle request from the PRCM, the module does not assert any new interrupt or DMA request.

Wakeup Event in Smart-Idle Mode

The wake-up feature is enabled when the following enable wake-up bits are set:

- MMCI.MMCHS_SYSCONFIG[2] ENAWAKEUP bit is set to 0x1
- MMCI.MMCHS_HCTL[24] IWE bit is set to 0x1
- MMCI.MMCHS_IE[8] CIRQ_ENABLE bit is set to 0x1

The wakeup is generated only in smart-idle mode only, when module is in idle mode.

Table 22-4 lists the supported cases in smart-idle mode.

Table 22-4. SmartIdle Mode and Wakeup Capabilities

Mode	MMCI_ICLK clock	MMCI_FCLK clock	Wake-up Event
Card interrupt	May be switched off ⁽¹⁾	May be switched off ⁽¹⁾	The module sends an asynchronous wake-up request on detection of a card interrupt on mmci_dat[1] signal

⁽¹⁾ The MMC/SD/SDIOi host controller assumes that both clocks may be switched off, whatever the value set in the MMCI.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY bit.

Transition from Smart-Idle Mode to Normal Mode

The MMC/SD/SDIO host controller detects the end of the idle period when the PRCM deasserts the idle request.

For the wake-up event, there is a corresponding interrupt status in the MMCI.MMCHS_STAT register. The MMC/SD/SDIOi host controller operates the conversion between wake-up and interrupt (or DMA request) upon exit from smart-idle mode if the associated enable bit is set in the MMCI.MMCHS_ISE register.

Interrupts and wake-up events have independent enable/disable controls, accessible through the MMCI.MMCHS_HCTL and MMCI.MMCHS_ISE registers. The overall consistency must be ensured by software.

The interrupt status register MMCI.MMCHS_STAT is updated with the event that caused the wake-up in the CIRQ bit when the MMCI.MMCHS_IE[8] CIRQ_ENABLE associated bit is enabled.

Then, the wake-up event at the origin of the transition from smart-idle mode to normal mode is converted into its corresponding interrupt or DMA request. (The MMCI.MMCHS_STAT register is updated and the status of the interrupt signal changes.)

When the idle request from the PRCM is deasserted, the module switches back to normal mode. The module is fully operational.

Force-Idle Mode

Force-idle mode is enabled when the MMCI.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0.

Force-idle mode is an idle mode where the MMC/SD/SDIOi host controller responds unconditionally to the idle request from the PRCM. Moreover, in this mode, the MMC/SD/SDIOi host controller unconditionally deasserts interrupts and DMA request lines asserted.

The transition from normal mode to force-idle mode does not affect the bits of the MMCi.MMCHS_STAT register.

In force-idle mode, the interrupt and DMA request lines are deasserted. MMCi_ICLK and MMCi_FCLK can be switched off.

CAUTION

In Force-Idle mode, an idle request from the PRCM during a command or a data transfer can lead to an unexpected and unpredictable result. When the module is idle, any access to the module generates an error as long as the MMCi_ICLK clock is alive.

The module exits the force-idle mode when the PRCM deasserts the idle request. Then the module switches back to normal mode. The module is fully operational. Interrupt and DMA request lines are optionally asserted one clock cycle later.

22.3.1.2 Resets

22.3.1.2.1 Hardware Reset

The module is reinitialized by the hardware when the active-low reset signal (CORE_RST), synchronous to the MMCi_ICLK clock is asserted on the input pin MMCi_RESET (see the *Power, Reset, and Clock Management* chapter for more information).

A global status bit RESETDONE is provided in the status register MMCi.MMCHS_SYSSTATUS[0]. This bit is set to 1 when all the different clock domain resets (interface domain, functional domain, and 32K domain) have been released.

The MMCi.MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by the software to check if the module is ready-to-use after a hardware reset.

Note: Functional clock MMCi_FCLK, interface clock MMCi_ICLK, and debounce clock MMCi_32K must be provided to the module to allow the RESETDONE status bit to be set.

This hardware reset signal has a global reset action on the module. All configuration registers and all statemachines are reset in all clock domains.

22.3.1.2.2 Software Reset

The module is reinitialized by software through the MMCi.MMCHS_SYSCONFIG[1] SOFTRESET bit. This bit has the same action on the module logic as the hardware MMCi_RESET signal except for:

- Debounce logic
- MMCi.MMCHS_PSTATE, MMCi.MMCHS_CAPA, and MMCi.MMCHS_CUR_CAPA registers (see corresponding register descriptions)

The SOFTRESET bit is active high. The bit is automatically reinitialized to 0 by the hardware. The MMCi.MMCHS_SYSCTL[24] SRA bit has the same action as the SOFTRESET bit on the design.

The MMCi.MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by the software to check if the module is ready-to-use after a software reset.

Moreover, two partial software reset bits are provided:

- MMCi.MMCHS_SYSCTL[26] SRD bit
- MMCi.MMCHS_SYSCTL[25] SRC bit

These two reset bits are useful to reinitialize data or command processes respectively in case of line conflict. When set to 1, a reset process is automatically released when the reset completes:

- The MMCI.MMCHS_SYSCCTL[26] SRD bit resets all finite state-machines and status management that handle data transfers on both the interface and functional side.
- The MMCI.MMCHS_SYSCCTL[25] SRC bit resets all finite state-machines and status management that handle command transfers on both the interface and functional side.

22.3.1.3 Power Domain

MMC/SD/SDIOi power is supplied by the CORE power domain (see the *Power Reset and Clock Management* chapter for more information).

When the MMC/SD/SDIOi power domain is off, the only way to wake up the power domain and different MMC/SD/SDIOi clocks is to monitor mmci_dat[1] input pin state via a different GPIO line for each MMC/SD/SDIO interface (see the *General-Purpose Interface* chapter for more information).

22.3.2 Hardware Requests

22.3.2.1 DMA Requests

The MMC/SD/SDIOi host controller can be interfaced with a DMA controller. At system level, the advantage is to discharge the LH of the data transfers. The module does not support wide DMA access (above 1024 bytes) for SD cards as specified in the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v1.00.

The DMA request is issued if the three following conditions are met:

- The MMCI.MMCHS_CMD[0] DE bit is set to 1 to trigger the initial DMA request (the write must be done when running the data transfer command).
- A command was emitted on the mmci_cmd line.
- There is enough space in the buffer of the MMC/SD/SDIOi host controller to write an entire block (BLEN writes).

DMA request lines are connected on the system DMA (sDMA) inputs:

- S_DMA_60 (MMC1_DMA_TX)
- S_DMA_61 (MMC1_DMA_RX)
- S_DMA_46 (MMC2_DMA_TX)
- S_DMA_47 (MMC2_DMA_RX)
- S_DMA_76 (MMC3_DMA_TX)
- S_DMA_77 (MMC3_DMA_RX)

22.3.2.1.1 DMA Receive Mode

In a DMA block read operation (single or multiple), the request signal MMCI_DMA_RX is asserted to its active level when a complete block is written in the buffer. The block size transfer is specified in the MMCI.MMCHS_BLK[10:0] BLEN field.

The MMCI_DMA_RX signal is deasserted to its inactive level when the sDMA has read one single word from the buffer.

Only one request is sent per block; the DMA controller can make a 1-shot read access or several DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to block size BLEN field.

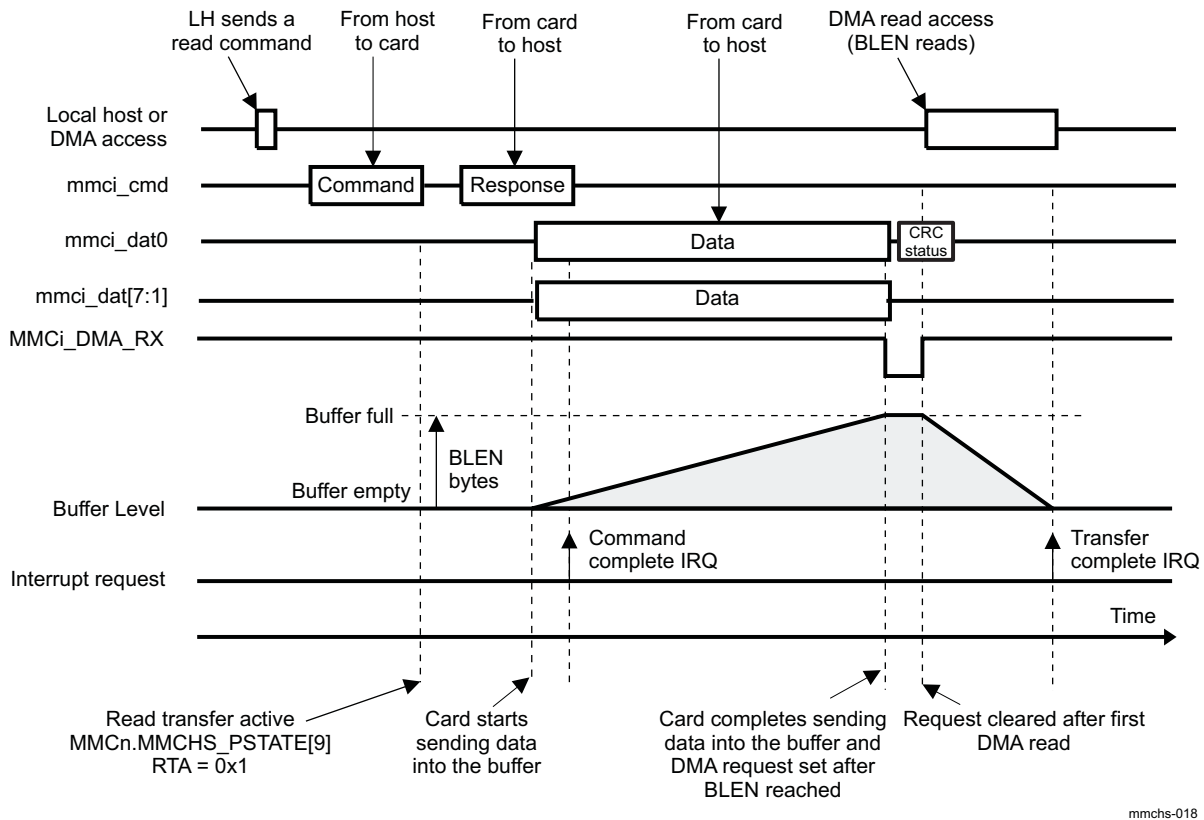

New DMA requests are internally masked if the sDMA has not read exactly BLEN bytes and a new complete block is not ready. As DMA accesses are in 32-bit, then the number of sDMA read is $\text{Integer}(\text{BLEN}/4)+1$.

The receive buffer never overflows. In multiple block transfers for block size above 512 bytes, when the buffer gets full, the mmci_clk clock signal (provided to the card) is momentarily stopped until the sDMA or the MPU performs a read access, which reads a complete block in the buffer.

Summary (see [Figure 22-18](#)):

- DMA transfer size = BLEN buffer size (maximum 1024 32-bit words) in one shot or by burst
- One DMA request per block

Figure 22-18. DMA Receive Mode

22.3.2.1.2 DMA Transmit Mode

In a DMA block write operation (single or multiple), the request signal MMCi_DMA_TX is asserted to its active level when a complete block is to be written to the buffer. The block size transfer is specified in the MMCi.MMCHS_BLK[10:0] BLEN field.

The MMCi_DMA_TX signal is deasserted to its inactive level when the sDMA has written one single word to the buffer.

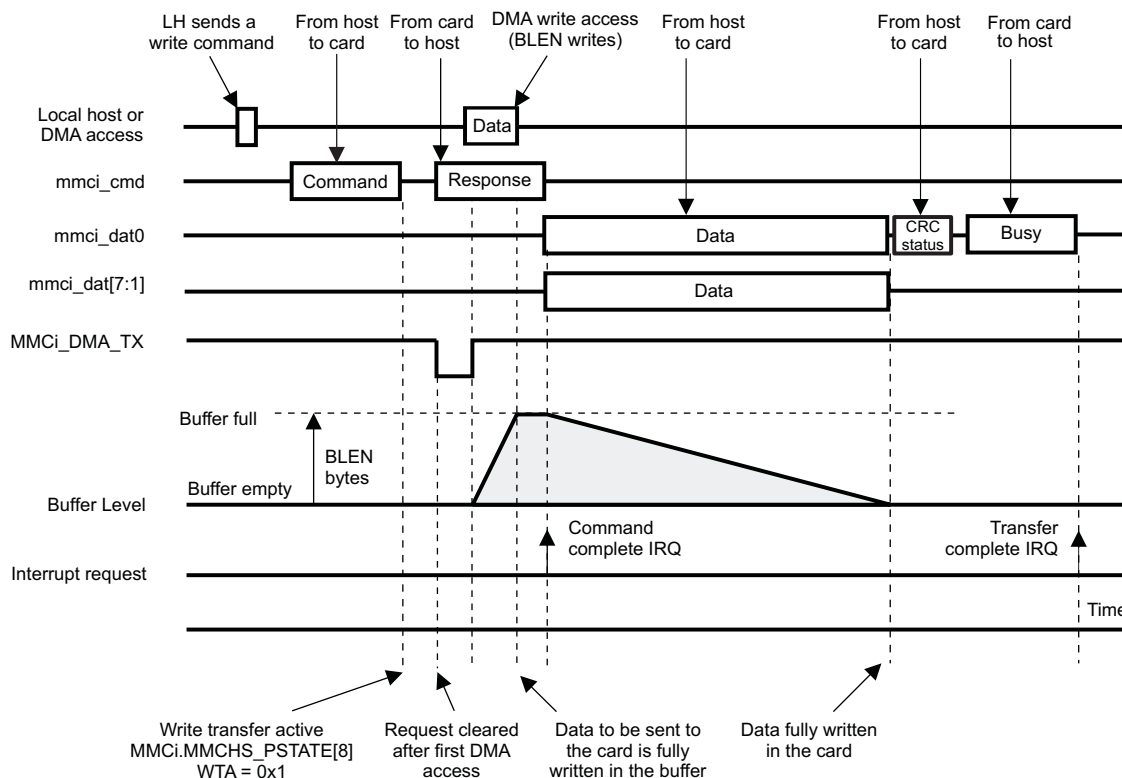

Only one request is sent per block; the DMA controller can make a 1-shot write access or multiple write DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to block size BLEN field.

New DMA requests are internally masked if the sDMA has not written exactly BLEN bytes (as DMA accesses are in 32-bit, then the number of sDMA read is $\text{Integer}(\text{BLEN}/4)+1$) and if there is not enough memory space to write a complete block in the buffer.

Summary (see Figure 22-19):

- DMA transfer size = BLEN buffer size (maximum 1024 32-bit words) in one shot or by burst
- One DMA request per block

Figure 22-19. DMA Transmit Mode

mmchs-019

22.3.2.2 Interrupt Requests

Several internal module events can generate an interrupt. Each interrupt has a status bit, an interrupt enable bit, and a signal status enable:

- The status of each type of interrupt is automatically updated in the MMCi.MMCHS_STAT register; it indicates which service is required.
- The interrupt status enable bits of the MMCi.MMCHS_IE register enable/disable the automatic update of the MMCi.MMCHS_STAT register on an event-by-event basis.
- The interrupt signal enable bits of the MMCi.MMCHS_ISE register enable/disable the transmission of an interrupt request on the interrupt line MMCi_IRQ (from the MMC/SD/SDIOi host controller to the MPU subsystem interrupt controller) on an event-by-event basis.

If an interrupt status is disabled in the MMCi.MMCHS_IE register, then the corresponding interrupt request is not transmitted, and the value of the corresponding interrupt signal enable in the MMCi.MMCHS_ISE register is ignored.

When an interrupt event occurs, the corresponding status bit is automatically set to 0x1 (the MMC/SD/SDIOi host controller updates the status bit) in the MMCi.MMCHS_STAT register. If later a mask is applied on the interrupt in the MMCi.MMCHS_ISE register, the interrupt request is deactivated.

When the interrupt source has not been serviced, if the interrupt status is cleared in the MMCi.MMCHS_STAT register and the corresponding mask is removed from the MMCi.MMCHS_ISE register, the interrupt status is not asserted again in the MMCi.MMCHS_STAT register and the MMC/SD/SDIOi host controller does not transmit an interrupt request.

CAUTION

If the buffer write ready interrupt (BWR) or the buffer read ready only interrupt (BRR) are not serviced and are cleared in the MMCi.MMCHS_STAT register, and the corresponding mask is removed, then the MMC/SD/SDIOi host controller will wait for the service of the interrupt without updating the status MMCi.MMCHS_STAT or transmitting an interrupt request.

The MMC/SD/SDIOi host controller supports interrupt-driven operation and polling.

There are one interrupt line for each instance of the MMC/SD/SDIOi host controller:

- MMC1_IRQ is connected to M_IRQ_83 for MMC/SD/SDIO1 instance.
- MMC2_IRQ is connected to M_IRQ_86 for MMC/SD/SDIO2 instance.
- MMC3_IRQ is connected to M_IRQ_94 for MMC/SD/SDIO3 instance.

22.3.2.2.1 Interrupt-Driven Operation

An interrupt enable bit must be set in the MMCi.MMCHS_IE register to enable the module internal source of interrupt.

When an interrupt event occurs, the single interrupt line is asserted and the LH must:

- Read the MMCi.MMCHS_STAT register to identify which event occurred.
- Write 1 into the corresponding bit of the MMCi.MMCHS_STAT register to clear the interrupt status and release the interrupt line (if a read is done after this write, this would return 0).

Note: In the MMCi.MMCHS_STAT register, Card Interrupt (CIRQ) and Error Interrupt (ERRI) bits cannot be cleared.

The MMCi.MMCHS_STAT[8] CIRQ status bit must be masked by disabling the MMCi.MMCHS_IE[8] CIRQ_ENABLE bit (set to 0x0), then the interrupt routine must clear SDIO interrupt source in SDIO card common control register (CCCR). See the *Interconnect* chapter for more information.

The MMCi.MMCHS_STAT[15] ERRI bit is automatically cleared when all status bits in MMCi.MMCHS_STAT[31:16] are cleared.

22.3.2.2.2 Polling

When the interrupt capability of an event is disabled in the MMCi.MMCHS_ISE register, the interrupt line is not asserted:

- Software can poll the status bit in the MMCi.MMCHS_STAT register to detect when the corresponding event occurs.
- Writing 1 into the corresponding bit of the MMCi.MMCHS_STAT register clears the interrupt status and does not affect the interrupt line state.

Note: Refer to the previous note concerning CIRQ and ERRI bits clearing.

22.4 MMC/SD/SDIO Functional Description

22.4.1 Description

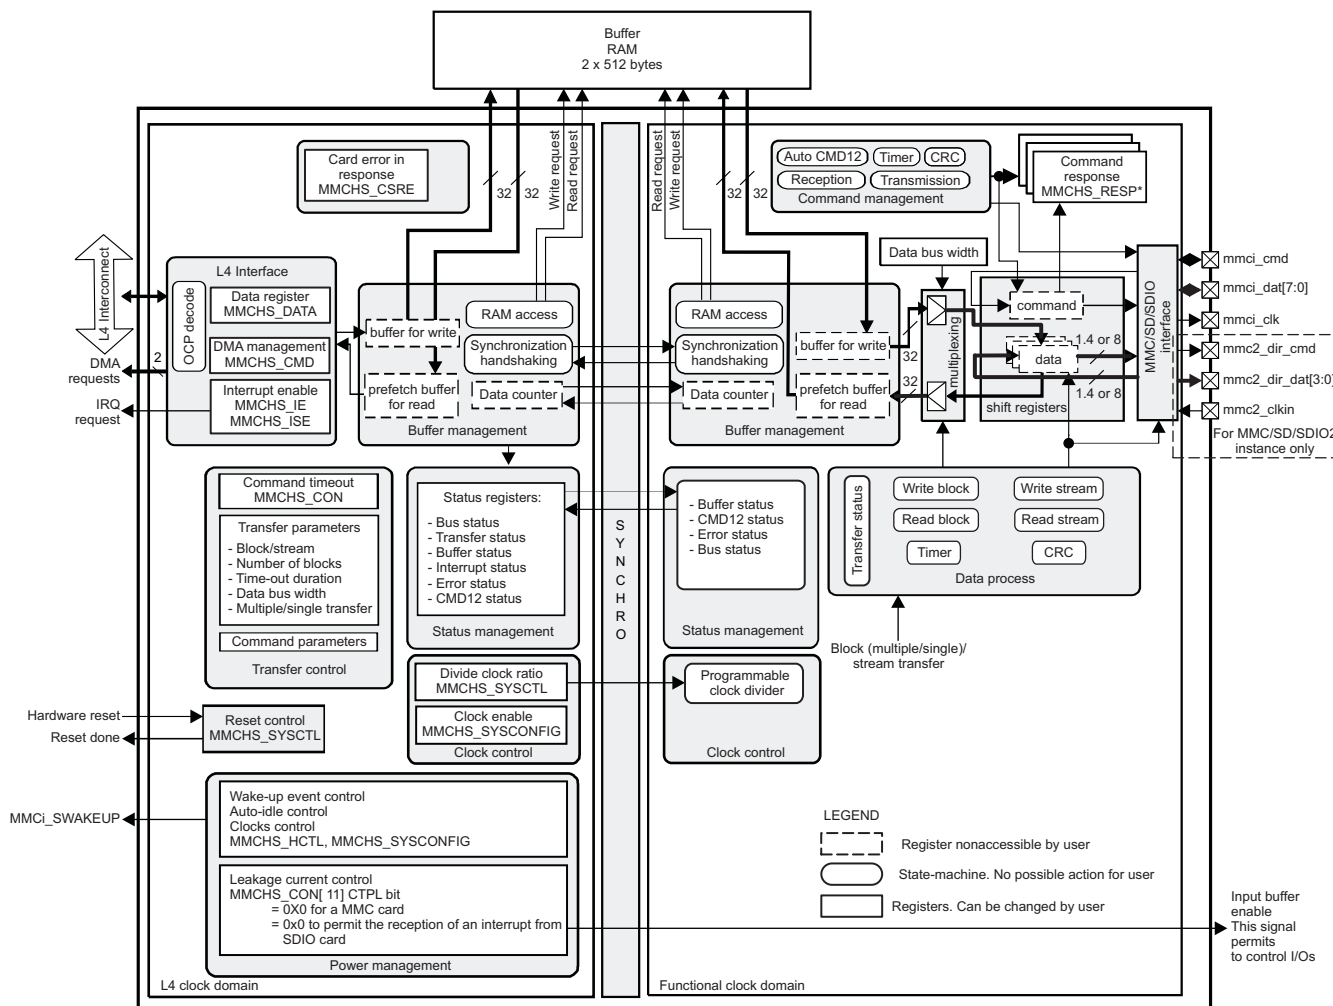

MMC/SD/SDIOi host controller is partitioned into two clock domains:

- The interface L4 clock domain
- The functional clock domain

Any two domains are considered asynchronous to each other, and exchanges between the two domains are synchronized through a synchronization stage and an asynchronous buffer. Data are transferred from one domain to other through the buffer (2*512 RAM).

[Figure 22-20](#) shows a block diagram of the MMC/SD/SDIO host controller.

Figure 22-20. MMC/SD/SDIO Diagram

mmchs-020

In the L4 clock domain, the user can:

- Control the transfer (configure parameters for the transfer)
- Control clock activities and reset
- Manage interrupts and hardware requests
- Consult different status:

- Bus
- Buffer
- Interrupts
- Errors
- Transmit and receive data through the buffer

In the functional clock domain, the internal mechanisms perform the transfers of data and commands.

For more detail see the command response registers (MMCi.MMCHS_RSPn registers: [Table 22-54](#), [Table 22-56](#), [Table 22-58](#), and [Table 22-60](#)).

CAUTION

Read access to the command response registers is allowed only when the command process is completed.

22.4.2 Mode Selection

The MMC/SD/SDIO host controller can be use in two modes: MMC and SD/SDIO modes. It has been designed to be the most transparent with the type of card.

The type of the card connected is differentiated by the software initialization procedure. Software identifies the type of card connected during software initialization. For each given card type, there are corresponding commands. Some commands are not supported by all cards. See the *Multimedia Card System Specification*, v4.2, the *SD Memory Card Specifications*, v2.0, and the *SDIO Card Specification, Part E1*, v1.10, for more details.

The purpose of the module is to transfer commands and data, to whatever card is connected, respecting the protocol of the connected card.

Writes and reads to the card must respect the appropriate protocol of that card.

22.4.3 Buffer Management

22.4.3.1 Data Buffer

The MMC/SD/SDIOi host controller uses a data buffer divided into two 512-byte portions that are 32 bits wide by 128 words deep. This buffer transfers data from one data bus (Interconnect) to another data bus (SD SDIO or MMC card bus) and vice versa.

The buffer is the heart of the interface and ensures the transfer between the two interfaces (L4 and the card).

To enhance performance, the data buffer is completed by a prefetch register and a post-write buffer that are not accessible by the host controller.

The read access time of the prefetch register is faster than the one of the data buffer. The prefetch register allows data to be read from the data buffer at an increased speed by preloading data into the prefetch register.

The entry point of the data buffer for the two portions, the prefetch buffer and the post-write buffer, is the 32-bit register MMCI.MMCHS_DATA. A write access to the MMCI.MMCHS_DATA register followed by a read access from the MMCI.MMCHS_DATA register corresponds to a write access to the post-write buffer followed by a read access to the prefetch buffer. As a consequence, it is normal that the data of the write access to the MMCI.MMCHS_DATA register and the data of the read access to the MMCI.MMCHS_DATA register are different.

The number of 32-bit accesses to the MMCI.MMCHS_DATA register that are needed to read (or write) a data block with a size of MMCI.MMCHS_BLK[10:0] BLEN, and equals the rounded up result of BLEN divided by 4.

The maximum block size supported by the host controller is 1024 bytes. This value is hard-coded in the register MMCI.MMCHS_CAPA[17:16] MBL field and cannot be changed.

A read access to the MMCI.MMCHS_DATA register is allowed only when the buffer read enable status is set to 1 (MMCI.MMCHS_PSTATE[11] BRE); otherwise, a bad access (MMCI.MMCHS_STAT[29] BADA) is signaled.

A write access to the MMCI.MMCHS_DATA register is allowed only when the buffer write enable status is set to 1 (MMCI.MMCHS_PSTATE[10] BWE); otherwise, a bad access (MMCI.MMCHS_STAT[29] BADA) is signaled and the data is not written.

The data buffer has two modes of operation to store and read of the first and second portions of the data buffer:

- When the size of the data block to transfer is less than or equal to 512 bytes, meaning the value written in BLEN is less than or equal to 0x200, two data transfers can occur from one data bus to the other data bus and vice versa at the same time. The MMC/SD/SDIOi host controller uses the two portions of the data buffer in a pingpong manner so that storing and reading of the first and second portions of the data buffer are automatically interchanged from time to time so that data may be read from one portion (for instance, through a DMA read access on the interconnect bus) while data (for instance, from the card) is being stored into the other portion and vice versa.

CAUTION

The MMCI.MMCHS_CMD[4] DDIR bit must be configured before a transfer to indicate the direction of the transfer.

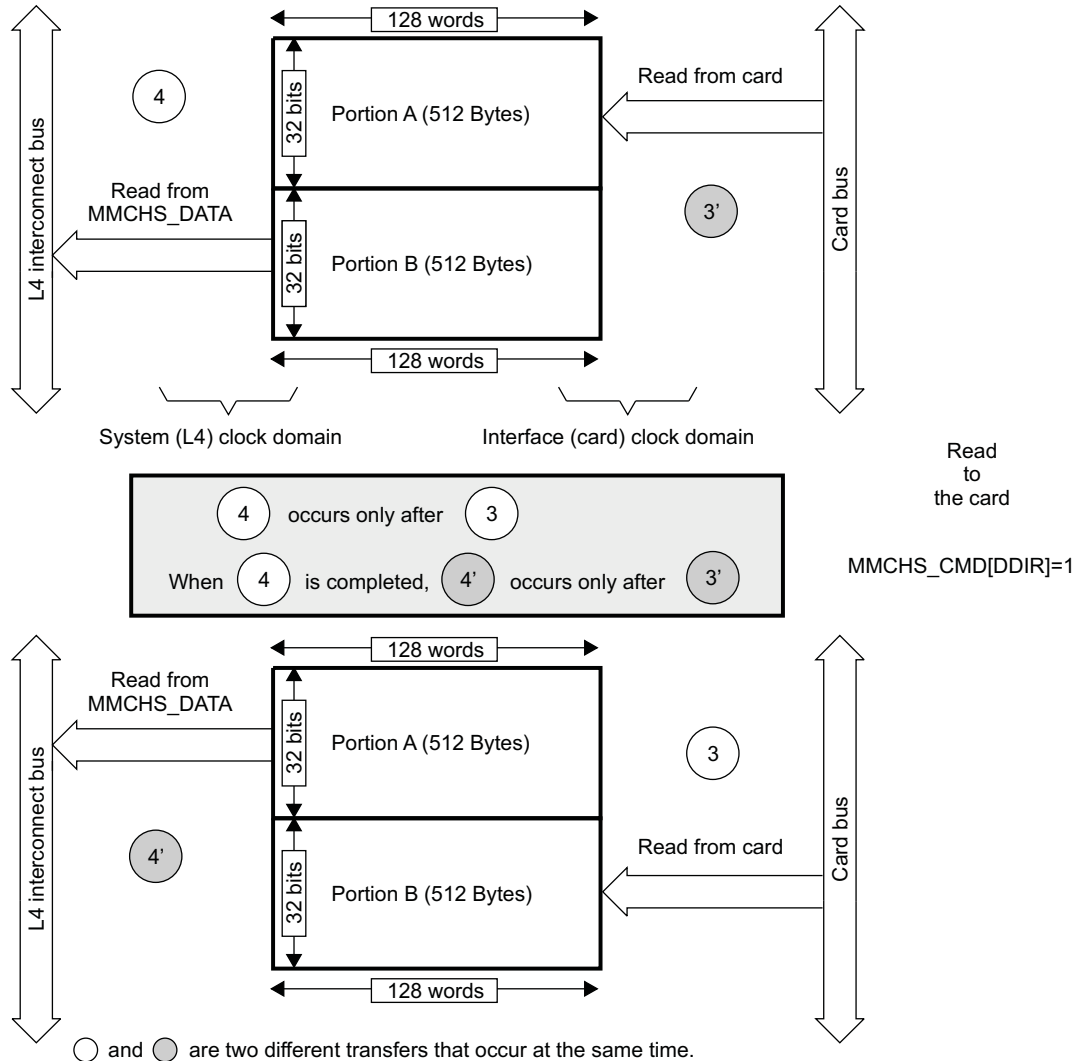

Figure 22-21 and Figure 22-22 show the buffer management for a write and for a read, respectively.

Figure 22-21. Buffer Management for a Write

mmchs-047

Figure 22-22. Buffer Management for a Read

- When the size of the data block to transfer is larger than 512 bytes, meaning the value written in BLEN is 0x201 or larger, only one data transfer can occur from one data bus to the other data bus at a time. The MMC/SD/SDIOi host controller uses the entire data buffer as a single 1024-byte portion. In this mode, a bad access (MMCi.MMCHS_STAT[29] BADA) is signaled when two data transfers occur from one data bus to the other data bus and vice versa at the same time.

22.4.3.1.1 Data Buffer Status

The data buffer status is defined in the following interrupt status register and status register:

- Interrupt status registers (see Table 22-70):
 - MMCi.MMCHS_STAT[29] BADA: Bad access to data space
 - MMCi.MMCHS_STAT[5] BRR: Buffer read ready
 - MMCi.MMCHS_STAT[4] BWR: Buffer write ready
- Status registers (see Table 22-64):
 - MMCi.MMCHS_PSTATE[11] BRE: Buffer read enable
 - MMCi.MMCHS_PSTATE[10] BWE: Buffer write enable

22.4.4 Transfer Process

The process of a transfer is dependent on the type of command. It can be with or without a response, with or without data.

22.4.4.1 Different Types of Commands

Different types of commands are specific to MMC, SD, or SDIO cards. See the *Multimedia Card System Specification*, v4.2, the *SD Memory Card Specifications*, v2.0, the *SDIO Card Specification, Part E1*, v1.10, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v1.00, for more details.

22.4.4.2 Different Types of Responses

Different types of responses are specific to MMC, SD, or SDIO cards. See the *Multimedia Card System Specification*, v4.2, the *SD Memory Card Specifications*, v2.0, the *SDIO Card Specification, Part E1*, v1.10, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v1.00, for more details.

Table 22-5 shows how the MMC, SD, and SDIO responses are stored in the MMCHS_RSPxx registers.

Table 22-5. MMC, SD, SDIO responses in the MMCHS_RSPxx registers

Kind of Response	Response Field	Response Register
R1, R1b (normal response), R3, R4, R5, R5b, R6	RESP[39:8] ⁽¹⁾	MMCHS_RSP10[31:0]
R1b (Auto CMD12 response)	RESP[39:8] ⁽¹⁾	MMCHS_RSP76[31:0]
R2	RESP[127:0] ⁽¹⁾	MMCHS_RSP76[31:0] MMCHS_RSP54[31:0] MMCHS_RSP32[31:0] MMCHS_RSP10[31:0]

⁽¹⁾ RESP refers to the command response format described in the specifications mentioned above.

When the host controller modifies part of the MMCHS_RSPxx registers, it preserves the unmodified bits.

The host controller stores the Auto CMD12 response in the MMCHS_RSP76[31:0] register because the Host Controller may have a multiple block data DAT line transfer executing concurrently with a command. This allows the host controller to avoid overwriting the Auto CMD12 response with the command response stored in MMCHS_RSP10 register and vice versa.

22.4.5 Transfer or Command Status and Errors Reporting

Flags in the MMC/SD/SDIOi host controller show status of communication with the card:

- A timeout (of a command, a data, or a response)
- A CRC

Error conditions generate interrupts. See Table 22-6 and register description for more details.

Table 22-6. CC and TC Values Upon Error Detected

Error hold in the MMCi.MMCHS_STAT register	CC	TC	Comments
29 BADA			No dependency with CC nor TC BADA is related to MMCHS_DATA register accesses. Its assertion is not dependent of the ongoing transfer.
28 CERR	1		CC is set upon CERR.
22 DEB		1	TC is set upon DEB.

Table 22-6. CC and TC Values Upon Error Detected (continued)

Error hold in the MMCi.MMCHS_STAT register		CC	TC	Comments
21	DCRC		1	TC is set upon DCRC.
20	DTO			DTO and TC are mutually exclusive. DCRC and DEB cannot occur with DTO.
19	CIE	1		CC is set upon CIE.
18	CEB	1		CC is set upon CEB.
17	CCRC	1		CC can be set upon CCRC - See CTO comment
16	CTO			CTO and CC are mutually exclusive. CIE, CEB and CERR cannot occur with CTO. CTO can occur at the same time as CCRC: it indicates a command abort due to a contention on CMD line. In this case no CC appears.

22.4.6 Transfer Stop

Whenever a transfer is initiated, the transmission may be willed to stop whereas it is still not finished. Several cases can be faced depending on the transfer type:

- Multiple blocks oriented transfers (for which transfer length is known)
- Continuous stream transfers (which have an infinite length)

Note: Since the MMC/SD/SDIOi controller manages transfers based on a block granularity, the buffer will accept a block only if there is enough space to completely store it. Consequently, if a block is pending in the buffer, no command will be sent to the card because the card clock will be shut off by the controller.

The MMC/SD/SDIOi controller includes two features which makes a transfer stop more convenient and easier to manage:

- Auto CMD12 (for MMC and SD only).
This feature is enabled by setting the MMCi.MMCHS_CMD[2] ACEN bit to 0x1 (this setting is relevant for a MMC/SD transfer with a known number of blocks to transfer). When the Auto CMD12 feature is enabled, the MMC/SD/SDIOi controller will automatically issue a CMD12 command when the expected number of blocks has been exchanged.
- Stop at block gap
This feature is enabled by setting the MMCi.MMCHS_HCTL[16] SBGR bit to 0x1. When enabled, this capability holds the transfer on until the end of a block boundary. If a stop transmission is needed, software can use this pause to send a CMD12 to the card.

Note: For MMC and SD cards, the stop at block gap feature is not supported in READ mode.

For SDIO cards, this setting can be supported in READ mode if the card has a read wait capability.

Table 22-7 shows the common way to stop a transfer, indicating command to send and features to enable.

Table 22-7. MMC/SD/SDIOi Controller Transfer Stop Command Summary

		WRITE transfer		READ transfer	
		SD / MMC	SDIO	SD / MMC	SDIO
Single block		Transfer ends automatically Wait TC	Transfer ends automatically Wait TC	Transfer ends automatically Wait TC	Transfer ends automatically Wait TC
Multi blocks (finite or infinite)	Before the programmed block boundary	Send CMD12 Wait TC	Send CMD52 Wait TC	Send CMD12 Wait TC	Send CMD52 Wait TC
	Stop at the end of the transfer (finite transfer only)	Auto CMD12 active Transfer ends automatically Wait TC	Set MMCi.MMCHS_HC TL[16] SBGR bit to 0x1. Send CMD52 Wait TC	Auto CMD12 active Transfer ends automatically Wait TC	If READ_WAIT supported Stop at block gap Wait TC If READ_WAIT not supported Send CMD52 Wait TC

Note: The MMC/SD/SDIOi controller will send the stop command to the card on a block boundary, regardless the moment the command was written to the controller registers.

22.4.7 MMC CE-ATA Command Completion Disable Management

The MMC/SD/SDIOi host controller supports CE-ATA features, in particular the detection of command completion token. When a command that requires a command completion signal ([MMCHS_CON\[12\]](#) CEATA and [MMCHS_CMD\[2\]](#) ACEN set to 1) is launched, host system is no longer allowed to emit a new command in parallel of data transfer unless it is a command completion disable.

The settings to emit a command completion disable token follow:

- [MMCHS_CON\[12\]](#) CEATA is set to 1.
- [MMCHS_CON\[2\]](#) HR set to 1.
- Clear the [MMCHS_ARG](#) register.
- Write into [MMCHS_CMD](#) register with value 0x00000000.

When a command completion disable token was emitted (that is, [MMCHS_STAT\[0\]](#) CC received), the host system is again allowed to emit another type of command (for example a transfer abort command CMD12 to abort transfer).

A critical case can be met when command completion signal disable (CCSD) is emitted during the last data block transfer, the sequence on command line could be sent very close to command completion signal (CCS) token sent by the card.

Three cases can be met:

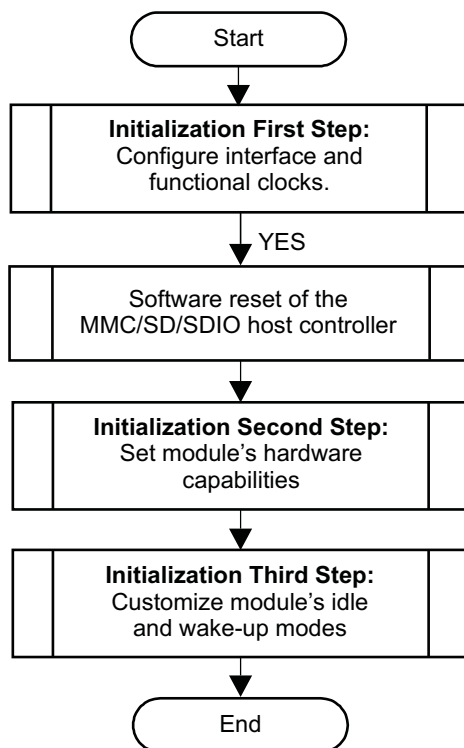

- CCS is receive just before CCSD is emitted:
An interrupt CIRQ is generated with CCS detection, CCSD is transmitted to card then an interrupt CC is generated when CCSD ends. In this case, card consider the CCSD sequence.
- CCS is not generated or generated during the CCSD transfer:
The CCS bit cannot be detected (conflict is not possible as they drive the same level on command line, then no CIRQ interrupt is generated; besides CC interrupt is generated when CCSD ends).
- CCS is generated without CCSD token required:
Only the interrupt CIRQ is generated when CCS is detected.

22.5 MMC/SD/SDIO Basic Programming Model

22.5.1 MMC/SD/SDIO Host Controller Initialization Flow

Figure 22-23 shows the general boot process.

Figure 22-23. MMC/SD/SDIO Controller Meta Initialization Steps

mmchs-024

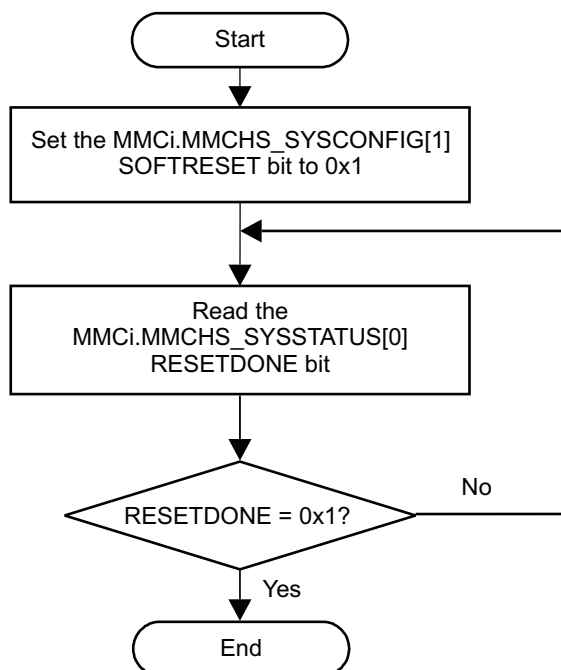

22.5.1.1 Enable Interface and Functional clock for MMC Controller

Prior to any MMCHS register access one must enable MMCHS interface clock and functional clock in PRCM module registers PRCM.CM_ICLKEN1_CORE and PRCM.CM_FCLKEN1_CORE. Please refer to the *Power, Reset, and Clock Management* chapter.

22.5.1.2 MMCHS Soft Reset Flow

Figure 22-24 shows the soft reset process of MMCHS controller.

Figure 22-24. MMC/SD/SDIO Controller Software Reset Flow

mmchs-025

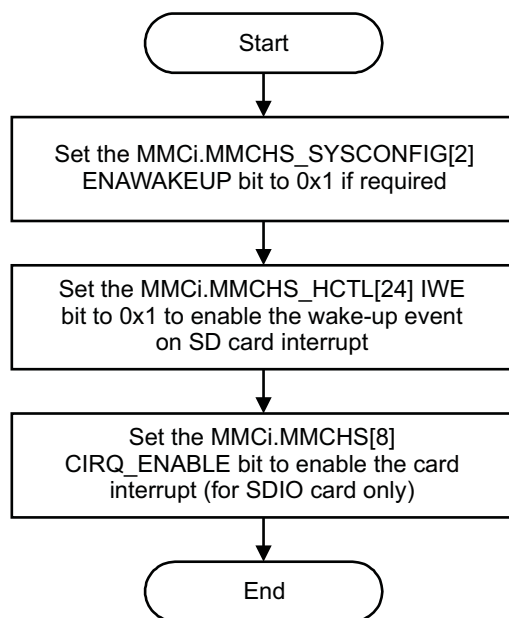

22.5.1.3 Set MMCHS Default Capabilities

Software must read capabilities (in boot ROM for instance) and is allowed to set (write) MMCi.MMCHS_CAPA[26:24] and MMCi.MMCHS_CUR_CAPA[23:0] registers before the MMC/SD/SDIO host driver is started.

22.5.1.4 Wakeup Configuration

Figure 22-25 details MMCHS controller wakeup configuration.

Figure 22-25. MMC/SD/SDIO Controller Wakeup Configuration

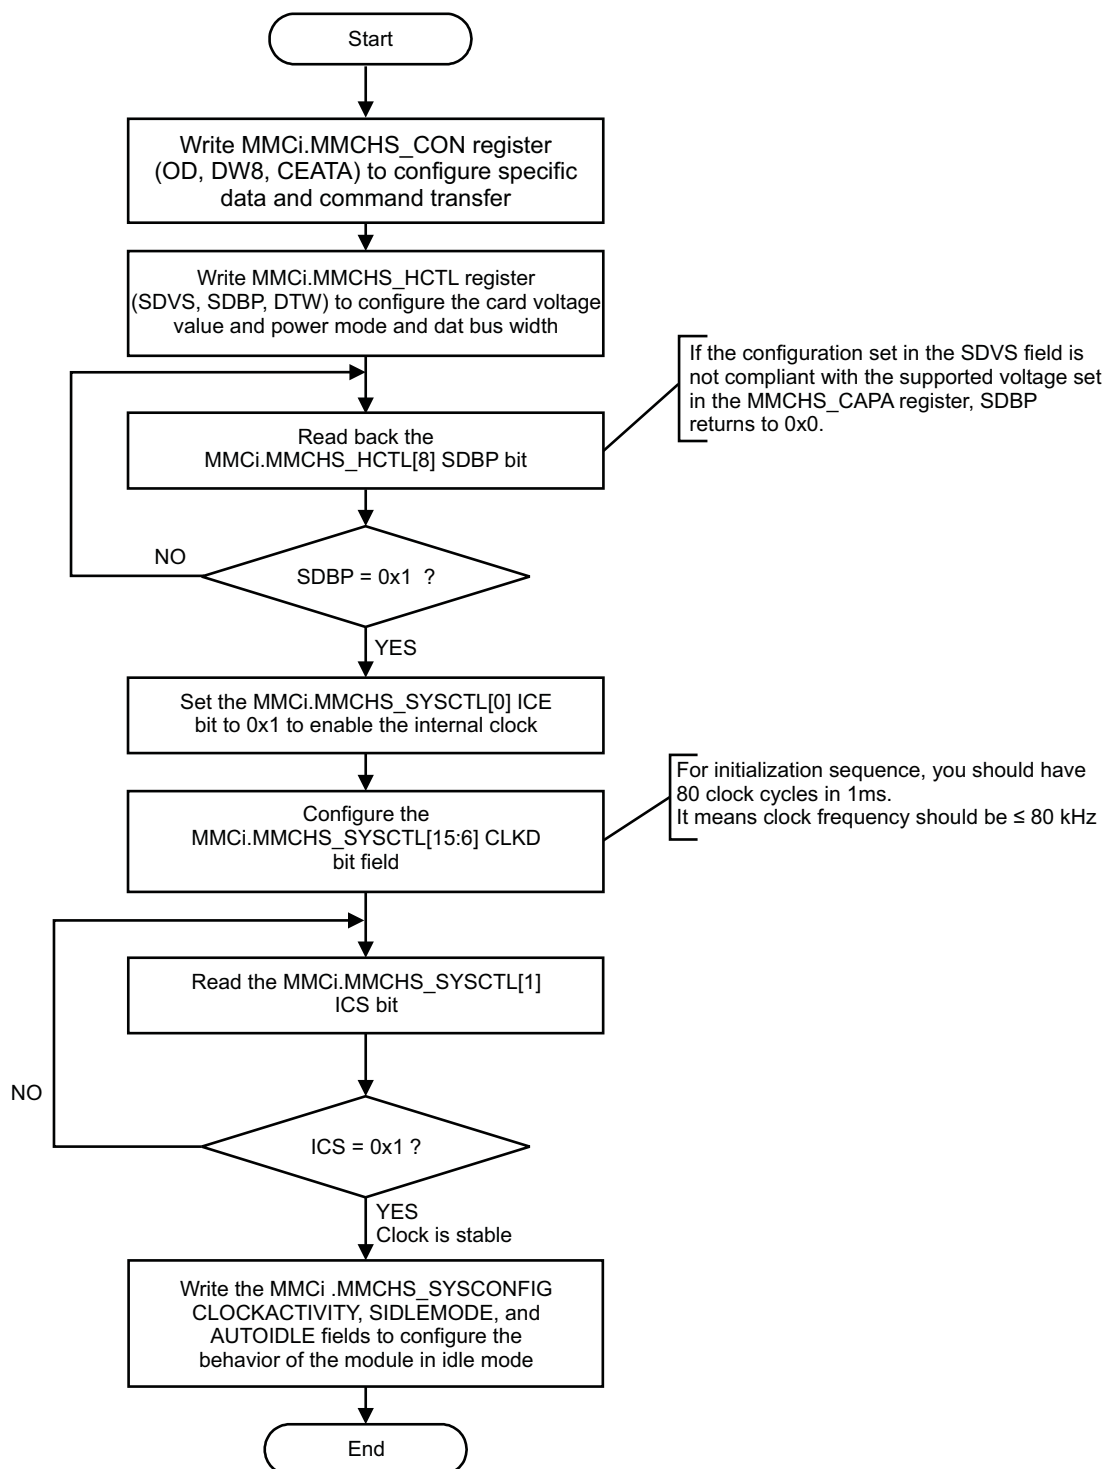

mmchs-027

22.5.1.5 MMC Host and Bus Configuration

Figure 22-26 details MMC bus configuration process.

Figure 22-26. MMC/SD/SDIO Controller Bus Configuration

mmchs-028

22.5.2 Basic Operations for MMC/SD/SDIO Host Controller

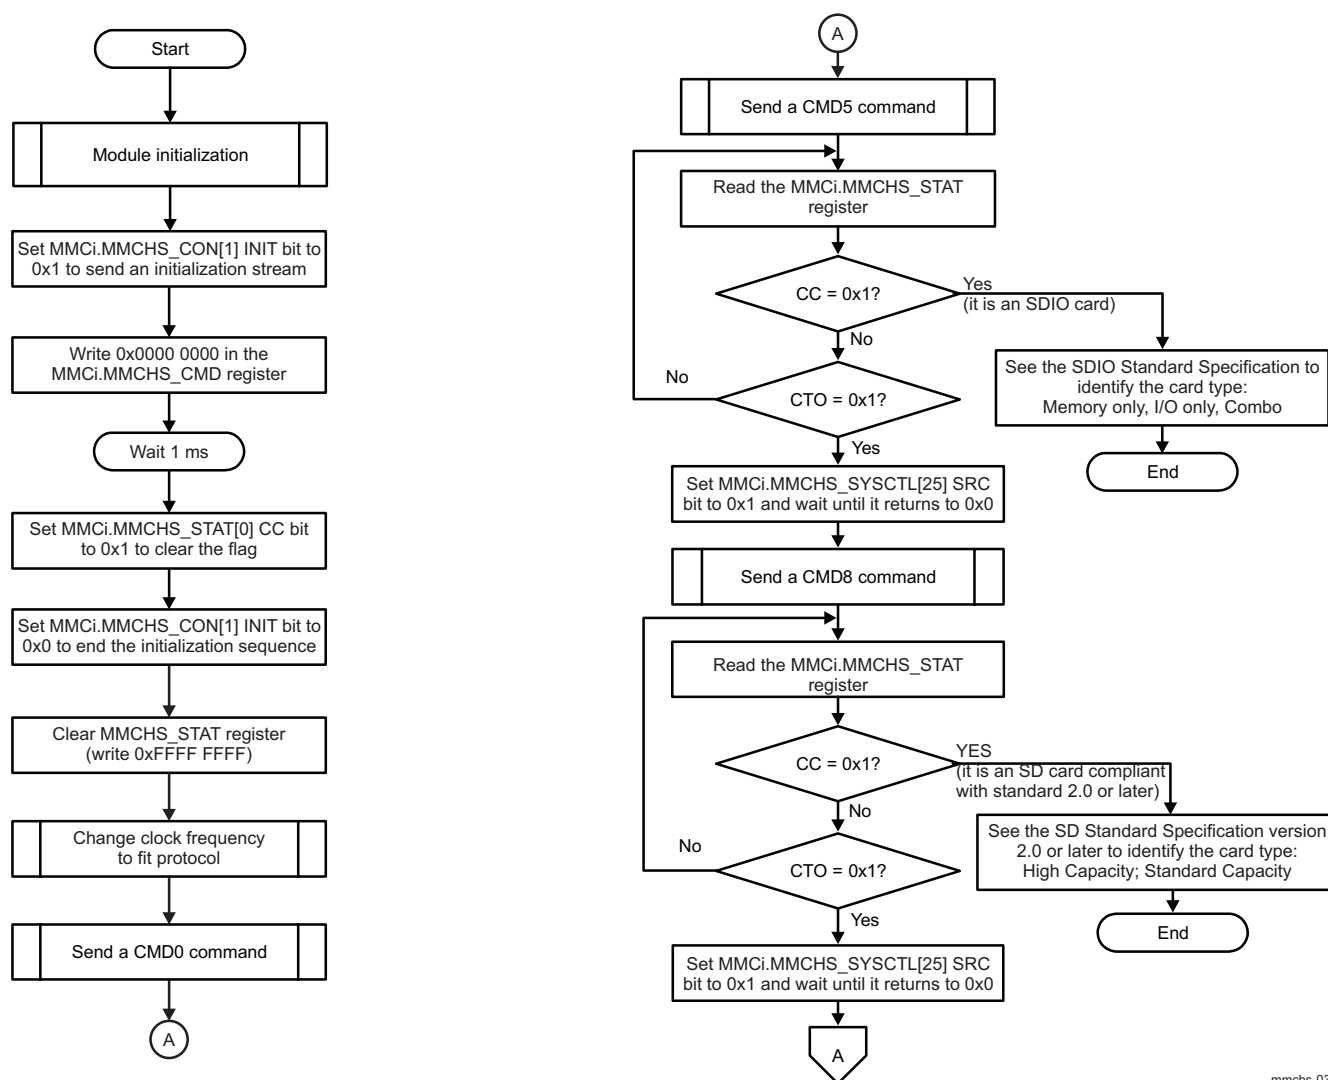

The MMC/SD/SDIO host controller performs data transfers: data to card (referred to as write transfers) and data from card (referred to as read transfers).

The host controller requires transfers to run on a block-by-block basis, rather than on a DMA burst size basis. A single DMA request (or block request interrupt) is signaled for each block. Pipelining is supported as long as the block size is less than one half of the memory buffer size.

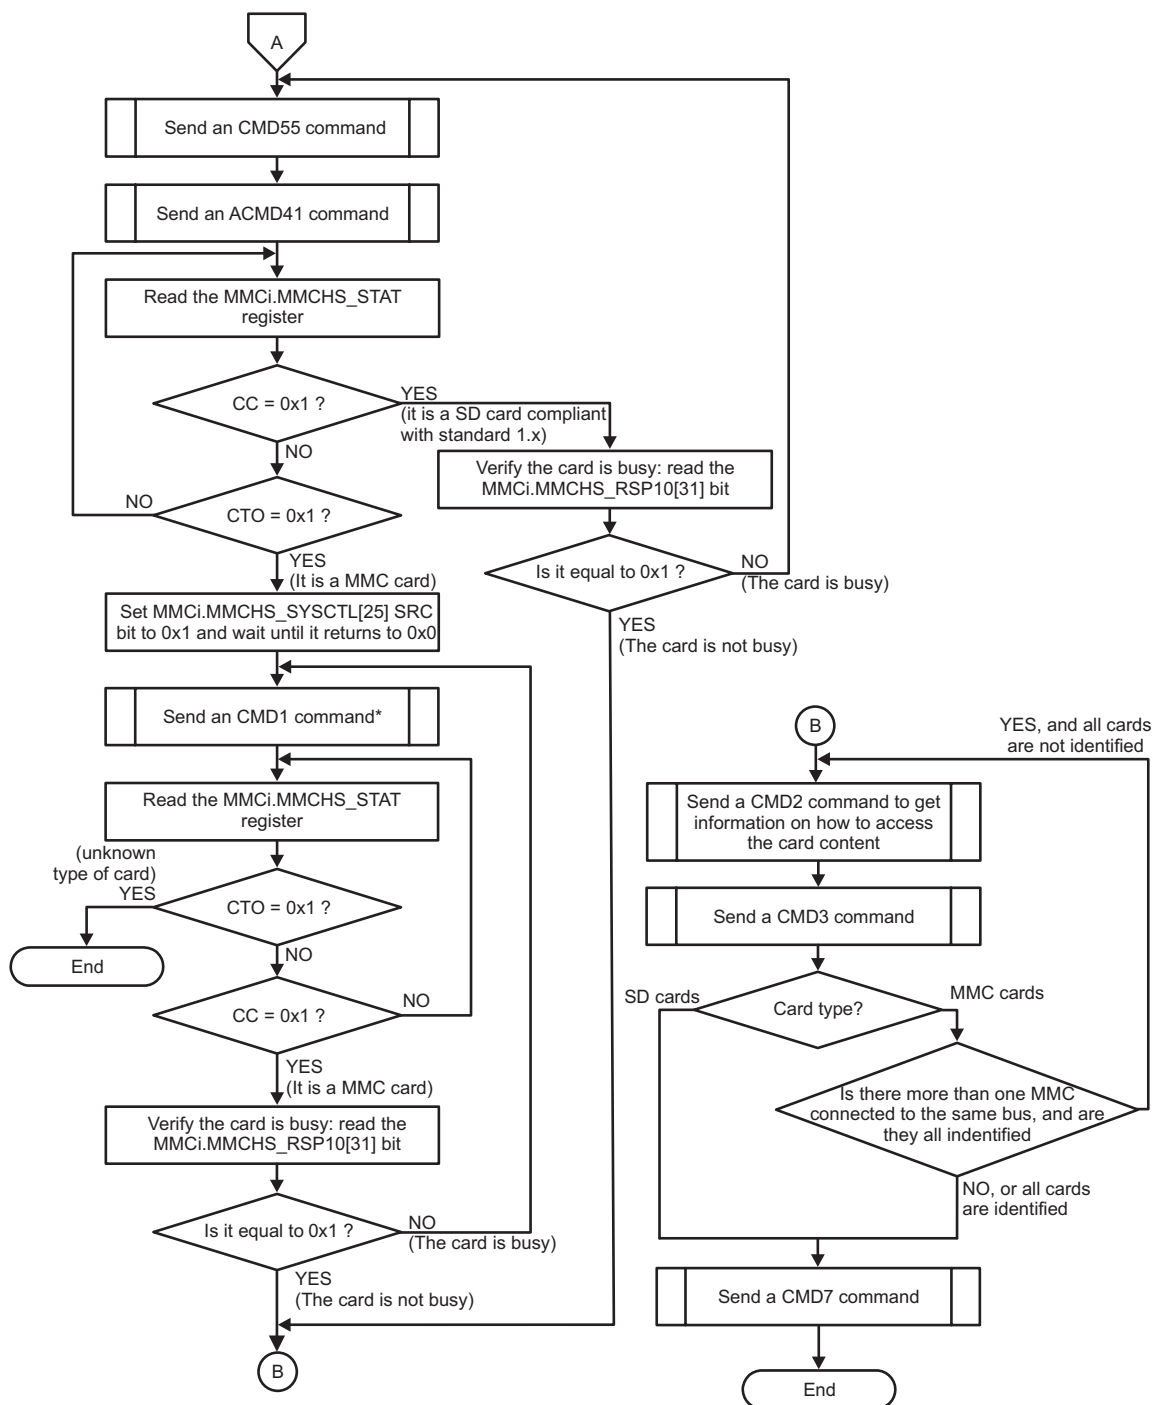

22.5.2.1 Card Detection, Identification, and Selection

Figure 22-27 and Figure 22-28 show the card identification and selection process.

Figure 22-27. MMC/SD/SDIO Controller Card Identification and Selection - part 1

mmchs-030

Figure 22-28. MMC/SD/SDIO Controller Card Identification and Selection - part 2

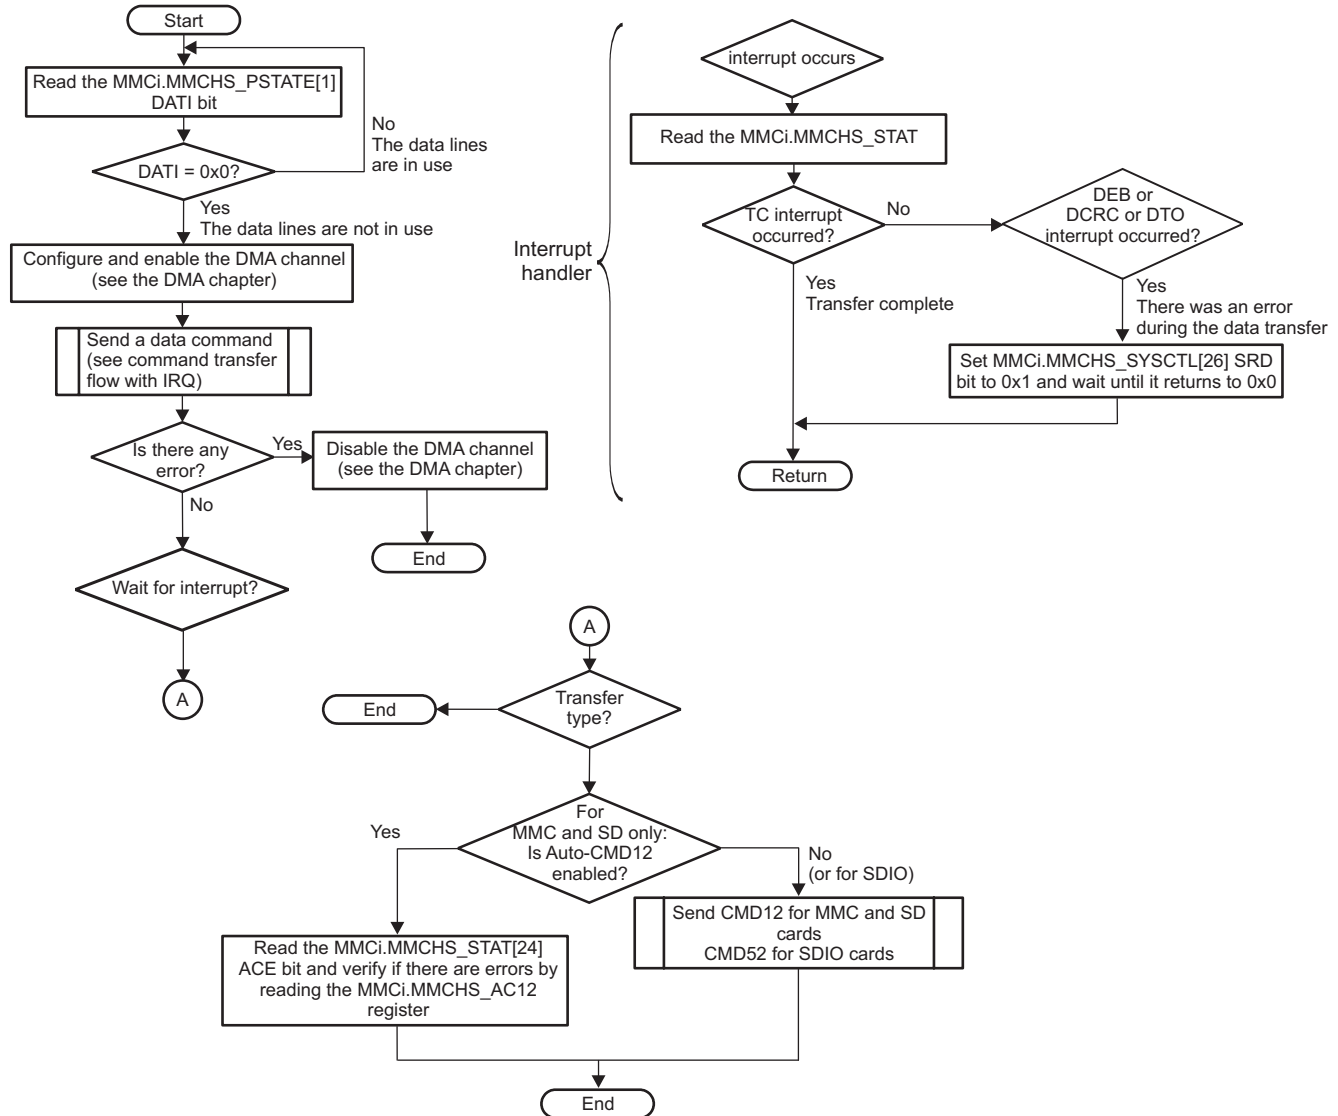

*With OCR 0.
In case of a CMD1 with OCR=0, a second CMD1 must be sent to the card with the "negotiated" voltage.

22.5.2.2 Read/Write Transfer Flow in DMA Mode with Interrupt

Figure 22-29 describes the read and write protocol in DMA mode with interrupt signaling. Refer to the DMA chapter for more information on the DMA settings.

Figure 22-29. MMC/SD/SDIO Controller Read/Write Transfer Flow in DMA mode with interrupt

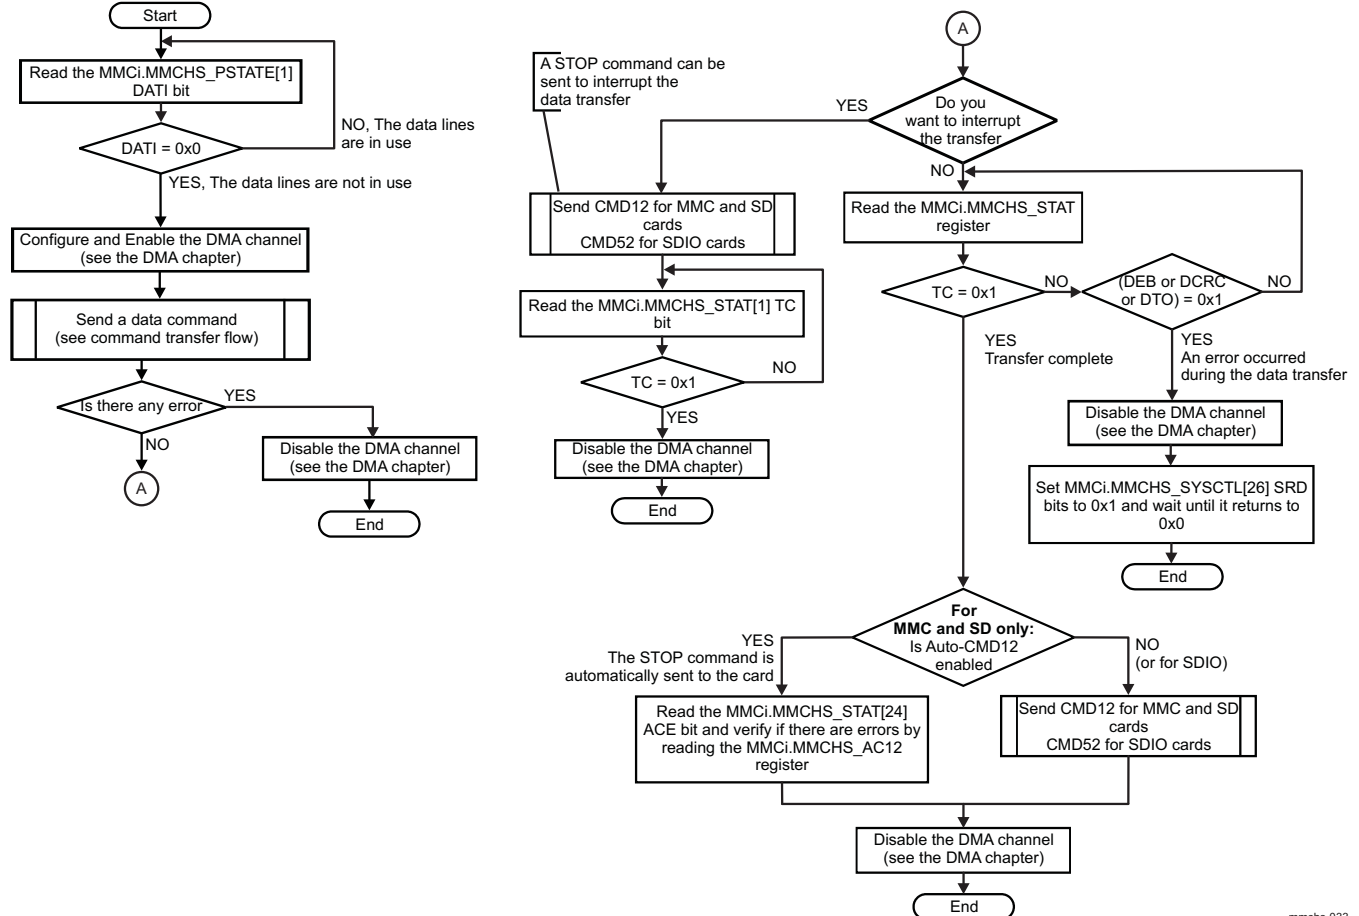

mmchs-032

22.5.2.3 Read/Write Transfer Flow in DMA Mode with Polling

Figure 22-30 describes the read and write protocol in DMA mode. Refer to the *DMA* chapter for more information on the DMA settings.

Figure 22-30. MMC/SD/SDIO Controller Read/Write Transfer Flow in DMA mode with Polling

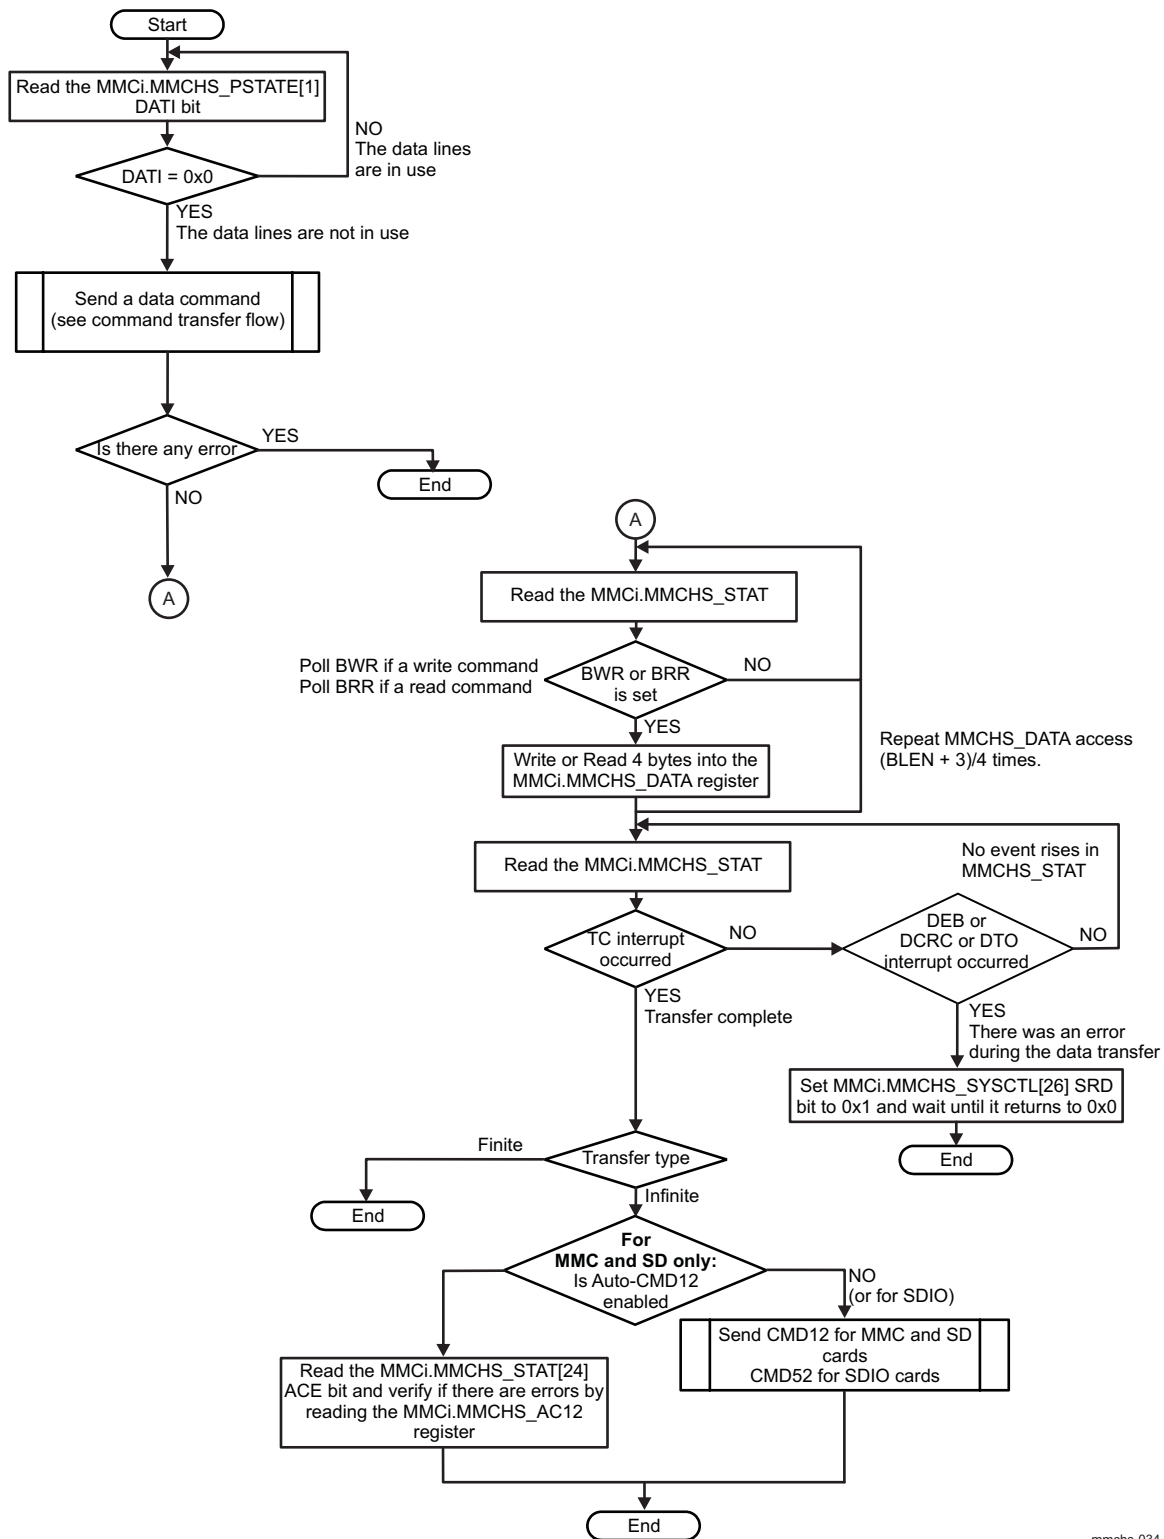

mmchs-033

22.5.2.4 Read/Write Transfer Flow without DMA with Polling

Figure 22-31 describes a read/write transfer without using the DMA and with polling.

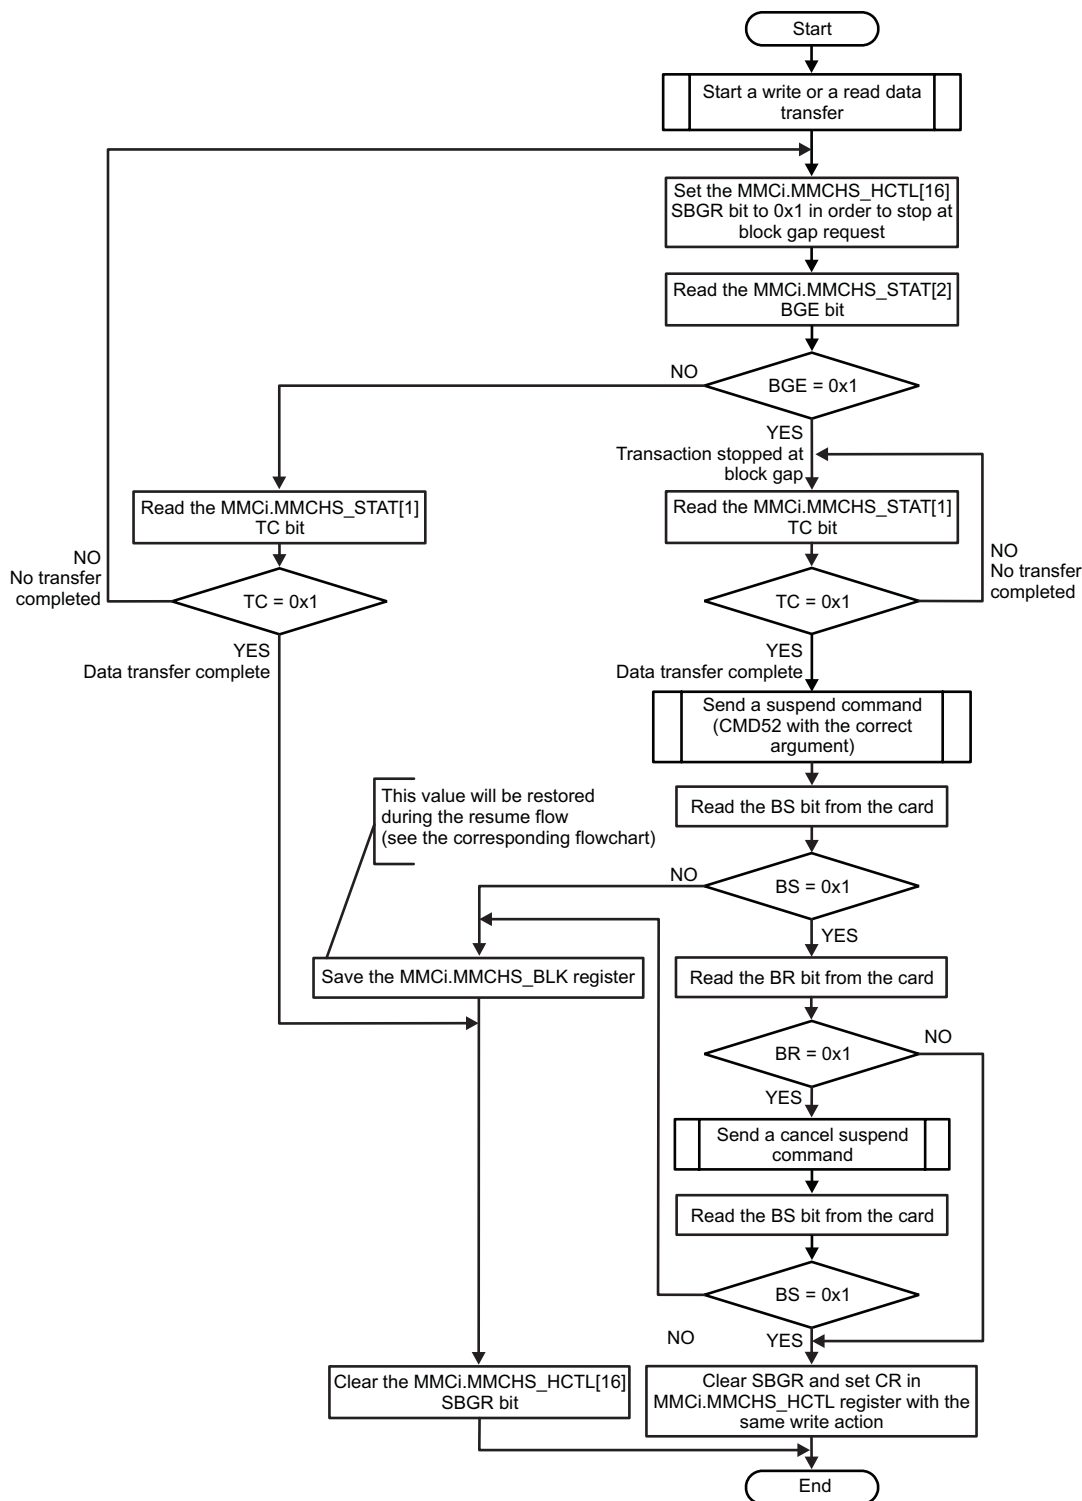

Figure 22-31. MMC/SD/SDIO Controller Read/Write Transfer Flow without DMA with Polling

22.5.2.6.1 Suspend Flow

Figure 22-33 describes the suspend flow for SDIO cards.

Figure 22-33. MMC/SD/SDIO Controller Suspend Flow

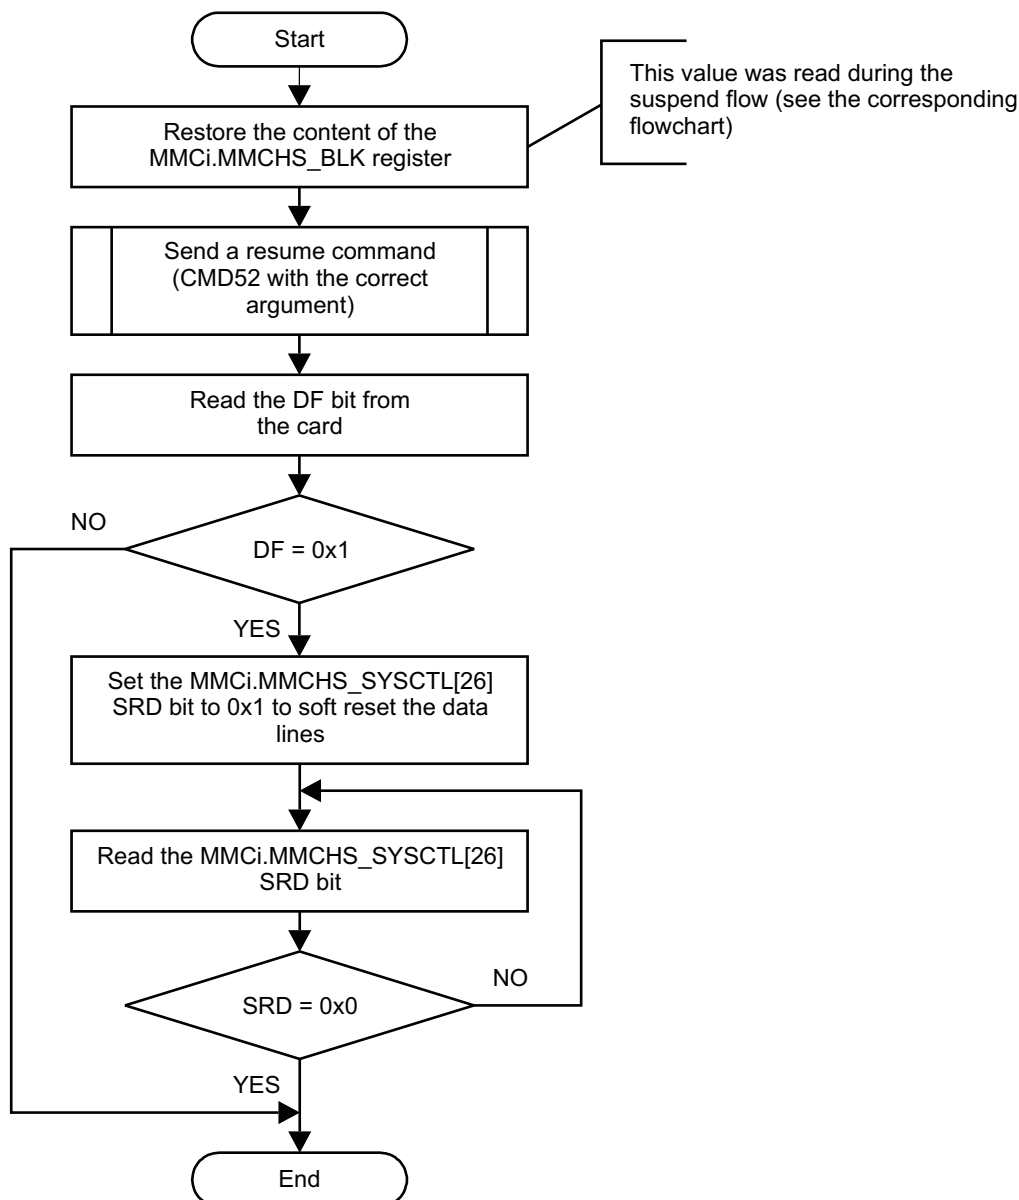

mmchs-038

22.5.2.6.2 Resume Flow

Figure 22-34 describes the resume flow for SDIO cards.

Figure 22-34. MMC/SD/SDIO Controller Resume Flow

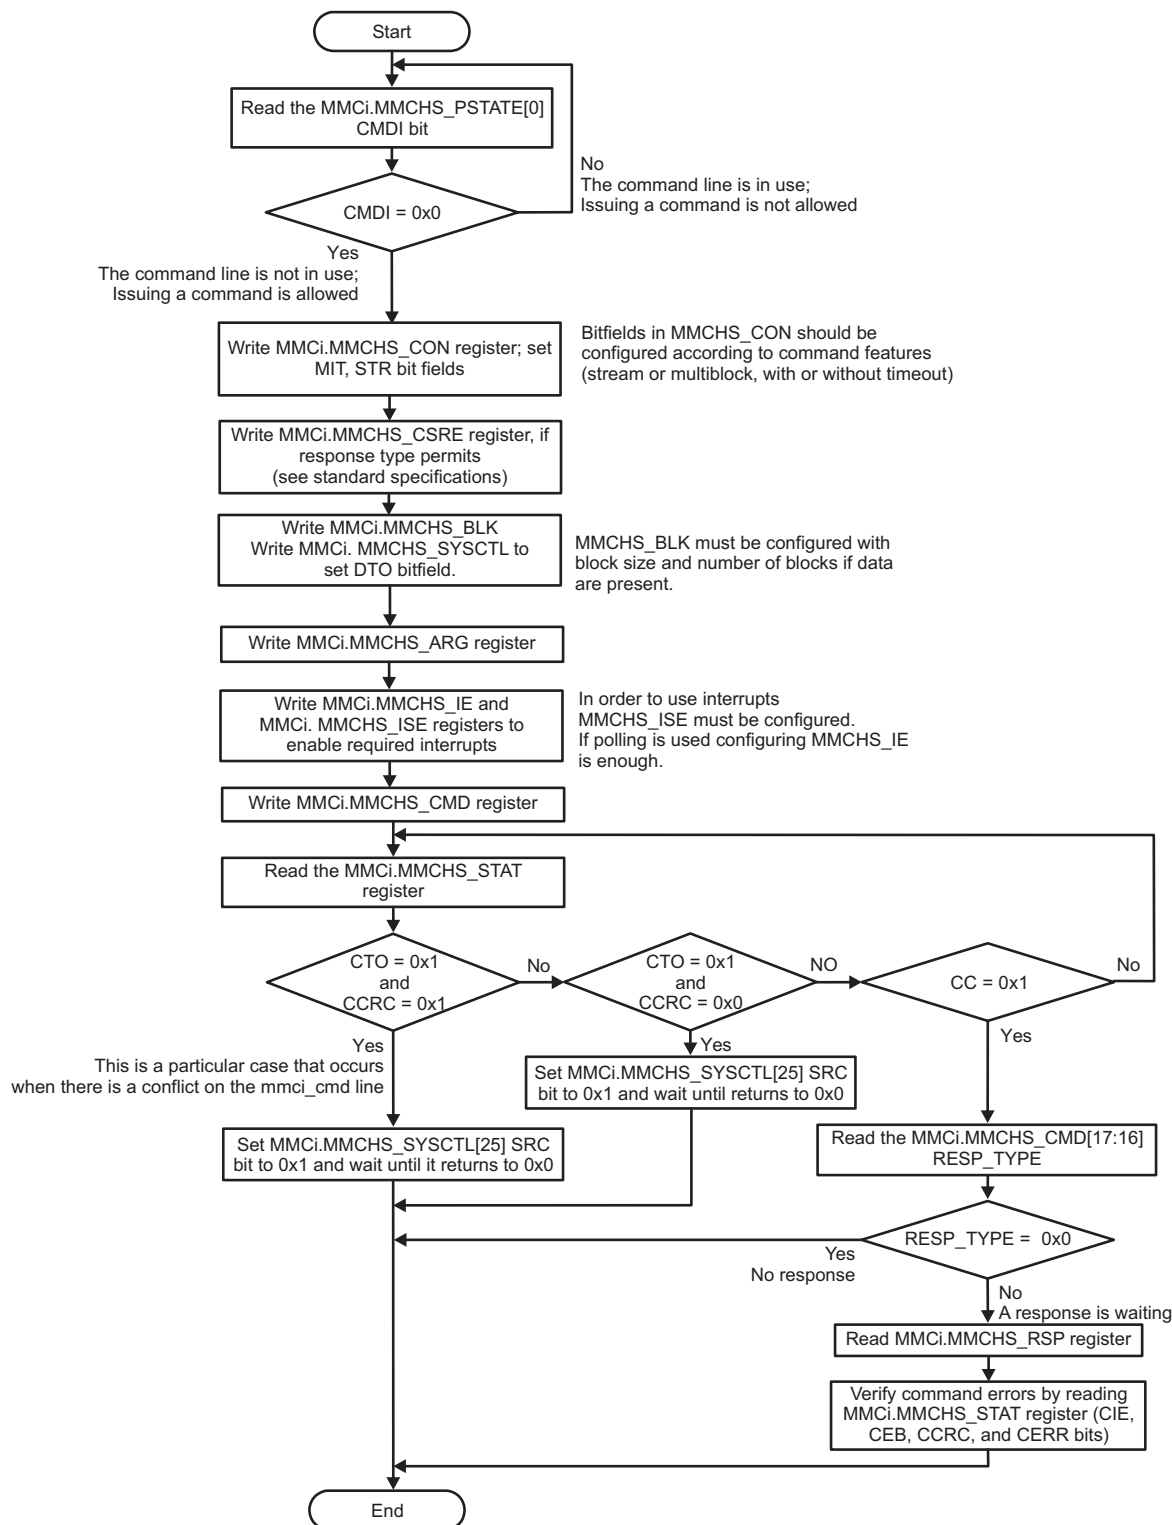

mmchs-039

22.5.2.7 Basic Operations - Steps Detailed

22.5.2.7.1 Command Transfer Flow

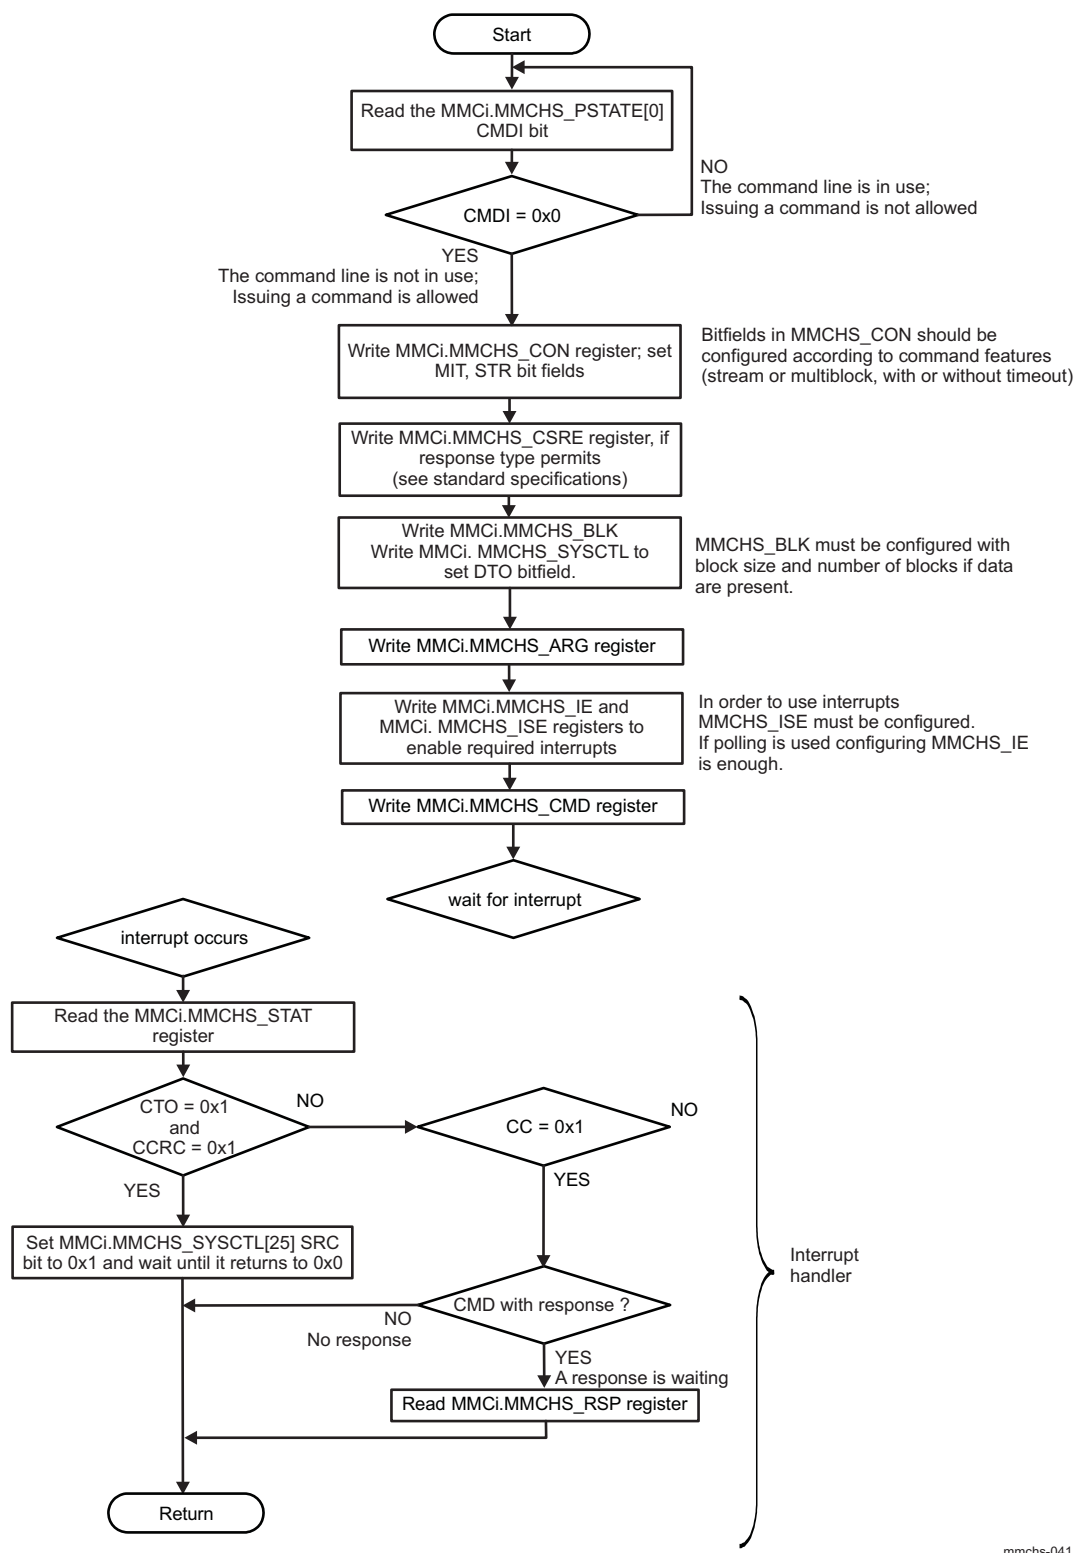

Figure 22-35 describes how to send a command to the card using polling instead of interrupts for event signaling.

Figure 22-35. MMC/SD/SDIO Controller Command Transfer Flow with polling

mmchs-040

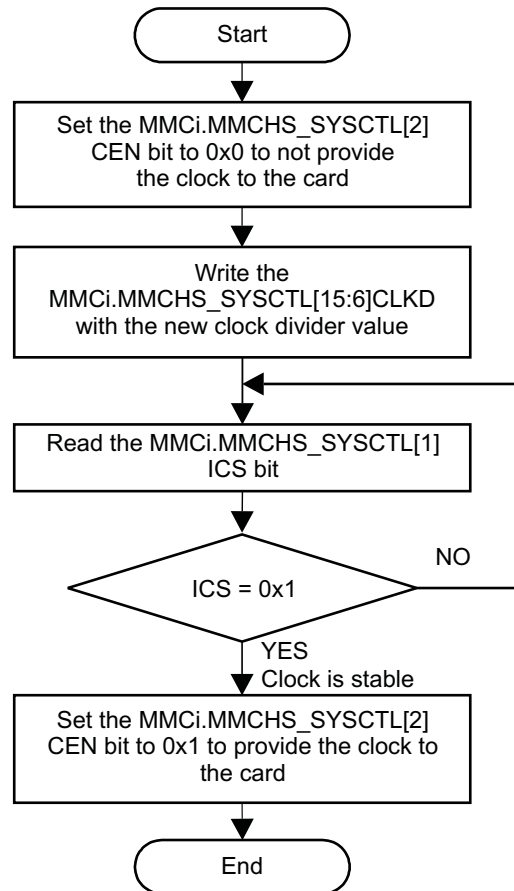

Figure 22-36 describes how to send a command to the card using interrupts for event signaling.

Figure 22-36. MMC/SD/SDIO Controller Command Transfer Flow with interrupts

22.5.2.7.2 MMCHS Clock Frequency Change

Figure 22-37 describes the different steps that allow to change the MMC/SD/SDIO output clock frequency.

Figure 22-37. MMC/SD/SDIO Controller Clock Frequency Change Flow

mmchs-042

22.5.3 MMC/SD/SDIO1 Bus Voltage Selection

The MMC/SD/SDIO1 controller can operate with two types of card voltages: 1.8 V and 3.0 V. For this reason, dual voltage pads are implemented on this interface. For technological concerns those pads must have an internal bias voltage reference to operate. The PBIAS_LITE module supplies this bias voltage, depending on the CONTROL.CONTROL_PBIAS_LITE register settings.

See the *Extended-Drain I/O Pin and PBIAS Cell* for more information about the PBIAS_LITE cell.

The *Extended-Drain I/Os and PBIAS Cell Basic Programming Guide* describes the steps involved in transitioning from 1.8 V to 3.0 V and from 3.0 V to 1.8 V, applicable to the MMC/SD/SDIO1 controller.

CAUTION

The BIAS voltage must be set using the procedure described in the *Extended-Drain I/Os and PBIAS Cell Basic Programming Guide*. Failure to follow this procedure can damage the MMCHS interface.

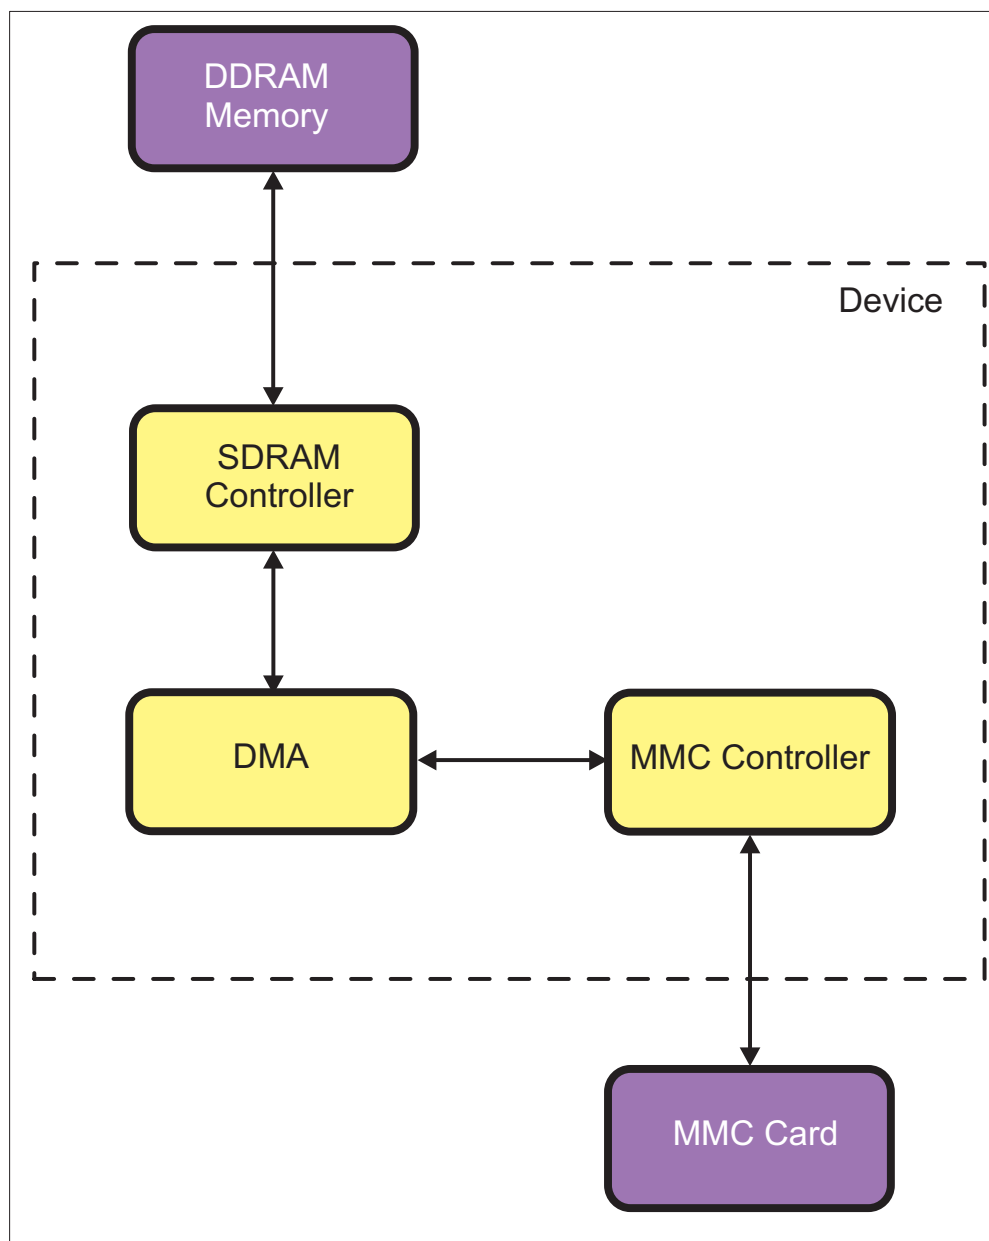

22.6 MMC/SD/SDIO Use Cases and Tips

22.6.1 MMCHS Controller Usage

22.6.1.1 Overview

The MMCHS controller is in charge of managing raw data storage in a MMC memory card. The MMCHS controller transfers data between DDRAM and MMC card. [Figure 22-38](#) gives an overview of MMCHS controller position in the use case.

Figure 22-38. Overview

mmchs_050

For the Camcorder use case, the MMCHS controller is configured to operate with the following features :

- High speed mode with a card clock frequency of 48 MHz.
- 8 data lines.

- 1.8 V and 3.0 V voltage capabilities.

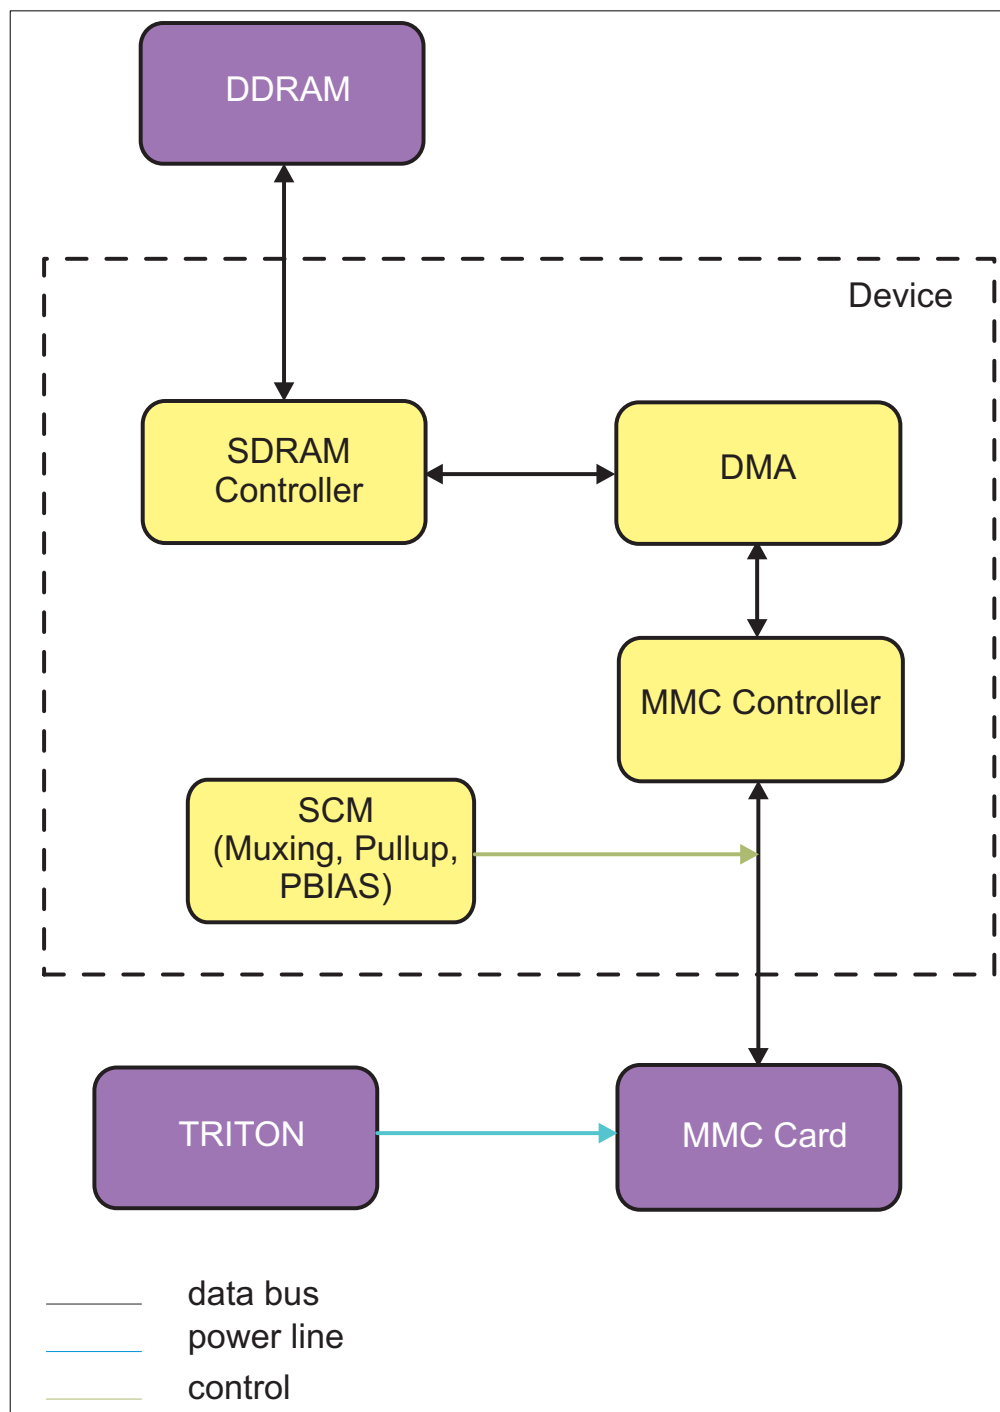

MMC card power supply is not provided by the MMCHS controller itself but rather by the companion device. please refer to I2C TRM output to learn how to set these voltage levels.

Only MMC1 controller is used in this configuration. Hence this document describes the output of the test carried out with MMC1 controller.

22.6.1.2 Environment

In order to operate in the correct manner, the MMCHS controller needs the System Control Module (SCM) to be configured with the right muxing mode and with the right pull up state. The MMC card needs to be powered with the right power level and this is done with the companion device. [Figure 22-39](#) gives the environment picture of the MMCHS controller.

Figure 22-39. Environment

mmchs_051

22.6.1.2.1 Command and Data Transfer Formats

When communicating with a MMC card, The MMCHS controller is always the master. The communication between the MMCHS controller and the MMC card always starts by sending a command. Both command and data transfers are started with a command.

The data transfer type used by the MMCHS controller is a finite multiple block transfer. [Figure 22-40](#) illustrates a command transfer without data. [Figure 22-41](#) and [Figure 22-42](#) illustrate a multiple block transfer between the MMCHS controller and the MMC card.

Figure 22-40. Command Transfer

Figure 22-41. Data Read Transfer

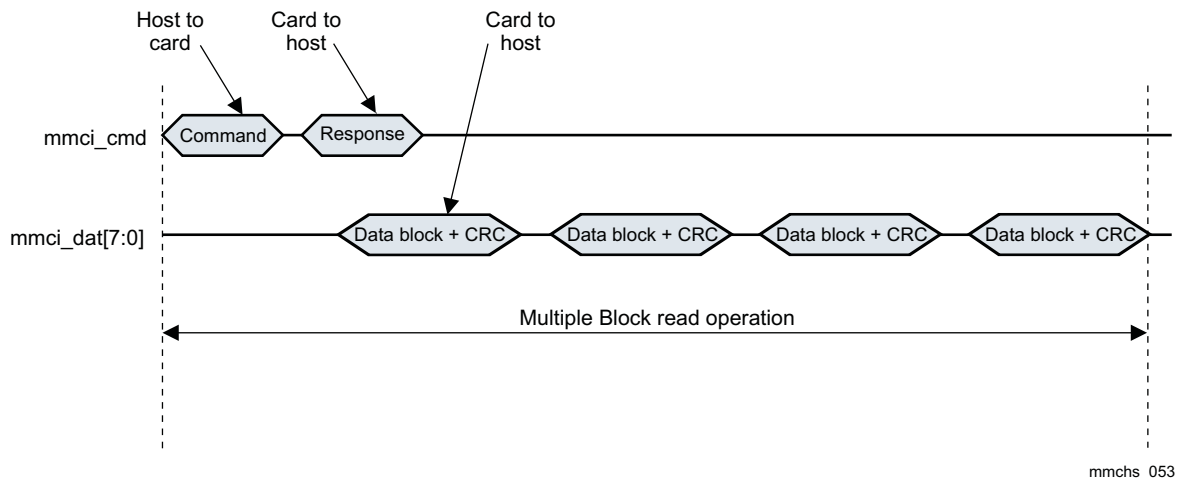

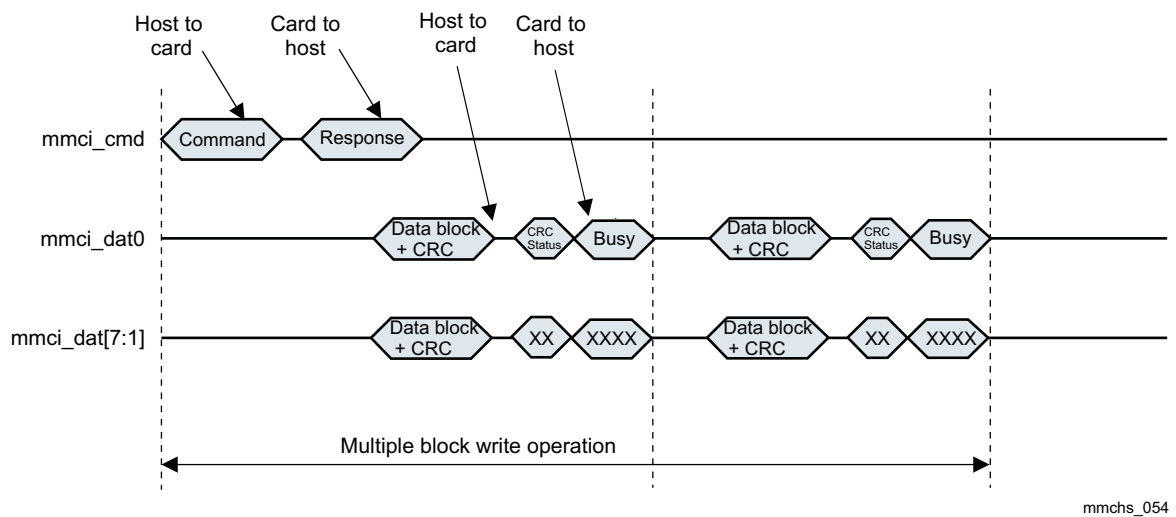

Figure 22-42. Data Write Transfer

22.6.1.3 Programming Flow

22.6.1.3.1 Initial Configuration

The initialization of the MMCHS controller is done through these steps :

1. MMCHS controller interface and functional clocks enabling.
2. MMCHS controller software reset.
3. MMCHS controller voltage capabilities initialization.
4. MMCHS controller default initialization.
5. MMCHS controller INIT procedure start.
6. MMCHS controller pre-card identification configuration.

For more information about different steps the MMCHS controller goes through during initial configuration refer to [Section 22.5](#), *MMC/SD/SDIO Basic Programming Model*.

22.6.1.3.1.1 MMCHS Controller Interface and Functional Clocks Enabling

To enable the interface and functional clocks of the MMCHS1 controller, the following steps must be done:

1. Enable the interface clock for the MMCHS1 controller (set the PRCM.CM_ICLKEN1_CORE[24] EN_MMCHS1).
2. Enable the functional clock for the MMCHS1 module (set the PRCM.CM_FCLKEN1_CORE[24] EN_MMCHS1).

[Table 22-8](#) shows all PRCM registers to be configured to enable interface and functional clocks for MMCHS1 controller.

Table 22-8. Register Print for the MMCHS1 controller's clocks Initialization

Register Name	Register Address	Value	Value Description
PRCM.CM_ICLKEN1_CORE	0x4800 4A10	0x01000000	MMCHS1 interface clock enabled
PRCM.CM_FCLKEN1_CORE	0x4800 4A00	0x01000000	MMCHS1 functional clock enabled

22.6.1.3.1.2 MMCHS Controller Software Reset

In order to software reset the MMCHS1 controller, the following steps must be done:

1. Write 0x2 in MMCHS1.MMCHS_SYSCONFIG register.
2. Wait until MMCHS1.MMCHS_SYSSTATUS[0] RESETDONE turns 1.

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_SYSCONFIG	0x4809 C010	0x00000002	Activate software reset
MMCHS1.MMCHS_SYSSTATUS	0x4809 C014	0x00000001	Reset is over.

22.6.1.3.1.3 MMCHS Controller Voltage Capabilities Initialization

MMCHS1 controller's voltage capabilities should be set in MMCHS1.MMCHS_CAPA. Refer to [Table 22-9](#).

Table 22-9. MMCHS Controller Voltage Capabilities Initialization

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CAPA	0x4809 C140	current_value 0x06000000	Activate VS18 and VS30 in MMCHS_CAPA register.

22.6.1.3.1.4 MMCHS Controller Default Initialization

Before sending any command, the MMCHS controller is configured with default values :

1. Default voltage support is set to 1.8 v in MMCHS1.MMCHS_HCTL[11:9] SDVS.
2. MMC bus is set to open drain in MMCHS1.MMCHS_CON[0] OD.
3. MMC data bus width is set to 1 in MMCHS1.MMCHS_HCTL[1] DTW.
4. MMC Card's power is off.
5. MMC Card's clock is on in MMCHS1.MMCHS_SYSCTL[0] ICE and MMCHS1.MMCHS_SYSCTL[2] CEN.
6. MMCHS controller bus power up in MMCHS1.MMCHS_HCTL[8] SDBP.
7. MMC card's clock frequency is set to 150 KHz in MMCHS1.MMCHS_SYSCTL[15:6] CLKD.

Table 22-10 shows the values that should be written in the right register pool.

Table 22-10. MMC Controller Default Initialization Values

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000b00	data bus width = 1, voltage = 1.8v, MMC bus power is on (not card's power)
MMCHS1.MMCHS_SYSCTL	0x4809C12C	0x0000a007	card's clock enable and card's clock frequency divider.
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	Set MMC bus mode to open drain.

A small notice about MMCHS1.MMCHS_HCTL. Even if the value written in it is 0x00000b00, the value read from it is equal to 0x00000a00. This is due to the fact that the MMCHS controller is not in a card state mode which sets automatically MMCHS_HCTL[8] SDBP bit to 0.

22.6.1.3.1.5 MMCHS Controller INIT Procedure Start

Prior to issuing any command, the MMCHS controller has to execute a special INIT procedure. The MMCHS controller has to generate a clock during 1ms. During the INIT procedure, the MMCHS controller generates 80 clock periods. In order to keep the 1ms gap, the MMCHS controller should be configured to generate a clock whose frequency is smaller or equal to 80 KHz. If the MMCHS controller divider bitfield width doesn't allow to choose big values, the MMCHS controller driver should perform the INIT procedure twice or three times. Twice is generally enough.

The INIT procedure is executed by setting MMCHS1.MMCHS_CON[1] INIT bitfield to 1 and by sending a dummy command, writing 0x00000000 in MMCHS1.MMCHS_CMD register.

Table 22-11 shows the values that should be written in the right register pool.

Table 22-11. MMCHS Controller INIT Procedure Start

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	current_value 0x00000002	sets MMCHS1.MMCHS_CON[1] INIT to 1
MMCHS1.MMCHS_CMD	0x4809C10C	0x00000000	sends dummy command.

22.6.1.3.1.6 MMCHS Controller Pre-card Identification Configuration

Before card identification starts, the MMCHS controller's configuration should change. MMC card's clock should now be 400 KHz according to MMC system spec requirements. Table 22-12 shows the values that should be written in the right register pool.

Table 22-12. MMCHS Controller Pre-Card Identification Configuration

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000b00	data bus width = 1, voltage = 1.8v, MMC bus power is on (not card's power)
MMCHS1.MMCHS_SYSCTL	0x4809C12C	0x00003C07	card's clock enable and card's clock frequency divider.
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	Set MMC bus mode to open drain.

22.6.1.3.2 MMC Card Identification

MMC card identification is performed by issuing many MMC commands. Each command imposes certain configuration values in a pool of registers. The status of command transfer is read in MMCHS1.MMCHS_STAT register and command response if any is read from MMCHS1.MMCHS_RSP10, MMCHS1.MMCHS_RSP32, MMCHS1.MMCHS_RSP54 and MMCHS1.MMCHS_RSP76.

This TRM output describes a use case where interrupts are used to signal MMCHS controller status changes.

For more details about the card identification sequence, please refer to [Section 22.5 MMC/SD/SDIO Basic Programming Model](#).

22.6.1.3.2.1 Sending CMD0

This command resets the MMC card (see [Table 22-13](#)).

Table 22-13. Sending CMD0

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x00040001	Enables CC and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x00040001	Enables CC and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x00000000	Sends CMD0 whose opcode is 0.

22.6.1.3.2.2 Sending CMD5

This command asks a SDIO card to send its operating conditions (see [Table 22-14](#)). This command will fail if there is no SDIO card. In case of success the response will be in MMCHS1.MMCHS_RSP10 register.

Table 22-14. Sending CMD5

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x00050001	Enables CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x00050001	Enables CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x05020000	Sends CMD5 whose opcode is 5 and response type is 48 bits.

22.6.1.3.2.2.1 Sending CMD8

This command asks a SD card version 2.X to send its operating conditions (see [Table 22-15](#)). This command will fail if there is no SD card version 2.X. In case of success the response will be in MMCHS1.MMCHS_RSP10 register.

Table 22-15. Sending CMD8

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x81a0000	Sends CMD8 whose opcode is 8, response type is 48 bits with CICE and CCCE enabled.

22.6.1.3.2.3 Sending CMD55

This is a special command used to prevent the card that the following command is going to be an application one (see [Table 22-16](#)). This is used to prepare the issuing of ACMD41 (opcode = 41) that usually asks a SD card version 1.X to send its operating conditions. If no SD card version 1.X is connected to the MMCHS controller this command will fail. In case of success, the response will be received in MMCHS1.MMCHS_RSP10 register.

Table 22-16. Sending CMD55

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x371a0000	Sends CMD55 whose opcode is 55, response type is 48 bits with CICE and CCCE enabled.

22.6.1.3.2.4 Sending CMD1

This command asks a MMC card to send its operating conditions (see [Table 22-17](#)). The response is received in MMCHS1.MMCHS_RSP10 register.

Table 22-17. Sending CMD1

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x00050001	Enables CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x00050001	Enables CC, CTO and CEB interrupts to rise.

Table 22-17. Sending CMD1 (continued)

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CMD	0x4809C10C	0x01020000	Sends CMD1 whose opcode is 1 and response type is 48 bits.

Once the card response is available in register MMCHS1.MMCHS_RSP10, the software is responsible to compare Card OCR and Host OCR, and then send a second CMD1 command with the cross-checked OCR. This way, the card is notified of the Operating Voltage to work with.

22.6.1.3.2.5 Sending CMD2

This command asks the MMC card to send its CID register's content (see [Table 22-18](#)). The response is 128 bit wide and is received in MMCHS1.MMCHS_RSP10, MMCHS1.MMCHS_RSP32, MMCHS1.MMCHS_RSP54 and MMCHS1.MMCHS_RSP76 registers.

Table 22-18. Sending CMD2

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x00070001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x00070001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x02090000	Sends CMD2 whose opcode is 2, response type is 136 bits with CCCE enabled.

22.6.1.3.2.6 Sending CMD3

This command sets MMC card address (see [Table 22-19](#)). Useful when MMCHS controller switches to addressed mode.

Table 22-19. Sending CMD3

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x031a0000	Sends CMD3 whose opcode is 3, response type is 48 bits with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00010000	MMCHS_ARG register carries MMC card's address. We choose to assign address 1 any other 16 bit wide value is valid.

22.6.1.3.3 MMC Bus Setting Change After Card Identification

After CMD3 command transfer is completed successfully, an auto-negotiation on voltage value an start. This is the frontier when the MMCHS controller should switch from identification mode to transfer mode. This impacts the controller in a way that it should change its bus state from open drain to push-pull.

[Table 22-20](#) gives several registers and their values.

Table 22-20. MMC Bus Setting Change Table

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	Bus is now in push-pull mode.
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000B00	Bus power is on, 1.8V is selected.
MMCHS1.MMCHS_SYSCTL	0x4809C12C	0x00003C07	MMCHS controller's internal clock is stable and enabled, MMC card's clock is on. Divider value is 240 which means that MMCHS controller is still supplying a 400 KHz clock.

22.6.1.3.4 Reading the CSD Register of a MMC Card

After settling on a voltage value, additional information must be read from the MMC card. This data is stored in MMC card CSD register. The card sends CSD register content after receiving CMD9 command. The CSD register holds important information on the card, MMC system specification version support, maximum clock speed support, memory capacity, minimum block length, read and write transfer latency timings.

22.6.1.3.4.1 Sending CMD9

This command asks the card to send its csd register's content (see [Table 22-21](#)). The 136 bit (128 bits are valid payload) response is received in MMCHS1.MMCHS_RSP10, MMCHS1.MMCHS_RSP32, MMCHS1.MMCHS_RSP54 and MMCHS1.MMCHS_RSP76 registers. CMD9 is an addressed command which means that card's address must be written in MMCHS1.MMCHS_ARG register before the command is issued.

Table 22-21. Sending CMD9

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_IE	0x4809C134	0x00070001	Enables CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x00070001	Enables CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x09090000	Sends CMD9 whose opcode is 9, response type is 136 bits with CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00010000	MMCHS_ARG register carries MMC card's address. We choose to assign address 1 any other 16 bit wide value is valid.

After receiving and parsing CMD9 response, MMC card clock speed must change to take advantage to card's maximum speed. This has an impact on MMC bus as we should perform a clock frequency change. At this stage the maximum clock frequency will be 20 MHz (please refer to MMC system specification from www.mmca.org).

Clock frequency change procedure is performed in several steps. Please refer to [Section 22.5](#), MMC/SD/SDIO Basic Programming Model, [Section 22.5.2.7.2](#), MMCHS Clock Frequency Change.

[Table 22-22](#) shows the value written in MMCHS1.MMCHS_SYSCTL register.

Table 22-22. MMCHS_SYSCTL Value

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_SYSCTL	0x4809C12C	0x00000147	MMCHS controller's internal clock is stable and enabled, MMC card's clock is on. Divider value is 5 which means that MMCHS controller is supplying a 19.2 MHz clock < 20 MHz.

Another important parameter read from CSD register is MMC system specification version. If this parameter points to a value greater than or equal to 4, the MMC card is capable of a speed up to 52 MHz and a bus width up to 8 (1, 4 or 8 are the possible options). In order to enable these two extra features, MMCHS controller must issue a CMD6 command with specific argument.

A CMD6 command is issued in the data transfer mode after MMC card is selected. MMC card selection consists of sending CMD7 command with MMC card's address in command argument.

Table 22-23 shows the set of register impacted by CMD7 issue action.

Table 22-23. Sending CMD7

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x071a0000	Sends CMD7 whose opcode is 7, response type is 48 bits with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00010000	MMCHS_ARG register carries MMC card's address. We choose to assign address 1 any other 16 bit wide value is valid.

After a CMD7 transfer is complete, the MMC card is ready to receive a CMD6 command. CMD6 command is used to write a byte in MMC card extended CSD register (ext_csd). It is an IO access function. There are two write actions, the first one enables a specific data bus width in the card. For our use case we used maximum data bus width 8. The second one enables high speed feature in the card.

22.6.1.3.4.1.1 Setting Data Bus Width to 8

Table 22-24 shows the set of registers impacted by issuing CMD6.

Table 22-24. Setting Data Bus Width with CMD6

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x061b0000	Sends CMD6 whose opcode is 6, response type is 48 bits with busy, with CICE and CCCE enabled.

Table 22-24. Setting Data Bus Width with CMD6 (continued)

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_ARG	0x4809C108	0x03b70200	(3 << 24) (byte_address << 16) (byte_value << 8). byte_address is the byte address in ext_csd register.

After issuing CMD6 completes successfully and MMC card leaves busy state, MMCHS controller should change its data bus width. This is done by changing MMCHS1.MMCHS_CON configuration value.

Table 22-25. MMCHS_CON Value

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000020	MMCHS controller's data bus width is set to 8.

22.6.1.3.4.1.2 Enable High Speed Feature

Table 22-26 shows the set of registers impacted by issuing CMD6 issuing.

Table 22-26. Enabling High Speed with CMD6

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000020	MMC bus is in push-pull mode. DW8 is enabled.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x061b0000	Sends CMD6 whose opcode is 6, response type is 48 bits with busy, with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x03b90100	(3 << 24) (byte_address << 16) (byte_value << 8). byte_address is the byte address in ext_csd register.

After issuing CMD6 completes successfully and MMC card leaves busy state, MMCHS controller should now change its output clock to bring it to 48 MHz. 52 MHz, max frequency value supported by MMC card version 4 and above, is not supported because 96 MHz, MMCHS controller functional clock, is not a multiple of 52 MHz. We fall off to 48 MHz.

Table 22-27. MMCHS_SYSCTL Value

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_SYSCTL	0x4809C12C	0x00000087	MMCHS controller's internal clock is stable and enabled, MMC card's clock is on. Divider value is 2 which means that MMCHS controller is supplying a 48 MHz clock.

22.6.1.3.5 MMC Write Transfer

Either data read or data write transfer uses DMA controller to perform memory (DDRAM) to/from MMCHS controller transfers. The DMA part is not described in this chapter; it is described in the *DMA* chapter.

Before any data transfer begins, the card must selected by issuing CMD7 command (Table 22-23).

A write transfer is a finite multiple block write transfer. In order to perform a write transfer, the following steps must be performed.

22.6.1.3.5.1 Send CMD16

Issuing CMD16 allows to set the block length. For our use case we decided to use a static block length of 512 bytes. The block length value is passed to the MMC card via MMCHS1.MMCHS_ARG register. The registers impacted by this operation are as follows:

Table 22-28. Setting Block Length

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000020	MMC bus is in push-pull mode. DW8 is enabled.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x101a0000	Sends CMD16 whose opcode is 16, response type is 48 bits, with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00000200	Block length is 512 = 0x200

22.6.1.3.5.2 Send CMD23

Issuing CMD23 allows to set the number of how many 512-byte blocks the MMC card should expect from the MMCHS controller. The number of blocks is passed to MMC card via MMCHS1.MMCHS_ARG register. The registers impacted by this operation are as follows:

Table 22-29. Setting Number of Blocks

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000020	MMC bus is in push-pull mode. DW8 is enabled.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x171a0000	Sends CMD23 whose opcode is 23, response type is 48 bits, with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00000008	Number of 512-byte blocks in 4 KB buffer is 8.

22.6.1.3.5.3 Send CMD25

Issuing CMD25 starts the finite, multiple block write transfer. Before the transfer starts, DMA controller should be configured for this operation. For more details about DMA configuration please refer to the *DMA* chapter.

Table 22-30. CMD25 Issuing

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000020	MMC bus is in push-pull mode. DW8 is enabled.

Table 22-30. CMD25 Issuing (continued)

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_IE	0x4809C134	0x107f0013	Enables CERR, CIE, CCRC, CC, TC, BWR, CTO, DTO, DCRC, DEB and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x107f0013	Enables CERR, CIE, CCRC, CC, TC, BWR, CTO, DTO, DCRC, DEB and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x193a0023	Sends CMD25 whose opcode is 25, response type is 48 bits, with CICE, DP, MSBS, BCE, DE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00000000	Not used.
MMCHS1.MMCHS_BLK	0x4809C104	0x00080200	(number_blocks << 16) (block_length)

22.6.1.3.6 MMC Read Transfer

Either data read or data write transfer uses DMA controller to perform memory (DDRAM) to/from MMCHS controller transfers. The DMA part is not described in this document; it is described in the *DMA* chapter.

Before any data transfer begins, the card must selected by issuing CMD7 command ([Table 22-23](#)).

A read transfer is a finite multiple block write transfer. In order to perform a read transfer, the following steps must be performed.

22.6.1.3.6.1 Send CMD16

Issuing CMD16 allows to set the block length. For our use case we decided to use a static block length of 512 bytes. The block length value is passed to the MMC card via MMCHS1.MMCHS_ARG register. See [Table 22-28](#).

22.6.1.3.6.2 Send CMD23

Issuing CMD23 allows to set the number of how many 512-byte blocks the MMC card should expect from the MMCHS controller. The number of blocks is passed to MMC card via MMCHS1.MMCHS_ARG register. See [Table 22-29](#).

22.6.1.3.6.3 Send CMD18

Issuing CMD18 starts the finite, multiple block read transfer. Before the transfer starts, DMA controller should be configured for this operation. For more details about DMA configuration please refer to the *DMA* chapter.

Table 22-31. CMD18 Issuing

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000020	MMC bus is in push-pull mode. DW8 is enabled.
MMCHS1.MMCHS_IE	0x4809C134	0x107f0023	Enables CERR, CIE, CCRC, CC, TC, BRR, CTO, DTO, DCRC, DEB and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x107f0023	Enables CERR, CIE, CCRC, CC, TC, BRR, CTO, DTO, DCRC, DEB and CEB interrupts to rise.

Table 22-31. CMD18 Issuing (continued)

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CMD	0x4809C10C	0x123a0033	Sends CMD18 whose opcode is 18, response type is 48 bits, with CICE, DP, MSBS, BCE, DE, DDIR and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00000000	Not used.
MMCHS1.MMCHS_BLK	0x4809C104	0x00080200	(number_blocks << 16) (block_length)

22.6.1.3.7 Dealing with High Capacity Cards

Unlike standard capacity cards, memory addressing mode for high capacity cards (SDHC and HC MMC) is not in byte format but in 512-byte block format. This means that byte access and partial access are not allowed with high capacity cards.

The 32-bit wide argument configured in MMCHS_ARG register and sent in data transfer commands CMD17, CMD18, CMD24, CMD25, carries the block index where the read/write should start and not the 32-bit byte address.

For high capacity cards, the block size is fixed and equals 512 bytes. Any data transfer, when data bus is involved, must be a multiple of 512 bytes.

The number of blocks for a high capacity card, which determines the capacity of the card block_count x 512 bytes, is accessible through field C_SIZE in card s CSD register version 2.0 for SD cards or through SEC_COUNT field in card s EXT_CSD register for MMC cards compliant with MMC specification version 4.x.

In case we need to write/read to/from a high capacity card a packet whose size is less than 512 bytes we must write/read the whole 512-byte block that contains the range of bytes we want to modify/read.

22.7 MMC/SD/SDIO Registers

Table 22-32 lists the instance summary.

Table 22-32. Instance Summary

Module Name	Base Address	Size
MMCHS1	0x4809 C000	512 bytes
MMCHS2	0x480B 4000	512 bytes
MMCHS3	0x480A D000	512 bytes

22.7.1 MMC/SD/SDIO Register Mapping Summary

Table 22-33 to Table 22-35 list the MMC/SD/SDIO1 to MMC/SD/SDIO3 registers. Table 22-36 through Table 22-82 describe the register bits.

CAUTION

The MMC/SD/SDIO/ registers are limited to 32-bit data accesses. 16-bit and 8-bit are not allowed and can corrupt register content.

Table 22-33. MMC/SD/SDIO1 Register Offset Addresses

22.7.2.4 MMCHS_SYSTEST

Table 22-42. MMCHS_SYSTEST

Address Offset	0x028	Instance	MMCHS1
Physical Address	0x4809 C028		MMCHS3
	0x480A D028		MMCHS2
	0x480B 4028		
Description	System Test register This register is used to control the signals that connect to I/O pins when the module is configured in system test (SYSTEST) mode for boundary connectivity verification. Note: In SYSTEST mode, a write into MMCi.MMCHS_CMD register will not start a transfer. The buffer behaves as a stack accessible only by the local host (push and pop operations). In this mode, the Transfer Block Size (MMCi.MMCHS_BLK[10:0] BLEN bits) and the Blocks count for current transfer (MMCi.MMCHS_BLK[31:16] NBLK bits) are needed to generate a Buffer write ready interrupt (MMCi.MMCHS_STAT[4] BWR bit) or a Buffer read ready interrupt (MMCi.MMCHS_STAT[5] BRR bit) and DMA requests if enabled.		
Type	RW

22.7.2.5 MMCHS_CON

Table 22-44. MMCHS_CON

Address Offset	0x02C	Instance	MMCHS1
Physical Address	0x4809 C02C		MMCHS3
	0x480A D02C		MMCHS2
	0x480B 402C		
Description	Configuration register This register is used: - to select the functional mode for any card. - to send an initialization sequence to any card. - to enable the detection on the mmci_dat[1] signal of a card interrupt for SDIO cards only. And also to configure: - specific data and command transfers for MMC cards only. - the parameters related to the card detect and write protect input signals.		
Type	RW		

Bits	Field Name	Description	Type	Reset
31:17	Reserved	Reserved bit field. Do not write any value	R	0x00000
16	CLKEXTFREE	External clock free running. This register is used to maintain card clock out of transfer transaction to enable slave module (for example to generate a synchronous interrupt on mmci_dat[1]). The Clock will be maintain only if MMCi.MMCHS_SYSTEST[2] CEN bit is set. 0x0: External card clock is cut off outside active transaction period. 0x1: External card clock is maintain even out of active transaction period only if MMCi.MMCHS_SYSTEST[2] CEN bit is set.	RW	0
15	PADEN	Control Power for MMC Lines. This register is only useful when MMC PADs contain power saving mechanism to minimize its leakage power. It works as a GPIO that directly control the ACTIVE pin of PADs. Excepted for mmci_dat[1], the signal is also combine outside the module with the dedicated power control MMCi.MMCHS_CON[11] CTPL bit.	RW	0

Bits	Field Name	Description	Type	Reset
		0x0: ADPIDLE module pin is not forced, it is automatically generated by the MMC fsms.		
		0x1: ADPIDLE module pin is forced to active state.		
14	OBIE	Out-of-Band Interrupt Enable (MMC cards only). This bit enables the detection of Out-of-Band Interrupt on MMC_OBI input pin. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration. 0x0: Out-of-Band interrupt detection disabled. 0x1: Out-of-Band interrupt detection enabled.	RW	0
13	OBIP	Out-of-Band Interrupt Polarity (MMC cards only). This bit selects the active level of the out-of-band interrupt coming from MMC cards. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration. 0x0: active high level. 0x1: active low level.	RW	0
12	CEATA	CE-ATA control mode (MMC cards compliant with CE-ATA): By default, this bit is set to 0. It is use to indicate that next commands are considered as specific CE-ATA commands that potentially use 'command completion' features. 0x0: Standard MMC/SD/SDIO mode. 0x1: CE-ATA mode. Next commands are considered as CE-ATA commands.	RW	0
11	CTPL	Control Power for mmci_dat[1] line (MMC and SD cards): By default, this bit is set to 0 and the host controller automatically disables all the input buffers outside of a transaction to minimize the leakage current. SDIO cards: When this bit is set to 1, the host controller automatically disables all the input buffers except the buffer of mmci_dat[1] outside of a transaction in order to detect asynchronous card interrupt on mmci_dat[1] line and minimize the leakage current of the buffers. 0x0: Disable all the input buffers outside of a transaction. 0x1: Disable all the input buffers except the buffer of mmci_dat[1] outside of a transaction.	RW	0
10:9	DVAL	Debounce filter value (All cards) This register is used to define a debounce period to filter the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: 33 us debounce period. 0x1: 231 us debounce period. 0x2: 1 ms debounce period. 0x3: 8.4 ms debounce period.	RW	0x3
8	WPP	Write protect polarity (SD and SDIO cards only) This bit selects the active level of the write protect input signal (SDWP). The usage of the write protect input signal (SDWP) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: Active high level. 0x1: Active low level.	RW	0
7	CDP	Card detect polarity (All cards) This bit selects the active level of the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: Active high level. 0x1: Active low level.	RW	0

Bits	Field Name	Description	Type	Reset
6	MIT	<p>MMC interrupt command (Only for MMC cards.) This bit must be set to 1, when the next write access to the command register (MMCI.MMCHS_CMD) is for writing a MMC interrupt command (CMD40) requiring the command timeout detection to be disabled for the command response.</p> <p>0x0: Command timeout enabled 0x1: Command timeout disabled</p>	RW	0
5	DW8	<p>8-bit mode MMC select For SD/SDIO cards, this bit must be set to 0. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliancy with MMC standard specification.</p> <p>0x0: 1-bit or 4-bit Data width (mmci_dat[0] or mmci_dat[3:0] used, MMC, SD cards) 0x1: 8-bit Data width (mmci_dat[7:0] used, MMC cards)</p>	RW	0
4	MODE	<p>Mode select (All cards) These bits select the functional mode.</p> <p>0x0: Functional mode. Transfers to the MMC/SD/SDIO cards follow the card protocol. MMC clock is enabled. MMC/SD transfers are operated under the control of the MMCI.MMCHS_CMD register.</p> <p>0x1: SYSTEST mode. The signal pins are configured as general-purpose input/output and the 1024-byte buffer is configured as a stack memory accessible only by the local host or system DMA. The pins retain their default type (input, output or in-out). SYSTEST mode is operated under the control of the SYSTEST register.</p>	RW	0
3	STR	<p>Stream command (Only for MMC cards). This bit must be set to 1 only for the stream data transfers (read or write) of the adtc commands. Stream read is a class 1 command (CMD11: READ_DAT_UNTIL_STOP). Stream write is a class 3 command (CMD20: WRITE_DAT_UNTIL_STOP).</p> <p>0x0: Block oriented data transfer. 0x1: Stream oriented data transfer.</p>	RW	0
2	HR	<p>Broadcast host response (Only for MMC cards). This register is used to force the host to generate a 48-bit response for bc command type. It can be used to terminate the interrupt mode by generating a CMD40 response by the core. In order to have the host response to be generated in open drain mode, the register MMCHS_CON[OD] must be set to 1. When MMCI.MMCHS_CON[12] CEATA bit is set to 1 and MMCI.MMCHS_ARG set to 0x00000000, when writing 0x00000000 into MMCI.MMCHS_CMD register, the host controller performs a 'command completion signal disable' token (i.e. mmci_cmd line held to '0' during 47 cycles followed by a 1).</p> <p>0x0: The host does not generate a 48-bit response instead of a command. 0x1: The host generates a 48-bit response instead of a command or a command completion signal disable token.</p>	RW	0

Bits	Field Name	Description	Type	Reset
1	INIT	<p>Send initialization stream (All cards).</p> <p>When this bit is set to 1, and the card is idle, an initialization sequence is sent to the card.</p> <p>An initialization sequence consists of setting the mmci_cmd line to 1 during 80 clock cycles. The initialization sequence is mandatory - but it is not required to do it through this bit - this bit makes it easier. Clock divider (MMCi.MMCHS_SYSCCTL[15:6] CLKD bits) should be set to ensure that 80 clock periods are greater than 1ms.</p> <p>Note: in this mode, there is no command sent to the card and no response is expected. A command complete interrupt will be generated once the initialization sequence is completed. MMCi.MMCHS_STAT[0] CC bit can be polled.</p> <p>0x0: The host does not send an initialization sequence.</p> <p>0x1: The host sends an initialization sequence.</p>	RW	0
0	OD	<p>Card open drain mode (Only for MMC cards).</p> <p>This bit must be set to 1 for MMC card commands 1, 2, 3 and 40, and if the MMC card bus is operating in open-drain mode during the response phase to the command sent. Typically, during card identification mode when the card is either in idle, ready or ident state.</p> <p>It is also necessary to set this bit to 1, for a broadcast host response (see Broadcast host response register MMCi.MMCHS_CON[2] HR bit)</p> <p>0x0: No Open Drain</p> <p>0x1: Open Drain or Broadcast host response</p>	RW	0

22.7.2.9 MMCHS CMD

Table 22-52. MMCHS_CMD

Address Offset	0x10C																																
Physical Address	0x4809 C10C																Instance	MMCHS1															
	0x480A D10C																	MMCHS3															
	0x480B 410C																	MMCHS2															
Description	<p>Command and transfer mode register</p> <p>MMCi.MMCHS_CMD[31:16] = the command register</p> <p>MMCi.MMCHS_CMD[15:0] = the transfer mode.</p> <p>This register configures the data and command transfers. A write into the most significant byte send the command. A write into MMCi.MMCHS_CMD[15:0] registers during data transfer has no effect.</p> <p>This register shall be used for any card.</p>																																
Type	RW																																

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved		INDX						CMD_TYPE		DP	CICE	CCCE	Reserved	RSP_TYPE		Reserved								MSBS	DDIR	Reserved	ACEN	BCE	DE		

Bits	Field Name	Description	Type	Reset
31:30	Reserved	Reserved bit field. Do not write any value	R	0x0
29:24	INDX	Command index Binary encoded value from 0 to 63 specifying the command number send to card 0x0: CMD0 or ACMD0 0x1: CMD1 or ACMD1 0x3F: CMD63 or ACMD63	RW	0x00
23:22	CMD_TYPE	Command type. This register specifies three types of special command: Suspend, Resume and Abort. These bits shall be set to 0b00 for all other commands. 0x0: Others Commands 0x1: Upon CMD52 "Bus Suspend" operation 0x2: Upon CMD52 "Function Select" operation 0x3: Upon CMD12 or CMD52 "I/O Abort" command	RW	0x0
21	DP	Data present select. This register indicates that data is present and mmci_dat line shall be used. It must be set to 0 in the following conditions: - Command using only mmci_cmd line -Command with no data transfer but using busy signal on mmci_dat[0] -Resume command 0x0: Command with no data transfer 0x1: Command with data transfer	RW	0
20	CICE	Command Index check enable. This bit must be set to 1 to enable index check on command response to compare the index field in the response against the index of the command. If the index is not the same in the response as in the command, it is reported as a command index error (MMCi.MMCHS_STAT[19] CIE bit set to1) Note: The CICE bit cannot be configured for an Auto CMD12, then index check is automatically checked when this command is issued. 0x0: Index check disable 0x1: Index check enable	RW	0
19	CCCE	Command CRC check enable. This bit must be set to 1 to enable CRC7 check on command response to protect the response against transmission errors on the bus. If an error is detected, it is reported as a command CRC error (MMCi.MMCHS_STAT[17] CCRC bit set to 1). Note: The CCCE bit cannot be configured for an Auto CMD12, and then CRC check is automatically checked when this command is issued.	RW	0

Bits	Field Name	Description	Type	Reset
		0x0: CRC7 check disable 0x1: CRC7 check enable		
18	Reserved	Reserved bit field. Do not write any value.	R	0
17:16	RSP_TYPE	Response type. This bits defines the response type of the command. 0x0: No response 0x1: Response Length 136 bits 0x2: Response Length 48 bits 0x3: Response Length 48 bits with busy after response	RW	0x0
15:6	Reserved	Reserved bit field. Do not write any value.	R	0x000
5	MSBS	Multi/Single block select. This bit must be set to 1 for data transfer in case of multi block command. For any others command this bit shall be set to 0. 0x0: Single block. If this bit is 0, it is not necessary to set the register MMCi.MMCHS_BLK[31:16] NBLK bits. 0x1: Multi block. When Block Count is disabled (MMCi.MMCHS_CMD[1] BCE bit is set to 0) in Multiple block transfers (MMCi.MMCHS_CMD[5] MSBS bit is set to 1), the module can perform infinite transfer.	RW	0
4	DDIR	Data transfer Direction. Select This bit defines either data transfer will be a read or a write. 0x0: Data Write (host to card) 0x1: Data Read (card to host)	RW	0
3	Reserved	Reserved bit field. Do not write any value.	R	0
2	ACEN	Auto CMD12 Enable. (SD cards only). When this bit is set to 1, the host controller issues a CMD12 automatically after the transfer completion of the last block. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop data transfer. In particular, secure commands do not require CMD12. For CE-ATA commands (MMCi.MMCHS_CON[12] CEATA bit set to 1), auto CMD12 is useless; therefore when this bit is set the mechanism to detect command completion signal, named CCS, interrupt is activated. 0x0: Auto CMD12 disable 0x1: Auto CMD12 enable or CCS detection enabled.	RW	0
1	BCE	Block Count Enable (Multiple block transfers only). This bit is used to enable the block count register (MMCHS_BLK[31:16] NBLK bits). When Block Count is disabled (MMCHS_CMD[1] BCE bit is set to 0) in Multiple block transfers (MMCHS_CMD[5] MSBS bits is set to 1), the module can perform infinite transfer. 0x0: Block count disabled for infinite transfer. 0x1: Block count enabled for multiple block transfer with known number of blocks	RW	0
0	DE	DMA Enable. This bit is used to enable DMA mode for host data access. 0x0: DMA mode disable 0x1: DMA mode enable	RW	0

22.7.2.14 MMCHS_DATA

Table 22-62. MMCHS_DATA

Address Offset	0x120		
Physical Address	0x4809 C120	Instance	MMCHS1
	0x480A D120		MMCHS3
	0x480B 4120		MMCHS2
Description	<p>Data Register</p> <p>This register is the 32-bit entry point of the buffer for read or write data transfers.</p> <p>The buffer size is 32bits x256(1024 bytes). Bytes within a word are stored and read in little endian format.</p> <p>This buffer can be used as two 512 byte buffers to transfer data efficiently without reducing the throughput.</p> <p>Sequential and contiguous access is necessary to increment the pointer correctly. Random or skipped access is not allowed. In little endian, if the local host accesses this register byte-wise or 16bit-wise, the least significant byte (bits [7:0]) must always be written/read first. The update of the buffer address is done on the most significant byte write for full 32-bit DATA register or on the most significant byte of the last word of block transfer.</p> <p>Example 1: Byte or 16-bit access</p> <p>Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1100 (2-bytes) OK</p> <p>Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=0100 (1-byte) OK</p> <p>Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1000 (1-byte) Bad</p>

22.7.2.15 MMCHS_PSTATE

Table 22-64. MMCHS_PSTATE

Address Offset	0x124	Instance	MMCHS1
Physical Address	0x4809 C124		MMCHS3
	0x480A D124		MMCHS2
	0x480B 4124		
Description	Present state register. The Host can get status of the Host Controller from this 32-bit read only register.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reserved								CLEV	DLEV				Reserved	Reserved	Reserved	Reserved					BRE	BWE	RTA	WTA	Reserved					DLA	DATI	CMDI

Bits	Field Name	Description	Type	Reset
31:25	Reserved	Reserved bit field. Do not write any value.	R	0x00
24	CLEV	mmci_cmd line signal level. This status is used to check the mmci_cmd line level to recover from errors, and for debugging. The value of this register after reset depends on the mmci_cmd line level at that time. Read 0x0: The mmci_cmd line level is 0. Read 0x1: The mmci_cmd line level is 1.	R	-
23:20	DLEV	mmci_dat[3:0] line signal level mmci_dat[3] => bit 23 mmci_dat[2] => bit 22 mmci_dat[1] => bit 21 mmci_dat[0] => bit 20 This status is used to check mmci_dat line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from mmci_dat[0]. The value of these registers after reset depends on the mmci_dat lines level at that time.	R	0x-
19	Reserved	Reserved bit field. Do not write any value	R	0
18	Reserved	Reserved bit field. Do not write any value This bit is not affected by soft reset.	R	1
17:16	Reserved	Reserved bit field. Do not write any value The value of these bits after soft reset is 0x0. These bits will be automatically set to 0x3 after debounce time. Debounce time is fixed to 256 x32kHz clock cycles.	R	00
15:12	Reserved	Reserved bit field. Do not write any value	R	0x0
11	BRE	Buffer read enable. This bit is used for non-DMA read transfers. It indicates that a complete block specified by MMCi.MMCHS_BLK[10:0] BLEN bits has been written in the buffer and is ready to be read. It is set to 0 when the entire block is read from the buffer. It is set to 1 when a block data is ready in the buffer and generates the Buffer read ready status of interrupt (MMCi.MMCHS_STAT[5] BRR bit). Read 0x0: Read BLEN bytes disable Read 0x1: Read BLEN bytes enable. Readable data exists in the buffer.	R	0
10	BWE	Buffer Write enable. This status is used for non-DMA write transfers. It indicates if space is available for write data. Read 0x0: There is no room left in the buffer to write BLEN bytes of data. Read 0x1: There is enough space in the buffer to write BLEN bytes of data.	R	0

Bits	Field Name	Description	Type	Reset
9	RTA	Read transfer active. This status is used for detecting completion of a read transfer. It is set to 1 after the end bit of read command or by activating a continue request (MMCi.MMCHS_HCTL[17] CR bit) following a stop at block gap request. This bit is set to 0 when all data have been read by the local host after last block or after a stop at block gap request. Read 0x0: No valid data on the mmci_dat lines. Read 0x1: Read data transfer on going.	R	0
8	WTA	Write transfer active. This status indicates a write transfer active. It is set to 1 after the end bit of write command or by activating a continue request (MMCi.MMCHS_HCTL[17] CR bit) following a stop at block gap request. This bit is set to 0 when CRC status has been received after last block or after a stop at block gap request. Read 0x0: No valid data on the mmci_dat lines. Read 0x1: Write data transfer on going.	R	0
7:3	Reserved	Reserved bit field. Do not write any value	R	0x00
2	DLA	mmci_dat line active. This status bit indicates whether one of the mmci_dat line is in use. In the case of read transactions (card to host): This bit is set to 1 after the end bit of read command or by activating continue request MMCi.MMCHS_HCTL[17] CR bit. This bit is set to 0 when the host controller received the end bit of the last data block or at the beginning of the read wait mode. In the case of write transactions (host to card): This bit is set to 1 after the end bit of write command or by activating continue request MMCi.MMCHS_HCTL[17] CR bit. This bit is set to 0 on the end of busy event for the last block; host controller must wait 8 clock cycles with line not busy to really consider not "busy state" or after the busy block as a result of a stop at gap request. Read 0x0: mmci_dat Line inactive Read 0x1: mmci_dat Line active	R	0
1	DATi	Command inhibit (mmci_dat). This status bit is generated if either mmci_dat line is active (MMCi.MMCHS_PSTATE[2] DLA bit) or Read transfer is active (MMCi.MMCHS_PSTATE[9] RTA bit) or when a command with busy is issued. This bit prevents the local host to issue a command. A change of this bit from 1 to 0 generates a transfer complete interrupt (MMCi.MMCHS_STAT[1] TC bit). Read 0x0: Issuing of command using the mmci_dat lines is allowed Read 0x1: Issuing of command using mmci_dat lines is not allowed	R	0
0	CMDi	Command inhibit(mmci_cmd). This status bit indicates that the mmci_cmd line is in use. This bit is set to 0 when the most significant byte is written into the command register. This bit is not set when Auto CMD12 is transmitted. This bit is set to 0 in either the following cases: - After the end bit of the command response, excepted if there is a command conflict error (MMCi.MMCHS_STAT[17] CCRC bit or MMCi.MMCHS_STAT[18] CEB bit set to 1) or a Auto CMD12 is not executed (MMCi.MMCHS_AC12[0] ACNE bit). - After the end bit of the command without response (MMCi.MMCHS_CMD[17:16] RSP_TYPE bits set to "00"). In case of a command data error is detected (MMCi.MMCHS_STAT[19] CTO bit set to 1), this register is not automatically cleared. Read 0x0: Issuing of command using mmci_cmd line is allowed Read 0x1: Issuing of command using mmci_cmd line is not allowed	R	0

22.7.2.16 MMCHS_HCTL

Table 22-66. MMCHS_HCTL

Address Offset	0x128			
Physical Address	0x4809 C128	Instance	MMCHS1	
	0x480A D128		MMCHS3	
	0x480B 4128		MMCHS2	
Description	Control register. This register defines the host controls to set power, wakeup and transfer parameters. MMCi.MMCHS_HCTL[31:24] = Wakeup control MMCi.MMCHS_HCTL[23:16] = Block gap control MMCi.MMCHS_HCTL[15:8] = Power control MMCi.MMCHS_HCTL[7:0] = Host control			
Type	RW			

Bits	Field Name	Description	Type	Reset
31:28	Reserved	Reserved bit field. Do not write any value.	R	0x00
27	OBWE	Wakeup event enable for 'Out-of-Band' Interrupt. This bit enables wakeup events for 'Out-of-Band' assertion. Wakeup is generated if the wakeup feature is enabled (MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit). The write to this register is ignored when MMCi.MMCHS_CON[14] OBIE bit is not set. 0x0: Disable wakeup on 'Out-of-Band' Interrupt. 0x1: Enable wakeup on 'Out-of-Band' Interrupt.	RW	0
26	REM	Wakeup event enable on SD card removal. This bit enables wakeup events for card removal assertion. Wakeup is generated if the wakeup feature is enabled (MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit). 0x0: Disable wakeup on card removal. 0x1: Enable wakeup on card removal.	RW	0
25	INS	Wakeup event enable on SD card insertion This bit enables wakeup events for card insertion assertion. Wakeup is generated if the wakeup feature is enabled (MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit). 0x0: Disable wakeup on card insertion. 0x1: Enable wakeup on card insertion.	RW	0
24	IWE	Wakeup event enable on SD card interrupt. This bit enables wakeup events for card interrupt assertion. Wakeup is generated if the wakeup feature is enabled (MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit) and enable status bit is set (MMCi.MMCHS_IE[8] CIRQ_ENABLE bit). 0x0: Disable wakeup on card interrupt 0x1: Enable wakeup on card interrupt	RW	0
23:20	Reserved	Reserved bit field. Do not write any value	R	0x0
19	IBG	Interrupt block at gap. This bit is valid only in 4-bit mode of SDIO card to enable interrupt detection in the interrupt cycle at block gap for a multiple block transfer. For MMC cards and for SD card this bit should be set to 0. 0x0: Disable interrupt detection at the block gap in 4-bit mode 0x1: Enable interrupt detection at the block gap in 4-bit mode	RW	0

Bits	Field Name	Description	Type	Reset
18	RWC	<p>Read wait control.</p> <p>The read wait function is optional only for SDIO cards. If the card supports read wait, this bit must be enabled, then requesting a stop at block gap (MMCi.MMCHS_HCTL[16] SBGR bit) generates a read wait period after the current end of block. Be careful, if read wait is not supported it may cause a conflict on mmci_dat line.</p> <p>0x0: Disable Read Wait Control. Suspend/Resume cannot be supported.</p> <p>0x1: Enable Read Wait Control</p>	RW	0
17	CR	<p>Continue request.</p> <p>This bit is used to restart a transaction that was stopped by requesting a stop at block gap (MMCi.MMCHS_HCTL[16] SBGR bit). Set this bit to 1 restarts the transfer. The bit is automatically set to 0 by the host controller when transfer has restarted i.e. mmci_dat line is active (MMCi.MMCHS_PSTATE[2] DLA bit) or transferring data (MMCi.MMCHS_PSTATE[8] WTA bit).</p> <p>The Stop at block gap request must be disabled (MMCi.MMCHS_HCTL[16] SBGR bit =0) before setting this bit.</p> <p>0x0: No affect</p> <p>0x1: transfer restart</p>	RW	0
16	SBGR	<p>Stop at block gap request.</p> <p>This bit is used to stop executing a transaction at the next block gap. The transfer can restart with a continue request (MMCi.MMCHS_HCTL[17] CR bit) or during a suspend/resume sequence. In case of read transfer, the card must support read wait control. In case of write transfer, the host driver shall set this bit after all block data written. Until the transfer completion (MMCi.MMCHS_STAT[1] TC bit set to 1), the host driver shall leave this bit set to 1.If this bit is set, the local host shall not write to the data register (MMCi.MMCHS_DATA).</p> <p>0x0: Transfer mode</p> <p>0x1: Stop at block gap</p>	RW	0
15:12	Reserved	Reserved bit field. Do not write any value.	R	0x0
11:9	SDVS	<p>SD bus voltage select (All cards).</p> <p>The host driver should set these bits to select the voltage level for the card according to the voltage supported by the system (MMCi.MMCHS_CAPA[26] VS18 bit, MMCi.MMCHS_CAPA[25] VS30 bit, MMCi.MMCHS_CAPA[24] VS33 bit) before starting a transfer.</p> <p>0x5: 1.8V (Typical)</p> <p>0x6: 3.0V (Typical)</p> <p>0x7: 3.3V (Typical)</p> <p>MMCHS2: This field must be set to 0x5.</p> <p>MMCHS3: This field must be set to 0x5.</p>	RW	0x0
8	SDBP	<p>SD bus power.</p> <p>Before setting this bit, the host driver shall select the SD bus voltage (MMCi.MMCHS_HCTL[11:9] SDVS bits). If the host controller detects the No card state, this bit is automatically set to 0. If the module is power off, a write in the command register (MMCi.MMCHS_CMD) will not start the transfer. A write to this bit has no effect if the selected SD bus voltage is not supported according to capability register (MMCi.MMCHS_CAPA[VS*]).</p> <p>0x0: Power off</p> <p>0x1: Power on</p>	RW	0
7:2	Reserved	Reserved bit field. Do not write any value.	R	0x00

Bits	Field Name	Description	Type	Reset
1	DTW	Data transfer width. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliance with <i>MMC standard specification 4.x</i> . This register has no effect when the MMC 8-bit mode is selected (MMCi.MMCHS_CON[5] DW8 bit set to 1). For SD/SDIO cards, this bit must be set following a valid SET_BUS_WIDTH command (ACMD6) with the value written in bit 1 of the argument. Prior to this command, the SD card configuration register (SCR) must be verified for the supported bus width by the SD card. 0x0: 1-bit Data width (mmci_dat[0] used) 0x1: 4-bit Data width (mmci_dat[3:0] used)	RW	0
0	Reserved	Reserved bit field. Do not write any value.	R	0

Bits	Field Name	Description	Type	Reset
		0x0: Reset completed 0x1: Software reset for mmci_dat line		
25	SRC	Software reset for mmci_cmd line. This bit is set to 1 for reset and released to 0 when completed. mmci_cmd finite state machine in both clock domain are also reset. Here below the registers cleared by the MMCi.MMCHS_SYCTL[25] SRC bit: MMCi.MMCHS_PSTATE: CMDI MMCi.MMCHS_STAT: CC Interconnect and MMC command status management is reinitialized. 0x0: Reset completed 0x1: Software reset for mmci_cmd line	RW	0
24	SRA	Software reset for all. This bit is set to 1 for reset , and released to 0 when completed. This reset affects the entire host controller except for the card detection circuit and capabilities registers. 0x0: Reset completed 0x1: Software reset for all the design	RW	0
23:20	Reserved	Reserved bit field. Do not write any value.	R	0x0
19:16	DTO	Data timeout counter value and busy timeout. This value determines the interval by which mmci_dat lines timeouts are detected. The host driver needs to set this bit field based on - the maximum read access time (NAC) (Refer to the SD Specification Part1 Physical Layer), - the data read access time values (TAAC and NSAC) in the card specific data register (CSD) of the card, - the timeout clock base frequency (MMCi.MMCHS_CAPA[5:0] TCF bits). If the card does not respond within the specified number of cycles, a data timeout error occurs (MMCi.MMCHS_STAT[20] DTO bit). The MMCi.MMCHS_SYCTL[19,16] DTO bitfield is also used to check busy duration, to generate busy timeout for commands with busy response or for busy programming during a write command. Timeout on CRC status is generated if no CRC token is present after a block write. 0x0: TCF x 2 ¹³ 0x1: TCF x 2 ¹⁴ 0xE: TCF x 2 ²⁷ 0xF: Reserved	RW	0x0
15:6	CLKD	Clock frequency select These bits define the ratio between a reference clock frequency (system dependant) and the output clock frequency on the mmci_clk pin of either the memory card (MMC, SD or SDIO). 0x0: Clock Ref bypass 0x1: Clock Ref bypass 0x2: Clock Ref / 2 0x3: Clock Ref / 3 0x3FF: Clock Ref / 1023	RW	0x000
5:3	Reserved	Reserved bit field. Do not write any value	R	0x0
2	CEN	Clock enable. This bit controls if the clock is provided to the card or not. 0x0: The clock is not provided to the card . Clock frequency can be changed . 0x1: The clock is provided to the card and can be automatically gated when MMCi.MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1 (default value) . The host driver shall wait to set this bit to 1 until the Internal clock is stable (MMCi.MMCHS_SYCTL[1] ICS bit).	RW	0
1	ICS	Internal clock stable (status)This bit indicates either the internal clock is stable or not. Read The internal clock is not stable. 0x0:	R	0

Bits	Field Name	Description	Type	Reset
		Read 0x1: The internal clock is stable after enabling the clock (MMCi.MMCHS_SYSCTL[0] ICE bit) or after changing the clock ratio (MMCi.MMCHS_SYSCTL[15:6] CLKD bits).		
0	ICE	Internal clock enable. This register controls the internal clock activity. In very low power state, the internal clock is stopped. Note: The activity of the debounce clock (used for wakeup events) and the interface clock (used for reads and writes to the module register map) are not affected by this register. 0x0: The internal clock is stopped (very low power state). 0x1: The internal clock oscillates and can be automatically gated when MMCi.MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1 (default value) .	RW	0

22.7.2.18 MMCHS_STAT

Table 22-70. MMCHS_STAT

Address Offset	0x130			
Physical Address	0x4809 C130	Instance	MMCHS1	
	0x480A D130		MMCHS3	
	0x480B 4130		MMCHS2	
Description	Interrupt status register The interrupt status regroups all the status of the module internal events that can generate an interrupt. MMCHS_STAT[31:16] = Error Interrupt Status MMCHS_STAT[15:0] = Normal Interrupt Status			
Type	RW			

Bits	Field Name	Description	Type	Reset
31:30	Reserved	Reserved bit field. Do not write any value	R	0x0
29	BADA	Bad access to data space. This bit is set automatically to indicate a bad access to buffer when not allowed: - During a read access to the data register (MMCi. MMCHS_DATA) while buffer reads are not allowed (MMCi. MMCHS_PSTATE [11] BRE bit =0) - During a write access to the data register (MMCi. MMCHS_DATA) while buffer writes are not allowed (MMCi. MMCHS_PSTATE [10] BWE bit=0) Read 0x0: No Interrupt. Write 0x0: Status bit unchanged Read 0x1: Bad Access Write 0x1: Status is cleared	RW	0

Bits	Field Name	Description	Type	Reset
28	CERR	<p>Card error.</p> <p>This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5 or R5b. Only bits referenced as type E (error) in status field in the response can set a card status error. An error bit in the response is flagged only if corresponding bit in card status response error MMCi.MMCHS_CSRE in set.</p> <p>There is no card error detection for autoCMD12 command. The host driver shall read MMCi.MMCHS_RSP76 register to detect error bits in the command response.</p> <p>Read 0x0: No Error</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Card error</p> <p>Write 0x1: Status is cleared</p>	RW	0
27:25	Reserved	Reserved bit field. Do not write any value	R	0x0
24	ACE	<p>Auto CMD12 error.</p> <p>This bit is set automatically when one of the bits in Auto CMD12 Error status register has changed from 0 to 1.</p> <p>Read 0x0: No Error</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: AutoCMD12 error</p> <p>Write 0x1: Status is cleared</p>	RW	0
23	Reserved	Reserved bit field. Do not write any value	R	0
22	DEB	<p>Data End Bit error.</p> <p>This bit is set automatically when detecting a 0 at the end bit position of read data on mmci_dat line or at the end position of the CRC status in write mode.</p> <p>Read 0x0: No Error</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Data end bit error</p> <p>Write 0x1: Status is cleared</p>	RW	0
21	DCRC	<p>Data CRC Error.</p> <p>This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status different of a position "010" token during a block write command.</p> <p>Read 0x0: No Error.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Data CRC error</p> <p>Write 0x1: Status is cleared</p>	RW	0
20	DTO	<p>Data timeout error. This bit is set automatically according to the following conditions:</p> <ul style="list-style-type: none"> - Busy timeout for R1b, R5b response type. - Busy timeout after write CRC status. - Write CRC status timeout. - Read data timeout. <p>Read 0x0: No error</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Time out</p> <p>Write 0x1: Status is cleared</p>	RW	0
19	CIE	<p>Command index error.</p> <p>This bit is set automatically when response index differs from corresponding command index previously emitted. It depends on the enable bit (MMCi.MMCHS_CMD[20] CICE).</p> <p>Read 0x0: No error</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Command index error</p> <p>Write 0x1: Status is cleared</p>	RW	0

Bits	Field Name	Description	Type	Reset
18	CEB	<p>Command end bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response.</p> <p>Read 0x0: No error Write 0x0: Status bit unchanged Read 0x1: Command end bit error Write 0x1: Status is cleared</p>	RW	0
17	CCRC	<p>Command CRC Error. This bit is set automatically when there is a CRC7 error in the command response depending on the enable bit (MMCi.MMCHS_CMD[19] CCCE).</p> <p>Read 0x0: No Error Write 0x0: Status bit unchanged Read 0x1: Command CRC error Write 0x1: Status is cleared</p>	RW	0
16	CTO	<p>Command Timeout Error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within 5 clock cycles - the timeout is still detected at 64 clock cycles.</p> <p>Read 0x0: No error Write 0x0: Status bit unchanged Read 0x1: Time Out Write 0x1: Status is cleared</p>	RW	0
15	ERRI	<p>Error Interrupt. If any of the bits in the Error Interrupt Status register (MMCi.MMCHS_STAT[31:16]) are set, then this bit is set to 1. Therefore the host driver can efficiently test for an error by checking this bit first. Writes to this bit are ignored.</p> <p>Read 0x0: No Interrupt Read 0x1: Error interrupt event(s) occurred</p>	R	0
14:10	Reserved	Reserved bit field. Do not write any value.	R	0x00
9	OBI	<p>Out-Of-Band interrupt (This interrupt is only useful for MMC card). This bit is set automatically when MMCi.MMCHS_CON[14] OBIE bit is set and an Out-of-Band interrupt occurs on OBI pin. The interrupt detection depends on polarity controlled by MMCi.MMCHS_CON[13] OBIP bit. The Out-of-Band interrupt signal is a system specific feature for future use, this signal is not required for existing specification implementation.</p> <p>Read 0x0: No Out-Of-Band interrupt. Write 0x0: Status bit unchanged. Read 0x1: Interrupt Out-Of-Band occurs. Write 0x1: Status is cleared.</p>	R	0
8	CIRQ	<p>Card interrupt. This bit is only used for SD and SDIO cards. In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wakeup). In 4-bit mode, interrupt source is sampled during the interrupt cycle. In CE-ATA mode, interrupt source is detected when the card drives mmci_cmd line to zero during one cycle after data transmission end. All modes above are fully exclusive. The controller interrupt must be clear by setting MMCi.MMCHS_IE[8] CIRQ_ENABLE to 0, then the host driver must start the interrupt service with card (clearing card interrupt status) to remove card interrupt source. Otherwise the Controller interrupt will be reasserted as soon as MMCi.MMCHS_IE[8] CIRQ_ENABLE is set to 1. Writes to this bit are ignored.</p> <p>Read 0x0: No card interrupt Read 0x1: Generate card interrupt</p>	R	0
7:6	Reserved	Reserved bit field. Do not write any value.	RW	00

Bits	Field Name	Description	Type	Reset
5	BRR	<p>Buffer read ready.</p> <p>This bit is set automatically during a read operation to the card (see class 2 - block oriented read commands) when one block specified by the MMCi.MMCHS_BLK[10:0] BLEN bitfield is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the local host needs to empty the buffer by reading it.</p> <p>Note: If the DMA receive-mode is enabled, this bit is never set; instead a DMA receive request to the main DMA controller of the system is generated.</p> <p>Read 0x0: Not Ready to read buffer</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Ready to read buffer</p> <p>Write 0x1: Status is cleared</p>	RW	0
4	BWR	<p>Buffer write ready.</p> <p>This bit is set automatically during a write operation to the card (see class 4 - block oriented write command) when the host can write a complete block as specified by MMCi.MMCHS_BLK[10:0] BLEN. It indicates that the memory card has emptied one block from the buffer and that the local host is able to write one block of data into the buffer.</p> <p>Note: If the DMA transmit mode is enabled, this bit is never set; instead, a DMA transmit request to the main DMA controller of the system is generated.</p> <p>Read 0x0: Not Ready to write buffer</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Ready to write buffer</p> <p>Write 0x1: Status is cleared</p>	RW	0
3	Reserved	Reserved bit field. Do not write any value	R	0
2	BGE	<p>Block gap event.</p> <p>When a stop at block gap is requested (MMCi.MMCHS_HCTL[16] SBGR bit), this bit is automatically set when transaction is stopped at the block gap during a read or write operation.</p> <p>This event does not occur when the stop at block gap is requested on the last block.</p> <p>In read mode, a 1-to-0 transition of the mmci_dat line active status (MMCi.MMCHS_PSTATE[2] DLA bit) between data blocks generates a Block gap event interrupt.</p> <p>Read 0x0: No block gap event</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Transaction stopped at block gap</p> <p>Write 0x1: Status is cleared</p>	RW	0
1	TC	<p>Transfer completed.</p> <p>This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap request (MMCi.MMCHS_HCTL[16] SBGR bit).</p> <p>This bit is also set when exiting a command in a busy state (if the command has a busy notification capability).</p> <p>In Read mode: This bit is automatically set on completion of a read transfer (MMCi.MMCHS_PSTATE[9] RTA bit).</p> <p>In write mode: This bit is set automatically on completion of the mmci_dat line use (MMCi.MMCHS_PSTATE[2] DLA bit).</p> <p>Read 0x0: No transfer complete</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Data transfer complete</p> <p>Write 0x1: Status is cleared</p>	RW	0
0	CC	<p>Command complete.</p> <p>This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCi.MMCHS_PSTATE[0] CMDI bit)</p> <p>If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command timeout error (MMCi.MMCHS_STAT[16] CTO bit) has higher priority than command complete (MMCi.MMCHS_STAT[0] CC bit).</p> <p>If a response is expected but none is received, then a command timeout error is detected and signaled instead of the command complete interrupt.</p>	RW	0

Bits	Field Name	Description	Type	Reset
		Read 0x0: No Command complete		
		Write 0x0: Status bit unchanged		
		Read 0x1: Command complete		
		Write 0x1: Status is cleared

Bits	Field Name		Description																		Type		Reset										
31:27	Reserved		Reserved bit field. Do not write any value.																		R		0x00										
26	VS18		Voltage support 1.8V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via MMCi_RESET signal). Read 0x0: 1.8V Not Supported Write 0x0: 1.8V Not supported Read 0x1: 1.8V Supported Write 0x1: 1.8V Supported MMCHS1, 2 and 3: This bit must be set to 1.																		RW		0										
25	VS30		Voltage support 3.0V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via MMCi_RESET signal) Read 0x0: 3.0V Not Supported Write 0x0: 3.0V Not supported Read 0x1: 3.0V Supported Write 0x1: 3.0V Supported MMCHS1: This bit must be set to 1. MMCHS2 and 3: This bit must be left to 0.																		RW		0										
24	VS33		Voltage support 3.3V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via MMCi_RESET signal) Read 0x0: 3.3V Not Supported Write 0x0: 3.3V Not supported Read 0x1: 3.3V Supported Write 0x1: 3.3V Supported MMCHS1, 2 and 3: This bit must be left to 0.																		RW		0										
23	SRS		Suspend/Resume support (SDIO cards only)This bit indicates whether the host controller supports Suspend/Resume functionality.																		R		1										

Bits	Field Name	Description	Type	Reset
		Read 0x0: The Host controller does not Suspend/Resume functionality. Read 0x1: The Host controller supports Suspend/Resume functionality.		
22	DS	DMA support. This bit indicates that the Host Controller is able to use DMA to transfer data between system memory and the Host Controller directly. Read 0x0: DMA Not Supported Read 0x1: DMA Supported	R	1
21	HSS	High speed support. This bit indicates that the host controller supports high speed operations and can supply an up-to-52 MHz clock to the card. Read 0x0: High Speed Not Supported Read 0x1: High Speed Supported	R	1
20:18	Reserved	Reserved bit field. Do not write any value.	R	0x0
17:16	MBL	Maximum block length. This value indicates the maximum block size that the host driver can read and write to the buffer in the host controller. The host controller supports 512 bytes and 1024 bytes block transfers. Read 0x0: 512 bytes Read 0x1: 1024 bytes Read 0x2: 2048 bytes	R	0x1
15:14	Reserved	Reserved bit field. Do not write any value	R	0x0
13:8	BCF	Base clock frequency for clock provided to the card. Read 0x0: The value indicating the base (maximum) frequency for the output clock provided to the card is system dependent and is not available in this register. Get the information via another method. See the <i>Power Reset and Clock Management</i> chapter for more information on the value of FUNC_96M_CLK clock signal.	R	0x00
7	TCU	Timeout clock unit. This bit shows the unit of base clock frequency used to detect Data Timeout Error (MMCi.MMCHS_STAT[20] DTO bit). Read 0x0: kHz Read 0x1: MHz	R	1
6	Reserved	Reserved. This bit is initialized to zero, and writes to it are ignored.	R	0
5:0	TCF	Timeout clock frequency. The timeout clock frequency is used to detect Data Timeout Error (MMCi.MMCHS_STAT[20] DTO bit). Read 0x0: The timeout clock frequency depends on the frequency of the clock provided to the card. The value of the timeout clock frequency is not available in this register. Note: You can have the timeout clock frequency by dividing FUNC_96M_CLK by the value of the MMCi.MMCHS_SYSCTL[15:6] CLKD bitfield.	R	0x00

Universal Serial Bus (USB)

This chapter describes the high-speed USB On-The-Go (OTG) controller and the high-speed universal serial bus (USB) host subsystem of the OMAP35x Applications Processor.

Figure 23-1. USB Modules Overview

Topic	Page

23.1 High-Speed USB OTG Controller

Note: The High-Speed USB OTG Controller is an instantiation of the MUSBMHDC from Mentor Graphics Corporation.

This document contains materials that are 2003-2007 Mentor Graphics Corporation.

Mentor Graphics is a registered trademark of Mentor Graphics Corporation or its affiliated companies in the United States and other countries.

The High-Speed USB OTG Controller is an instantiation of the MUSBMHDC from Mentor Graphics Corporation.

23.1.1 Introduction

This chapter describes the high-speed universal serial bus (USB) host subsystem and the high-speed USB On-The-Go (OTG) controller of the OMAP35x Applications Processor. The controller complies with the USB 2.0 standard high-speed and full-speed functions and low-speed, full-speed, and high-speed limited host mode operations. It also includes support for the Session Request and Host Negotiation Protocols used in point-to-point communications, details of which are given in the USB On-the-Go supplement to the USB 2.0 specification. In addition, the four test modes for high-speed operation described in the USB 2.0 specification. It also allows options that allow it to be forced into full-speed mode, high-speed mode or host mode which may be used in helping debug PHY problems in hardware.

23.1.1.1 Purpose of the Peripheral

The USB controller supports data throughput rates up to 480 Mbps. It provides a mechanism for data transfer between USB devices and also supports host negotiation.

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

23.1.1.2 Features

The high-speed USB controller has the following features:

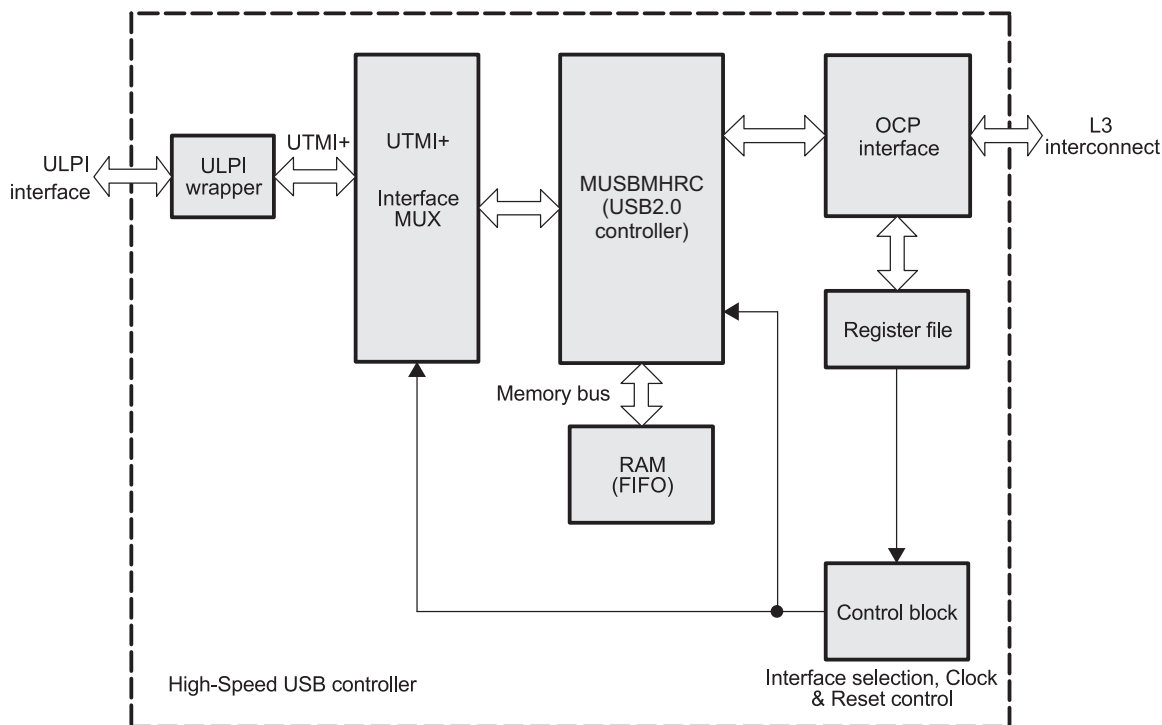

- Supports USB 2.0 peripheral at High Speed (480 Mbps) and Full Speed (12 Mbps)
- Supports USB 2.0 host at High Speed (480 Mbps), Full Speed (12 Mbps), and Low Speed (1.5 Mbps)
- Operates either as the function controller of a high-/full-speed USB peripheral or as the host/peripheral in point-to-point or multipoint communications with other USB functions
- Complies the USB 2.0 standard for high-speed (480 Mbps) functions and with the on-the-go (OTG) supplement (Revision 1.0a)
- Each endpoint can support all transfer types (control, bulk, interrupt, and isochronous)
- Supports USB extensions for Session Request (SRP) and Host Negotiation (HNP)
- Supports suspend/resume and remote wakeup
- Supports high-bandwidth Isochronous and Interrupt Transfers
- Contains one PHY (physical layer) interface: ULPI Interface (12/8 pin/data version)
- Supports 15 Transmit and 15 Receive endpoints in addition to control endpoint 0
- Each endpoint has its own FIFO, with the following properties:
 - Implemented within a single, 16K-byte internal RAM
 - Can be dynamically sized by software
 - Can be configured to hold multiple packets (up to 8192 bytes per FIFO)
 - can be accessed either by direct access or by DMA controller

- Software connect/disconnect option for peripheral
- Performs all transaction scheduling in hardware

23.1.1.3 Functional Block Diagram

The USB functional block diagram is shown in [Figure 23-2](#).

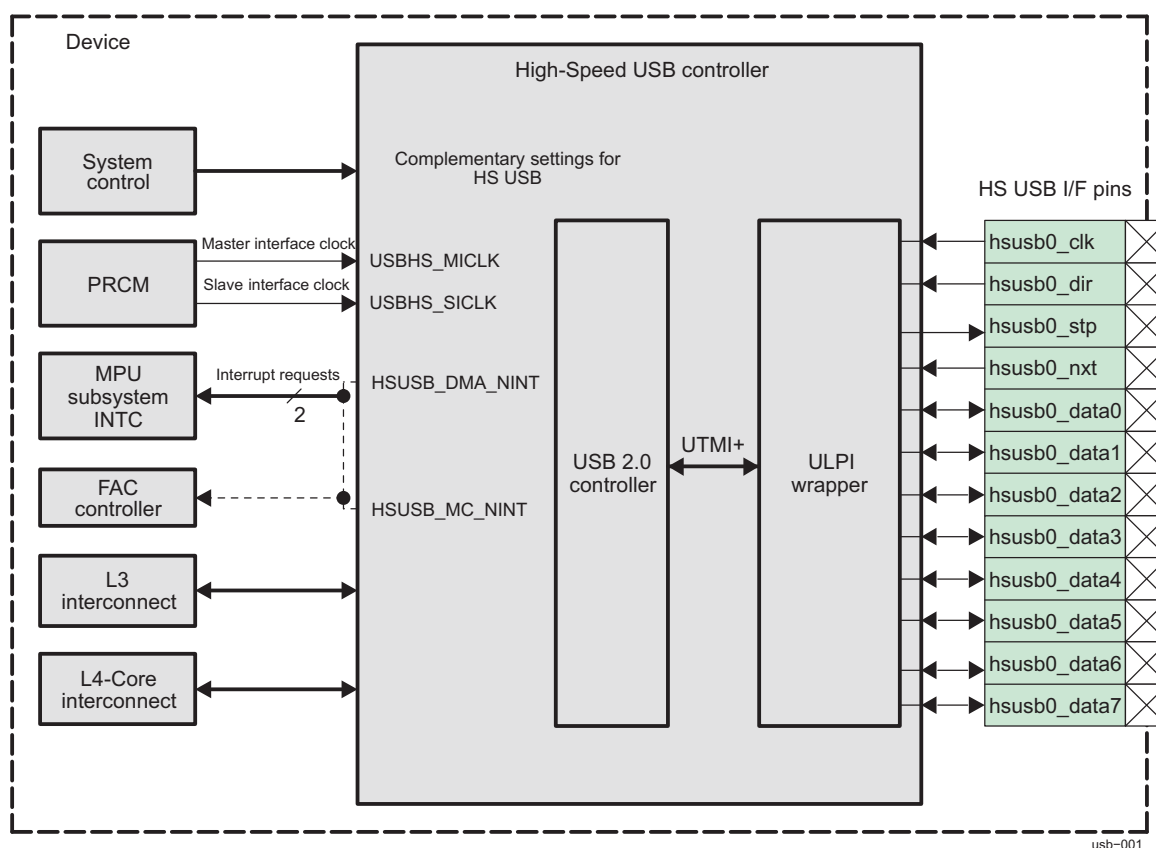

Figure 23-2. Functional Block Diagram

usb-005

Figure 23-3 highlights the high-speed USB controller.

Figure 23-3. High-Speed USB Controller Highlight

23.1.1.4 Industry Standard(s) Compliance Statement

This device conforms to USB 2.0 Specification and On-The-Go Supplement to the USB 2.0 Specification Rev 1.0a.

23.1.2 Peripheral Architecture

23.1.2.1 Clocks

23.1.2.1.1 Module Clocks

Three clocks are provided to the high-speed USB controller, as shown in [Table 23-1](#).

Table 23-1. USB Clocks

Attributes	Frequency	Name	Mapping	Comments
Functional clock	60 MHz	USBHS_FCLK	hsusb0_clk	Source is external transceiver (ULPI)
Master Interface clock	Depending on PRCM register settings	USBHS_MICLK	CORE_L3_ICLK	Source is PRCM module
Slave Interface clock	Depending on PRCM register settings	USBHS_SICLK	CORE_L4_ICLK	Source is PRCM module

23.1.2.1.2 Master Interface Clock

The master interface clock, USBHS_MICLK, comes from the PRCM module. This clock is controlled by the PRCM register bits PRCM.CM_ICLKEN1_CORE[4] (0= disabled, 1 = enabled) and PRCM.CM_AUTOIDLE1_CORE[4] (enables/disables automatic control of the interface clock)—see [Table 23-2](#).

Table 23-2. High-Speed USB Interface Clock

PRCM.CM_AUTOIDLE1_CORE[4]	PRCM.CM_ICLKEN1_CORE[4]	Interface Clock
0	0	Disabled
0	1	Enabled
1	0	Disabled
1	1	Automatic enabling/disabling

23.1.2.1.3 Functional Clock

The functional clock (60MHz), USBHS_FCLK, comes from the external ULPI transceiver through the hsusb0_clk input pin.

23.1.2.2 Signal Descriptions

Figure 23-4 shows the high-speed USB controller functional interface.

Figure 23-4. High-Speed USB Controller Functional Interface Signals

Table 23-3 describes the I/O of the high-speed USB controller interface.

Table 23-3. Input/Output Description

Signal Name	I/O	Description	Reset Value
hsub0_clk	I	60-MHz clock input from ULPI PHY	Unknown
hsub0_dir	I	Data direction control from ULPI PHY	Unknown
hsub0_stp	O	Stop signal to ULPI PHY	1
hsub0_nxt	I	Next signal from ULPI PHY	Unknown
hsub0_data0	I/O	Bidirectional DATA0	Unknown
hsub0_data1	I/O	Bidirectional DATA1	Unknown
hsub0_data2	I/O	Bidirectional DATA2	Unknown
hsub0_data3	I/O	Bidirectional DATA3	Unknown
hsub0_data4	I/O	Bidirectional DATA4	Unknown
hsub0_data5	I/O	Bidirectional DATA5	Unknown
hsub0_data6	I/O	Bidirectional DATA6	Unknown
hsub0_data7	I/O	Bidirectional DATA7	Unknown

23.1.2.3 Indexed and Non-Indexed Registers

USB controller provides two mechanism of accessing the endpoint control and status registers:

- Indexed Endpoint Control/Status Registers – These registers are memory-mapped at offset address 010h to 01Fh. The endpoint is selected by programming the INDEX register of the controller.
- Non-indexed Endpoint Control/Status Registers – These registers are memory-mapped at offset address 100h to 10Fh for endpoint 0 and offset 110h to 11Fh for Endpoint 1, and so on.

For detailed information about the USB controller registers, see [Section 23.1.4](#).

23.1.2.4 Dynamic FIFO Sizing

The USB controller supports a total of 16K RAM to dynamically allocate FIFO to all endpoints. The allocation of FIFO space to the different endpoints requires the specification for each Tx and Rx endpoint of:

- The start address of the FIFO within the RAM block
- The maximum size of packet to be supported
- Whether double-buffering is required.

These details are specified through four registers, which are added to the indexed area of the memory map. That is, the registers for the desired endpoint are accessed after programming the INDEX register with the desired endpoint value. [Section 23.1.4.31](#), [Section 23.1.4.32](#), [Section 23.1.4.33](#), and [Section 23.1.4.34](#) provide details of these registers.

Note: The option of setting FIFO sizes dynamically only applies to Endpoints 1 ... 15. Endpoint 0 FIFO has a fixed size (64 bytes) and a fixed location (start address 0).

It is the responsibility of the firmware to ensure that all the Tx and Rx endpoints that are active in the current USB configuration have a block of RAM assigned exclusively to that endpoint that is at least as large as the maximum packet size set for that endpoint.

23.1.3 USB Controller Host and Peripheral Modes Operation

The USB controller can be used in a range of different environments. It can be used as either a high-speed or a full-speed USB peripheral device attached to a conventional USB host (such as a PC). It can be used as either host or peripheral device in point-to-point data transfers with another peripheral device - or, if the other device also contains a Dual-Role Controller, the two devices can switch roles as required. (This second device may be either a high-speed, full-speed or low-speed USB function.) Or the controller can be used as the host to a range of such peripheral devices in a multi-point setup.

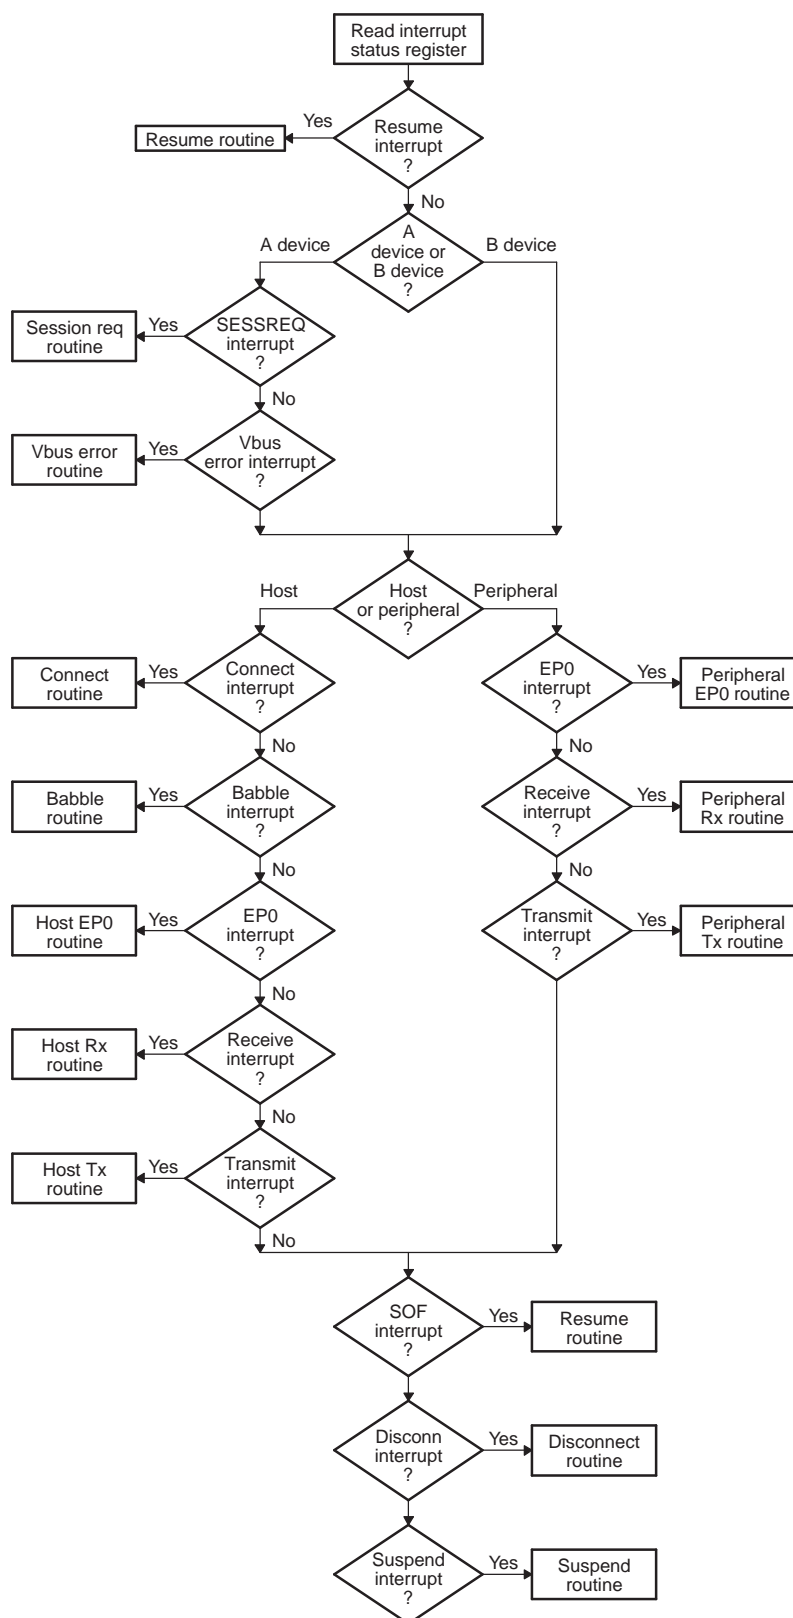

Whether the controller expects to behave as a host or as a peripheral device depends on the way the devices are cabled together. Each USB cable has an A end and a B end. If the A end of the cable is plugged into the controller, it will take the role of the Host device and go into host mode. If the B end of the cable is plugged in, the controller will go instead into peripheral mode.

The USB controller interrupts the ARM on completion of the data transfer on any of the endpoints or on detecting reset, resume, suspend, connect, disconnect, or SOF on the bus.

When the ARM is interrupted with a USB interrupt, it needs to read the interrupt status register to determine the endpoints that have caused the interrupt and jump to the appropriate routine. If multiple endpoints have caused the interrupt, endpoint 0 should be serviced first, followed by the other endpoints. The suspend interrupt should be serviced last.

The flowchart in [Figure 23-5](#) describes the interrupt service routine for the USB module.

The following sections describe the programming of USB controller in Peripheral mode and Host mode. DMA Operations and Interrupt Handler mechanisms are common to both peripheral and host mode operations and are discussed after the programming in Peripheral and Host Mode.

Figure 23-5. Interrupt Service Routine Flow Chart

23.1.3.1 USB Controller Peripheral Mode Operation

- **Soft connect** - After a reset, the SOFTCONN bit of POWER register (bit 6) is cleared to 0. The controller will therefore appear disconnected until the software has set the SOFTCONN bit to 1. The application software can then choose when to set the PHY into its normal mode. Systems with a lengthy initialization procedure may use this to ensure that initialization is complete and the system is ready to perform enumeration before connecting to the USB.
Once the SOFTCONN bit has been set, the software can also simulate a disconnect by clearing this bit to 0.
- **Entry into suspend mode**
When operating as a peripheral device, the controller monitors activity on the bus and when no activity has occurred for 3 ms, it goes into Suspend mode. If the Suspend interrupt has been enabled, an interrupt will be generated at this time.
At this point, the controller can then be left active (and hence able to detect when Resume signaling occurs on the USB), or the application may arrange to disable the controller by stopping its clock. However, the controller will not then be able to detect Resume signaling on the USB. As a result, some external hardware will be needed to detect Resume signaling (by monitoring the DM and DP signals), so that the clock to the controller can be restarted.
- **Resume Signaling** - When resume signaling occurs on the bus, first the clock to the controller must be restarted if necessary. Then the controller will automatically exit Suspend mode. If the Resume interrupt is enabled, an interrupt will be generated.
- **Initiating a remote wakeup** - If the software wants to initiate a remote wakeup while the controller is in Suspend mode, it should write to the Power register to set the RESUME bit to 1. The software should leave then this bit set for approximately 10 ms (minimum of 2 ms, a maximum of 15 ms) before resetting it to 0.

Note: No resume interrupt will be generated when the software initiates a remote wakeup.

- **Reset Signaling** - When reset signaling occurs on the bus, the controller will perform the following actions:
 - Sets FADDR register to 0
 - Sets INDEX register to 0
 - Flushes all endpoint FIFOs
 - Clears all control/status registers
 - Generates a reset interrupt.

If the HSENA bit in the POWER register (bit 5) was set, the controller also tries to negotiate for high-speed operation.

Whether high-speed operation is selected is indicated by HSMODE bit of POWER register (bit 4).

When the application software receives a reset interrupt, it should close any open pipes and wait for bus enumeration to begin.

23.1.3.1.1 Peripheral Mode: Control Transactions

Endpoint 0 is the main control endpoint of the core. The software is required to handle all the standard device requests that may be sent or received via endpoint 0. These are described in Universal Serial Bus Specification, Revision 2.0, Chapter 9. The protocol for these device requests involves different numbers and types of transactions per transfer. To accommodate this, the software needs to take a state machine approach to command decoding and handling.

The Standard Device Requests received by a USB peripheral device can be divided into three categories: Zero Data Requests (in which all the information is included in the command), Write Requests (in which the command will be followed by additional data), and Read Requests (in which the device is required to send data back to the host).

This section looks at the sequence of actions that the software must perform to process these different types of device request.

Note: The Setup packet associated with any standard device request should include an 8-byte command. Any setup packet containing a command field of anything other than 8 bytes will be automatically rejected by the controller.

23.1.3.1.1.1 Zero Data Requests

Zero data requests have all their information included in the 8-byte command and require no additional data to be transferred. Examples of Zero Data standard device requests are:

- SET_FEATURE
- CLEAR_FEATURE
- SET_ADDRESS
- SET_CONFIGURATION
- SET_INTERFACE

The sequence of events will begin, as with all requests, when the software receives an endpoint 0 interrupt. The RXPKTRDY bit of PERI_CSR0 (bit 0) will also have been set. The 8-byte command should then be read from the endpoint 0 FIFO, decoded and the appropriate action taken.

For example, if the command is SET_ADDRESS, the 7-bit address value contained in the command should be written to the FADDR register. The PERI_CSR0 register should then be written to set the SERV_RXPKTRDY bit (bit 6) (indicating that the command has been read from the FIFO) and to set the DATAEND bit (bit 3) (indicating that no further data is expected for this request). The interval between setting SERV_RXPKTRDY bit and DATAEND bit should be very small to avoid getting a SetupEnd error condition.

When the host moves to the status stage of the request, a second endpoint 0 interrupt will be generated to indicate that the request has completed. No further action is required from the software. The second interrupt is just a confirmation that the request completed successfully. For SET_ADDRESS command, the address should be set in FADDR register only after the status stage interrupt is received.

If the command is an unrecognized command, or for some other reason cannot be executed, then when it has been decoded, the PERI_CSR0 register should be written to set the SERV_RXPKTRDY bit (bit 6) and to set the SENDSTALL bit (bit 5). When the host moves to the status stage of the request, the controller will send a STALL to tell the host that the request was not executed. A second endpoint 0 interrupt will be generated and the SENTSTALL bit (bit 2 of PERI_CSR0) will be set.

If the host sends more data after the DATAEND bit has been set, then the controller will send a STALL. An endpoint 0 interrupt will be generated and the SENTSTALL bit (bit 2 of PERI_CSR0) will be set.

Note: DMA is not supported for endpoint 0, so the command should be read by accessing the endpoint 0 FIFO register.

23.1.3.1.1.2 Write Requests

Write requests involve an additional packet (or packets) of data being sent from the host after the 8-byte command. An example of a Write standard device request is: SET_DESCRIPTOR.

The sequence of events will begin, as with all requests, when the software receives an endpoint 0 interrupt. The RXPKTRDY bit of PERI_CSR0 will also have been set. The 8-byte command should then be read from the Endpoint 0 FIFO and decoded.

As with a zero data request, the PERI_CSR0 register should then be written to set the SERV_RXPKTRDY bit (bit 6) (indicating that the command has been read from the FIFO) but in this case the DATAEND bit (bit 3) should not be set 11xc (indicating that more data is expected).

When a second endpoint 0 interrupt is received, the PERI_CSR0 register should be read to check the endpoint status. The RXPKTRDY bit of PERI_CSR0 should be set to indicate that a data packet has been received. The COUNT0 register should then be read to determine the size of this data packet. The data packet can then be read from the endpoint 0 FIFO.

If the length of the data associated with the request (indicated by the `wLength` field in the command) is greater than the maximum packet size for endpoint 0, further data packets will be sent. In this case, `PERI_CSR0` should be written to set the `SERV_RXPKTRDY` bit, but the `DATAEND` bit should not be set.

When all the expected data packets have been received, the `PERI_CSR0` register should be written to set the `SERV_RXPKTRDY` bit and to set the `DATAEND` bit (indicating that no more data is expected).

When the host moves to the status stage of the request, another endpoint 0 interrupt will be generated to indicate that the request has completed. No further action is required from the software, the interrupt is just a confirmation that the request completed successfully.

If the command is an unrecognized command, or for some other reason cannot be executed, then when it has been decoded, the `PERI_CSR0` register should be written to set the `SERV_RXPKTRDY` bit (bit 6) and to set the `SENDSTALL` bit (bit 5). When the host sends more data, the controller will send a `STALL` to tell the host that the request was not executed. An endpoint 0 interrupt will be generated and the `SENTSTALL` bit of `PERI_CSR0` (bit 2) will be set.

If the host sends more data after the `DATAEND` has been set, then the controller will send a `STALL`. An endpoint 0 interrupt will be generated and the `SENTSTALL` bit of `PERI_CSR0` (bit 2) will be set.

23.1.3.1.3 Read Requests

Read requests have a packet (or packets) of data sent from the function to the host after the 8-byte command. Examples of Read Standard Device Requests are:

- `GET_CONFIGURATION`
- `GET_INTERFACE`
- `GET_DESCRIPTOR`
- `GET_STATUS`
- `SYNCH_FRAME`

The sequence of events will begin, as with all requests, when the software receives an endpoint 0 interrupt. The `RXPKTRDY` bit of `PERI_CSR0` (bit 0) will also have been set. The 8-byte command should then be read from the endpoint 0 FIFO and decoded. The `PERI_CSR0` register should then be written to set the `SERV_RXPKTRDY` bit (bit 6) (indicating that the command has read from the FIFO).

The data to be sent to the host should then be written to the endpoint 0 FIFO. If the data to be sent is greater than the maximum packet size for endpoint 0, only the maximum packet size should be written to the FIFO. The `PERI_CSR0` register should then be written to set the `TXPKTRDY` bit (bit 1) (indicating that there is a packet in the FIFO to be sent). When the packet has been sent to the host, another endpoint 0 interrupt will be generated and the next data packet can be written to the FIFO.

When the last data packet has been written to the FIFO, the `PERI_CSR0` register should be written to set the `TXPKTRDY` bit and to set the `DATAEND` bit (bit 3) (indicating that there is no more data after this packet).

When the host moves to the status stage of the request, another endpoint 0 interrupt will be generated to indicate that the request has completed. No further action is required from the software: the interrupt is just a confirmation that the request completed successfully.

If the command is an unrecognized command, or for some other reason cannot be executed, then when it has been decoded, the `PERI_CSR0` register should be written to set the `SERV_RXPKTRDY` bit (bit 6) and to set the `SENDSTALL` bit (bit 5). When the host requests data, the controller will send a `STALL` to tell the host that the request was not executed. An endpoint 0 interrupt will be generated and the `SENTSTALL` bit of `PERI_CSR0` (bit 2) will be set.

If the host requests more data after `DATAEND` (bit 3) has been set, then the controller will send a `STALL`. An endpoint 0 interrupt will be generated and the `SENTSTALL` bit of `PERI_CSR0` (bit 2) will be set.

23.1.3.1.4 Endpoint 0 States

When the USB controller is operating as a peripheral device, the endpoint 0 control needs three modes – `IDLE`, `TX` and `RX` – corresponding to the different phases of the control transfer and the states endpoint 0 enters for the different phases of the transfer (described in later sections).

The default mode on power-up or reset should be IDLE. RXPKT RDY bit of PERI_CSR0 (bit 0) becoming set when endpoint 0 is in IDLE state indicates a new device request. Once the device request is unloaded from the FIFO, the controller decodes the descriptor to find whether there is a data phase and, if so, the direction of the data phase of the control transfer (in order to set the FIFO direction). See [Figure 23-6](#).

Depending on the direction of the data phase, endpoint 0 goes into either TX state or RX state. If there is no Data phase, endpoint 0 remains in IDLE state to accept the next device request.

The actions that the CPU needs to take at the different phases of the possible transfers (e.g., loading the FIFO, setting TXPKTRDY) are indicated in [Figure 23-7](#).

Note: The controller changes the FIFO direction, depending on the direction of the data phase independently of the CPU.

Figure 23-6. CPU Actions at Transfer Phases

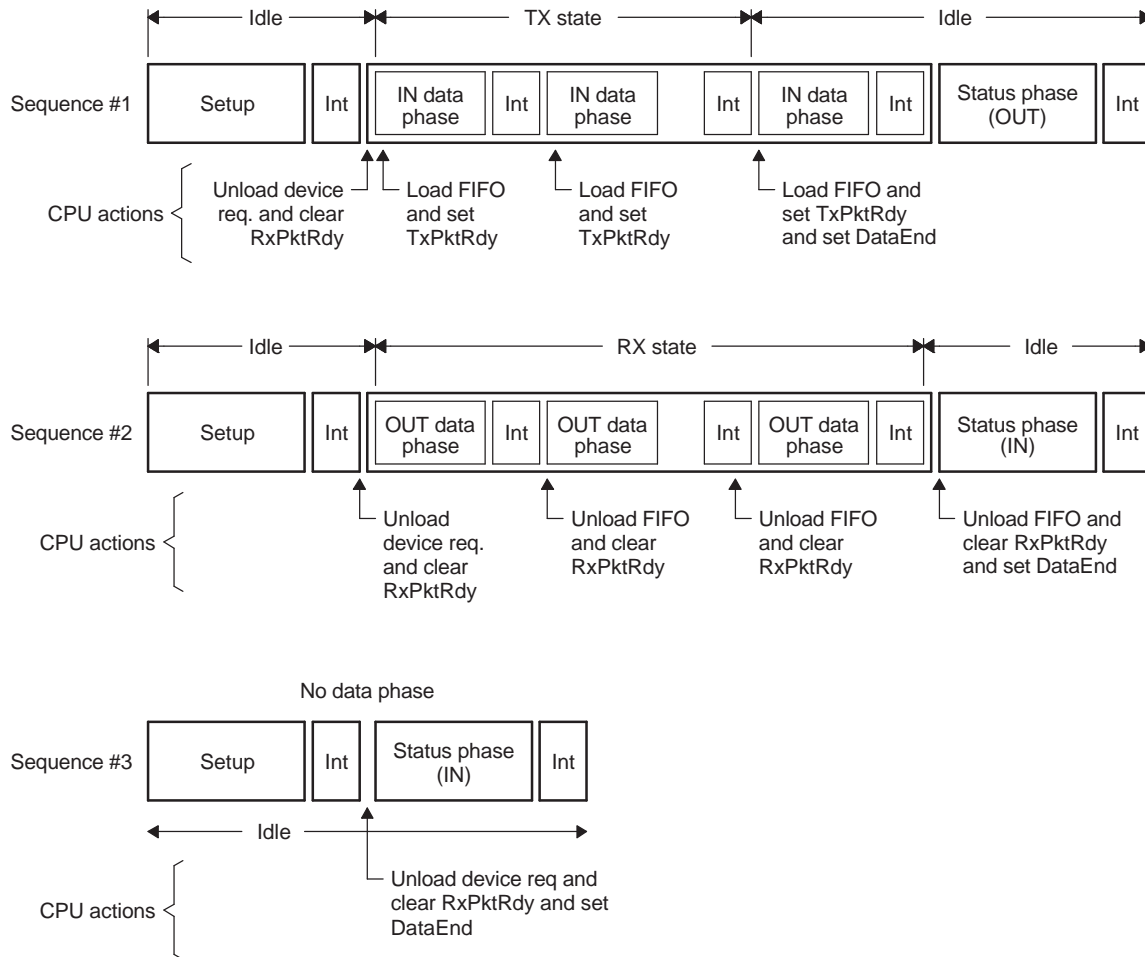

Figure 23-7. Sequence of Transfer

23.1.3.1.1.5 Endpoint 0 Service Routine

An Endpoint 0 interrupt is generated when:

- The controller sets the RXPkTRDY bit of PERI_CSR0 (bit 0) after a valid token has been received and data has been written to the FIFO.
- The controller clears the TXPKTRDY bit of PERI_CSR0 (bit 1) after the packet of data in the FIFO has been successfully transmitted to the host.
- The controller sets the SENTSTALL bit of PERI_CSR0 (bit 2) after a control transaction is ended due to a protocol violation.
- The controller sets the SETUPEND bit of PERI_CSR0 (bit 4) because a control transfer has ended before DATAEND (bit 3 of PERI_CSR0) is set.

Whenever the endpoint 0 service routine is entered, the software must first check to see if the current control transfer has been ended due to either a STALL condition or a premature end of control transfer. If the control transfer ends due to a STALL condition, the SENTSTALL bit would be set. If the control transfer ends due to a premature end of control transfer, the SETUPEND bit would be set. In either case, the software should abort processing the current control transfer and set the state to IDLE.

Once the software has determined that the interrupt was not generated by an illegal bus state, the next action taken depends on the endpoint state. [Figure 23-8](#) shows the flow of this process.

If endpoint 0 is in IDLE state, the only valid reason an interrupt can be generated is as a result of the controller receiving data from the bus. The service routine must check for this by testing the RXPTRDY bit of PERI_CSR0 (bit 0). If this bit is set, then the controller has received a SETUP packet. This must be unloaded from the FIFO and decoded to determine the action the controller must take. Depending on the command contained within the SETUP packet, endpoint 0 will enter one of three states:

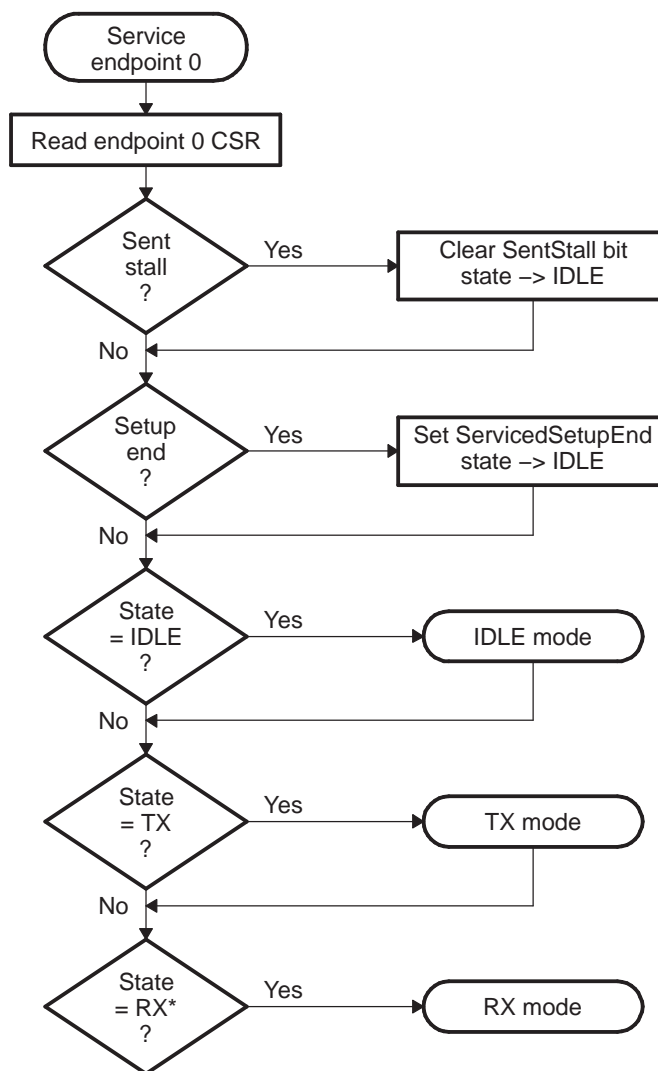

- If the command is a single packet transaction (SET_ADDRESS, SET_INTERFACE etc.) without any data phase, the endpoint will remain in IDLE state.
- If the command has an OUT data phase (SET_DESCRIPTOR etc.), the endpoint will enter RX state.
- If the command has an IN data phase (GET_DESCRIPTOR etc.), the endpoint will enter TX state.

If the endpoint 0 is in TX state, the interrupt indicates that the core has received an IN token and data from the FIFO has been sent. The software must respond to this either by placing more data in the FIFO if the host is still expecting more data or by setting the DATAEND bit to indicate that the data phase is complete. Once the data phase of the transaction has been completed, endpoint 0 should be returned to IDLE state to await the next control transaction.

Note: All command transactions include a field that indicates the amount of data the host expects to receive or is going to send.

If the endpoint is in RX state, the interrupt indicates that a data packet has been received. The software must respond by unloading the received data from the FIFO. The software must then determine whether it has received all of the expected data. If it has, the software should set the DATAEND bit and return endpoint 0 to IDLE state. If more data is expected, the firmware should set the SERV_RXPTRDY bit of PERI_CSR0 (bit 6) to indicate that it has read the data in the FIFO and leave the endpoint in RX state.

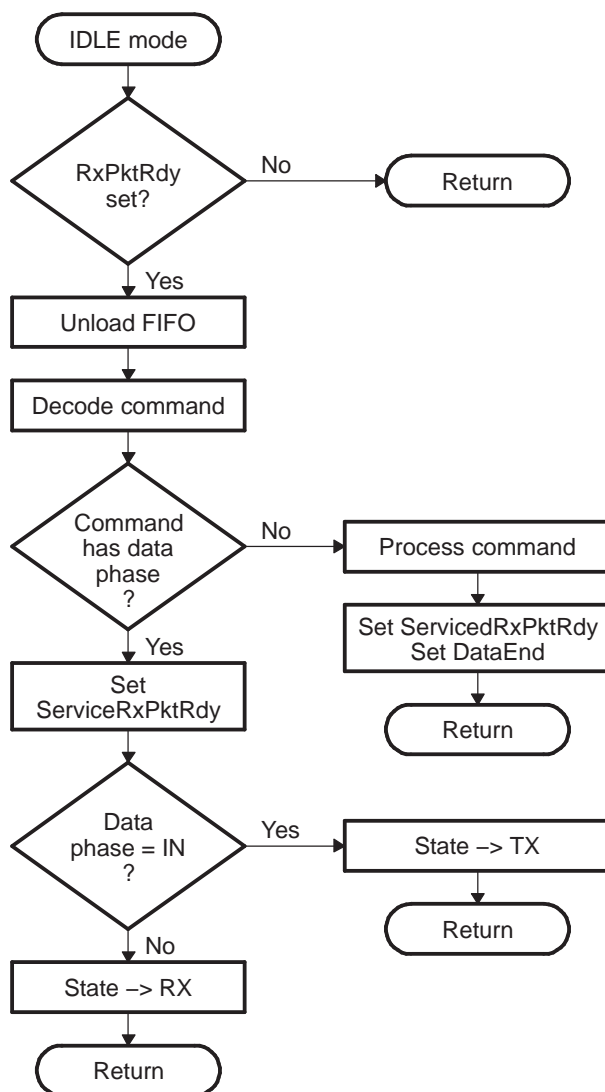

Figure 23-8. Service Endpoint 0 Flow Chart

* By default

23.1.3.1.1.5.1 IDLE Mode

IDLE mode is the mode the endpoint 0 control must select at power-on or reset and is the mode to which the endpoint 0 control should return when the RX and TX modes are terminated. It is also the mode in which the SETUP phase of control transfer is handled (as outlined in [Figure 23-9](#)).

Figure 23-9. IDLE Mode Flow Chart

23.1.3.1.1.5.2 TX Mode

When the endpoint is in TX state all arriving IN tokens need to be treated as part of a data phase until the required amount of data has been sent to the host. If either a SETUP or an OUT token is received while the endpoint is in the TX state, this will cause a SetupEnd condition to occur as the core expects only IN tokens. See [Figure 23-10](#).

Three events can cause TX mode to be terminated before the expected amount of data has been sent:

1. The host sends an invalid token causing a SETUPEND condition (bit 4 of PERI_CSR0 set).
2. The software sends a packet containing less than the maximum packet size for endpoint 0.
3. The software sends an empty data packet.

Until the transaction is terminated, the software simply needs to load the FIFO when it receives an interrupt that indicates a packet has been sent from the FIFO. (An interrupt is generated when TXPKTRDY is cleared.)

When the software forces the termination of a transfer (by sending a short or empty data packet), it should set the DATAEND bit of PERI_CSR0 (bit 3) to indicate to the core that the data phase is complete and that the core should next receive an acknowledge packet.

Figure 23-10. TX Mode Flow Chart

23.1.3.1.1.5.3 RX Mode

In RX mode, all arriving data should be treated as part of a data phase until the expected amount of data has been received. If either a SETUP or an IN token is received while the endpoint is in RX state, a SetupEnd condition will occur as the controller expects only OUT tokens.

Three events can cause RX mode to be terminated before the expected amount of data has been received as shown in [Figure 23-11](#):

1. The host sends an invalid token causing a SETUPEND condition (setting bit 4 of PERI_CSR0).
2. The host sends a packet which contains less than the maximum packet size for endpoint 0.
3. The host sends an empty data packet.

Until the transaction is terminated, the software unloads the FIFO when it receives an interrupt that indicates new data has arrived (setting RXPkTRDY bit of PERI_CSR0) and to clear RXPkTRDY by setting the SERV_RXPkTRDY bit of PERI_CSR0 (bit 6).

When the software detects the termination of a transfer (by receiving either the expected amount of data or an empty data packet), it should set the DATAEND bit (bit 3 of PERI_CSR0) to indicate to the controller that the data phase is complete and that the core should receive an acknowledge packet next.

Figure 23-11. RX Mode Flow Chart

23.1.3.1.1.5.4 Error Handling

A control transfer may be aborted due to a protocol error on the USB, the host prematurely ending the transfer, or if the software wishes to abort the transfer (e.g., because it cannot process the command).

The controller automatically detects protocol errors and sends a STALL packet to the host under the following conditions:

- The host sends more data during the OUT Data phase of a write request than was specified in the command. This condition is detected when the host sends an OUT token after the DATAEND bit (bit 3 of PERI_CSR0) has been set.
- The host requests more data during the IN Data phase of a read request than was specified in the command. This condition is detected when the host sends an IN token after the DATAEND bit in the PERI_CSR0 register has been set.
- The host sends more than Max Packet Size data bytes in an OUT data packet.
- The host sends a non-zero length DATA1 packet during the STATUS phase of a read request.

When the controller has sent the STALL packet, it sets the SENTSTALL bit (bit 2 of PERI_CSR0) and generates an interrupt. When the software receives an endpoint 0 interrupt with the SENTSTALL bit set, it should abort the current transfer, clear the SENTSTALL bit, and return to the IDLE state.

If the host prematurely ends a transfer by entering the STATUS phase before all the data for the request has been transferred, or by sending a new SETUP packet before completing the current transfer, then the SETUPEND bit (bit 4 of PERI_CSR0) will be set and an endpoint 0 interrupt generated. When the software receives an endpoint 0 interrupt with the SETUPEND bit set, it should abort the current transfer, set the SERV_SETUPEND bit (bit 7 of PERI_CSR0), and return to the IDLE state. If the RXPKT_RDY bit (bit 0 of PERI_CSR0) is set this indicates that the host has sent another SETUP packet and the software should then process this command.

If the software wants to abort the current transfer, because it cannot process the command or has some other internal error, then it should set the SENDSTALL bit (bit 5 of PERI_CSR0). The controller will then send a STALL packet to the host, set the SENTSTALL bit (bit 2 of PERI_CSR0) and generate an endpoint 0 interrupt.

23.1.3.1.1.5.5 Additional Conditions

When working as a peripheral device, the controller automatically responds to certain conditions on the USB bus or actions by the host. The details are given below:

- Stall Issued to Control Transfers
 - The host sends more data during an OUT Data phase of a Control transfer than was specified in the device request during the SETUP phase. This condition is detected by the controller when the host sends an OUT token (instead of an IN token) after the software has unloaded the last OUT packet and set DataEnd.
 - The host requests more data during an IN data phase of a Control transfer than was specified in the device request during the SETUP phase. This condition is detected by the controller when the host sends an IN token (instead of an OUT token) after the software has cleared TXPKTRDY and set DataEnd in response to the ACK issued by the host to what should have been the last packet.
 - The host sends more than MaxPktSize data with an OUT data token.
 - The host sends the wrong PID for the OUT Status phase of a Control transfer.
 - The host sends more than a zero length data packet for the OUT Status phase.
- Zero Length Out Data Packets In Control Transfer
 - A zero length OUT data packet is used to indicate the end of a Control transfer. In normal operation, such packets should only be received after the entire length of the device request has been transferred (i.e., after the software has set DataEnd). If, however, the host sends a zero length OUT data packet before the entire length of device request has been transferred, this signals the premature end of the transfer. In this case, the controller will automatically flush any IN token loaded by software ready for the Data phase from the FIFO and set SETUPEND bit (bit 4 of PERI_CSR0).

23.1.3.1.2 Bulk Transactions

23.1.3.1.2.1 Peripheral Mode: Bulk IN Transactions

A Bulk IN transaction is used to transfer non-periodic data from the USB peripheral device to the host.

The following optional features are available for use with a Tx endpoint used in peripheral mode for Bulk IN transactions:

- **Double packet buffering:** When enabled, up to two packets can be stored in the FIFO awaiting transmission to the host. Double packet buffering is enabled by setting the DPB bit of TXFIFOSZ register (bit 4).
- **DMA:** If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint is able to accept another packet in its FIFO. This feature allows the DMA controller to load packets into the FIFO without processor intervention.

When DMA is enabled and DMAMODE bit of PERI_TXCSR is set, an endpoint interrupt is not generated for completion of the packet transfer. An endpoint interrupt is generated only in the error conditions.

- **AutoSet:** When the AUTOSSET feature is enabled, the TXPKTRDY bit (PERI_TXCSR bit 0) will be automatically set when a packet of TXMAXP bytes has been loaded into the FIFO. This is particularly useful when DMA is used to load the FIFO as it avoids the need for any processor intervention when loading individual packets during a large Bulk transfer.
- **Automatic Packet Splitting:** For some system designs, it may be convenient for the application software to write larger amounts of data to an endpoint in a single operation than can be transferred in a single USB operation. A particular case in point is where the same endpoint is used for high-speed transfers of 512 bytes under certain circumstances but for full-speed transfers under other circumstances. When operating at full-speed, the maximum amount of data transferred in a single operation is then just 64 bytes. To cater for such circumstances, the USB controller includes a configuration option which allows larger data packets to be written to Bulk endpoints which are then split into packets of an appropriate (specified) size for transfer across the USB bus. The necessary packet size information is set via the TXMAXP register.

23.1.3.1.2.1.1 Setup

In configuring a TX endpoint for bulk transactions, the TXMAXP register must be written with the maximum packet size (in bytes) for the endpoint. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the endpoint and the PERI_TXCSR register should be set as shown in [Table 23-4](#):

Table 23-4. PERI_TXCSR Register Bit Configuration for Bulk IN Transactions

Bit Position	Bit Field Name	Configuration
Bit 14	ISO	Cleared to 0 for bulk mode operation
Bit 13	MODE	Set to 1 to make sure the FIFO is enabled (only necessary if the FIFO is shared with an RX endpoint)
Bit 12	DMAEN	Set to 1 if DMA requests must be enabled
Bit 11	FRCDATATOG	Cleared to 0 to allow normal data toggle operations
Bit 10	DMAMODE	Set to 1/0 when DMA is enabled and EP interrupt is not needed for each packet transmission/ EP interrupt is generated for every transfer.

When the endpoint is first configured (following a SET_CONFIGURATION or SET_INTERFACE command on Endpoint 0), the lower byte of PERI_TXCSR should be written to set the CLRDATATOG bit (bit 6). This will ensure that the data toggle (which is handled automatically by the controller) starts in the correct state.

Also if there are any data packets in the FIFO (indicated by the FIFONOTEMPTY bit (bit 1 of PERI_TXCSR) being set), they should be flushed by setting the FLUSHFIFO bit (bit 3 of PERI_TXCSR).

Note: It may be necessary to set this bit twice in succession if double buffering is enabled.

23.1.3.1.2.1.2 Operation

When data is to be transferred over a Bulk IN pipe, a data packet needs to be loaded into the FIFO and the PERI_TXCSR register written to set the TXPKTRDY bit (bit 0). When the packet has been sent, the TXPKTRDY bit will be cleared by the USB controller and an interrupt generated so that the next packet can be loaded into the FIFO. If double packet buffering is enabled, then after the first packet has been loaded and the TXPKTRDY bit set, the TXPKTRDY bit will immediately be cleared by the USB controller and an interrupt generated so that a second packet can be loaded into the FIFO. The software should operate in the same way, loading a packet when it receives an interrupt, regardless of whether double packet buffering is enabled or not.

In the general case, the packet size must not exceed the size specified by the lower 11 bits of the TXMAXP register. This part of the register defines the payload (packet size) for transfers over the USB and is required by the USB Specification to be either 8, 16, 32, 64 (Full-Speed or High-Speed) or 512 bytes (High-Speed only).

The host may determine that all the data for a transfer has been sent by knowing the total amount of data that is expected. Alternatively it may infer that all the data has been sent when it receives a packet which is smaller than the stated payload (TXMAXP [bit 10 : bit 0]). In the latter case, if the total size of the data block is a multiple of this payload, it will be necessary for the function to send a null packet after all the data has been sent. This is done by setting TXPKTRDY when the next interrupt is received, without loading any data into the FIFO.

If large blocks of data are being transferred, then the overhead of calling an interrupt service routine to load each packet can be avoided by using DMA.

23.1.3.1.2.1.3 Error Handling

If the software wants to shut down the Bulk IN pipe, it should set the SENDSTALL bit (bit 4 of PERI_TXCSR). When the controller receives the next IN token, it will send a STALL to the host, set the SENTSTALL bit (bit 5 of PERI_TXCSR) and generate an interrupt.

When the software receives an interrupt with the SENTSTALL bit (bit 5 of PERI_TXCSR) set, it should clear the SENTSTALL bit. It should however leave the SENDSTALL bit set until it is ready to re-enable the Bulk IN pipe.

Note: If the host failed to receive the STALL packet for some reason, it will send another IN token, so it is advisable to leave the SENDSTALL bit set until the software is ready to re-enable the Bulk IN pipe. When a pipe is re-enabled, the data toggle sequence should be restarted by setting the CLRDATATOG bit in the PERI_TXCSR register (bit 6).

23.1.3.1.2.2 Peripheral Mode: Bulk OUT Transactions

A Bulk OUT transaction is used to transfer non-periodic data from the host to the function controller.

The following optional features are available for use with an Rx endpoint used in peripheral mode for Bulk OUT transactions:

- **Double packet buffering:** When enabled, up to two packets can be stored in the FIFO on reception from the host. Double packet buffering is enabled by setting the DPB bit of the RXFIFOSZ register (bit 4).
- **DMA:** If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint has a packet in its FIFO. This feature can be used to allow the DMA controller to unload packets from the FIFO without processor intervention.
When DMA is enabled, endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions.
- **AutoClear:** When the AUTOCLEAR feature is enabled, i.e. AUTOCLEAR bit is set within the PERI_RXCSR register, the RXPTRDY bit (bit 0) will be automatically cleared when a packet of RXMAXP bytes has been unloaded from the FIFO. This is particularly useful when DMA is used to unload the FIFO as it avoids the need for any processor intervention when unloading individual packets during a large Bulk transfer.
- **Automatic Packet Combining:** For some system designs, it may be convenient for the application

software to read larger amounts of data from an endpoint in a single operation than can be transferred in a single USB operation. A particular case in point is where the same endpoint is used for high-speed transfers of 512 bytes under certain circumstances but for full-speed transfers under other circumstances. When operating at full-speed, the maximum amount of data transferred in a single operation is then just 64 bytes. To cater for such circumstances, the USB controller includes a configuration option which causes the USB controller to combine the packets received across the USB bus into larger data packets prior to being read by the application software. The necessary packet size information is set via the RXMAXP register, while the size of the amalgamated packet currently in line to be read is given in the RXCOUNT register.

23.1.3.1.2.2.1 Setup

In configuring an Rx endpoint for Bulk OUT transactions, the RXMAXP register must be written with the maximum packet size (in bytes) for the endpoint. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the endpoint. In addition, the relevant interrupt enable bit in the INTRRXE register should be set (if an interrupt is required for this endpoint) and the PERI_RXCSR register should be set as shown in [Table 23-5](#).

Table 23-5. PERI_RXCSR Register Bit Configuration for Bulk OUT Transactions

Bit Position	Bit Field Name	Configuration
Bit 14	ISO	Cleared to 0 to enable Bulk protocol
Bit 13	DMAEN	Set to 1 if a DMA request is required for this endpoint
Bit 12	DISNYET	Cleared to 0 to allow normal PING flow control. This will affect only high speed transactions.
Bit 11	DMAMODE	Set to 1/0 when DMA is enabled and EP interrupt is not needed for each packet transmission/EP interrupt is generated for every transfer.

When the endpoint is first configured (following a SET_CONFIGURATION or SET_INTERFACE command on Endpoint 0), the lower byte of PERI_RXCSR should be written to set the CLRDATATOG bit (bit 7). This will ensure that the data toggle (which is handled automatically by the USB controller) starts in the correct state.

Also if there are any data packets in the FIFO (indicated by the RXPKTRDY bit (bit 0 of PERI_RXCSR) being set), they should be flushed by setting the FLUSHFIFO bit (bit 4 of PERI_RXCSR).

Note: It may be necessary to set this bit twice in succession if double buffering is enabled.

23.1.3.1.2.2.2 Operation

When a data packet is received by a Bulk Rx endpoint, the RXPKTRDY bit (bit 0 of PERI_RXCSR) is set and an interrupt is generated. The software should read the RXCOUNT register for the endpoint to determine the size of the data packet. The data packet should be read from the FIFO, then the RXPKTRDY bit should be cleared.

The packets received should not exceed the size specified in the RXMAXP register (as this should be the value set in the wMaxPacketSize field of the endpoint descriptor sent to the host). When a block of data larger than wMaxPacketSize needs to be sent to the function, it will be sent as multiple packets. All the packets will be wMaxPacketSize in size, except the last packet which will contain the residue. The software may use an application specific method of determining the total size of the block and hence when the last packet has been received. Alternatively it may infer that the entire block has been received when it receives a packet which is less than wMaxPacketSize in size. (If the total size of the data block is a multiple of wMaxPacketSize, a null data packet will be sent after the data to signify that the transfer is complete.)

In the general case, the application software will need to read each packet from the FIFO individually. If large blocks of data are being transferred, the overhead of calling an interrupt service routine to unload each packet can be avoided by using DMA.

23.1.3.1.2.2.3 Error Handling

If the software wants to shut down the Bulk OUT pipe, it should set the SENDSTALL bit (bit 5 of PERI_RXCSR). When the controller receives the next packet it will send a STALL to the host, set the SENTSTALL bit (bit 6 of PERI_RXCSR) and generate an interrupt.

When the software receives an interrupt with the SENTSTALL bit (bit 6 of PERI_RXCSR) set, it should clear this bit. It should however leave the SENDSTALL bit set until it is ready to re-enable the Bulk OUT pipe.

Note: If the host failed to receive the STALL packet for some reason, it will send another packet, so it is advisable to leave the SENDSTALL bit set until the software is ready to re-enable the Bulk OUT pipe. When a Bulk OUT pipe is re-enabled, the data toggle sequence should be restarted by setting the CLRDATATOG bit (bit 7) in the PERI_RXCSR register.

23.1.3.1.3 Interrupt Transactions

An Interrupt IN transaction uses the same protocol as a Bulk IN transaction and can be used the same way. Similarly, an Interrupt OUT transaction uses almost the same protocol as a Bulk OUT transaction and can be used the same way.

Tx endpoints in the USB controller have one feature for Interrupt IN transactions that they do not support in Bulk IN transactions. In Interrupt IN transactions, the endpoints support continuous toggle of the data toggle bit.

This feature is enabled by setting the FRCDATATOG bit in the PERI_TXCSR register (bit 11). When this bit is set, the controller will consider the packet as having been successfully sent and toggle the data bit for the endpoint, regardless of whether an ACK was received from the host.

Another difference is that interrupt endpoints do not support PING flow control. This means that the controller should never respond with a NYET handshake, only ACK/NAK/STALL. To ensure this, the DISNYET bit in the PERI_RXCSR register (bit 12) should be set to disable the transmission of NYET handshakes in high-speed mode.

Though DMA can be used with an interrupt OUT endpoint, it generally offers little benefit as interrupt endpoints are usually expected to transfer all their data in a single packet.

23.1.3.1.4 Isochronous Transactions

23.1.3.1.4.1 Peripheral Mode: Isochronous IN Transactions

An Isochronous IN transaction is used to transfer periodic data from the function controller to the host.

The following optional features are available for use with a Tx endpoint used in Peripheral mode for Isochronous IN transactions:

- **Double packet buffering:** When enabled, up to two packets can be stored in the FIFO awaiting transmission to the host. Double packet buffering is enabled by setting the DPB bit of TXFIFOSZ register (bit 4).

Note: Double packet buffering is generally advisable for Isochronous transactions in order to avoid Underrun errors as described in later section.

- **DMA:** If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint is able to accept another packet in its FIFO. This feature allows the DMA controller to load packets into the FIFO without processor intervention.

However, this feature is not particularly useful with Isochronous endpoints because the packets transferred are often not maximum packet size and the PERI_TXCSR register needs to be accessed following every packet to check for Underrun errors.

When DMA is enabled and DMAMODE bit of PERI_TXCSR is set, endpoint interrupt will not be generated for completion of packet transfer. Endpoint interrupt will be generated only in the error

conditions.

23.1.3.1.4.1.1 Setup

In configuring a Tx endpoint for Isochronous IN transactions, the TXMAXP register must be written with the maximum packet size (in bytes) for the endpoint. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the endpoint. In addition, the relevant interrupt enable bit in the INTRTXE register should be set (if an interrupt is required for this endpoint) and the PERI_TXCSR register should be set as shown in [Table 23-6](#).

Table 23-6. PERI_TXCSR Register Bit Configuration for Isochronous IN Transactions

Bit Position	Bit Field Name	Configuration
Bit 14	ISO	Set to 1 to enable Isochronous transfer protocol
Bit 13	MODE	Set to 1 to ensure the FIFO is enabled (only necessary if the FIFO is shared with an Rx endpoint).
Bit 12	DMAEN	Set to 1 if DMA Requests have to be enabled
Bit 11	FRCDATATOG	Ignored in Isochronous mode
Bit 10	DMAMODE	Set to 1/0 when DMA is enabled and EP interrupt is not needed for each packet transmission/EP interrupt is generated for every transfer.

23.1.3.1.4.1.2 Operation

An Isochronous endpoint does not support data retries, so if data underrun is to be avoided, the data to be sent to the host must be loaded into the FIFO before the IN token is received. The host will send one IN token per frame (or up to three IN token per microframe if high bandwidth operation is exercised in High-speed mode), however the timing within the frame (or microframe) can vary. If an IN token is received near the end of one frame and then at the start of the next frame, there will be little time to reload the FIFO. For this reason, double buffering of the endpoint is usually necessary.

An interrupt is generated whenever a packet is sent to the host and the software may use this interrupt to load the next packet into the FIFO and set the TXPKTRDY bit in the PERI_TXCSR register (bit 0) in the same way as for a Bulk Tx endpoint. As the interrupt could occur almost any time within a frame(/microframe), depending on when the host has scheduled the transaction, this may result in irregular timing of FIFO load requests. If the data source for the endpoint is coming from some external hardware, it may be more convenient to wait until the end of each frame(/microframe) before loading the FIFO as this will minimize the requirement for additional buffering. This can be done by using either the SOF interrupt or the external SOF_PULSE signal from the controller to trigger the loading of the next data packet. The SOF_PULSE is generated once per frame(/microframe) when a SOF packet is received. (The controller also maintains an external frame(/microframe) counter so it can still generate a SOF_PULSE when the SOF packet has been lost.) The interrupts may still be used to set the TXPKTRDY bit in PERI_TXCSR (bit 0) and to check for data overruns/underruns.

Starting up a double-buffered Isochronous IN pipe can be a source of problems. Double buffering requires that a data packet is not transmitted until the frame(/microframe) after it is loaded. There is no problem if the function loads the first data packet at least a frame(/microframe) before the host sets up the pipe (and therefore starts sending IN tokens). But if the host has already started sending IN tokens by the time the first packet is loaded, the packet may be transmitted in the same frame(/microframe) as it is loaded, depending on whether it is loaded before, or after, the IN token is received. This potential problem can be avoided by setting the ISOUPDATE bit in the POWER register (bit 7). When this bit is set, any data packet loaded into an Isochronous Tx endpoint FIFO will not be transmitted until after the next SOF packet has been received, thereby ensuring that the data packet is not sent too early.

23.1.3.1.4.1.3 Error Handling

If the endpoint has no data in its FIFO when an IN token is received, it will send a null data packet to the host and set the UNDERRUN bit in the PERI_TXCSR register (bit 2). This is an indication that the software is not supplying data fast enough for the host. It is up to the application to determine how this error condition is handled.

If the software is loading one packet per frame(/microframe) and it finds that the TXPKTRDY bit in the PERI_TXCSR register (bit 0) is set when it wants to load the next packet, this indicates that a data packet has not been sent (perhaps because an IN token from the host was corrupted). It is up to the application how it handles this condition: it may choose to flush the unsent packet by setting the FLUSHFIFO bit in the PERI_TXCSR register (bit 3), or it may choose to skip the current packet.

23.1.3.1.4.2 Peripheral Mode: Isochronous OUT Transactions

An Isochronous OUT transaction is used to transfer periodic data from the host to the function controller.

Following optional features are available for use with an Rx endpoint used in Peripheral mode for Isochronous OUT transactions:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO on reception from the host. Double packet buffering is enabled by setting the DPB bit of RXFIFOSZ register (bit 4).

Note: Double packet buffering is generally advisable for Isochronous transactions in order to avoid Overrun errors.

- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint has a packet in its FIFO. This feature can be used to allow the DMA controller to unload packets from the FIFO without processor intervention.

However, this feature is not particularly useful with Isochronous endpoints because the packets transferred are often not maximum packet size and the PERI_RXCSR register needs to be accessed following every packet to check for Overrun or CRC errors.

When DMA is enabled, endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions.

23.1.3.1.4.2.1 Setup

In configuring an Rx endpoint for Isochronous OUT transactions, the RXMAXP register must be written with the maximum packet size (in bytes) for the endpoint. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the endpoint. In addition, the relevant interrupt enable bit in the INTRRXE register should be set (if an interrupt is required for this endpoint) and the PERI_RXCSR register should be set as shown in [Table 23-7](#).

Table 23-7. PERI_RXCSR Register Bit Configuration for Isochronous OUT Transactions

Bit Position	Bit Field Name	Configuration
Bit 14	ISO	Set to 1 to enable isochronous protocol
Bit 13	DMAEN	Set to 1 if a DMA request is required for this endpoint
Bit 12	DISNYET	Ignored in isochronous transfers
Bit 11	DMAMODE	Set to 1/0 when DMA is enabled and EP interrupt is not needed for each packet transmission/EP interrupt is generated for every transfer.

23.1.3.1.4.2.2 Operation

An Isochronous endpoint does not support data retries so, if a data overrun is to be avoided, there must be space in the FIFO to accept a packet when it is received. The host will send one packet per frame (or microframe in High-speed mode); however, the time within the frame can vary. If a packet is received near the end of one frame(/microframe) and another arrives at the start of the next frame, there will be little time to unload the FIFO. For this reason, double buffering of the endpoint is usually necessary.

An interrupt is generated whenever a packet is received from the host and the software may use this interrupt to unload the packet from the FIFO and clear the RXPkTRDY bit in the PERI_RXCSR register (bit 0) in the same way as for a Bulk Rx endpoint. As the interrupt could occur almost any time within a frame(/microframe), depending on when the host has scheduled the transaction, the timing of FIFO unload requests will probably be irregular. If the data sink for the endpoint is going to some external hardware, it may be better to minimize the requirement for additional buffering by waiting until the end of each frame(/microframe) before unloading the FIFO. This can be done by using either the SOF interrupt or the

external SOF_PULSE signal from the controller to trigger the unloading of the data packet. The SOF_PULSE is generated once per frame(/microframe) when a SOF packet is received. (The controller also maintains an external frame(/microframe) counter so it can still generate a SOF_PULSE when the SOF packet has been lost.) The interrupts may still be used to clear the RXPKT_RDY bit in PERI_RXCSR and to check for data overruns/underruns.

23.1.3.1.4.2.3 Error Handling

If there is no space in the FIFO to store a packet when it is received from the host, the OVERRUN bit in the PERI_RXCSR register (bit 2) will be set. This is an indication that the software is not unloading data fast enough for the host. It is up to the application to determine how this error condition is handled.

If the controller finds that a received packet has a CRC error, it will still store the packet in the FIFO and set the RXPKT_RDY bit (bit 0 of PERI_RXCSR) and the DATA_ERROR bit (bit 3 of PERI_RXCSR). It is left up to the application how this error condition is handled.

23.1.3.2 USB Controller Host Mode Operation

- *Entry into Suspend mode.* When operating as a host, the controller can be prompted to enter Suspend mode by setting the SUSPENDM bit in the POWER register. When this bit is set, the controller will complete the current transaction then stop the transaction scheduler and frame counter. No further transactions will be started and no SOF packets will be generated. If the ENSUSPM bit (bit 0 of POWER register) is set, PHY will go into low-power mode when the controller enters Suspend mode.
- *Sending Resume Signaling.* When the application requires the controller to leave Suspend mode, it must clear the SUSPENDM bit in the POWER register (bit 1), set the RESUME bit (bit 2) and leave it set for 20ms. While the RESUME bit is high, the controller will generate Resume signaling on the bus. After 20 ms, the application should clear the Resume bit, at which point the frame counter and transaction scheduler will be started.
- *Responding to Remote Wake-up.* If Resume signaling is detected from the target while the controller is in Suspend mode, the PHY will be brought out of low-power mode. The controller will then exit Suspend mode and automatically set the RESUME bit in the POWER register (bit 2) to take over generating the Resume signaling from the target. If the Resume interrupt is enabled, an interrupt will be generated.
- *Reset Signaling.* If the RESET bit in the POWER register (bit 3) is set while the controller is in Host mode, it will generate Reset signaling on the bus. If the HSENAB bit in the POWER register (bit 5) was set, it will also try to negotiate for high-speed operation. The software should keep the RESET bit set for at least 20 ms to ensure correct resetting of the target device. After the software has cleared the bit, the controller will start its frame counter and transaction scheduler. Whether high-speed operation is selected will be indicated by HSMODE bit of POWER register (bit 4).

23.1.3.2.1 Host Mode: Control Transactions

Host Control Transactions are conducted through Endpoint 0 and the software is required to handle all the Standard Device Requests that may be sent or received via Endpoint 0 (as described in Universal Serial Bus Specification, Revision 2.0, Chapter 9).

As for a USB peripheral device, there are three categories of Standard Device Requests to be handled: Zero Data Requests (in which all the information is included in the command), Write Requests (in which the command will be followed by additional data), and Read Requests (in which the device is required to send data back to the host).

1. Zero Data Requests consist of a SETUP command followed by an IN Status Phase
2. Write Requests consist of a SETUP command, followed by an OUT Data Phase which is in turn followed by an IN Status Phase
3. Read Requests consist of a SETUP command, followed by an IN Data Phase which is in turn followed by an OUT Status Phase

A timeout may be set to limit the length of time for which the controller will retry a transaction which is continually NAKed by the target. This limit can be between 2 and 215 frames/ microframes and is set through the HOST_NAKLIMIT0 register. The following sections describe the CPU actions required for these different types of requests by examining the steps to take in the different Control Transaction phases.

23.1.3.2.1.1 Setup Phase

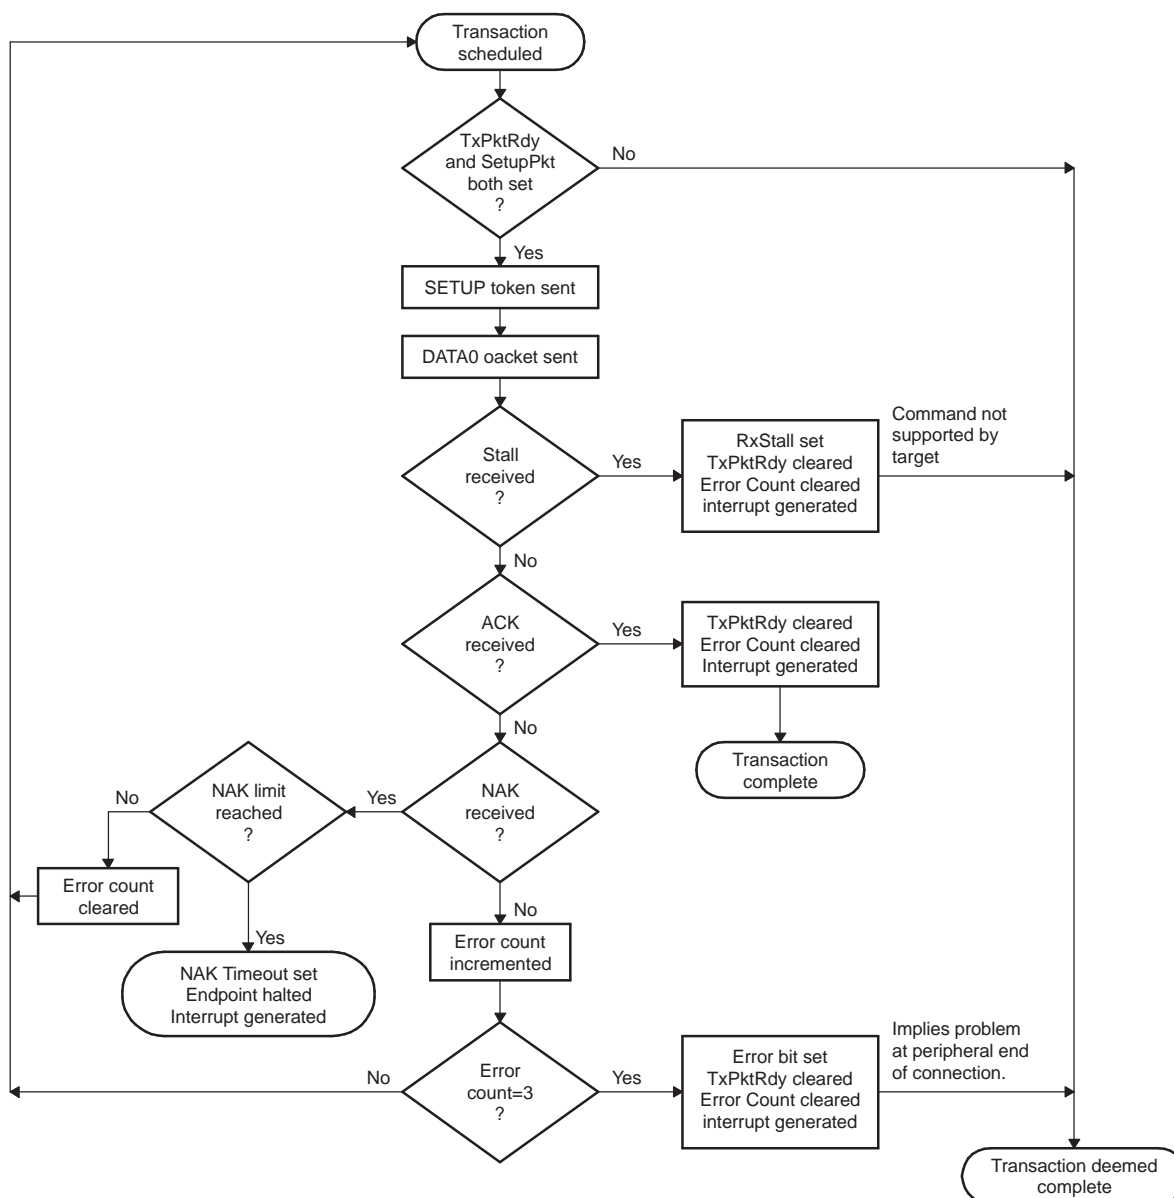

For the SETUP Phase of a control transaction (Figure 23-12), the software driving the US host device needs to:

1. Load the 8 bytes of the required Device request command into the Endpoint 0 FIFO.
2. Set SETUPPKT and TXPKTRDY (bits 3 and 1 of HOST_CSR0, respectively).

Note: These bits must be set together.

The controller then proceeds to send a SETUP token followed by the 8-byte command to Endpoint 0 of the addressed device, retrying as necessary. (On errors, controller retries the transaction three times.)

Figure 23-12. Setup Phase of a Control Transaction Flow Chart

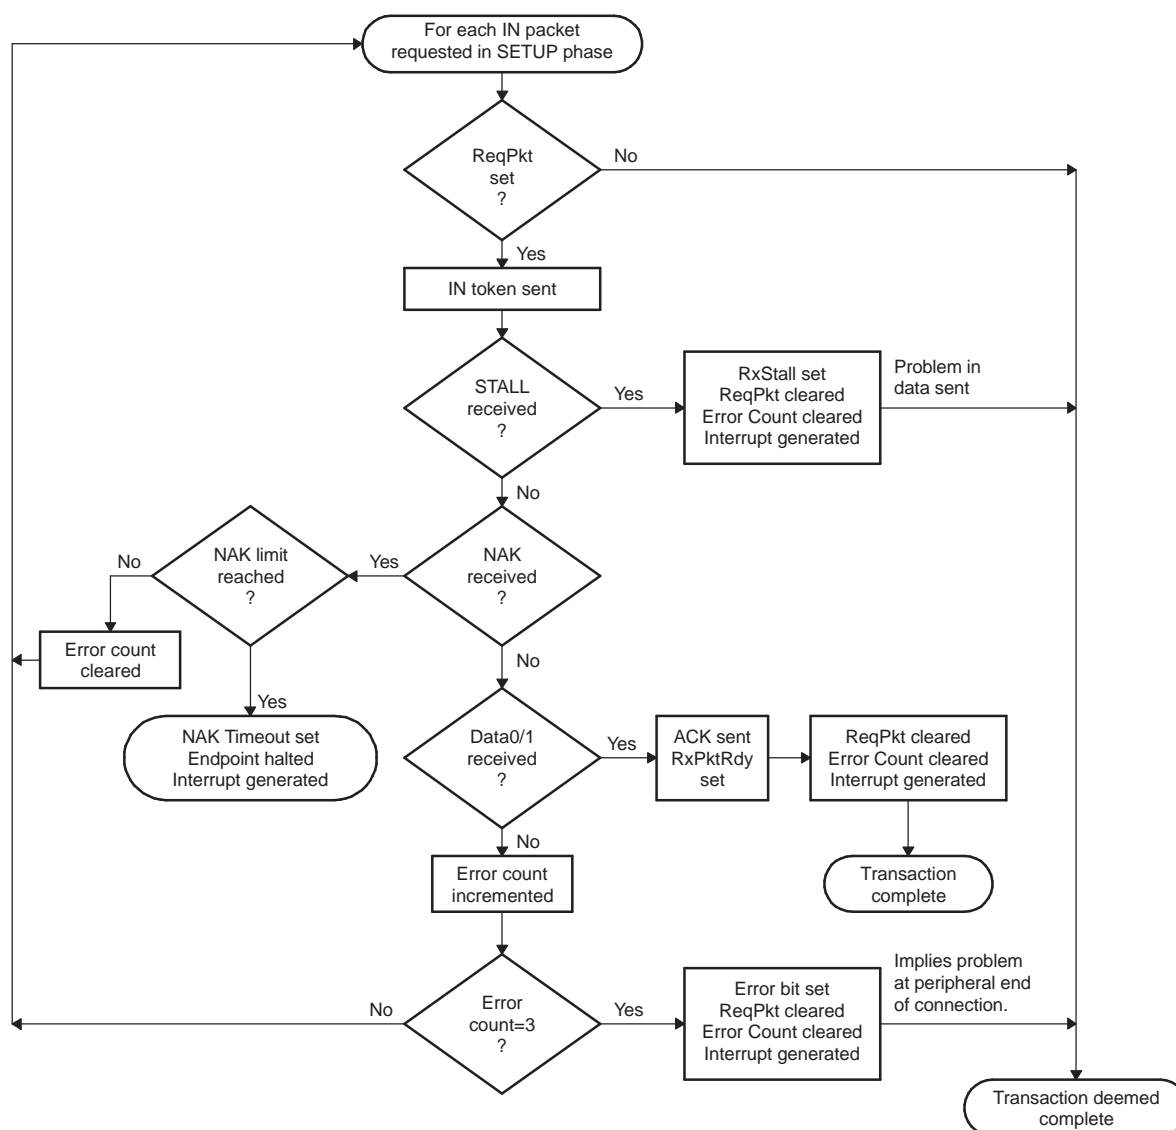

3. At the end of the attempt to send the data, the controller will generate an Endpoint 0 interrupt. The software should then read HOST_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4) or the NAK_TIMEOUT bit (bit 7) has been set.
 If RXSTALL is set, it indicates that the target did not accept the command (e.g., because it is not supported by the target device) and so has issued a STALL response.
 If ERROR is set, it means that the controller has tried to send the SETUP Packet and the following data packet three times without getting any response.
 If NAK_TIMEOUT is set, it means that the controller has received a NAK response to each attempt to send the SETUP packet, for longer than the time set in HOST_NAKLIMIT0. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK_TIMEOUT bit or to abort the transaction by flushing the FIFO before clearing the NAK_TIMEOUT bit.
4. If none of RXSTALL, ERROR or NAK_TIMEOUT is set, the SETUP Phase has been correctly ACKed and the software should proceed to the following IN Data Phase, OUT Data Phase or IN Status Phase specified for the particular Standard Device Request.

23.1.3.2.1.2 IN Data Phase

For the IN Data Phase of a control transaction ([Figure 23-13](#)), the software driving the USB host device needs to:

1. Set REQPKT bit of HOST_CSR0 (bit 5).
2. Wait while the controller sends the IN token and receives the required data back.
3. When the controller generates the Endpoint 0 interrupt, read HOST_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4), the NAK_TIMEOUT bit (bit 7) or RXPKT RDY bit (bit 0) has been set.
 If RXSTALL is set, it indicates that the target has issued a STALL response.
 If ERROR is set, it means that the controller has tried to send the required IN token three times without getting any response.
 If NAK_TIMEOUT bit is set, it means that the controller has received a NAK response to each attempt to send the IN token, for longer than the time set in HOST_NAKLIMIT0. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK_TIMEOUT bit or to abort the transaction by clearing REQPKT before clearing the NAK_TIMEOUT bit.
4. If RXPKT RDY has been set, the software should read the data from the Endpoint 0 FIFO, then clear RXPKT RDY.
5. If further data is expected, the software should repeat Steps 1-4.

When all the data has been successfully received, the CPU should proceed to the OUT Status Phase of the Control Transaction.

Figure 23-13. IN Data Phase Flow Chart

23.1.3.2.1.3 OUT Data Phase

For the OUT Data Phase of a control transaction (Figure 23-14), the software driving the USB host device needs to:

1. Load the data to be sent into the endpoint 0 FIFO.
2. Set the TXPKTRDY bit of HOST_CSR0 (bit 1). The controller then proceeds to send an OUT token followed by the data from the FIFO to Endpoint 0 of the addressed device, retrying as necessary.
3. At the end of the attempt to send the data, the controller will generate an Endpoint 0 interrupt. The software should then read HOST_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4) or the NAK_TIMEOUT bit (bit 7) has been set.

If RXSTALL bit is set, it indicates that the target has issued a STALL response.

If ERROR bit is set, it means that the controller has tried to send the OUT token and the following data packet three times without getting any response.

If NAK_TIMEOUT is set, it means that the controller has received a NAK response to each attempt to send the OUT token, for longer than the time set in the HOST_NAKLIMIT0 register. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK_TIMEOUT bit or to abort the transaction by flushing the FIFO before clearing the NAK_TIMEOUT bit.

If none of RXSTALL, ERROR or NAKLIMIT is set, the OUT data has been correctly ACKed.

4. If further data needs to be sent, the software should repeat Steps 1-3.

When all the data has been successfully sent, the software should proceed to the IN Status Phase of the Control Transaction.

Figure 23-14. OUT Data Phase Flow Chart

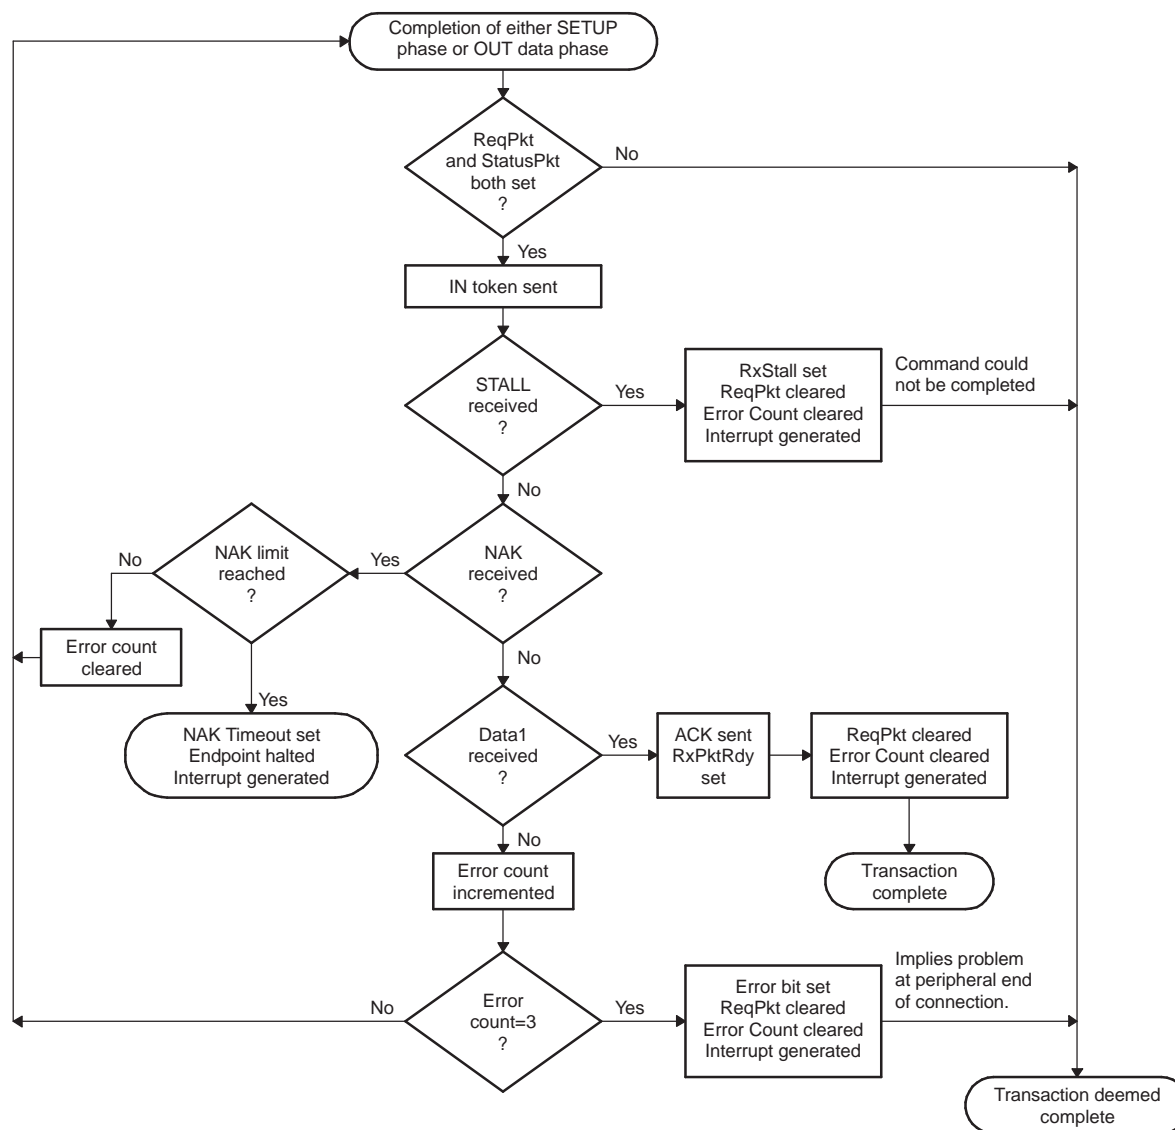

23.1.3.2.1.4 IN Status Phase (following SETUP Phase or OUT Data Phase)

For the IN Status Phase of a Control Transaction (Figure 23-15), the software driving the USB Host device needs to:

1. Set the STATUSPKT and REQPKT bits of HOST_CSR0 (bit 6 and bit 5, respectively).
2. Wait while the controller sends an IN token and receives a response from the USB peripheral device.

Figure 23-15. Completion of SETUP or OUT Data Phase Flow Chart

3. When the controller generates the Endpoint 0 interrupt, read HOST_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4), the NAK_TIMEOUT bit (bit 7) or RXPkTRDY bit (bit 0) has been set.
 If RXSTALL bit is set, it indicates that the target could not complete the command and so has issued a STALL response.
 If ERROR bit is set, it means that the controller has tried to send the required IN token three times without getting any response.
 If NAK_TIMEOUT bit is set, it means that the controller has received a NAK response to each attempt to send the IN token, for longer than the time set in the HOST_NAKLIMIT0 register. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK_TIMEOUT bit or to abort the transaction by clearing REQPKT bit and STATUSPKT bit before clearing the NAK_TIMEOUT bit.
4. If RxPktRdy has been set, the CPU should simply clear RxPktRdy.

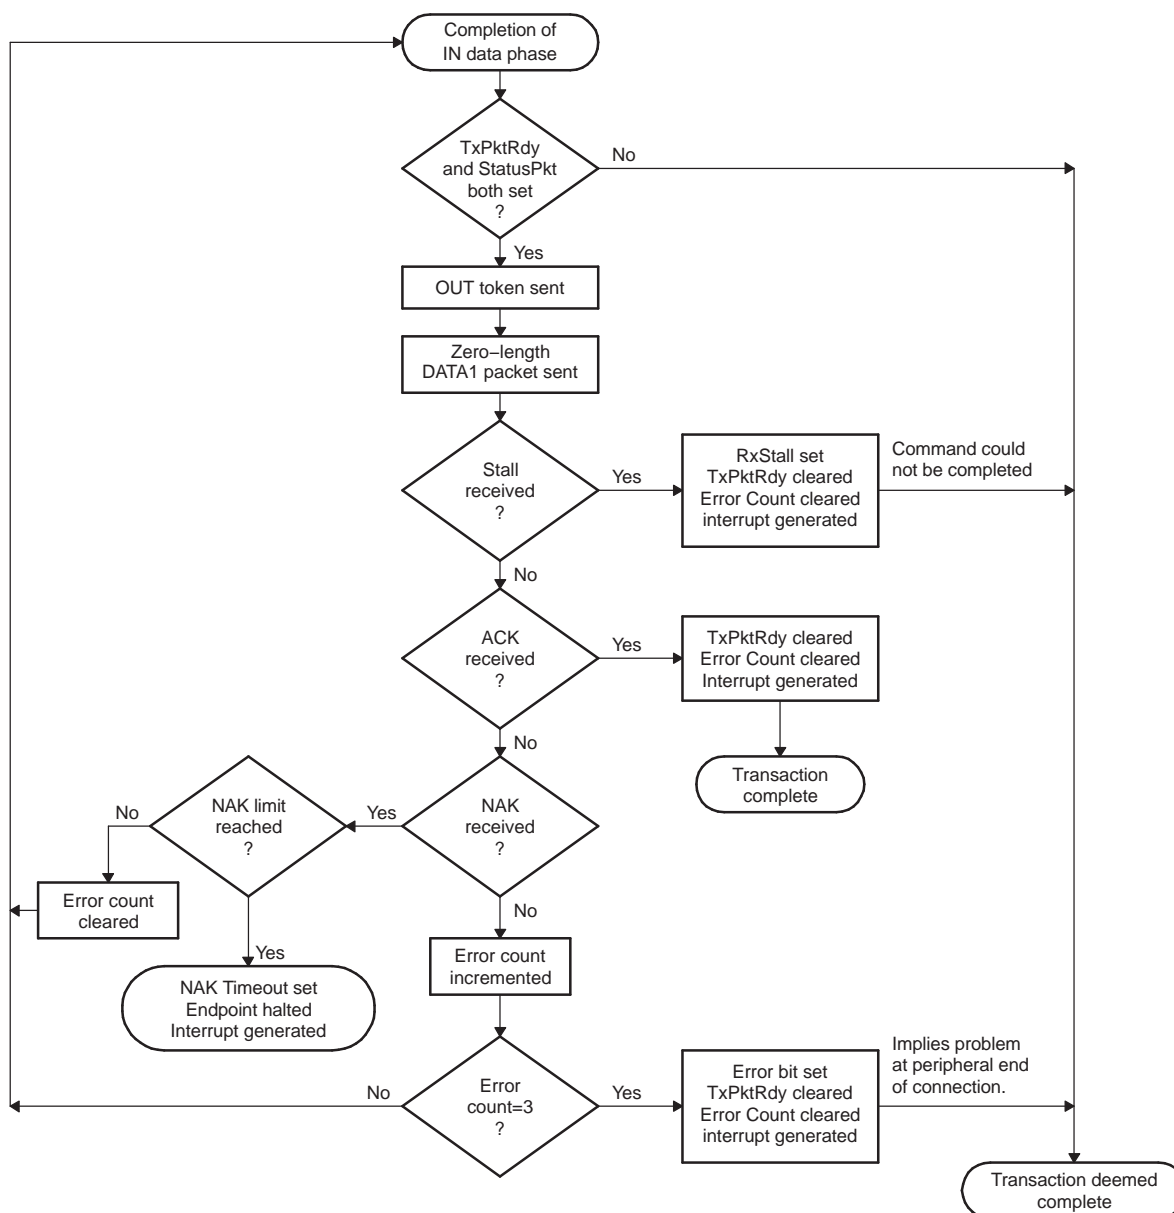

23.1.3.2.1.5 OUT Status Phase (following IN Data Phase)

For the OUT Status Phase of a control transaction ([Figure 23-16](#)), the CPU driving the host device needs to:

1. Set STATUSPKT and TXPKTRDY bits of HOST_CSR0 (bit 6 and bit 1, respectively).

Note: These bits need to be set together.

2. Wait while the controller sends the OUT token and a zero-length DATA1 packet.
3. At the end of the attempt to send the data, the controller will generate an Endpoint 0 interrupt. The software should then read HOST_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4) or the NAK_TIMEOUT bit (bit 7) has been set.
 If RXSTALL bit is set, it indicates that the target could not complete the command and so has issued a STALL response.
 If ERROR bit is set, it means that the controller has tried to send the STATUS Packet and the following data packet three times without getting any response.
 If NAK_TIMEOUT bit is set, it means that the controller has received a NAK response to each attempt to send the IN token, for longer than the time set in the HOST_NAKLIMIT0 register. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK_TIMEOUT bit or to abort the transaction by flushing the FIFO before clearing the NAK_TIMEOUT bit.
4. If none of RXSTALL, ERROR or NAK_TIMEOUT bits is set, the STATUS Phase has been correctly ACKed.

Figure 23-16. Completion of IN Data Phase Flow Chart

23.1.3.2.2 Bulk Transactions

23.1.3.2.2.1 Host Mode: Bulk IN Transactions

A Bulk IN transaction may be used to transfer non-periodic data from the external USB peripheral to the host.

The following optional features are available for use with an Rx endpoint used in host mode to receive the data:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO on reception from the host. This allows that one packet can be received while another is being read. Double packet buffering is enabled by setting the DPB bit of RXFIFOSZ register (bit 4).
- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint has a packet in its FIFO. This feature can be used to allow the DMA controller to unload packets from the FIFO without processor intervention.

When DMA is enabled, endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions.

- AutoRequest: When the AutoReq(uest) feature is enabled, the REQPKT bit of HOST_RXCSR (bit 5) will be automatically set when the RXPKT RDY bit is cleared.

This feature may be used in conjunction with the RQPKTCOUNT register to request the required number of maximum-size packets.

- Automatic Packet Combining: For some system designs, it may be convenient for the application software to read larger amounts of data from an endpoint in a single operation than can be transferred in a single USB operation. A particular case in point is where the same endpoint is used for high-speed transfers of 512 bytes under certain circumstances but for full-speed transfers under other circumstances. When operating at full-speed, the maximum amount of data transferred in a single operation is then just 64 bytes. To cater for such circumstances, the USB CONTROLLER includes a configuration option which, causes the USB controller to combine the packets received across the USB bus into larger data packets prior to being read by the application software. The necessary packet size information is set via the RXMAXP register, while the size of the amalgamated packet currently in line to be read is given in the RXCOUNT register.

23.1.3.2.2.1.1 Setup

Before initiating any Bulk IN Transactions in Host mode:

- The target function address needs to be set in the RXFUNCADDR register for the selected controller endpoint. (RXFUNCADDR register is available for all endpoints from EP0 to EP4.)
- The HOST_RXTYPE register for the endpoint that is to be used needs to be programmed as follows:
 - Operating speed in the SPEED bit field (bits 7 and 6).
 - Set 10 (binary value) in the PROT field for bulk transfer.
 - Endpoint Number of the target device in RENDPN field. This is the endpoint number contained in the Rx endpoint descriptor returned by the target device during enumeration.
- The RXMAXP register for the controller endpoint must be written with the maximum packet size (in bytes) for the transfer. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the target endpoint.
- The HOST_RXINTERVAL register needs to be written with the required value for the NAK limit (2 - 215 frames/microframes), or cleared to 0 if the NAK timeout feature is not required.
- The relevant interrupt enable bit in the INTRRXE register should be set (if an interrupt is required for this endpoint).
- The following bits of HOST_RXCSR register should be set as shown below:
 - Set DMAEN (bit 13) to 1 if a DMA request is required for this endpoint.
 - Clear DSINYET (bit 12) to 0 to allow normal PING flow control. This will affect only High Speed transactions.
 - Always clear DMAMODE (bit 11) to 0.
- If DMA is enabled, the AUTOREQ register can be set for generating IN tokens automatically after receiving the data. Set the bit field RXn_AUTOREQ (where n is the endpoint number) with binary value 01 or 11.

When the endpoint is first configured, the endpoint data toggle should be cleared to 0 either by using the DATATOGWREN and DATATOG bits of HOST_RXCSR (bit 10 and bit 9) to toggle the current setting or by setting the CLRDATATOG bit of HOST_RXCSR (bit 7). This will ensure that the data toggle (which is handled automatically by the controller) starts in the correct state. Also if there are any data packets in the FIFO (indicated by the RXPKT RDY bit (bit 0 of HOST_RXCSR) being set), they should be flushed by setting the FLUSHFIFO bit of HOST_RXCSR (bit 4).

Note: It may be necessary to set this bit twice in succession if double buffering is enabled.

23.1.3.2.1.2 Operation

When Bulk data is required from the USB peripheral device, the software should set the REQPKT bit in the corresponding HOST_RXCSR register (bit 5). The controller will then send an IN token to the selected peripheral endpoint and waits for data to be returned.

If data is correctly received, RXPKT RDY bit of HOST_RXCSR (bit 0) is set. If the USB peripheral device responds with a STALL, RXSTALL bit (bit 6 of HOST_RXCSR) is set. If a NAK is received, the controller tries again and continues to try until either the transaction is successful or the POLINTVL_NAKLIMIT set in the HOST_RXINTERVAL register is reached. If no response at all is received, two further attempts are made before the controller reports an error by setting the ERROR bit of HOST_RXCSR (bit 2).

The controller then generates the appropriate endpoint interrupt, whereupon the software should read the corresponding HOST_RXCSR register to determine whether the RXPKT RDY, RXSTALL, ERROR or DATAERR_NAKTIMEOUT bit is set and act accordingly. If the DATAERR_NAKTIMEOUT bit is set, the controller can be directed either to continue trying this transaction (until it times out again) by clearing the DATAERR_NAKTIMEOUT bit or to abort the transaction by clearing REQPKT bit before clearing the DATAERR_NAKTIMEOUT bit.

The packets received should not exceed the size specified in the RXMAXP register (as this should be the value set in the wMaxPacketSize field of the endpoint descriptor sent to the host).

In the general case, the application software will need to read each packet from the FIFO individually. If large blocks of data are being transferred, the overhead of calling an interrupt service routine to unload each packet can be avoided by using DMA.

23.1.3.2.1.3 Error Handling

If the target wants to shut down the Bulk IN pipe, it will send a STALL response to the IN token. This will result in the RXSTALL bit of HOST_RXCSR (bit 6) being set.

23.1.3.2.2 Host Mode: Bulk OUT Transactions

A Bulk OUT transaction may be used to transfer non-periodic data from the host to the USB peripheral.

Following optional features are available for use with a Tx endpoint used in Host mode to transmit this data:

- **Double packet buffering:** When enabled, up to two packets can be stored in the FIFO awaiting transmission to the peripheral device. Double packet buffering is enabled by setting the DPB bit of TXFIFOSZ register (bit 4).
- **DMA:** If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint is able to accept another packet in its FIFO. This feature can be used to allow the DMA controller to load packets into the FIFO without processor intervention.

When DMA is enabled and DMAMODE bit in HOST_TXCSR register is set, an endpoint interrupt will not be generated for completion of packet reception. An endpoint interrupt will be generated only in the error conditions.

- **AutoSet:** When the AutoSet feature is enabled, the TXPKTRDY bit of HOST_TXCSR (bit 0) will be automatically set when a packet of TXMAXP bytes has been loaded into the FIFO. This is particularly useful when DMA is used to load the FIFO as it avoids the need for any processor intervention when loading individual packets during a large Bulk transfer.
- **Automatic Packet Splitting:** For some system designs, it may be convenient for the application software to write larger amounts of data to an endpoint in a single operation than can be transferred in a single

USB operation. A particular case in point is where the same endpoint is used for high-speed transfers of 512 bytes under certain circumstances but for full-speed transfers under other circumstances. When operating at full-speed, the maximum amount of data transferred in a single operation is then just 64 bytes. To cater for such circumstances, the USB controller includes a configuration option which, allows larger data packets to be written to Bulk endpoints which are then split into packets of an appropriate (specified) size for transfer across the USB bus. The necessary packet size information is set via the TXMAXP register.

23.1.3.2.2.2.1 Setup

Before initiating any bulk OUT transactions:

- The target function address needs to be set in the TXFUNCADDR register for the selected controller endpoint. (TXFUNCADDR register is available for all endpoints from EP0 to EP4.)
- The HOST_TXTYPE register for the endpoint that is to be used needs to be programmed as follows:
 - Operating speed in the SPEED bit field (bits 7 and 6).
 - Set 10b in the PROT field for bulk transfer.
 - Endpoint Number of the target device in TENDPN field. This is the endpoint number contained in the OUT(Tx) endpoint descriptor returned by the target device during enumeration.
- The TXMAXP register for the controller endpoint must be written with the maximum packet size (in bytes) for the transfer. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the target endpoint.
- The HOST_TXINTERVAL register needs to be written with the required value for the NAK limit (2 - 215 frames/microframes), or cleared to 0 if the NAK timeout feature is not required.
- The relevant interrupt enable bit in the INTRTXE register should be set (if an interrupt is required for this endpoint).
- The following bits of HOST_TXCSR register should be set as shown below:
 - Set the MODE bit (bit 13) to 1 to ensure the FIFO is enabled (only necessary if the FIFO is shared with an Rx endpoint).
 - Set the DMAEN bit (bit 12) to 1 if a DMA request is required for this endpoint.
 - Clear the FRCDATATOG bit (bit 11) to 0 to allow normal data toggle operations.
 - Set the DMAMODE bit (bit 10) to 1 when DMA is enabled and the endpoint interrupt is not needed for each packet transmission.

When the endpoint is first configured, the endpoint data toggle should be cleared to 0 either by using the DATATOGWREN bit and DATATOG bit of HOST_TXCSR (bit 9 and bit 8) to toggle the current setting or by setting the CLRDATATOG bit of HOST_TXCSR (bit 6). This will ensure that the data toggle (which is handled automatically by the controller) starts in the correct state. Also, if there are any data packets in the FIFO (indicated by the FIFONOTEMPTY bit of HOST_TXCSR register (bit 1) being set), they should be flushed by setting the FLUSHFIFO bit (bit 3 of HOST_TXCSR).

Note: It may be necessary to set this bit twice in succession if double buffering is enabled.

23.1.3.2.2.2.2 Operation

When Bulk data is required to be sent to the USB peripheral device, the software should write the first packet of the data to the FIFO (or two packets if double-buffered) and set the TXPKTRDY bit in the corresponding HOST_TXCSR register (bit 0). The controller will then send an OUT token to the selected peripheral endpoint, followed by the first data packet from the FIFO.

If data is correctly received by the peripheral device, an ACK should be received whereupon the controller will clear TXPKTRDY bit of HOST_TXCSR (bit 0). If the USB peripheral device responds with a STALL, the RXSTALL bit (bit 5) of HOST_TXCSR is set. If a NAK is received, the controller tries again and continues to try until either the transaction is successful or the NAK limit set in the HOST_TXINTERVAL register is reached. If no response at all is received, two further attempts are made before the controller reports an error by setting ERROR bit in HOST_TXCSR (bit 2).

The controller then generates the appropriate endpoint interrupt, whereupon the software should read the corresponding HOST_TXCSR register to determine whether the RXSTALL (bit 5), ERROR (bit 2) or NAK_TIMEOUT (bit 7) bit is set and act accordingly. If the NAK_TIMEOUT bit is set, the controller can be directed either to continue trying this transaction (until it times out again) by clearing the NAK_TIMEOUT bit or to abort the transaction by flushing the FIFO before clearing the NAK_TIMEOUT bit.

If large blocks of data are being transferred, then the overhead of calling an interrupt service routine to load each packet can be avoided by using DMA.

23.1.3.2.2.3 Error Handling

If the target wants to shut down the Bulk OUT pipe, it will send a STALL response. This is indicated by the RXSTALL bit of HOST_TXCSR register (bit 5) being set.

23.1.3.2.3 Host Mode: Interrupt Transactions

When the controller is operating as the host, interactions with an Interrupt endpoint on the USB peripheral device are handled in very much the same way as the equivalent Bulk transactions (described in previous sections).

The principal difference as far as operational steps are concerned is that PROT field of HOST_RXTYPE and HOST_TXTYPE (bits 5:4) need to be set (binary value) to represent an Interrupt transaction.

The required polling interval also needs to be set in the HOST_RXINTERVAL and HOST_TXINTERVAL registers.

23.1.3.2.4 Isochronous Transactions

23.1.3.2.4.1 Host Mode: Isochronous IN Transactions

An Isochronous IN transaction is used to transfer periodic data from the USB peripheral to the host.

The following optional features are available for use with an Rx endpoint used in Host mode to receive this data:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO on reception from the host. This allows that one packet can be received while another is being read. Double packet buffering is enabled by setting the DPB bit of RXFIFOSZ register (bit 4).
- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint has a packet in its FIFO. This feature can be used to allow the DMA controller to unload packets from the FIFO without processor intervention. However, this feature is not particularly useful with isochronous endpoints because the packets transferred are often not maximum packet size.

When DMA is enabled, endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions.

- AutoClear: When the AUTOCLEAR feature is enabled, the RXPkTRDY bit (HOST_RXCSR (bit0)) will be automatically cleared when a packet of RXMAXP bytes has been unloaded from the FIFO. However, this feature is not particularly useful with Isochronous endpoints because the packets transferred are often not maximum packet size and the HOST_RXCSR register needs to be accessed following every packet to check for Overrun or CRC errors.
- AutoRequest: When the AutoRequest feature is enabled, the REQPKT bit of HOST_RXCSR (bit 5) will be automatically set when the RXPkTRDY bit is cleared.

This feature is applicable only when DMA is enabled. To enable AutoRequest feature, set the AUTOREQ register for the DMA channel associated for the endpoint.

23.1.3.2.4.1.1 Setup

Before initiating an Isochronous IN Transactions in Host mode:

- The target function address needs to be set in the RXFUNCADDR register for the selected controller endpoint (RXFUNCADDR register is available for all endpoints from EP0 to EP4).
- The HOST_RXTYPE register for the endpoint that is to be used needs to be programmed as follows:
 - Operating speed in the SPEED bit field (bits 7 and 6).

- Set 01 (binary value) in the PROT field for isochronous transfer.
- Endpoint Number of the target device in RENDPN field. This is the endpoint number contained in the Rx endpoint descriptor returned by the target device during enumeration.
- The RXMAXP register for the controller endpoint must be written with the maximum packet size (in bytes) for the transfer. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the target endpoint.
- The HOST_RXINTERVAL register needs to be written with the required transaction interval (usually one transaction per frame/microframe).
- The relevant interrupt enable bit in the INTRRXE register should be set (if an interrupt is required for this endpoint).
- The following bits of HOST_RXCSR register should be set as shown below:
 - Set the DMAEN bit (bit 13) to 1 if a DMA request is required for this endpoint.
 - Clear the DISNYET it (bit 12) to 0 to allow normal PING flow control. This will only affect High Speed transactions.
 - Always clear the DMAMODE bit (bit 11) to 0.
- If DMA is enabled, AUTOREQ register can be set for generating IN tokens automatically after receiving the data. Set the bit field RX n _AUTOREQ (where n is the endpoint number) with binary value 01 or 11.

23.1.3.2.4.1.2 Operation

The operation starts with the software setting REQPKT bit of HOST_RXCSR (bit 5). This causes the controller to send an IN token to the target.

When a packet is received, an interrupt is generated which the software may use to unload the packet from the FIFO and clear the RXPBKTRDY bit in the HOST_RXCSR register (bit 0) in the same way as for a Bulk Rx endpoint. As the interrupt could occur almost any time within a frame(/microframe), the timing of FIFO unload requests will probably be irregular. If the data sink for the endpoint is going to some external hardware, it may be better to minimize the requirement for additional buffering by waiting until the end of each frame before unloading the FIFO. This can be done by using the SOF_PULSE signal from the controller to trigger the unloading of the data packet. The SOF_PULSE is generated once per frame(/microframe). The interrupts may still be used to clear the RXPBKTRDY bit in HOST_RXCSR.

23.1.3.2.4.1.3 Error Handling

If a CRC or bit-stuff error occurs during the reception of a packet, the packet will still be stored in the FIFO but the DATAERR_NAKTIMEOUT bit of HOST_RXCSR (bit 3) is set to indicate that the data may be corrupt.

23.1.3.2.4.2 Isochronous Out Transactions

An Isochronous OUT transaction may be used to transfer periodic data from the host to the USB peripheral.

Following optional features are available for use with a Tx endpoint used in Host mode to transmit this data:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO awaiting transmission to the peripheral device. Double packet buffering is enabled by setting the DPB bit of TXFIFOSZ register (bit 4).
- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint is able to accept another packet in its FIFO. This feature can be used to allow the DMA controller to load packets into the FIFO without processor intervention.
However, this feature is not particularly useful with isochronous endpoints because the packets transferred are often not maximum packet size.
When DMA is enabled and DMAMODE bit in HOST_TXCSR register is set, endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions.
- AutoSet: When the AUTOSSET feature is enabled with a low-bandwidth Isochronous endpoint, the TXPKTRDY bit (HOST_TXCSR (bit 0)) will be automatically set when a packet of TXMAXP bytes has been loaded into the FIFO. However, this feature is not particularly useful with Isochronous endpoints

because the packets transferred are often not maximum packet size.

23.1.3.2.4.2.1 Setup

Before initiating any Isochronous OUT transactions:

- The target function address needs to be set in the TXFUNCADDR register for the selected controller endpoint (TXFUNCADDR register is available for all endpoints from EP0 to EP4).
- The HOST_TXTYPE register for the endpoint that is to be used needs to be programmed as follows:
 - Operating speed in the SPEED bit field (bits 7 and 6).
 - Set 01 (binary value) in the PROT field for isochronous transfer.
 - Endpoint Number of the target device in TENDPN field. This is the endpoint number contained in the OUT(Tx) endpoint descriptor returned by the target device during enumeration.
- The TXMAXP register for the controller endpoint must be written with the maximum packet size (in bytes) for the transfer. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the target endpoint.
- The HOST_TXINTERVAL register needs to be written with the required transaction interval (usually one transaction per frame/microframe).
- The relevant interrupt enable bit in the INTRTXE register should be set (if an interrupt is required for this endpoint).
- The following bits of HOST_TXCSR register should be set as shown below:
 - Set the MODE bit (bit 13) to 1 to ensure the FIFO is enabled (only necessary if the FIFO is shared with an Rx endpoint).
 - Set the DMAEN bit (bit 12) to 1 if a DMA request is required for this endpoint.
 - The FRCDATATOG bit (bit 12) is ignored for isochronous transactions.
 - Set the DMAMODE bit (bit 10) to 1 when DMA is enabled and the endpoint interrupt is not needed for each packet transmission.

23.1.3.2.4.2.2 Operation

The operation starts when the software writes to the FIFO and sets TXPKTRDY bit of HOST_TXCSR (bit 0). This triggers the controller to send an OUT token followed by the first data packet from the FIFO.

An interrupt is generated whenever a packet is sent and the software may use this interrupt to load the next packet into the FIFO and set the TXPKTRDY bit in the HOST_TXCSR register (bit 0) in the same way as for a Bulk Tx endpoint. As the interrupt could occur almost any time within a frame, depending on when the host has scheduled the transaction, this may result in irregular timing of FIFO load requests. If the data source for the endpoint is coming from some external hardware, it may be more convenient to wait until the end of each frame before loading the FIFO as this will minimize the requirement for additional buffering. This can be done by using the SOF_PULSE signal from the controller to trigger the loading of the next data packet. The SOF_PULSE is generated once per frame(/microframe). The interrupts may still be used to set the TXPKTRDY bit in HOST_TXCSR.

23.1.3.3 DMA Operation

The built in DMA may be used in connection with any type of transfer (excluding control transfer) but it is particularly useful when large blocks of data are to be transferred through a Bulk endpoint. DMA operation is discussed based on Bulk transfer. However, the procedure applies to Interrupt and Isochronous DMA employed transfers.

The DMA facilities of the USB Controller may be used in either Peripheral mode or Host mode to avoid the overhead of having to interrupt the processor after each individual packet, instead only interrupting the processor after the transfer has completed.

23.1.3.3.1 Using DMA with Bulk Tx Endpoints

To use DMA to send a large block of data to over a Bulk Tx endpoint, we recommend setting up the DMA controller and the USB core as follows.

- Program TXMAXP Register with the maximum size of packet for the endpoint.

- Set HOST/PERI_TXCSR.AUTOSSET. This allows the USB controller to automatically set the HOST/PERI_TXCSR.TXPKTRDY bit field when the DMA performs a burst read of a maximum packet for the endpoint.

Note: When performing a large block of data, since the end of the block of data is indicated by the last packet which is a short packet and the USB core is not capable of identifying this packet, the user/firmware is required to set the HOST/PERI_TXCSR.TXPKTRDY bit. A short packet is a packet that is less in size compared to the max size packet and can have a zero length. When the last packet has been loaded by the DMA controller, the controller will interrupt the processor. If the last packet loaded was less than the maximum packet size, then TXPKTRDY bit will not have been set and will therefore need to be set manually (i.e. by the CPU) to allow the last packet to be sent. The TXPKTRDY bit will also need to be set manually if the last packet was the maximum packet size and a null packet is to be sent to indicate the end of the transfer.

- Set HOST/PERI_TXCSR.DMAMEN. This enables the DMA.
- Set HOST/PERI_TXCSR.DMAMODE. DMA mode 1 is useful for a large block of data transfer while DMA mode 0 is useful for a single transfer a max packet size or less.

If, when operating in Host mode, the core fails to successfully transmit a packet three times, the ERROR bit in the HOST_TXCSR register will become set and the DMA request line will be disabled until this ERROR bit is cleared again. It should also be noted that the DMAMODE bit in the HOST_TXCSR register must not be cleared either before or in the same cycle as the corresponding DMAEN bit is cleared.

23.1.3.3.2 Using DMA with Bulk Rx Endpoints

The behavior of the DMA request line for an Rx Endpoint depends on the DMA Request Mode selected through the HOST/PERI_RXCSR register (DMAMODE). In DMA Request Mode 0 (DMAMODE=0), the Rx DMA request line goes high when a data packet is available in the endpoint FIFO and goes low either when the last byte of the data packet has been read – or when the RXPKTRDY bit in HOST/PERI_RXCSR is cleared. In DMA Request Mode 1 (DMAMODE=1), the DMA request line only goes high when the packet received is of the maximum packet size (as set in the RXMAXP register). If the packet received is of some other size, the DMA request line stays low with the result that the packet remains in the FIFO with RXPKTRDY set. This causes an Rx Endpoint interrupt to be generated (if enabled).

The DMA Request Modes are primarily designed to be used where large packets of data are transferred. The USB protocol requires such packets to be split into a series of packets of maximum packet size. The last packet in the series may be less than the maximum packet size (or a null packet if the total size of the transfer is an exact multiple of the maximum packet size) and the receiver may interpret this ‘short’ packet as signaling the end of the transfer. DMA Request Mode 1 can be used, with a suitably programmed DMA controller, to avoid the overhead of having to interrupt the processor after each individual packet – instead just interrupting the processor after the transfer has completed.

23.1.3.4 Test Modes

The controller supports the four USB 2.0 test modes defined for High-speed functions. It also supports an additional “FIFO access” test mode that can be used to test the operation of the CPU interface, the DMA controller (if configured) and the RAM block.

The test modes are entered by writing to the TestMode register (offset address 0x40F). At test mode is usually requested by the host sending a SET_FEATURE request to Endpoint 0. When the software receives the request, it should wait until the Endpoint 0 transfer has completed (when it receives the Endpoint 0 interrupt indicating the status phase has completed) then write to the TestMode register.

Note: These test modes have no purpose in normal operation.

23.1.3.4.1 TEST_SE0_NAK

To enter the TEST_SE0_NAK test mode, the software should set the TEST_SE0-NAK bit by writing 0x01 to the TestMode register. The controller will then go into a mode in which it responds to any valid IN token with a NAK.

23.1.3.4.2 TEST_J

To enter the TEST_J test mode, the software should set the TEST_J bit by writing 0x02 to the TestMode register. The controller will then go into a mode in which it transmits a continuous J on the bus.

23.1.3.4.3 TEST_K

To enter the TEST_K test mode, the software should set the TEST_K bit by writing 0x04 to the TestMode register. The controller will go into a mode in which it transmits a continuous K on the bus.

23.1.3.4.4 TEST_PACKET

To execute the TEST_PACKET, the software should:

1. Start a session (if the core is being used in Host mode).
2. Write the standard test packet (shown below) to the Endpoint 0 FIFO.
3. Write 0x8 to the TestMode register to enter Test_Packet test mode.
4. Set the TTPKTRDY bit in the HOST/PERI_CSR0.TXPKTRDY register.

The 53 byte test packet to load is as follows (all bytes in hex). The test packet only has to be loaded once; the controller will keep re-sending the test packet without any further intervention from the software.

00	00	00	00	00	00	00	00
00	AA	AA	AA	AA	AA	AA	AA
AA	EE	EE	EE	EE	EE	EE	EE
EE	FE	FF	FF	FF	FF	FF	FF
FF	FF	FF	FF	FF	7F	BF	DF
EF	F7	FB	FD	FC	7E	BF	DF
EF	F7	FB	FD	7E			

This data sequence is defined in Universal Serial Bus Specification Revision 2.0, Section 7.1.20. The controller will add the DATA0 PID to the head of the data sequence and the CRC to the end.

23.1.3.4.5 FIFO_ACCESS

The FIFO Access test mode allows the user to test the operation of CPU Interface and the RAM block by loading a packet of up to 64 bytes into the Endpoint 0 FIFO and then reading it back out again. Endpoint 0 is used because it is a bi-directional endpoint that uses the same area of RAM for its Tx and Rx FIFOs.

Note: The core does not need to be connected to the USB bus to run this test. If it is connected, then no session should be in progress when the test is run.

The test procedure is as follows:

1. Load a packet of up to 64 bytes into the Endpoint 0 Tx FIFO.
2. Set HOST/PERI_CSR0.TXPKTRDY.
3. Write 0x40 to the Testmode register.
4. Unload the packet from the Endpoint Rx FIFO, again.
5. Set HOST/PERI_CSR0.SERV_RXPKTRY

Writing 0x40 to the Testmode register causes the following sequence of events:

1. The Endpoint 0 CPU pointer (which records the number of bytes to be transmitted) is copied to the Endpoint 0 USB pointer (which records the number of bytes received).
2. The Endpoint 0 CPU pointer is reset.
3. HOST/PERI_CSR0.TXPKTRDY is cleared.
4. HOST/PERI_CSR0.RXPKTRDY is set.
5. An Endpoint 0 interrupt is generated (if enabled).

The effect of these steps is to make the Endpoint 0 controller act as if the packet loaded into the Tx FIFO has flushed and the same packet received over the USB. The data that was loaded in the Tx FIFO can now be read out of the Rx FIFO.

23.1.3.4.6 FORCE_HOST

The Force Host test mode enables the user to instruct the core to operate in Host mode, regardless of whether it is actually connected to any peripheral i.e. the state of the CID input and the LINESTATE and HOSTDISCON signals are ignored. (While in this mode, the state of the HOSTDISCON signal can be read from bit 7 of the DevCtl register.)

This mode, which is selected by setting bit 7 within the Testmode register, allows implementation of the USB TEST_FORCE_ENABLE (7.1.20). It can also be used for debugging PHY problems in hardware.

While the FORCE_HOST bit remains set, the core will enter Host mode when the Session bit is set and remain in Host mode until the Session bit is cleared even if a connected device is disconnected during the session. The operating speed while in this mode is determined for the setting of the FORCE_HS and FORCE_FS bits of the Testmode register in [Section 23.1.4.11](#).

23.1.3.4.7 USB Core Interrupts

There are two methods available for software to access USB core interrupts, selectable by the UINT bit of CTRLR. The UINT bit cleared to 0 selects the PDR 2.0 compliant register set (INTSRCR, INTSETR, INTCLRR, INTMSKR, INTMSKSETR, INTMSKCLRR, INTMASKEDR). This is the default, and should be used for most systems. The DRVVBUS level change interrupt is only available in the PDR compliant register. UINT set to one selects direct access to the USB core interrupt registers (INTRUSB, INTRUSBE, INTRTX, INTRRX). Software should select a single method for interrupts and use its corresponding registers exclusively.

Interrupt status can be determined using the INTSRCR (interrupt source) register. This register is non-masked. To clear the interrupt source, set the corresponding interrupt bit in INTCLRR register. For debugging purposes, interrupt can be set manually through INTSETR register.

The interrupt controller provides the option of masking the interrupts. A mask can be set using INTMSKSETR register and can be cleared by setting the corresponding bit in the INTMSKCLRR register. The mask can be read from INTMSKR register. The masked interrupt status is determined using the INTMASKEDR register.

Software should write all zeros to the End Of Interrupt Register (EOIR) to acknowledge the completion of the USB core interrupt.

Note: If the EOIR is not written, the interrupt output to the CPU will not be pulsed again for the next interrupt.

23.1.3.4.8 DMA Interrupts

Interrupt status for the DMA interrupts is determined by TCCPIRAWSR and RCPPIRAWSR registers. These are the raw interrupt status registers for DMA interrupts.

Tx DMA interrupts mask is set using TCPPIENSETR register and cleared using TCPPIENCLRR register. The masked status is read using TCPPIMSKSR register.

Rx DMA interrupts mask is set using RCPPIENSETR register and cleared using RCPPIENCLRR register. The masked status is read using RCPPIMSKSR register.

Like USB core interrupts, the CPPIEOIR register needs to be written by the host processor software to acknowledge the completion of the interrupt.

Upon receipt of a DMA interrupt, software should check TCCPIRAWSR/RCPPIRAWSR to determine which DMA channel(s) to service. Check the CPPI buffer descriptor ownership field for the completed channel for error conditions and add or update buffer descriptors as needed. Write the RCPPICOMPTR or TCPPICOMPTR completion pointer with the address of the buffer descriptor serviced in order to clear the interrupt. Finally, write the DMA End Of Interrupt register CPPIEOIR with all zeros to enable future (or current unserviced) interrupts to pulse the interrupt output to the CPU.

When using DMA with a TX endpoint, set the TXCSR register DMAMODE bit to one in order to receive only error (not packet completion) interrupts. For DMA with an RX endpoint, the DMAMODE bit in RXCSR should be cleared to 0.

23.1.3.5 EDMA Event Support

The USB is an internal bus master peripheral and therefore does not utilize any EDMA events. The registers support only individual access. Bursting data to or from the USB register space through EDMA is not supported.

23.1.3.6 Power Management

The USB controller can be placed in reduced power modes to conserve power during periods of low activity. The power management of the peripheral is controlled by the processor Power and Sleep Controller (PSC). The PSC acts as a master controller for power management for all of the peripherals on the device. For detailed information on power management procedures using the PSC, see the *TMS320dm644x DMSoC ARM Subsystem Reference Guide* ([SPRUE14](#)).

23.1.3.6.1 Power-Management Scheme

23.1.3.6.1.1 Overview

To save dynamic power consumption, an efficient idle scheme in the device is based on the following:

- An efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated/deactivated safely without complex software intervention. In both cases, the high-speed USB controller power management is applied only to the interface clock domain. The USB functional clock (60 MHz), USBHS_FCLK, is controlled by the transceiver and is responsible only for a very small percentage of the module overall power consumption.

The high-speed USB controller has both master (initiator) and slave (target) interfaces.

- As an initiator, the high-speed USB controller implements the standby handshake protocol to inform the PRCM module when it enters standby mode and does not generate traffic on the interconnect.
- As a target, the high-speed USB controller implements the IDLE handshake protocol to allow the PRCM module requiring it to enter idle mode.

23.1.3.6.1.2 System Power Management

Master Interface Power Management

The high-speed USB controller can choose to go to standby mode, in which case it stops generating transactions on the interconnect. The module standby leads the PRCM to disable the USB clocks to save power.

The high-speed USB controller has a MSTANDBY handshake mechanism with the PRCM module.

The module is ready to enter standby mode (indicated by the MSTANDBY signal to the PRCM asserted) when there is no USB activity and the module is idle. It means the following:

- The module is committed not to start any new transaction on its master interface.
- The module is idle and, therefore, the power manager can start the procedure to turn off the interface clock, if needed. This procedure must be implemented using the slave power-management protocol.

The handshake mechanism lets the module to go to standby state based on the USBOTG.OTG_SYSCONFIG[13:12] MIDDLEMODE field.

- Smart standby

The high-speed USB controller is configured in smart-standby mode (USBOTG.OTG_SYSCONFIG[13:12] MIDDLEMODE field = 0x2). The module is ready to enter standby mode (MSTANDBY is asserted) when there is no more activity on the USB master interface of the interconnect. MSTANDBY is asserted when the module is idle and deasserted when the module is activated by either an external USB event or an appropriate register access. The module then waits for MWAIT deassertion before a DMA transfer is started.

- Force standby

The high-speed USB controller is configured in force-standby mode (USBOTG.OTG_SYSCONFIG[13:12] MIDDLEMODE field = 0x0).

- When the high-speed USB controller operates as a host: the USBOTG.POWER[1] SUSPENDMODE bit is set to 1 to bring the module to low-power mode (suspend mode). After this setting, the high-speed USB controller waits for its idle state. The USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit must be set to 1 to assert MSTANDBY. Similarly, to release the MSTANDBY signal, an appropriate register access must be applied, which can be either of the following two cases:

- Remote wakeup causes a RESUME interrupt
 - Set the USBOTG.POWER[3] RESET bit to 1.
 - Write 0 to the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit.
OR
 - Set the USBOTG.POWER[3] RESET bit to 1.
 - Write 0 to the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit.
 - When the high-speed USB controller operates as a peripheral: When the USB bus is idle for 3 ms, a SUSPEND interrupt is generated by the high-speed USB controller. The USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit must be set to 1 to enable the MSTANDBY signal. The high-speed USB controller then asserts MSTANDBY. Similarly, to release the MSTANDBY signal, an appropriate register access must be applied, which can be either of the following two cases:
 - Set the USBOTG.POWER[2] RESUME bit to 1.
 - Write 0 to the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit.
OR
 - RESET interrupt is generated by the high-speed USB controller.
 - Write 0 to the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit.
- When MSTANDBY is deasserted as a consequence of the previous register access, the module waits for MWAIT deassertion before a DMA transfer is started.
- No standby
The high-speed USB controller is configured in no-standby mode (USBOTG.OTG_SYSCONFIG[13:12] MIDDLEMODE field = 0x1). The module never enters standby mode (that is, MSTANDBY is never asserted).

Table 23-8 describes the high-speed USB master interface power management modes.

Table 23-8. High-Speed USB Master Interface Power Management Modes

Power Management Mode Requested by the PRCM	USBOTG.OTG_SYSCONFIG[13:12] MIDDLEMODE Field
Force-standby	0x0
No-standby	0x1
Smart-standby	0x2
Reserved	0x3

Slave Interface Power Management

The high-speed USB controller can be configured through the USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE field as one of the following acknowledgment modes:

- Smart-Idle Mode
When the high-speed USB controller receives an IDLE request from the PRCM module:
 - The interface clock USBHS_ICLK is disabled (PRCM register bit PRCM.CM_ICLKEN1_CORE[4] set to 0) or under automatic control (PRCM register bits PRCM.CM_ICLKEN1_CORE[4] and PRCM.CM_AUTOIDLE1_CORE[4] both set to 1)
 - L4 interface clock idle transitions:
Configured in smart-idle mode (USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE field = 0x2), the high-speed USB controller checks for no ongoing activity. The idle acknowledge then is asserted and the module waits for active system clock gating by the PRCM module (this occurs only when all peripherals supplied by the same L3 clock domain are also ready for idle).
Once in idle mode (when the PRCM module gates the interface clock), the module has no activity, the interface clock paths are gated, no interrupt request can be generated, and the module is ready to issue a wake-up request. If a wake-up condition occurs, the high-speed USB controller exits from idle mode if the USBOTG.OTG_SYSCONFIG[2] ENABLEWAKEUP bit is set to 1 (wake-up capability enabled) and the PRCM register bit PRCM.PM_WKEN1_CORE[4] is also set to 1.
- Force-Idle Mode
When the high-speed USB controller receives an IDLE request from the PRCM module:

- The interface clock USBHS_ICLK is disabled (PRCM register bit PRCM.CM_ICLKEN1_CORE[4] set to 0) or under automatic control (PRCM register bits PRCM.CM_ICLKEN1_CORE[4] and PRCM.CM_AUTOIDLE1_CORE[4] both set to 1)
- The L4 interface clock idle transitions:
Configured in force-idle mode (USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE field = 0x0), the high-speed USB controller waits unconditionally for active system clock gating by the PRCM module (this occurs only when all peripherals supplied by the same L3 clock domain are also ready for idle).

Once in idle mode (when the PRCM module gates the interface clock), the module has no activity, the interface clock paths are gated, no interrupt request can be generated, and the wake-up feature is totally inhibited.

- **No-Idle Mode**

When the high-speed USB controller receives an IDLE request from the PRCM module:

- The interface clock(s) USBHS_ICLK are disabled (PRCM register bit PRCM.CM_ICLKEN1_CORE[4] set to 0) or under automatic control (PRCM register bits PRCM.CM_ICLKEN1_CORE[4] and PRCM.CM_AUTOIDLE1_CORE[4] both set to 1)
- L4 interface clock idle transitions
Configured in no-idle mode (USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE field = 0x1), the high-speed USB controller module does not go to idle mode and the idle acknowledge is never sent.

Table 23-9 describes the high-speed USB slave interface power management modes.

Table 23-9. High-Speed USB Slave Interface Power Management Modes

Power Management Mode Requested by the PRCM	USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE Field
Force-idle	0x0
No-idle	0x1
Smart-idle	0x2
Reserved	0x3

Note: The high-speed USB controller standby status can be checked by the PRCM module register bit CM_IDLEST1_CORE[4]:

- 0: High-Speed USB is active.
- 1: High-Speed USB is in standby mode.

The high-speed USB controller wake-up status can be checked by the PRCM module register bit PM_WKST1_CORE[4]:

- Read 0: Wakeup has not occurred or was masked.
- Read 1: Wakeup has occurred.
- Write 0: Status bit unchanged.
- Write 1: Status bit is cleared to 0.

23.1.3.6.1.3 Local Power Management

The high-speed USB controller has local power management by internal clock gating features:

Internal interface clock autogating: Clock for the L3 interconnect logic can be gated when the module is not accessed, if the USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit is set. Otherwise, this logic is free-running on the interface clock. This bit is used to save power when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits.

23.1.3.6.2 Power Domain

The high-speed USB controller is attached to the CORE power domain (see the *Power, Reset, and Clock Management* chapter).

23.1.3.6.3 IDLE Handshake Protocol

The PRCM handles an IDLE handshake protocol for the high-speed USB controller. The IDLE handshake protocol allows the PRCM requiring the high-speed USB controller to enter idle mode. The high-speed USB controller acknowledges when it is ready.

23.1.3.6.4 MSTANDBY Handshake Protocol

The PRCM module handles an MSTANDBY handshake protocol for the high-speed USB controller, which initiates the MSTANDBY handshake to inform the PRCM module when it enters standby mode and does not generate traffic on interconnect.

23.1.3.6.5 Wake-Up Request

The high-speed USB controller generates a wake-up request signal (UBSHS_SWAKEUP) to the PRCM module.

23.1.3.6.6 Enabling MSTANDBY in Force-Standby Mode

The USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit controls MSTANDBY behavior in force-standby mode only (see [Section 23.1.4.58](#)). In this mode, only when the internal core is idle (the module has no activity; that is, the USB is in suspend state) and when 1 is written to this bit, MSTANDBY goes high. Similarly, when ENABLEFORCE is 0 and the internal core is also in a non-idle state, MSTANDBY is deasserted. This bit does not influence MSTANDBY behavior in all other modes, such as no-standby and smart-standby.

23.1.3.6.7 Power Management Basic Programming Model

This section describes the settings for optimal High-Speed USB controller power management, depending on the use of this module in the application.

Two registers are involved in power management: USBOTG.OTG_SYSCONFIG and USBOTG.OTG_FORCESTDBY.

On reset, the high-speed USB controller has the following configuration:

- Master interface power management is in force-standby mode (USBOTG.OTG_SYSCONFIG[13:12] MIDDLEMODE field = 0x0).
- Slave interface power management is in force-idle mode (USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE field = 0x0).
- Internal clock autogating feature is disabled (USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit = 0).
- MSTANDBY signal assertion is enabled (USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit = 1).

23.1.3.6.7.1 High-Speed USB Controller Not Used for Application

In this scenario, the high-speed USB controller is not used by the system software. Default settings must be changed to reduce power consumption. Enabling the internal clock autogating feature cuts off the module internal interface clock as soon as it is no longer required. This is done by setting the USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit to 1.

The optimal configuration when the high-speed USB controller is not used by the application is as follows:

- Master interface power management is in force-standby mode (USBOTG.OTG_SYSCONFIG[13:12] MIDDLEMODE field = 0x0).
- Slave interface power management is in force-idle mode (USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE field = 0x0).
- Internal clock autogating feature is enabled (USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit = 1).

- MSTANDBY signal assertion enabled (USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit = 1)

23.1.3.6.7.2 High-Speed USB Controller in Host Mode

When used as a host, the high-speed USB controller must be programmed as follows:

- Master interface power management in smart-standby mode
- Slave interface power management in smart-idle mode
- Internal clock autogating feature enabled
- MSTANDBY signal assertion disabled

The programming sequence must be as follows:

1. Write 0 to the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit to disable the MSTANDBY assertion before programming to smart-standby and smart-idle modes.
2. Set the USBOTG.OTG_SYSCONFIG[13:12] MIDDLEMODE field to 0x2, the USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE field to 0x2, and the USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit to 0 to program the smart-standby and smart-idle modes. Ensure that internal clock autogating is not enabled while programming smart-idle mode.
3. Set the USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit to 1 to cut off the internal clocks to save power.

Note: The internal clock autogating feature and smart-idle mode must not be programmed simultaneously.

23.1.3.6.7.3 High-Speed USB Controller in Peripheral Mode

When used as a peripheral, the high-speed USB controller must be programmed as follows:

- Master interface power management in smart-standby mode
- Slave interface power management in smart-idle mode
- Internal clock autogating feature enabled
- MSTANDBY signal assertion disabled

The programming sequence must be as follows:

1. Write 0 to the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit to disable the MSTANDBY assertion before programming to smart-standby mode.
2. Set the USBOTG.OTG_SYSCONFIG[13:12] MIDDLEMODE field to 0x2, the USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE field to 0x2, and the USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit to 0 to program the smart-standby and smart-idle modes. Ensure that the internal clock autogating is not enabled while programming the smart-idle mode..
3. Set the USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit to 1 to cut off the internal clocks to save power.

Note: The internal clock autogating feature and smart-idle mode must not be programmed simultaneously.

23.1.3.6.7.4 High-Speed USB Controller in Host/Peripheral Mode

When used as a host/peripheral, the high-speed USB controller must be programmed as follows:

- Master interface power management in smart-standby mode
- Slave interface power management in smart-idle mode
- Internal clock autogating feature enabled
- MSTANDBY signal assertion disabled

See [Section 23.1.3.6.7.2](#) and [Section 23.1.3.6.7.3](#) for the programming sequence.

As an application required to disable the master interface, the high-speed USB controller can also be programmed as follows:

- Master interface power management in force-standby mode
- Slave interface power management in smart-idle mode
- Internal clock autogating feature enabled

- MSTANDBY signal assertion enabled

The programming sequence must be as follows:

1. Write 0 to the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit to disable the MSTANDBY assertion before programming to smart-standby mode.
2. Set the USBOTG.OTG_SYSCONFIG[13:12] MIDLEMODE field to 0x0, the USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE field to 0x2, and the USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit to 0 to program the force-standby and smart-idle modes. Ensure that the internal clock autogating is not enabled while programming smart-idle mode.
3. Set the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit to 1 to enable the MSTANDBY assertion before enabling internal clock autogating feature.
4. Set the USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit to 1 to cut off the internal clocks to save power.

Note: The internal clock the autogating feature and smart-idle mode must not be programmed simultaneously.

23.1.4 Registers

Table 23-10 lists the memory-mapped registers for the high speed universal serial bus (USB). The base address is 480A B000h.

Note: The six high-speed USB registers are limited to 32-bit data accesses; 16-bit and 8-bit accesses are not allowed and can corrupt register content.

Note: In some cases, a single register address can have different names or meanings depending on the mode (host/peripheral) or the setting of the index register. The meaning of some bit fields varies with the mode.

Table 23-10. Universal Serial Bus (USB) Registers

Offset	Acronym	Register Description	Section
Common USB Registers			
0	FADDR	Function Address Register	Section 23.1.4.1
1h	POWER	Power Management Register	Section 23.1.4.2
2h	INTRTX	Interrupt Register for Endpoint 0 and for Transmit Endpoints 1 to 15	Section 23.1.4.3
4h	INTRRX	Interrupt Register for Receive Endpoints 1 to 15	Section 23.1.4.4
6h	INTRTXE	Interrupt Enable Register for INTRTX	Section 23.1.4.5
8h	INTRRXE	Interrupt Enable Register for INTRRX	Section 23.1.4.6
Ah	INTRUSB	Interrupt Register for Common USB Interrupts	Section 23.1.4.7
Bh	INTRUSBE	Interrupt Enable Register for INTRUSB	Section 23.1.4.8
Ch	FRAME	Frame Number Register	Section 23.1.4.9
Eh	INDEX	Index Register for Selecting the Endpoint Status and Control Registers	Section 23.1.4.10
Fh	TESTMODE	Register to Enable the USB 2.0 Test Modes	Section 23.1.4.11
Indexed Registers (These registers operate on the endpoint selected by the INDEX register)			
10h	TXMAXP	Maximum Packet Size for Peripheral/Host Transmit Endpoint (Index register set to select Endpoints 1-15)	Section 23.1.4.12
12h	PERI_CSR0	Control Status Register for Endpoint 0 in Peripheral Mode. (Index register set to select Endpoint 0)	Section 23.1.4.13
	HOST_CSR0	Control Status Register for Endpoint 0 in Host Mode (Index register set to select Endpoint 0)	Section 23.1.4.14
	PERI_TXCSR	Control Status Register for Peripheral Transmit Endpoint. (Index register set to select Endpoints 1-15)	Section 23.1.4.15
	HOST_TXCSR	Control Status Register for Host Transmit Endpoint (Index register set to select Endpoints 1-15)	Section 23.1.4.16
14h	RXMAXP	Maximum Packet Size for Peripheral/Host Receive Endpoint (Index register set to select Endpoints 1-15)	Section 23.1.4.17
16h	PERI_RXCSR	Control Status Register for Peripheral Receive Endpoint. (Index register set to select Endpoints 1-15)	Section 23.1.4.18
	HOST_RXCSR	Control Status Register for Host Receive Endpoint (Index register set to select Endpoints 1-15)	Section 23.1.4.19
18h	COUNT0	Number of Received Bytes in Endpoint 0 FIFO (Index register set to select Endpoint 0)	Section 23.1.4.20
	RXCOUNT	Number of Bytes in Host Receive Endpoint FIFO (Index register set to select Endpoints 1-15)	Section 23.1.4.21
1Ah	HOST_TYPE0	Defines the speed of Endpoint 0	Section 23.1.4.22
	HOST_TXTYPE	Sets the operating speed, transaction protocol and peripheral endpoint number for the host Transmit endpoint. (Index register set to select Endpoints 1-15)	Section 23.1.4.23

Table 23-10. Universal Serial Bus (USB) Registers (continued)

Offset	Acronym	Register Description	Section
1Bh	HOST_NAKLIMIT0	Sets the NAK response timeout on Endpoint 0 (Index register set to select Endpoint 0)	Section 23.1.4.24
	HOST_TXINTERVAL	Sets the polling interval for Interrupt/ISOC transactions or the NAK response timeout on Bulk transactions for host Transmit endpoint. (Index register set to select Endpoints 1-15)	Section 23.1.4.25
1Ch	HOST_RXTYPE	Sets the operating speed, transaction protocol and peripheral endpoint number for the host Receive endpoint. (Index register set to select Endpoints 1-15)	Section 23.1.4.26
1Dh	HOST_RXINTERVAL	Sets the polling interval for Interrupt/ISOC transactions or the NAK response timeout on Bulk transactions for host Receive endpoint. (Index register set to select Endpoints 1-15)	Section 23.1.4.27
1Fh	CONFIGDATA	Returns details of core configuration. (Index register set to select Endpoint 0)	Section 23.1.4.28
FIFOs			
20h	FIFO0	Transmit and Receive FIFO Register for Endpoint 0	Section 23.1.4.29
24h	FIFO1	Transmit and Receive FIFO Register for Endpoint 1	Section 23.1.4.29
28h	FIFO2	Transmit and Receive FIFO Register for Endpoint 2	Section 23.1.4.29
2Ch	FIFO3	Transmit and Receive FIFO Register for Endpoint 3	Section 23.1.4.29
30h	FIFO4	Transmit and Receive FIFO Register for Endpoint 4	Section 23.1.4.29
34h	FIFO5	Transmit and Receive FIFO Register for Endpoint 5	Section 23.1.4.29
38h	FIFO6	Transmit and Receive FIFO Register for Endpoint 6	Section 23.1.4.29
3Ch	FIFO7	Transmit and Receive FIFO Register for Endpoint 7	Section 23.1.4.29
40h	FIFO8	Transmit and Receive FIFO Register for Endpoint 8	Section 23.1.4.29
44h	FIFO9	Transmit and Receive FIFO Register for Endpoint 9	Section 23.1.4.29
48h	FIFO10	Transmit and Receive FIFO Register for Endpoint 10	Section 23.1.4.29
4Ch	FIFO11	Transmit and Receive FIFO Register for Endpoint 11	Section 23.1.4.29
50h	FIFO12	Transmit and Receive FIFO Register for Endpoint 12	Section 23.1.4.29
54h	FIFO13	Transmit and Receive FIFO Register for Endpoint 13	Section 23.1.4.29
58h	FIFO14	Transmit and Receive FIFO Register for Endpoint 14	Section 23.1.4.29
5Ch	FIFO15	Transmit and Receive FIFO Register for Endpoint 15	Section 23.1.4.29
OTG Device Control			
60h	DEVCTL	OTG Device Control Register	Section 23.1.4.30
Dynamic FIFO Control			
62h	TXFIFOSZ	Transmit Endpoint FIFO Size (Index register set to select Endpoints 1-15)	Section 23.1.4.31
63h	RXFIFOSZ	Receive Endpoint FIFO Size (Index register set to select Endpoints 1-15)	Section 23.1.4.32
64h	TXFIFOADDR	Transmit Endpoint FIFO Address (Index register set to select Endpoints 1-15)	Section 23.1.4.33
66h	RXFIFOADDR	Receive Endpoint FIFO Address (Index register set to select Endpoints 1-15)	Section 23.1.4.34
ULPI Registers			
70h	ULPIVBUSCONTROL	ULPI VBUS Control Register	Section 23.1.4.35
71h	ULPIUTMICONTROL	ULPI UTMI Control Register	Section 23.1.4.36
72h	ULPIINTMASK	ULPI Interrupt Mask Register	Section 23.1.4.37
73h	ULPIINTSRC	ULPI Interrupt Source Register	Section 23.1.4.38
74h	ULPIREGDATA	ULPI Data Register	Section 23.1.4.39
75h	ULPIREGADDR	ULPI Address Register	Section 23.1.4.40
76h	ULPIREGCONTROL	ULPI Control Register	Section 23.1.4.41
77h	ULPIRAWDATA	ULPI Raw Data Register	Section 23.1.4.42

Table 23-10. Universal Serial Bus (USB) Registers (continued)

Offset	Acronym	Register Description	Section
Target Endpoint 0 Control Registers, Valid Only in Host Mode			
80h	TXFUNCADDR	Address of the target function that has to be accessed through the associated Transmit Endpoint.	Section 23.1.4.43
82h	TXHUBADDR	Address of the hub that has to be accessed through the associated Transmit Endpoint. This is used only when full speed or low speed device is connected via a USB2.0 high-speed hub.	Section 23.1.4.44
83h	TXHUBPORT	Port of the hub that has to be accessed through the associated Transmit Endpoint. This is used only when full speed or low speed device is connected via a USB2.0 high-speed hub.	Section 23.1.4.45
84h	RXFUNCADDR	Address of the target function that has to be accessed through the associated Receive Endpoint.	Section 23.1.4.46
86h	RXHUBADDR	Address of the hub that has to be accessed through the associated Receive Endpoint. This is used only when full speed or low speed device is connected via a USB2.0 high-speed hub.	Section 23.1.4.47
87h	RXHUBPORT	Port of the hub that has to be accessed through the associated Receive Endpoint. This is used only when full speed or low speed device is connected via a USB2.0 high-speed hub.	Section 23.1.4.48
Target Endpoint 1 Control Registers, Valid Only in Host Mode			
88h	TXFUNCADDR	Address of the target function that has to be accessed through the associated Transmit Endpoint.	Section 23.1.4.43
8Ah	TXHUBADDR	Address of the hub that has to be accessed through the associated Transmit Endpoint. This is used only when full speed or low speed device is connected via a USB2.0 high-speed hub.	Section 23.1.4.44
8Bh	TXHUBPORT	Port of the hub that has to be accessed through the associated Transmit Endpoint. This is used only when full speed or low speed device is connected via a USB2.0 high-speed hub.	Section 23.1.4.45
8Ch	RXFUNCADDR	Address of the target function that has to be accessed through the associated Receive Endpoint.	Section 23.1.4.46
8Eh	RXHUBADDR	Address of the hub that has to be accessed through the associated Receive Endpoint. This is used only when full speed or low speed device is connected via a USB2.0 high-speed hub.	Section 23.1.4.47
8Fh	RXHUBPORT	Port of the hub that has to be accessed through the associated Receive Endpoint. This is used only when full speed or low speed device is connected via a USB2.0 high-speed hub.	Section 23.1.4.48
Target Endpoint 2 Control Registers, Valid Only in Host Mode			
90h	TXFUNCADDR	Address of the target function that has to be accessed through the associated Transmit Endpoint.	Section 23.1.4.43
92h	TXHUBADDR	Address of the hub that has to be accessed through the associated Transmit Endpoint. This is used only when full speed or low speed device is connected via a USB2.0 high-speed hub.	Section 23.1.4.44
93h	TXHUBPORT	Port of the hub that has to be accessed through the associated Transmit Endpoint. This is used only when full speed or low speed device is connected via a USB2.0 high-speed hub.	Section 23.1.4.45
94h	RXFUNCADDR	Address of the target function that has to be accessed through the associated Receive Endpoint.	Section 23.1.4.46

Table 23-10. Universal Serial Bus (USB) Registers (continued)

Offset	Acronym	Register Description	Section
96h	RXHUBADDR	Address of the hub that has to be accessed through the associated Receive Endpoint. This is used only when full speed or low speed device is connected via a USB2.0 high-speed hub.	Section 23.1.4.47
97h	RXHUBPORT	Port of the hub that has to be accessed through the associated Receive Endpoint. This is used only when full speed or low speed device is connected via a USB2.0 high-speed hub.	Section 23.1.4.48
Target Endpoint 3 Control Registers, Valid Only in Host Mode			
98h	TXFUNCADDR	Address of the target function that has to be accessed through the associated Transmit Endpoint.	Section 23.1.4.43
9Ah	TXHUBADDR	Address of the hub that has to be accessed through the associated Transmit Endpoint. This is used only when full speed or low speed device is connected via a USB2.0 high-speed hub.	Section 23.1.4.44
9Bh	TXHUBPORT	Port of the hub that has to be accessed through the associated Transmit Endpoint. This is used only when full speed or low speed device is connected via a USB2.0 high-speed hub.	Section 23.1.4.45
9Ch	RXFUNCADDR	Address of the target function that has to be accessed through the associated Receive Endpoint.	Section 23.1.4.46
9Eh	RXHUBADDR	Address of the hub that has to be accessed through the associated Receive Endpoint. This is used only when full speed or low speed device is connected via a USB2.0 high-speed hub.	Section 23.1.4.47
9Fh	RXHUBPORT	Port of the hub that has to be accessed through the associated Receive Endpoint. This is used only when full speed or low speed device is connected via a USB2.0 high-speed hub.	Section 23.1.4.48
Target Endpoint 4 Control Registers, Valid Only in Host Mode			
A0h	TXFUNCADDR	Address of the target function that has to be accessed through the associated Transmit Endpoint.	Section 23.1.4.43
A2h	TXHUBADDR	Address of the hub that has to be accessed through the associated Transmit Endpoint. This is used only when full speed or low speed device is connected via a USB2.0 high-speed hub.	Section 23.1.4.44
A3h	TXHUBPORT	Port of the hub that has to be accessed through the associated Transmit Endpoint. This is used only when full speed or low speed device is connected via a USB2.0 high-speed hub.	Section 23.1.4.45
A4h	RXFUNCADDR	Address of the target function that has to be accessed through the associated Receive Endpoint.	Section 23.1.4.46
A6h	RXHUBADDR	Address of the hub that has to be accessed through the associated Receive Endpoint. This is used only when full speed or low speed device is connected via a USB2.0 high-speed hub.	Section 23.1.4.47
A7h	RXHUBPORT	Port of the hub that has to be accessed through the associated Receive Endpoint. This is used only when full speed or low speed device is connected via a USB2.0 high-speed hub.	Section 23.1.4.48
Control and Status Register for Endpoint 0			
102h	PERI_CSR0	Control Status Register for Endpoint 0 in Peripheral Mode	Section 23.1.4.13
	HOST_CSR0	Control Status Register for Endpoint 0 in Host Mode	Section 23.1.4.14
108h	COUNT0	Number of Received Bytes in Endpoint 0 FIFO	Section 23.1.4.20
10Ah	HOST_TYPE0	Defines the Speed of Endpoint 0	Section 23.1.4.22
10Bh	HOST_NAKLIMIT0	Sets the NAK Response Timeout on Endpoint 0	Section 23.1.4.24
10Fh	CONFIGDATA	Returns details of core configuration.	Section 23.1.4.28

Table 23-10. Universal Serial Bus (USB) Registers (continued)

Offset	Acronym	Register Description	Section
Control and Status Register for Endpoint 1			
110h	TXMAXP	Maximum Packet Size for Peripheral/Host Transmit Endpoint	Section 23.1.4.12
112h	PERI_TXCSR	Control Status Register for Peripheral Transmit Endpoint (peripheral mode)	Section 23.1.4.15
	HOST_TXCSR	Control Status Register for Host Transmit Endpoint (host mode)	Section 23.1.4.16
114h	RXMAXP	Maximum Packet Size for Peripheral/Host Receive Endpoint	Section 23.1.4.17

23.1.4.1 Function Address Register (FADDR)

The Function Address Register (FADDR) is shown in [Figure 23-17](#) and described in [Table 23-11](#).

Figure 23-17. Function Address Register (FADDR)

7	6	0
Reserved	FUNCADDR	
R-0	R/W-0	

LEGEND: R/W = Read/Write; -n = value after reset

Table 23-11. Function Address Register (FADDR) Field Descriptions

Bit	Field	Value	Description
7	Reserved	0	Reserved
6-0	FUNCADDR	0-7Fh	<p>7-bit address of the peripheral part of the transaction</p> <p>When used in Peripheral mode (DevCtl.D2=0), this register should be written with the address received through a SET_ADDRESS command, which will then be used for decoding the function address in subsequent token packets.</p> <p>When used in Host mode (DevCtl.D2=1), this register should be set to the value sent in a SET_ADDRESS command during device enumeration as the address for the peripheral device.</p>

23.1.4.2 Power Management Register (POWER)

The Power Management Register (POWER) is shown in [Figure 23-18](#) and described in [Table 23-12](#).

Figure 23-18. Power Management Register (POWER)

7	6	5	4	3	2	1	0
ISOUPDATE	SOFTCONN	HSEN	HSMODE	RESET	RESUME	SUSPENDM	ENSUSPM
R/W-0	R/W-0	R/W-1	R-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 23-12. Power Management Register (POWER) Field Descriptions

Bit	Field	Value	Description
7	ISOUPDATE	0-1	When set, the USB controller will wait for an SOF token from the time TxPktRdy is set before sending the packet. If an IN token is received before an SOF token, then a zero length data packet will be sent. Note: This is only valid in Peripheral Mode. This bit only affects endpoints performing Isochronous transfers.
6	SOFTCONN	0-1	If Soft Connect/Disconnect feature is enabled, then the USB D+/D- lines are enabled when this bit is set and tri-stated when this bit is cleared. Note: This is only valid in Peripheral Mode.
5	HSEN	0-1	When set, the USB controller will negotiate for high-speed mode when the device is reset by the hub. If not set, the device will only operate in full-speed mode.
4	HSMODE	0-1	This bit is set when the USB controller has successfully negotiated for high-speed mode.
3	RESET	0-1	This bit is set when Reset signaling is present on the bus. Note: This bit is Read/Write in Host Mode, but read-only in Peripheral Mode.
2	RESUME	0-1	Set to generate Resume signaling when the controller is in Suspend mode. The bit should be cleared after 10 ms (a maximum of 15 ms) to end Resume signaling. In Host mode, this bit is also automatically set when Resume signaling from the target is detected while the USB controller is suspended.
1	SUSPENDM	0-1	In Host mode, this bit should be set to enter Suspend mode. In Peripheral mode, this bit is set on entry into Suspend mode. It is cleared when the interrupt register is read, or the RESUME bit is set.
0	ENSUSPM	0-1	Set to enable the SUSPENDM output.

23.1.4.3 Interrupt Register for Endpoint 0 Plus Transmit Endpoints 1 to 15 (INTRTX)

The Interrupt Register for Endpoint 0 Plus Transmit Endpoints 1 to 15 (INTRTX) is shown in [Figure 23-19](#) and described in [Table 23-13](#).

23.1.4.7 Interrupt Register for Common USB Interrupts (INTRUSB)

The Interrupt Register for Common USB Interrupts (INTRUSB) is shown in [Figure 23-23](#) and described in [Table 23-17](#). Reading this register causes all bits to be cleared.

Note: Unless the UINT bit of CTRLR is set, do not read or write this register directly. Use the INTSRCR register instead.

Figure 23-23. Interrupt Register for Common USB Interrupts (INTRUSB)

7	6	5	4	3	2	1	0
VBUSERR	SESSREQ	DISCON	CONN	SOF	RESET_BABBLE	RESUME	SUSPEND
R-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0

LEGEND: R = Read only; -n = value after reset

Table 23-17. Interrupt Register for Common USB Interrupts (INTRUSB) Field Descriptions

Bit	Field	Value	Description
7	VBUSERR	0-1	Set when VBus drops below the VBus valid threshold during a session. Only valid when the USB controller is 'A' device. All active interrupts will be cleared when this register is read.
6	SESSREQ	0-1	Set when session request signaling has been detected. Only valid when USB controller is 'A' device.
5	DISCON	0-1	Set in host mode when a device disconnect is detected. Set in peripheral mode when a session ends.
4	CONN	0-1	Set when a device connection is detected. Only valid in host mode.
3	SOF	0-1	Set when a new frame starts.
2	RESET_BABBLE	0-1	Set in peripheral mode when reset signaling is detected on the bus set in host mode when babble is detected.
1	RESUME	0-1	Set when resume signaling is detected on the bus while the USB controller is in suspend mode.
0	SUSPEND	0-1	Set when suspend signaling is detected on the bus only valid in peripheral mode.

23.1.4.8 Interrupt Enable Register for INTRUSB (INTRUSBE)

The Interrupt Enable Register for INTRUSB (INTRUSBE) is shown in [Figure 23-24](#) and described in [Table 23-18](#).

Note: Unless the UINT bit of CTRLR is set, do not read or write this register directly. Use the INTMSKSETR/INTMSKCLRR registers instead.

Figure 23-24. Interrupt Enable Register for INTRUSB (INTRUSBE)

6	SESSREQ	0-1	Session request interrupt enable
5	DISCON	0-1	Disconnect interrupt enable
4	CONN	0-1	Connect interrupt enable
3	SOF	0-1	Start of frame interrupt enable
2	RESET_BABBLE	0-1	Reset interrupt enable
1	RESUME	0-1	Resume interrupt enable
0	SUSPEND	0-1	Suspend interrupt enable

23.1.4.9 Frame Number Register (FRAME)

The Frame Number Register (FRAME) is shown in [Figure 23-25](#) and described in [Table 23-19](#).

Figure 23-25. Frame Number Register (FRAME)

15	11	10	0
Reserved		FRAMENUMBER	
R-0		R-0	

LEGEND: R = Read only; -n = value after reset

Table 23-19. Frame Number Register (FRAME) Field Descriptions

Bit	Field	Value	Description
15-11	Reserved	0	Reserved
10-0	FRAMENUMBER	0-7FFh	Last received frame number

23.1.4.10 Index Register for Selecting the Endpoint Status and Control Registers (INDEX)

The Index Register for Selecting the Endpoint Status and Control Registers (INDEX) is shown in [Figure 23-26](#) and described in [Table 23-20](#).

Figure 23-26. Index Register for Selecting the Endpoint Status and Control Registers (INDEX)

7	4	3	0
Reserved		EPSEL	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 23-20. Index Register for Selecting the Endpoint Status and Control Registers (INDEX) Field Descriptions

Bit	Field	Value	Description
7-4	Reserved	0	Reserved
3-0	EPSEL	0-Fh	Each transmit endpoint and each receive endpoint have their own set of control/status registers. EPSEL determines which endpoint control/status registers are accessed. Before accessing an endpoint's control/status registers, the endpoint number should be written to the Index register to ensure that the correct control/status registers appear in the memory map.

23.1.4.11 Register to Enable the USB 2.0 Test Modes (TESTMODE)

The Register to Enable the USB 2.0 Test Modes (TESTMODE) is shown in [Figure 23-27](#) and described in [Table 23-21](#).

Figure 23-27. Register to Enable the USB 2.0 Test Modes (TESTMODE)

7	6	5	4	3	2	1	0
FORCE_HOST	FIFO_ACCESS	FORCE_FS	FORCE_HS	TEST_PACKET	TEST_K	TEST_J	TEST_SE0_NAK
R/W-0	W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; W = Write only; -n = value after reset

Table 23-21. Register to Enable the USB 2.0 Test Modes (TESTMODE) Field Descriptions

Bit	Field	Value	Description
7	FORCE_HOST	0-1	Set this bit to forcibly put the USB controller into Host mode when SESSION bit is set, regardless of whether it is connected to any peripheral. The controller remains in Host mode until the Session bit is cleared, even if a device is disconnected. And if the FORCE_HOST bit remains set, it will re-enter Host mode next time the SESSION bit is set. The operating speed is determined using the FORCE_HS and FORCE_FS bits.
6	FIFO_ACCESS	0-1	Set this bit to transfer the packet in EP0 Tx FIFO to EP0 Receive FIFO. It is cleared automatically.
5	FORCE_FS	0-1	Set this bit to force the USB controller into full-speed mode when it receives a USB reset.
4	FORCE_HS	0-1	Set this bit to force the USB controller into high-speed mode when it receives a USB reset.
3	TEST_PACKET	0-1	Set this bit to enter the Test_Packet test mode. In this mode, the USB controller repetitively transmits a 53-byte test packet on the bus, the form of which is defined in the Universal Serial Bus Specification Revision 2.0. Note: The test packet has a fixed format and must be loaded into the Endpoint 0 FIFO before the test mode is entered.
2	TEST_K	0-1	Set this bit to enter the Test_K test mode. In this mode, the USB controller transmits a continuous K on the bus.
1	TEST_J	0-1	Set this bit to enter the Test_J test mode. In this mode, the USB controller transmits a continuous J on the bus.
0	TEST_SE0_NAK	0-1	Set this bit to enter the Test_SE0_NAK test mode. In this mode, the USB controller remains in high-speed mode, but responds to any valid IN token with a NAK.

23.1.4.12 Maximum Packet Size for Peripheral/Host Transmit Endpoint (TXMAXP)

The Maximum Packet Size for Peripheral/Host Transmit Endpoint (TXMAXP) is shown in [Figure 23-28](#) and described in [Table 23-22](#).

Figure 23-28. Maximum Packet Size for Peripheral/Host Transmit Endpoint (TXMAXP)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 23-22. Maximum Packet Size for Peripheral/Host Transmit Endpoint (TXMAXP)
Field Descriptions**

Bit	Field	Value	Description
15-11	M	0	For Bulk Endpoints, M can be upto 32 and defines the maximum number of USB packets of the specified payload into which a single data packet placed in the FIFO should be split prior to transfer. For Isochronous/Interrupt endpoints operating in High-Speed mode, M may only be either 2 or 3 (corresponding to bit 11 or 12 set, respectively) and it specifies the maximum number of such transaction that can take place in a single microframe.
10-0	MAXPAYLOAD	0-FFh	The maximum payload transmitted in a single transaction. The value set can be up to 1024 bytes, but is subject to the constraints placed by the USB Specification on packet sizes for Bulk, Interrupt, and Isochronous transfers in full-speed and high-speed operations. The value written to this register should match the wMaxPacketSize field of the Standard Endpoint Descriptor for the associated endpoint. A mismatch could cause unexpected results.

23.1.4.13 Control Status Register for Endpoint 0 in Peripheral Mode (PERI_CSR0)

The Control Status Register for Endpoint 0 in Peripheral Mode (PERI_CSR0) is shown in [Figure 23-29](#) and described in [Table 23-23](#).

Figure 23-29. Control Status Register for Endpoint 0 in Peripheral Mode (PERI_CSR0)

15						9		8							
Reserved								FLUSHFIFO

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -n = value after reset

**Table 23-23. Control Status Register for Endpoint 0 in Peripheral Mode (PERI_CSR0)
Field Descriptions**

Bit	Field	Value	Description
15-9	Reserved	0	Reserved
8	FLUSHFIFO	0-1	Set this bit to flush the next packet to be transmitted/read from the Endpoint 0 FIFO. The FIFO pointer is reset and the TXPKTRDY/RXPTRDY bit is cleared. Note: FLUSHFIFO has no effect unless TXPKTRDY/RXPTRDY is set.
7	SERV_SETUPEND	0-1	Set this bit to clear the SETUPEND bit. It is cleared automatically.
6	SERV_RXPKTRDY	0-1	Set this bit to clear the RXPTRDY bit. It is cleared automatically.
5	SENDSTALL	0-1	Set this bit to terminate the current transaction. The STALL handshake will be transmitted and then this bit will be cleared automatically.
4	SETUPEND	0-1	This bit will be set when a control transaction ends before the DATAEND bit has been set. An interrupt will be generated, and the FIFO will be flushed at this time. The bit is cleared by the writing a 1 to the SERV_SETUPEND bit.
3	DATAEND	0-1	Set this bit to: 1 - When setting TXPKTRDY for the last data packet 2 - When clearing RXPTRDY after unloading the last data packet 3 - When setting TXPKTRDY for a zero length data packet. It is cleared automatically.
2	SENTSTALL	0-1	This bit is set when a STALL handshake is transmitted. This bit should be cleared.
1	TXPKTRDY	0-1	Set this bit after loading a data packet into the FIFO. It is cleared automatically when the data packet has been transmitted. An interrupt is generated (if enabled) when the bit is cleared.
0	RXPTRDY	0-1	This bit is set when a data packet has been received. An interrupt is generated when this bit is set. This bit is cleared by setting the SERV_RXPKTRDY bit.

23.1.4.14 Control Status Register for Endpoint 0 in Host Mode (HOST_CSR0)

The Control Status Register for Endpoint 0 in Host Mode (HOST_CSR0) is shown in [Figure 23-30](#) and described in [Table 23-24](#).

Figure 23-30. Control Status Register for Endpoint 0 in Host Mode (HOST_CSR0)

W-0		R/W-0		R/W-0		W-0		R/W-0		R/W-0	
2				1		0					
TXPKTRDY		RXPKTRDY									
R/W-0		R/W-0									

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -n = value after reset

Table 23-24. Control Status Register for Endpoint 0 in Host Mode (HOST_CSR0) Field Descriptions

Bit	Field	Value	Description
15-11	Reserved	0	Reserved
10	DATATOGWREN	0-1	Set this bit to enable the DATATOG bit to be written. This bit is automatically cleared once the new value is written to DATATOG.
9	DATATOG	0-1	When read, this bit indicates the current state of the EP0 data toggle. If DATATOGWREN is high, this bit can be written with the required setting of the data toggle. If DATATOGWREN is low, any value written to this bit is ignored.
8	FLUSHFIFO	0-1	Set this bit to flush the next packet to be transmitted/read from the Endpoint 0 FIFO. The FIFO pointer is reset and the TXPKTRDY/RXPKTRDY bit is cleared. Note: FLUSHFIFO has no effect unless TXPKTRDY/RXPKTRDY is set.
7	NAK_TIMEOUT	0-1	This bit will be set when Endpoint 0 is halted following the receipt of NAK responses for longer than the time set by the NAKLIMIT0 register. This bit should be cleared to allow the endpoint to continue.
6	STATUSPKT	0-1	Set this bit at the same time as the TXPKTRDY or REQPKT bit is set, to perform a status stage transaction. Setting this bit ensures that the data toggle is set so that a DATA1 packet is used for the Status Stage transaction.
5	REQPKT	0-1	Set this bit to request an IN transaction. It is cleared when RXPKTRDY is set.
4	ERROR	0-1	This bit will be set when three attempts have been made to perform a transaction with no response from the peripheral. You should clear this bit. An interrupt is generated when this bit is set.
3	SETUPPKT	0-1	Set this bit, at the same time as the TXPKTRDY bit is set, to send a SETUP token instead of an OUT token for the transaction.
2	RXSTALL	0-1	This bit is set when a STALL handshake is received. You should clear this bit.
1	TXPKTRDY	0-1	Set this bit after loading a data packet into the FIFO. It is cleared automatically when the data packet has been transmitted. An interrupt is generated (if enabled) when the bit is cleared.
0	RXPKTRDY	0-1	This bit is set when a data packet has been received. An interrupt is generated when this bit is set. Clear this bit by setting the SERV_RXPKTRDY bit.

23.1.4.15 Control Status Register for Peripheral Transmit Endpoint (PERI_TXCSR)

The Control Status Register for Peripheral Transmit Endpoint (PERI_TXCSR) is shown in [Figure 23-31](#) and described in [Table 23-25](#).

Figure 23-31. Control Status Register for Peripheral Transmit Endpoint (PERI_TXCSR)

6	5	4	3	2	1	0	
CLRDATATOG	SENTSTALL	SENDSTALL	FLUSHFIFO	UNDERRUN	FIFONOTEMPTY	TXPKTRDY	
W-0	R/W-0	R/W-0	W-0	R/W-0	R/W-0	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -n = value after reset

**Table 23-25. Control Status Register for Peripheral Transmit Endpoint (PERI_TXCSR)
Field Descriptions**

Bit	Field	Value	Description
15	AUTOSET	0	If the CPU sets this bit, TXPKTRDY will be automatically set when data of the maximum packet size (value in TXMAXP) is loaded into the Tx FIFO. If a packet of less than the maximum packet size is loaded, then TXPKTRDY will have to be set manually. Note: Should not be set for either high-bandwidth Isochronous endpoints or high-bandwidth Interrupt endpoints.
14	ISO	0-1	Set this bit to enable the Tx endpoint for Isochronous transfers, and clear this bit to enable the Tx endpoint for Bulk or Interrupt transfers.
13	MODE	0-1	Set this bit to enable the endpoint direction as Tx, and clear this bit to enable it as Rx. Note: This bit has any effect only where the same endpoint FIFO is used for both Transmit and Receive transactions.
12	DMAEN	0-1	Set this bit to enable the DMA request for the Tx endpoint.
11	FRCDATATOG	0-1	Set this bit to force the endpoint data toggle to switch and the data packet to be cleared from the FIFO, regardless of whether an ACK was received. This can be used by Interrupt Tx endpoints that are used to communicate rate feedback for Isochronous endpoints.
10	DMAMODE	0-1	When using DMA, clear this bit to receive an interrupt for each packet, or set this bit to only receive error interrupts.
9-7	Reserved	0	Reserved
6	CLRDATATOG	0-1	Set this bit to reset the endpoint data toggle to 0.
5	SENTSTALL	0-1	This bit is set automatically when a STALL handshake is transmitted. The FIFO is flushed and the TXPKTRDY bit is cleared. You should clear this bit.
4	SENDSTALL	0-1	Set this bit to issue a STALL handshake to an IN token. Clear this bit to terminate the stall condition. Note: This bit has no effect where the endpoint is being used for Isochronous transfers.
3	FLUSHFIFO	0-1	Set this bit to flush the next packet to be transmitted from the endpoint Tx FIFO. The FIFO pointer is reset and the TXPKTRDY bit is cleared. Note: FlushFIFO has no effect unless TXPKTRDY is set. Also note that, if the FIFO is double-buffered, FlushFIFO may need to be set twice to completely clear the FIFO.
2	UNDERRUN	0-1	This bit is set automatically if an IN token is received when TXPKTRDY is not set. You should clear this bit.
1	FIFONOTEMPTY	0-1	This bit is set when there is at least 1 packet in the Tx FIFO. You should clear this bit.
0	TXPKTRDY	0-1	Set this bit after loading a data packet into the FIFO. It is cleared automatically when a data packet has been transmitted. An interrupt is generated (if enabled) when the bit is cleared.

23.1.4.16 Control Status Register for Host Transmit Endpoint (HOST_TXCSR)

The Control Status Register for Host Transmit Endpoint (HOST_TXCSR) is shown in [Figure 23-32](#) and described in [Table 23-26](#).

Figure 23-32. Control Status Register for Host Transmit Endpoint (HOST_TXCSR)

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -n = value after reset

Table 23-26. Control Status Register for Host Transmit Endpoint (HOST_TXCSR) Field Descriptions

Bit	Field	Value	Description
15	AUTOSET	0	If the CPU sets this bit, TXPKTRDY will be automatically set when data of the maximum packet size (value in TXMAXP) is loaded into the Tx FIFO. If a packet of less than the maximum packet size is loaded, then TXPKTRDY will have to be set manually. Note: Should not be set for either high-bandwidth Isochronous endpoints or high-bandwidth Interrupt endpoints.
14	RESERVED	0	Reserved.
13	MODE	0-1	Set this bit to enable the endpoint direction as Tx, and clear this bit to enable it as Rx. Note: This bit has any effect only where the same endpoint FIFO is used for both Transmit and Receive transactions.
12	DMAEN	0-1	Set this bit to enable the DMA request for the Tx endpoint.
11	FRCDATATOG	0-1	Set this bit to force the endpoint data toggle to switch and the data packet to be cleared from the FIFO, regardless of whether an ACK was received. This can be used by Interrupt Tx endpoints that are used to communicate rate feedback for Isochronous endpoints.
10	DMAMODE	0-1	When using DMA, clear this bit to receive an interrupt for each packet, or set this bit to only receive error interrupts.
9	DATATOGWREN	0-1	Set this bit to enable the DATATOG bit to be written. This bit is automatically cleared once the new value is written to DATATOG.
8	DATATOG	0-1	When read, this bit indicates the current state of the Tx EP data toggle. If DATATOGWREN is high, this bit can be written with the required setting of the data toggle. If DATATOGWREN is low, any value written to this bit is ignored.
7	NAK_TIMEOUT	0-1	This bit will be set when the Tx endpoint is halted following the receipt of NAK responses for longer than the time set as the NAKLIMIT by the TXINTERVAL register. It should be cleared to allow the endpoint to continue. Note: This is valid only for Bulk endpoints.
6	CLRDATATOG	0-1	Set this bit to reset the endpoint data toggle to 0.
5	RXSTALL	0-1	This bit is set when a STALL handshake is received. The FIFO is flushed and the TXPKTRDY bit is cleared. You should clear this bit.
4	SETUPPKT	0-1	Set this bit at the same time as TXPKTRDY is set, to send a SETUP token instead of an OUT token for the transaction. Note: Setting this bit also clears the DATATOG bit.
3	FLUSHFIFO	0-1	Set this bit to flush the next packet to be transmitted from the endpoint Tx FIFO. The FIFO pointer is reset and the TXPKTRDY bit is cleared. Note: FlushFIFO has no effect unless TXPKTRDY is set. Also note that, if the FIFO is double-buffered, FLUSHFIFO may need to be set twice to completely clear the FIFO.
2	ERROR	0-1	The USB controller sets this bit when 3 attempts have been made to send a packet and no handshake packet has been received. You should clear this bit. An interrupt is generated when the bit is set. This is valid only when the endpoint is operating in Bulk or Interrupt mode.
1	FIFONOTEMPTY	0-1	The USB controller sets this bit when there is at least 1 packet in the Tx FIFO.
0	TXPKTRDY	0-1	Set this bit after loading a data packet into the FIFO. It is cleared automatically when a data packet has been transmitted. An interrupt is generated (if enabled) when the bit is cleared.

23.1.4.17 Maximum Packet Size for Peripheral Host Receive Endpoint (RXMAXP)

The Maximum Packet Size for Peripheral Host Receive Endpoint (RXMAXP) is shown in [Figure 23-33](#) and described in [Table 23-27](#).

Figure 23-33. Maximum Packet Size for Peripheral Host Receive Endpoint (RXMAXP)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 23-27. Maximum Packet Size for Peripheral Host Receive Endpoint (RXMAXP) Field Descriptions

Bit	Field	Value	Description
15-11	M	0	For Bulk Endpoints, M can be up to 32 and defines the number of USB packets of the specified payload which are to be combined into a single data packet within the FIFO. For Isochronous/Interrupt endpoints operating in High-Speed mode, M may only be either 2 or 3 (corresponding to bit 11 set or bit 12 set, respectively) and it specifies the maximum number of such transaction that can take place in a single microframe.
10-0	MAXPAYLOAD	0-FFh	Defines the maximum amount of data that can be transferred through the selected Receive endpoint in a single frame/microframe (high-speed transfers). The value set can be up to 1024 bytes, but is subject to the constraints placed by the USB Specification on packet sizes for Bulk, Interrupt, and Isochronous transfers in full-speed and high-speed operations. The value written to this register should match the wMaxPacketSize field of the Standard Endpoint Descriptor for the associated endpoint. A mismatch could cause unexpected results.

23.1.4.18 Control Status Register for Peripheral Receive Endpoint (PERI_RXCSR)

The Control Status Register for Peripheral Receive Endpoint (PERI_RXCSR) is shown in [Figure 23-34](#) and described in [Table 23-28](#).

Figure 23-34. Control Status Register for Peripheral Receive Endpoint (PERI_RXCSR)

**Table 23-28. Control Status Register for Peripheral Receive Endpoint (PERI_RXCSR)
Field Descriptions**

Bit	Field	Value	Description
15	AUTOCLEAR	0	If the CPU sets this bit, then RXPKTRDY will be automatically cleared when a packet of RXMAXP bytes has been unloaded from the Rx FIFO. When packets of less than the maximum packet size are unloaded, RXPKTRDY will have to be cleared manually. Note: Should not be set for high bandwidth Isochronous endpoints.
14	ISO	0-1	Set this bit to enable the Receive endpoint for Isochronous transfers, and clear this bit to enable the Receive endpoint for Bulk/Interrupt transfers.
13	DMAEN	0-1	Set this bit to enable the DMA request for the Receive endpoints.
12	DISNYET	0-1	Set this bit to disable the sending of NYET handshakes. When set, all successfully received Receive packets are ACKed, including at the point at which the FIFO becomes full. Note: This bit only has any effect in high-speed mode, in which mode it should be set for all Interrupt endpoints.
11	DMAMODE	0	This bit should always be cleared to 0.
10-8	Reserved	0	Reserved
7	CLRDATATOG	0-1	Set this bit to reset the endpoint data toggle to 0.
6	SENTSTALL	0-1	This bit is set when a STALL handshake is transmitted. The FIFO is flushed and the TXPKTRDY bit is cleared. You should clear this bit.
5	SENDSTALL	0-1	Set this bit to issue a STALL handshake. Clear this bit to terminate the stall condition. Note: This bit has no effect where the endpoint is being used for Isochronous transfers.
4	FLUSHFIFO	0-1	Set this bit to flush the next packet to be read from the endpoint Receive FIFO. The FIFO pointer is reset and the RXPKTRDY bit is cleared. Note: FLUSHFIFO has no effect unless RXPKTRDY is set. Also note that, if the FIFO is double-buffered, FLUSHFIFO may need to be set twice to completely clear the FIFO.
3	DATAERROR	0-1	This bit is set when RXPKTRDY is set if the data packet has a CRC or bit-stuff error. It is cleared when RXPKTRDY is cleared. Note: This bit is only valid when the endpoint is operating in ISO mode. In Bulk mode, it always returns zero.
2	OVERRUN	0-1	This bit is set if an OUT packet cannot be loaded into the Receive FIFO. You should clear this bit. Note: This bit is only valid when the endpoint is operating in ISO mode. In Bulk mode, it always returns zero.
1	FIFOFULL	0-1	This bit is set when no more packets can be loaded into the Receive FIFO.
0	RXPKTRDY	0-1	This bit is set when a data packet has been received. You should clear this bit when the packet has been unloaded from the Receive FIFO. An interrupt is generated when the bit is set.

23.1.4.19 Control Status Register for Host Receive Endpoint (HOST_RXCSR)

The Control Status Register for Host Receive Endpoint (HOST_RXCSR) is shown in [Figure 23-35](#) and described in [Table 23-29](#).

Figure 23-35. Control Status Register for Host Receive Endpoint (HOST_RXCSR)

Table 23-29. Control Status Register for Host Receive Endpoint (HOST_RXCSR) Field Descriptions

Bit	Field	Value	Description
15	AUTOCLEAR	0	If the CPU sets this bit, then RXPBKTRDY will be automatically cleared when a packet of RXMAXP bytes has been unloaded from the Rx FIFO. When packets of less than the maximum packet size are unloaded, RXPBKTRDY will have to be cleared manually. Note: Should not be set for high bandwidth Isochronous endpoints.
14	RESERVED	0	Reserved.
13	DMAEN	0-1	Set this bit to enable the DMA request for the Receive endpoints.
12	DISNYET	0-1	Set this bit to disable the sending of NYET handshakes. When set, all successfully received Receive packets are ACKED including at the point at which the FIFO becomes full. Note: This bit only has any effect in high-speed mode, in which mode it should be set for all Interrupt endpoints.
11	DMAMODE	0	This bit should always be cleared to 0.
10	DATATOGWREN	0-1	Set this bit to enable the DATATOG bit to be written. This bit is automatically cleared once the new value is written to DATATOG.
9	DATATOG	0-1	When read, this bit indicates the current state of the Receive EP data toggle. If DATATOGWREN is high, this bit can be written with the required setting of the data toggle. If DATATOGWREN is low, any value written to this bit is ignored.
8	Reserved	0	Reserved
7	CLRDATATOG	0-1	Set this bit to reset the endpoint data toggle to 0.
6	RXSTALL	0-1	When a STALL handshake is received, this bit is set and an interrupt is generated. You should clear this bit.
5	REQPKT	0-1	Set this bit to request an IN transaction. It is cleared when RXPBKTRDY is set.
4	FLUSHFIFO	0-1	Set this bit to flush the next packet to be read from the endpoint Receive FIFO. The FIFO pointer is reset and the RXPBKTRDY bit is cleared. Note: FLUSHFIFO has no effect unless RXPBKTRDY is set. Also note that, if the FIFO is double-buffered, FLUSHFIFO may need to be set twice to completely clear the FIFO.
3	DATAERR_NAKTIMEOUT	0-1	When operating in ISO mode, this bit is set when RXPBKTRDY is set if the data packet has a CRC or bit-stuff error and cleared when RXPBKTRDY is cleared. In Bulk mode, this bit will be set when the Receive endpoint is halted following the receipt of NAK responses for longer than the time set as the NAK Limit by the RXINTERVAL register. You should clear this bit to allow the endpoint to continue.
2	ERROR	0-1	The USB controller sets this bit when 3 attempts have been made to receive a packet and no data packet has been received. You should clear this bit. An interrupt is generated when the bit is set. Note: This bit is only valid when the transmit endpoint is operating in Bulk or Interrupt mode. In ISO mode, it always returns zero.
1	FIFOFULL	0-1	This bit is set when no more packets can be loaded into the Receive FIFO.

**Table 23-29. Control Status Register for Host Receive Endpoint (HOST_RXCSR) Field Descriptions
(continued)**

Bit	Field	Value	Description
0	RXPKTRDY	0-1	This bit is set when a data packet has been received. You should clear this bit when the packet has been unloaded from the Receive FIFO. An interrupt is generated when the bit is set.

23.1.4.20 Count 0 Register (COUNT0)

The Count 0 Register (COUNT0) is shown in [Figure 23-36](#) and described in [Table 23-30](#).

Figure 23-36. Count 0 Register (COUNT0)

Table 23-33. Transmit Type Register (Host mode only) (HOST_TXTYPE) Field Descriptions

Bit	Field	Value	Description
7-6	SPEED	0-3h 0 1h 2h 3h	Operating Speed of Target Device Illegal High Full Low
5-4	PROT	0-3h 0 1h 2h 3h	Set this to select the required protocol for the transmit endpoint Control Isochronous Bulk Interrupt
3-0	TENDPN	0-Fh	Set this value to the endpoint number contained in the transmit endpoint descriptor returned to the USB controller during device enumeration.

23.1.4.24 NAKLimit0 Register (Host mode only) (HOST_NAKLIMIT0)

The NAKLimit0 Register (Host mode only) (HOST_NAKLIMIT0) is shown in [Figure 23-40](#) and described in [Table 23-34](#).

Figure 23-40. NAKLimit0 Register (Host mode only) (HOST_NAKLIMIT0)

7	5	4	0
Reserved		EP0NAKLIMIT	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 23-34. NAKLimit0 Register (Host mode only) (HOST_NAKLIMIT0) Field Descriptions

Bit	Field	Value	Description
7-5	Reserved	0	Reserved
4-0	EP0NAKLIMIT	0-1Fh	Sets the number of frames/microframes (high-speed transfers) after which Endpoint 0 should time out on receiving a stream of NAK responses. The number of frames/microframes selected is $2^{(n-1)}$ (where m is the value set in the register, valid values 2-16). If the host receives NAK responses from the target for more frames than the number represented by the Limit set in this register, the endpoint will be halted. Note: A value of 0 or 1 disables the NAK timeout function.

23.1.4.25 Transmit Interval Register (Host mode only) (HOST_TXINTERVAL)

The Transmit Interval Register (Host mode only) (HOST_TXINTERVAL) is shown in [Figure 23-41](#) and described in [Table 23-35](#).

Figure 23-41. Transmit Interval Register (Host mode only) (HOST_TXINTERVAL)

7	0
POLINTVL_NAKLIMIT	
R/W-0	

LEGEND: R/W = Read/Write; -n = value after reset

Table 23-35. Transmit Interval Register (Host mode only) (HOST_TXINTERVAL) Field Descriptions

Bit	Field	Value	Description
7-0	POLINTVL_NAKLIMIT	0-FFh	For Interrupt and Isochronous transfers, defines the polling interval for the currently-selected transmit endpoint. For Bulk endpoints, this register sets the number of frames/microframes after which the endpoint should timeout on receiving a stream of NAK responses There is a transmit Interval register for each configured transmit endpoint (except Endpoint 0). In each case the value that is set defines a number of frames/microframes (High Speed transfers), as follows: Transfer Type Speed Valid values (m) Interpretation Interrupt Low Speed or Full Speed 1 - 255 Polling interval is m frames High Speed 1 - 16 Polling interval is $2^{(n-1)}$ microframes Isochronous Full Speed or High Speed 1 - 16 Polling interval is $2^{(n-1)}$ frames/microframes Bulk Full Speed or High Speed 2 - 16 NAK Limit is $2^{(n-1)}$ frames/microframes Note: A value of 0 or 1 disables the NAK timeout function.

23.1.4.26 Receive Type Register (Host mode only) (HOST_RXTYPE)

The Receive Type Register (Host mode only) (HOST_RXTYPE) is shown in [Figure 23-42](#) and described in [Table 23-36](#).

Table 23-38. Configuration Data Register (CONFIGDATA) Field Descriptions

Bit	Field	Value	Description
7	MPRXE	0 1	Indicates automatic amalgamation of bulk packets. Automatic amalgamation of bulk packets is not selected. Automatic amalgamation of bulk packets is selected.
6	MPTXE	0 1	Indicates automatic splitting of bulk packets. Automatic splitting of bulk packets is not selected. Automatic splitting of bulk packets is selected.
5	BIGENDIAN	0 1	Indicates endian ordering. Little-endian ordering is selected. Big-endian ordering is selected.
4	HBRXE	0 1	Indicates high-bandwidth Rx ISO endpoint support. High-bandwidth Rx ISO endpoint support is not selected. High-bandwidth Rx ISO endpoint support is selected.
3	HBTXE	0 1	Indicates high-bandwidth Tx ISO endpoint support. High-bandwidth Tx ISO endpoint support is not selected. High-bandwidth Tx ISO endpoint support is selected.
2	DYNFIFO	0 1	Indicates dynamic FIFO sizing. Dynamic FIFO sizing option is not selected. Dynamic FIFO sizing option is selected.
1	SOFTCONE	0 1	Indicates soft connect/disconnect. Soft connect/disconnect option is not selected Soft connect/disconnect option is selected
0	UTMIDATAWIDTH	0 1	Indicates selected UTMI data width. 8 bits 16 bits

23.1.4.29 Transmit and Receive FIFO Register for Endpoints n (FIFO n)

The Transmit and Receive FIFO Register for Endpoints n (FIFO n) is shown in [Figure 23-45](#) and described in [Table 23-39](#).

Notes:

1. Transfers to and from FIFOs may be 8-bit, 16-bit or 32-bit as required, and any combination of access is allowed provided the data accessed is contiguous. However, all the transfers associated with one packet must be of the same width so that the data is consistently byte-, word- or double-word-aligned. The last transfer may however contain fewer bytes than the previous transfers in order to complete an odd-byte or odd-word transfer.
2. Depending on the size of the FIFO and the expected maximum packet size, the FIFOs support either single-packet or doublepacket buffering. However, burst writing of multiple packets is not supported as flags need to be set after each packet is written.
3. Following a STALL response or a Tx Strike Out error on Endpoint 1 – 15, the associated FIFO is completely flushed.

Figure 23-45. Transmit and Receive FIFO Register for Endpoints n (FIFO n)

31		0
DATA		
R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 23-40. OTG Device Control Register (DEVCTL) Field Descriptions

Bit	Field	Value	Description
7	BDEVICE	0 1	This read-only bit indicates whether the USB controller is operating as the 'A' device or the 'B' device. 'A' device 'B' device Only valid while a session is in progress.
6	FSDEV	0-1	This read-only bit is set when a full-speed or high-speed device has been detected being connected to the port (high-speed devices are distinguished from full-speed by checking for high-speed chirps when the device is reset). Only valid in Host mode.
5	LSDEV	0-1	This read-only bit is set when a low-speed device has been detected being connected to the port. Only valid in Host mode.
4-3	VBUS	0-3h 0 1h 2h 3h	These read-only bits encode the current VBus level as follows: Below Session End Above Session End, below AValid Above AValid, below VBusValid Above VBusValid
2	HOSTMODE	0-1	This read-only bit is set when the USB controller is acting as a Host.
1	HOSTREQ	0-1	When set, the USB controller will initiate the Host Negotiation when Suspend mode is entered. It is cleared when Host Negotiation is completed. ('B' device only)
0	SESSION	0-1	When operating as an 'A' device, you must set or clear this bit start or end a session. When operating as a 'B' device, this bit is set/cleared by the USB controller when a session starts/ends. You must also set this bit to initiate the Session Request Protocol. When the USB controller is in Suspend mode, you may clear the bit to perform a software disconnect. A special software routine is required to perform SRP. Details will be made available in a later document version.

23.1.4.31 Transmit Endpoint FIFO Size (TXFIFOSZ)

Section 23.1.2.4 describes dynamically setting endpoint FIFO sizes.

The Transmit Endpoint FIFO Size (TXFIFOSZ) is shown in Figure 23-47 and described in Table 23-41.

Figure 23-47. Transmit Endpoint FIFO Size (TXFIFOSZ)

15-13	Reserved	0	Reserved
12-0	ADDR	0-1FFFh	Start Address of endpoint FIFO in units of 8 bytes If m = ADDR[12:0], then the start address is 8*m

23.1.4.35 ULPI VBUS Control Register (ULPIVBUSCONTROL)

ULPI PHYs may use an external charge pump to generate VBus rather than an internal charge pump. This register allows selection of the external charge pump. It also allows this selection to be displayed via an external VBus indicator. Note: This register is read back from the PHY clock domain. These bits will not therefore return updated values while the PHY is suspended.

The ULPI VBUS Control Register (ULPIVBUSCONTROL) is shown in Figure 23-51 and described in Table 23-45.

Figure 23-51. ULPI VBUS Control Register (ULPIVBUSCONTROL)

Bit	Field	Value	Description
7-3	Reserved	0	Reserved.
1	USEEXTVB USIND	0-1	When '1', selects the use of an external VBus indicator (overcurrent indicator) in the PHY's VbusState determination.
0	USEEXTVB US	0-1	When '1', selects the use of an external charge pump.

23.1.4.36 ULPI UTMI Control Register (ULPIUTMICONTROL)

This register provides the ability to de-couple the reconstituted UTMI signals from the USB controller.

The ULPI UTMI Control Register (ULPIUTMIControl) is shown in [Figure 23-52](#) and described in [Table 23-46](#).

Figure 23-52. ULPI UTMI Control Register (ULPIUTMICONTROL)

Bit	Field	Value	Description
7-1	Reserved	0	Reserved.
0	DISABLEU TMI	0-1	Set and cleared by software to de-couple the reconstituted UTMI signals from the USB controller.

23.1.4.37 ULPI Interrupt Mask Register (ULPIINTMASK)

This register enables the assertion of MC_NINT in response to the possible interrupt sources.

The ULPI Interrupt Mask Register (ULPIINTMASK) is shown in [Figure 23-53](#) and described in [Table 23-47](#).

Figure 23-53. ULPI Interrupt Mask Register (ULPIINTMASK)

7	1	0
Reserved		REGINTEN

7-1	Reserved	0	Reserved.
0	REGINT	0-1	Asserted if ULPIRegControl.ULPIRegCmplt is set. Note: To clear the interrupt, the software must clear ULPIRegControl.ULPIRegCmplt.

23.1.4.39 ULPI Data Register (ULPIREGDATA)

ULPIRegData contains the data associated with register reads/writes conducted through the ULPI interface.

The ULPI Data Register (ULPIREGDATA) is shown in [Figure 23-55](#) and described in [Table 23-49](#).

Figure 23-55. ULPI Data Register (ULPIREGDATA)

Bit	Field	Value	Description
7-3	Reserved	0	Reserved.
2	ULPIRDNWR	0-1	Set to 1 by software for register read access. Cleared to 0 by software for register write access.
1	ULPIREGCMPLT	0-1	Set to 1 by link when register access is complete. This bit must be cleared to 0 by software.
0	ULPIREGREQ	0-1	Set to 1 by software to initiate register access. This is cleared to 0 when ULPIRegCmpl goes true.

23.1.4.42 ULPI Raw Data Register (ULPIRAWDATA)

ULPIRAWDATA This register is used in asynchronous modes to sample the ULPI bus and in synchronous mode to store the last RxCmd. The details are as follows:

Asynchronous Modes

When one of the PHY's asynchronous modes is selected, the ULPIRawData register is used to indicate the present value of the ULPI bus, latched by any transition on int (i.e. on data(3)).

The ULPI Raw Data Register (ULPIRAWDATA) is shown in [Figure 23-58](#) and described in [Table 23-52](#).

Figure 23-58. Asynchronous Modes (ULPIRAWDATA)

7		4	3	2	1	0
Reserved			DATA(3)	DATA(2)	DATA(1)	DATA(0)
R-0			R-0	R-0	R-0	R-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 23-52. Asynchronous Modes (ULPIRAWDATA) Field Descriptions

Bit	Field	Value	Description
7-4	Reserved	0	Reserved.
3	DATA(3)	0-1	Active high interrupt indication (int)
2	DATA(2)	0-1	Single-ended zero (se0)
1	DATA(1)	0-1	Differential data (dat)
0	DATA(0)	0-1	Active high transmit enable (tx_enable)

Synchronous Modes

When synchronous mode is being used, the ULPIRawData register is used to store the last RxCmd. Note: Because RxCMDS are received in the PHY clock domain and this register is read in the CPU clock domain, RxCMDS may be missed if they are concurrent and the CPU clock is slower than the PHY clock. This feature should not be relied upon to monitor transactions carried out at USB bus speed.

The Synchronous Mode (ULPIRAWDATA) is shown in [Figure 23-59](#) and described in [Table 23-53](#).

Figure 23-59. Synchronous Modes (ULPIRAWDATA)

23.1.4.49 DMA Interrupts (DMA_INTR)

The DMA registers are only available if the USB controller is configured to use at least one internal DMA channel.

This register provides an interrupt for each DMA channel. This interrupt register is cleared when read. Bits in this register will only be set if the DMA Interrupt Enable bit for the corresponding channel is enabled (register DMA_CNTL_CHn).

The DMA Interrupt (DMA_INTR) is shown in [Figure 23-66](#) and described in [Table 23-60](#).

23.1.4.50 DMA Control Register for Channeln (CNTL_CHn)

This register is only available if the USB controller is configured to use at least one internal DMA channel. This register provides the DMA transfer control for each channel. The enabling, transfer direction, transfer mode, the DMA burst modes are all controlled by this register.

The DMA Control Register for Channeln (CNTL_CHn) is shown in [Figure 23-67](#) and described in [Table 23-61](#).

Figure 23-67. DMA Control Register for Channeln (CNTL_CHn)

2	DMA_MODE	0 1	This bit selects the DMA Transfer Mode. DMA Mode0 Transfer DMA Mode1 Transfer
1	DMA_DIR	0 1	This bit selects the DMA Transfer Direction. DMA Write (RX Endpoint) DMA Read (TX Endpoint)
0	DMA_ENAB		This bit enables the DMA transfer and will cause the transfer to begin.

23.1.4.51 DMA Address Register for DMA Channel n (ADDR_CH n)

This register identifies the current memory address of the corresponding DMA channel. The Initial memory address written to this register must have a value such that its modulo 4 value is equal to 0. That is, DMA_ADDR[1:0] must be equal to 2'b00. As the DMA transfer progresses, the memory address will increment as bytes are tranfered.

The DMA Address Register for DMA Channel n (ADDR_CH n) is shown in [Figure 23-68](#) and described in [Table 23-62](#).

Figure 23-68. DMA Address Register for DMA Channel n (ADDR_CH n)

Table 23-62. DMA Address Register for DMA Channel n (ADDR_CH n)

Bit	Field	Value	Description
31-0	DMA_ADDR n	0	The DMA memory address. Note that the initial memory address written to this register must have a value such that it's module 4 value is equal to 0. That is, DMA_ADDR[1:0] must be equal to 2' b00. The lower two bits of this register are read only and cannot be set by software. The lower two bits of this register are read only and cannot be set by software.

23.1.4.52 DMA Count Register for DMA Channel n (COUNT_CH n)

This register identifies the current DMA count of the transfer. Software will set the initial count of the transfer which identifies the entire transfer length. As the count progresses this count is decremented as bytes are transferred.

The DMA Count Register for DMA Channel n (COUNT_CH n) is shown in [Figure 23-69](#) and described in [Table 23-63](#).

Figure 23-69. DMA Count Register for DMA Channel n (COUNT_CH n)

Table 23-63. DMA Count Register for DMA Channel n (COUNT_CH n)

Bit	Field	Value	Description
31-0	DMA_COUNT n	0	The DMA memory address for the corresponding DMA channel. Note: If DMA is enabled with a count of 0, the bus will not be requested and a DMA interrupt will be generated.

23.1.4.53 Number of Requested Packets for Receive Endpoint n (RqPktCount n)

For each Rx Endpoint 1 – 15, the USB Controller provides a 16-bit RqPktCount register. This read/write register is used in Host mode to specify the number of packets that are to be transferred in a block transfer of one or more Bulk packets of length MaxP to Rx Endpoint n . The core uses the value recorded in this register to determine the number of requests to issue where the AutoReq option (included in the RxCSR register) has been set.

Note: Multiple packets combined into a single bulk packet within the FIFO count as one packet.

The Number of Requested Packets for Receive Endpoint n (RqPktCount n) is shown in [Figure 23-70](#) and described in [Table 23-64](#).

Figure 23-70. Number of Requested Packets for Receive Endpoint n (RqPktCount n)

LEGEND: R/W = Read/Write; R = Read only; - n = value after reset

Table 23-64. Number of Requested Packets for Receive Endpoint n (RqPktCount n)

Bit	Field	Value	Description
15-0	RQPKTCOUNT n	0	Sets the number of packets of size MaxP that are to be transferred in a block transfer. Only used in Host mode when AutoReq is set. Has no effect in Peripheral mode or when AutoReq is not set.

23.1.4.54 OTG High-Speed Core Revision Register (OTG_REVISION)

The OTG High-Speed Core Revision Register (OTG_REVISION) is shown in [Figure 23-71](#) and described in [Table 23-65](#).

23.2 High-Speed USB Host Subsystem

Copyright 2004,2005, 2006, 2007, 2008 Synopsys, Inc. All rights reserved. Used with permission.

23.2.1 High-Speed USB Host Subsystem Overview

The high-speed universal serial bus (USB) host subsystem is composed of the high-speed multiport USB host controller and the USBTLL module.

The USB controller is a high-speed multiport USB2.0 host controller. It contains two independent, 3-port host controllers that operate in parallel:

- The EHCI controller, based on the *Enhanced Host Controller Interface (EHCI) specification for USB Release 1.0*, is in charge of high-speed traffic (480M bit/s), over the ULPI/UTMI interface
- The OHCI controller, based on the *Open Host Controller Interface (OHCI) specification for USB Release 1.0a*, is in charge of full-speed/low-speed traffic (12/1.5M bit/s, respectively), over a serial interface

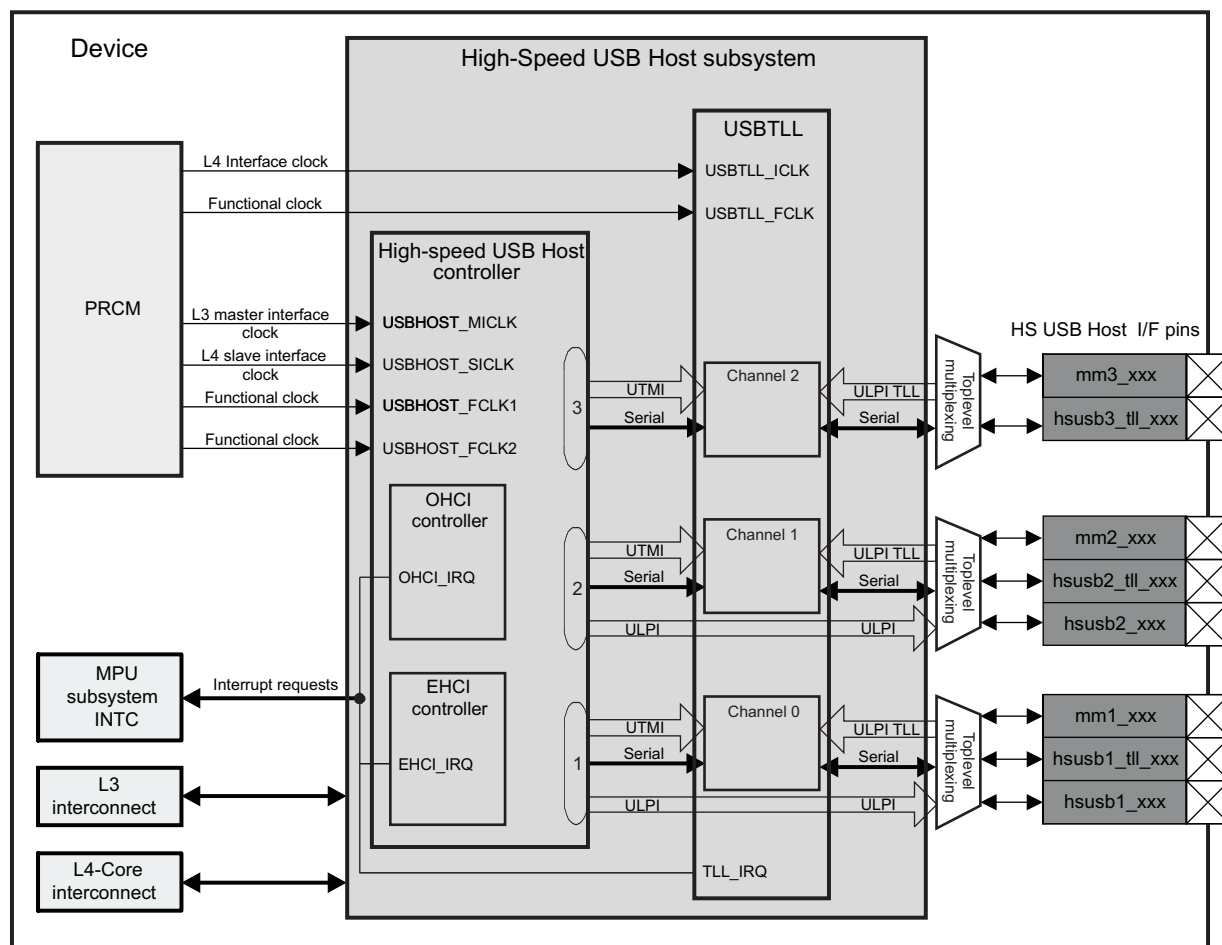

Each of the three external ports is owned by exactly one of the controllers at any time.

Note: If one port is configured as a high-speed ULPI transceiver interface, then all other ports must be likewise configured.

The USBTLL module is a high-speed USB UTMI low-pin interface (ULPI) transceiverless link logic (TLL) adapter. It implements a TLL compatible with a number of USB standard interface protocols. It consists of three channels, defined as independent USB path through the TLL module, which always converts the UTMI+ PHY interface protocol coming from the high-speed USB host controller.

Each USB port (1, 2, and 3) can connect either to an external-to-OMAP chip USB transceiver or directly using a transceiverless link to an external integrated circuit (IC) supporting the same TLL protocol.

[Figure 23-76](#) highlights the high-speed USB host subsystem.

Figure 23-76. High-Speed USB Host Subsystem Highlight

usb-007

23.2.1.1 Main Features

The high-speed USB host subsystem includes the following features:

- Multiport high-speed USB host controller:
 - Complies with the USB 2.0 standard for high-speed (480M bit/s) functions
 - USB 2.0 low-speed (1.5M bit/s) and full-speed (12M bit/s) over serial interface
 - High-speed (480M bit/s) operations over ULPI
 - Three downstream ports (3-port root hub)
 - Complies with EHCI (high-speed host controller)
 - Complies with OHCI (low-speed/full-speed host controller)
 - Supports suspend/resume and remote wakeup
 - Interface with ULPI PHYs (transceivers) on two ports
 - 12-pin/8-bit data single data rate (SDR) mode
 - 60-MHZ clock, generated by the host: ULPI "input" clocking mode

CAUTION

The HS USB host subsystem only supports PHYs that can accept a 60 MHz input clock.

The HS USB host subsystem can only support the external charge pump of PHY (no support of internal charge pump for ULPI PHY).

- Hardware-driven save-and-restore of the suspended host hardware context
- Two interrupt lines
- USBTLL module
 - Three channels
 - Three ports (A, C, and D) by channel
 - Port A: PHY-side UTMI+ port. Connects to the local link controller. The UTMI “local” port is used in all configurations, (that is, the entire channel can be seen as a protocol converted from that port to one of the other, “remote” ports).
 - Compliant with UTMI+ (USB 2.0 Transceiver Macrocell Interface) version 1.0
 - 8-data-bit, 60-MHZ UTMI (HS/FS/LS-capable)
 - UTMI+ Level 3 extensions
 - Vcontrol/Vstatus (from UTMI)
 - Serial FS/LS “6-pin” mode
 - Port C: PHY-side ULPI port. Connects to a remote (off-chip) ULPI link controller through I/O pads.
 - SDR and dual data rate (DDR) ULPI capable (8/4-bit data width modes)
 - Supports optional 6-pin/3-pin serial modes
 - Supports optional input clocking mode
 - Port D: Serial multimode port. Connects to either a serial link controller (TLL modes) or a serial PHY (PHY interface modes).
 - Supports 6-pin unidirectional, 4-pin bidirectional, 3-pin bidirectional, 2-pin bidirectional modes
 - All modes are supported for TLL or PHY interface configuration.
 - Supports sideband signals (pullup/down control, speed/suspend enable, etc)
 - An interrupt line
 - OCP target slave interface (L4) for configuration
- USB port signal pins interface supporting:
 - External USB transceivers
 - ULPI interface: 12-pin/8-bit data SDR version supporting "input" clocking mode
 - Serial 6-pin PHY (transceiver) interfaces: 6-pin mode (TX: DAT/SE0 or TX: DP/DM unidirectional mode), 4-pin mode (DP/DM bidirectional mode), and 3-pin mode (DAT/SE0 bidirectional mode)
 - TLL mode
 - ULPI TLL interfaces: 12-pin/8-bit data SDR and 8-pin/4-bit data DDR versions
 - Serial 6-pin TLL interfaces: 6-pin mode (DAT/SE0 and DP/DM unidirectional modes), 4-pin mode, (DP/DM bidirectional mode), 3-pin mode (DAT/SE0 bidirectional mode) and 2-pin mode (DAT/SE0 and DP/DM bidirectional modes)

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

Table 23-70. USB Connectivity Modes

USB Connectivity Modes	Port 1	Port 2	Port 3
ULPI interface	√	√	
Serial 6-pin transceiver interfaces	√	√	√
ULPI TLL interfaces	√	√	√
Serial 6-pin TLL interfaces	√	√	√

Note: If either port 1 or port 2 is configured as a ULPI interface, then both ports must be configured as a ULPI interface.

Only FS/LS USB transceivers can be connected to port 3; HS ULPI transceivers are not supported on port 3.

23.2.2 High-Speed USB Host Subsystem Environment

The high-speed USB host controller provides two kinds of interfaces for connection:

- ULPI interfaces for high-speed data transactions (up to 480M bit/s)
- Serial interfaces (with the use of the USBTLL module) for full- and low-speed data transactions (up to 12M bit/s)

The high-speed USB host controller connects to either controllers (TLL modes) and/or transceivers. It supports the following configurations with the serial interfaces and ULPI interfaces:

- External USB transceiver configurations
 - ULPI interface: 12-pin/8-bit data SDR version supporting "input" clocking mode
 - Serial 6-pin PHY (transceiver) interfaces: 6-pin mode (TX: DAT/SE0 or TX: DP/DM unidirectional mode), 4-pin mode (DP/DM bidirectional mode) and 3-pin mode (DAT/SE0 bidirectional mode)
- TLL configurations
 - ULPI TLL interfaces: 12-pin/8-bit data SDR and 8-pin/4-bit data DDR versions
 - Serial 6-pin TLL interfaces: 6-pin mode (DAT/SE0 and DP/DM unidirectional modes), 4-pin mode (DP/DM bidirectional mode), 3-pin mode (DAT/SE0 bidirectional mode), and 2-pin mode (DAT/SE0 and DP/DM bidirectional modes)

23.2.2.1 Standard USB Implementation: Transceiver Connection

From a logical point of view, a point-to-point USB connection is composed of several blocks, organized in protocol layers, and shown in [Figure 23-77](#).

Figure 23-77. USB Connection

The host system (USB master) and the peripheral system (USB slave) connected through the USB cable include a link or controller (link layer) and a PHY or transceiver (physical layer). Each system talks to its own controller, which talks to its own transceiver, which is connected to the opposite side (transceiver) through an assembly of connectors, receptacles, and cable.

23.2.2.2 TLL Connection

The TLL feature enables connection of the high-speed USB host subsystem to an external, onboard USB peripheral controller, without using USB transceivers or associated circuitry. When TLL is used, the following components are removed from the system:

- Both USB transceivers
- The series resistors
- Pullup and pulldown resistors
- VBUS switching components
- USB connectors and cables, typically used between a USB host controller and the downstream USB peripheral controller

The TLL signaling system is not suitable for use across a cable. It is intended only for use when the device is used with an external USB integrated circuit (IC) that is on the same board.

When using the TLL, signals of the external USB IC pins, which typically connect to a USB transceiver, instead directly connect to the device pins. Signaling on these pins use CMOS levels. TLL logic can be used with external devices that support ULPI TLL interface and serial 6-pin TLL interface connectivity.

The TLL function in the device interprets the transmit control signals from the external USB IC and similar signals from the device USB host controller, and computes the equivalent USB differential-pair state. The computed differential-pair state is interpreted and the appropriate transceiver output signals are provided to the external USB IC and to the device USB host controller.

Figure 23-78 shows the device and how TLL can be compared to a typical USB implementation. The top portion of Figure 23-78 shows the a transceiver-based solution, and the bottom portion shows a transceiverless solution using TLL.

Figure 23-78. High-Speed USB Host Controller Connection—With and Without TLL

usb-009

Note: The USB bus lines (D+/D-) no longer appear in subsequent figures: They are emulated by the TLL.

23.2.2.3 ULPI Interfaces

The high-speed USB host subsystem supports the following configurations with the ULPI interfaces:

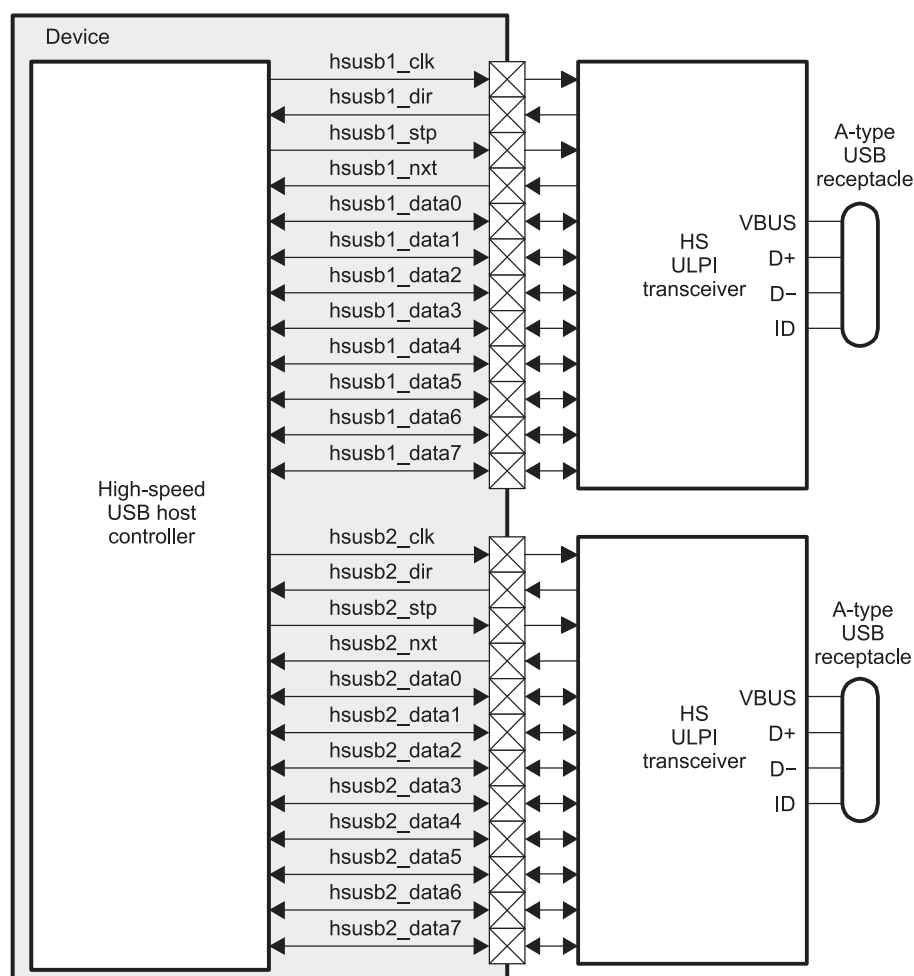

- External USB transceiver
 - ULPI interfaces: 12-pin/8-bit data SDR version supporting "input" clocking mode
- TLL
 - ULPI TLL interfaces: 12-pin/8-bit data SDR and 8-pin/4-bit data DDR versions

Figure 23-79 and Figure 23-80 show typical applications using the high-speed USB host subsystem with the ULPI and with the ULPI TLL, respectively.

The high-speed USB host subsystem supports USB ports, which use the ULPI interface mode to connect to an off-chip high-speed ULPI transceiver (12-pin/8-bit data SDR mode) for high-speed data transactions (up to 480M bit/s). Using the ULPI interfaces in 12-pin/8-bit data version, the device and the transceiver achieve the USB function. An A-type external receptacle allows the connection of an external device.

The device supports TLL logic interfaces on its ports in the ULPI interface mode. TLL modes enable glueless interconnect to another USB device port without a costly transceiver.

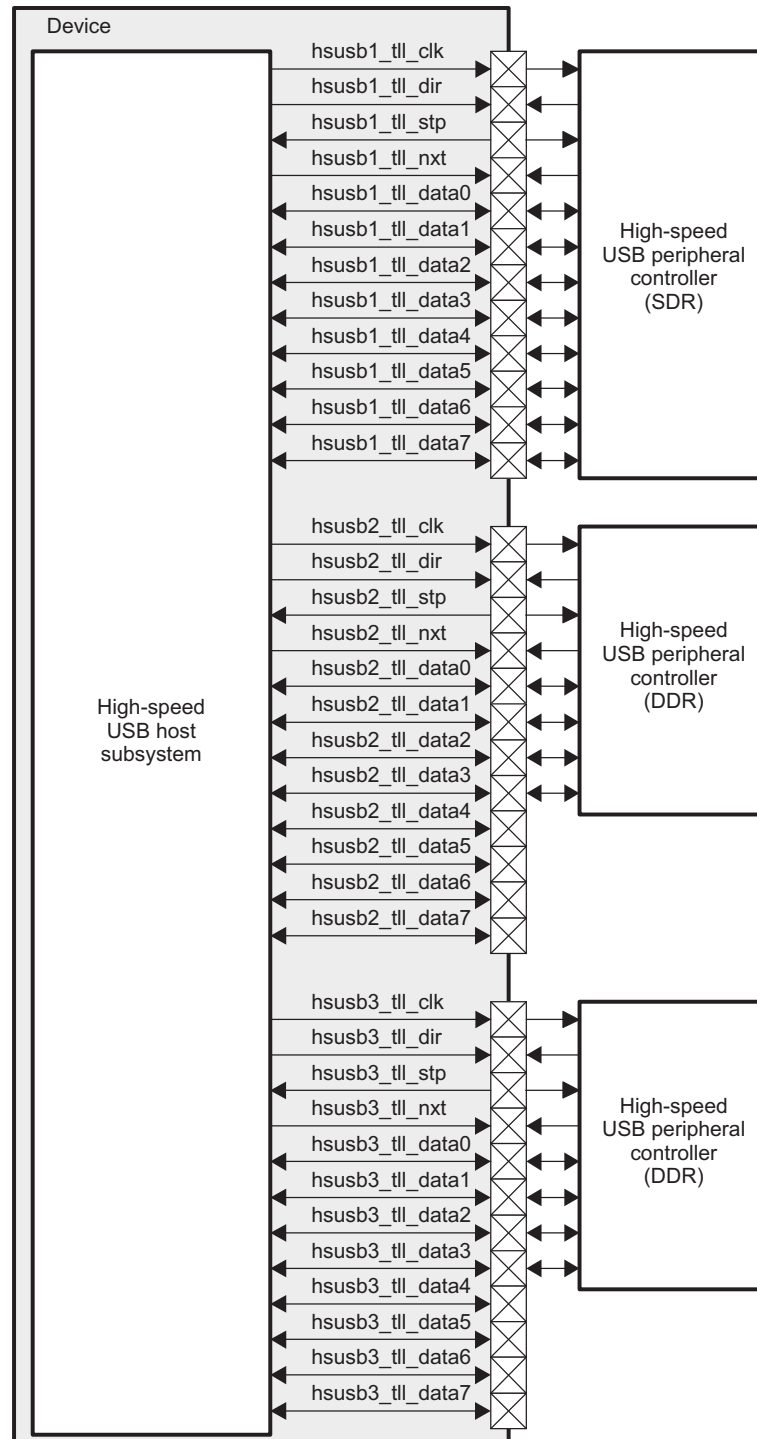

Figure 23-79. High-Speed USB Host Controller Typical Application System – ULPI Interfaces

ULPI Interfaces - USBTLL is bypassed and high-speed USB host controller ports 1 and 2 are connected directly to external transceivers

usb-010

Figure 23-80. High-Speed USB Host Subsystem Typical Application System - ULPI TLL Interfaces

ULPI TLL Interfaces -The high-speed USB host controller is coupled with the USBTLL module to compose the ULPITLL interface modes

usb-032

The current implementation of the ULPI includes a method for manual, software-controlled generation of PHY-side register accesses. This implies support of the following features:

- Access to vendor-specific or optional PHY-side registers
- Access to vendor ID, product ID, and scratch and debug registers

The 12-pin ULPI interface uses an 8-bit data bus with data synchronous to the rising edge of the PHY (transceiver) clock (SDR mode), whereas the 8-pin ULPI uses a 4-bit data bus with data generated on both the rising and falling clock edges (DDR mode).

23.2.2.3.1 Transceiver Interface Configurations

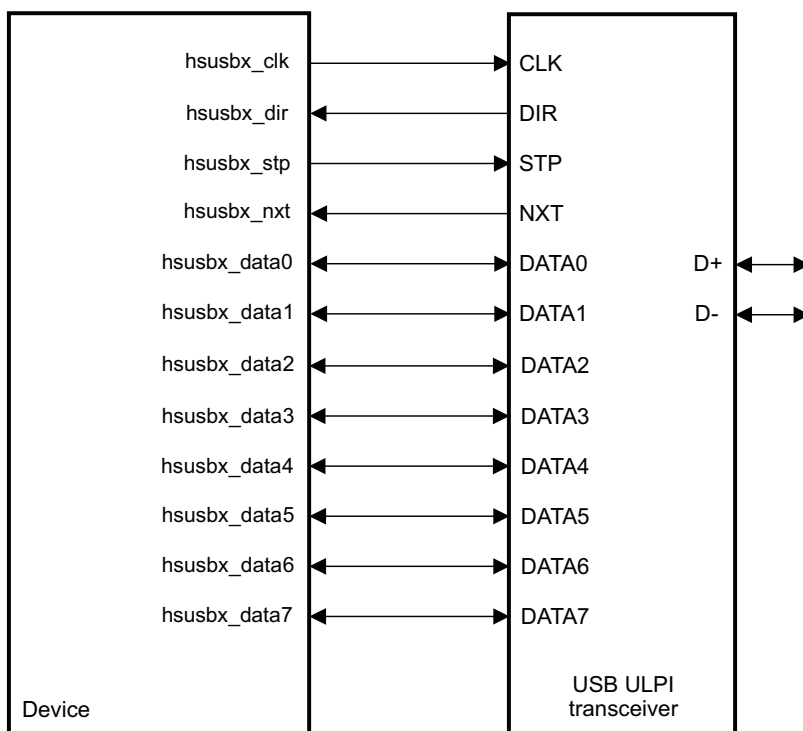

The high-speed USB host subsystem supports only the 12-pin/8-bit data SDR version of the ULPI interface mode.

Note: In the device, only the ULPI ports 1 and 2 of the high-speed USB host controller are mapped and can be connected directly to external transceivers.

The ULPI transceiver must support "input" clocking mode, that is, it must accept a 60 MHz input clock.

Figure 23-81 shows USB ports using the 12-pin/8-bit data SDR version of the ULPI interface mode.

Figure 23-81. ULPI Interfaces – 12-Pin/8-Bit Data SDR Version

x is the USB port number (1 or 2)

usb-011

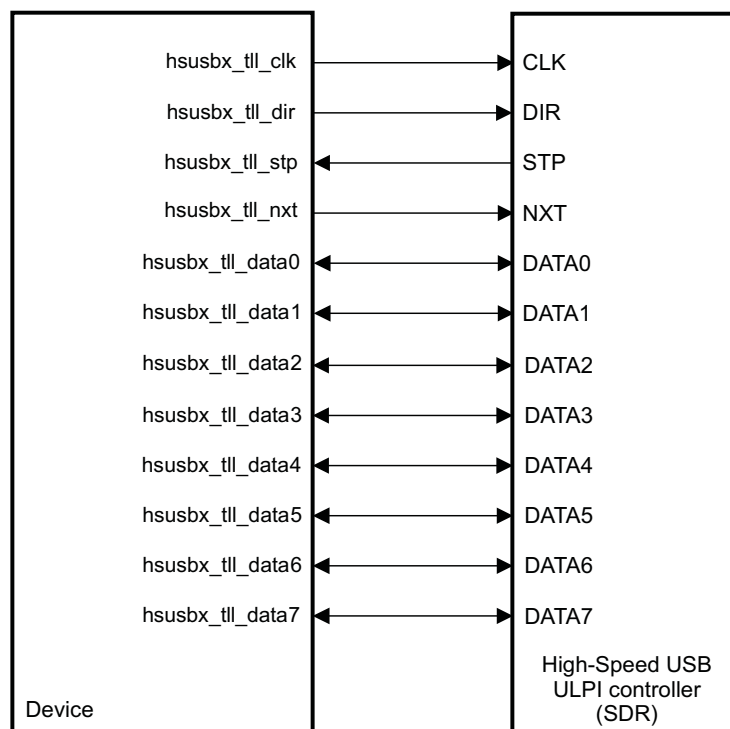

23.2.2.3.2 TLL Configurations

The high-speed USB host controller is coupled with the USBTLL module to compose the ULPI TLL interface modes.

The high-speed USB host subsystem supports the 12-pin/8-bit data SDR and 8-pin/4-bit data DDR versions of the ULPI TLL interface mode.

Figure 23-82 shows USB ports using the 12-pin/8-bit data SDR version of the ULPI TLL interface mode.

23.2.2.4 Serial Interfaces

The high-speed USB host subsystem supports the following configurations with the serial interfaces:

- External USB transceiver
 - Serial 6-pin PHY (transceiver) interfaces: 6-pin mode (TX: DAT/SE0 or TX: DP/DM unidirectional mode), 4-pin mode (DP/DM bidirectional mode), and 3-pin mode (DAT/SE0 bidirectional mode)
- TLL
 - Serial 6-pin TLL interfaces: 6-pin mode (DAT/SE0 and DP/DM unidirectional modes), 4-pin mode (DP/DM bidirectional mode), 3-pin mode (DAT/SE0 bidirectional mode), and 2-pin mode (DAT/SE0 and DP/DM bidirectional modes)

Figure 23-85 shows a typical application using the high-speed USB host subsystem with the serial interfaces.

Figure 23-85. High-Speed USB Host Subsystem Typical Application System

The high-speed USB host controller is coupled with the USBTLL module to compose the serial interface modes. The USBTLL module translates the parallel, synchronous UTMI+ (Level 3) protocol to a serial, asynchronous one. The benefit of the conversion is a simplified interface to the transceiver.

CAUTION

Only full- and low-speed data transactions are possible in serial mode. Transceiver interface is serial (its frequency is that of the actual USB line) and combinatorial (no clock is passed).

Whether in TLL or transceiver configuration, the serial interface follows the same principles. It is limited to full/low speed, and that high speed requires a parallel interface.

23.2.2.4.1 Encoding in Serial Mode

23.2.2.4.1.1 Unidirectional

When a USB transceiver is connected to the device and used in 6-pin unidirectional DAT/SE0 encoding mode, the encoding described in [Table 23-72](#) is used.

Table 23-72. Signaling Between High-Speed USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DAT/SE0 Signaling)

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description				
TXEN	Output	Input	When low, the USB transceiver drives D+ and D-.				
DAT and SE0	Output	Input	Controls the values output by the USB transceiver on D+ and D- when TXEN is low; ignored when TXEN is high.				
			TXEN	DAT	SE0	D+	D-
			0	0	0	0	1
				1	0	1	0
				X	1	0	0
			1	X	X	Undriven	Undriven
RCV	Input	Output	Output from transceiver differential receiver				
			D+		D-	RCV	
			0		0	X	
			0		1	0	
			1		0	1	
			1		1	X	
DP	Input	Output	Output from transceiver single-ended D+ signal receiver				
			D+		DP		
			0		0		
			1		1		
DM	Input	Output	Output from transceiver single-ended D- signal receiver				
			D-		DM		
			0		0		
			1		1		

When a USB transceiver is connected to the device and used in 6-pin unidirectional DP/DM encoding mode, the encoding described in [Table 23-73](#) is used.

Table 23-73. Signaling Between High-Speed USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DP/DM Signaling)

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description				
TXEN	Output	Input	When low, the USB transceiver drives D+ and D-.				
DAT and SE0	Output	Input	Controls the values output by the USB transceiver on D+ and D- when TXEN is low; ignored when TXEN is high.				
			TXEN	DAT	SE0	D+	D-
			0	0	0	0	1
				1	0	1	0
				X	1	0	0
			1	X	X	Undriven	Undriven

Table 23-73. Signaling Between High-Speed USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DP/DM Signaling) (continued)

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description
RCV	Input	Output	Output from transceiver differential receiver
			D+ D- RCV
			0 0 X
			0 1 0
			1 0 1
			1 1 X
DP	Input	Output	Output from transceiver single-ended D+ signal receiver
			D+ DP
			0 0
			1 1
DM	Input	Output	Output from transceiver single-ended D- signal receiver
			D- DM
			0 0
			1 1

23.2.2.4.1.2 Bidirectional

When a USB or USB OTG transceiver is connected to the device and is used in 3-pin bidirectional DAT/SE0 encoding mode, the encoding described in [Table 23-74](#) is used.

Table 23-74. Signaling Between High-Speed USB Host Subsystem and 3-Pin Bidirectional USB Transceiver Using DAT/SE0 Signaling

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description
TXEN	Output	Input	When low, USB transceiver drives D+ and D-.
DAT and SE0	Output	Input	When TXEN is low, the device drives DAT and SE0 and the transceiver drives D+ and D- based on the values of DAT and SE0.
			TXEN DAT SE0 D+ D-
			0 0 0 0 1
			1 0 0 1 0
			X 1 0 0 0
	Input	Output	TXEN D+ D- DAT SE0
			1 0 0 0 1
			0 1 0 0 0
			1 0 1 0 0
			1 1 1 Undefined Undefined

Note: The device does not support 3-wire bidirectional signaling using DP/DM signals.

When a USB or USB OTG transceiver is connected to the device and is used in 4-pin bidirectional DP/DM encoding mode, the encoding described in [Table 23-75](#) is used.

Table 23-75. Signaling Between High-Speed USB Host Subsystem and 4-Pin Bidirectional USB Transceiver Using DP/DM Signaling

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description		
TXEN	Output	Input	When low, USB transceiver drives D+ and D-.		
DM			Value driven to or received from D-		
	Output	Input	TXEN	DM	D-
			0	0	0
			0	1	1
	Input	Output	TXEN	D-	DM
			1	0	0
			1	1	1
DP			Value driven to or received from D+		
	Output	Input	TXEN	DP	D+
			0	0	0
			0	1	1
	Input	Output	TXEN	D+	DP
			1	0	0
			1	1	1
RCV	Input	Output	Output from transceiver single-ended D- signal receiver		
			D+	D-	RCV
			0	0	X
			0	1	0
			1	0	1
			1	1	X

Note: The device does not support 4-pin bidirectional signaling using DAT/SE0 signals.

23.2.2.4.2 Sideband Signals for Serial Modes

Serial interfaces only carry the USB data information. Sideband control and status (respectively, to/from the transceiver/TLL or to the bus lines themselves) require additional signals, which are usually implemented in a case-by-case, ad hoc way.

- Sideband control examples: FS/LS (slew rate control), transceiver suspend, connect (D+/D- pullup), pulldown enable, VBUS drive, etc.
- Sideband status example: VBUS level (VBUS valid, session valid, session end), etc.
- Sideband signal implementations: dedicated lines (one per sideband information bit), serial bus + interrupt line with register-mapped control/status (I2C, UART, etc.)

Figure 23-86 and Figure 23-87 show system integration for sideband signals for two logically identical USB connections: one in transceiver configuration, and one in TLL configuration. Although the sideband (purple) arrows are all oriented from controller to transceiver in the two figures, the sideband information flow is bidirectional (that is, it flows from controller to transceiver [control] but also from transceiver to controller [status]).

Figure 23-86 shows the transceiver configuration, where each side connects the sideband signals to its own transceiver. On the device (containing the USBTLL module), the sideband is decoded/re-encoded. The sideband signals available at the device boundary (and the USBTLL module) are decoded from the standard UTMI+ interface.

- Sideband output signals from the USBTLL module (speed, suspend, puen, etc.)
- The software-driven VBUS reporting procedure is described in [Section 23.2.4.2.4.1.1](#).

Figure 23-86. Serial Interface Sideband Integration - Transceiver Configuration

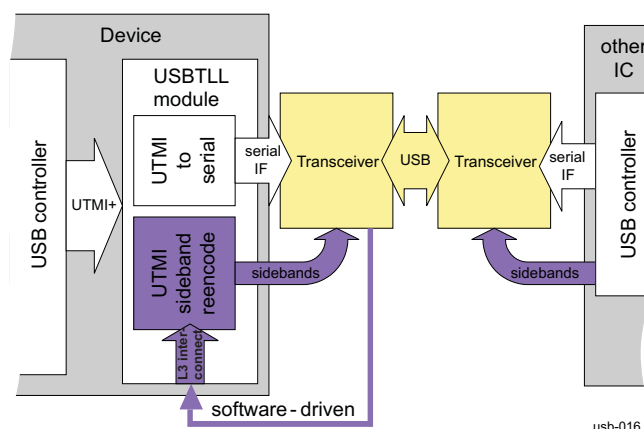

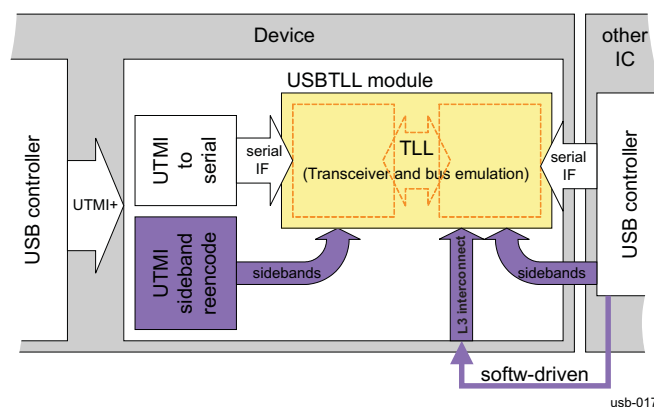

Figure 23-87 shows the TLL configuration, where both transceivers are actually emulated inside the USBTLL module.

- The transceiver of the local controller (left) is working with the sideband information to/from the UTMI+ port. This is internal to the USBTLL module.
- The transceiver of the remote controller (right) must communicate with its controller, located on another IC. This is done in two ways:
 - Sideband input signals at the TLL module boundary (tlmpuen, tlldrvbus, tllvbusvalid, etc.)
 - The software-driven VBUS control procedure is described in [Section 23.2.4.2.4.2.2](#)

Figure 23-87. Serial Interface Sideband Integration - TLL Configuration

23.2.2.4.3 Transceiver Interface Configurations

An external USB transceiver is required for each USB port used in the system. It converts between appropriate signaling for the high-speed USB host subsystem and appropriate signaling for the USB wire.

The serial interface mode of the high-speed USB host subsystem includes support for several types of USB transceivers. It provides signaling to up to three external USB transceivers.

Several types of external transceiver signaling are supported. Signaling between the high-speed USB subsystem in the serial-interface mode and the external USB transceiver for monitoring and controlling the differential USB signal can be done through a 6-, 4-, or 3-wire signaling interface, with two or more control signals provided either by additional signals or through an I²C link.

The following subsections describe the transceiver interface modes supported by the high-speed USB host subsystem in the serial interface mode. In each case, the subsystem is connected to external transceivers, on the other side of which are the actual USB lines (D+/D-).

23.2.2.4.3.1 Unidirectional Transceiver Interface Modes: 6-Pin

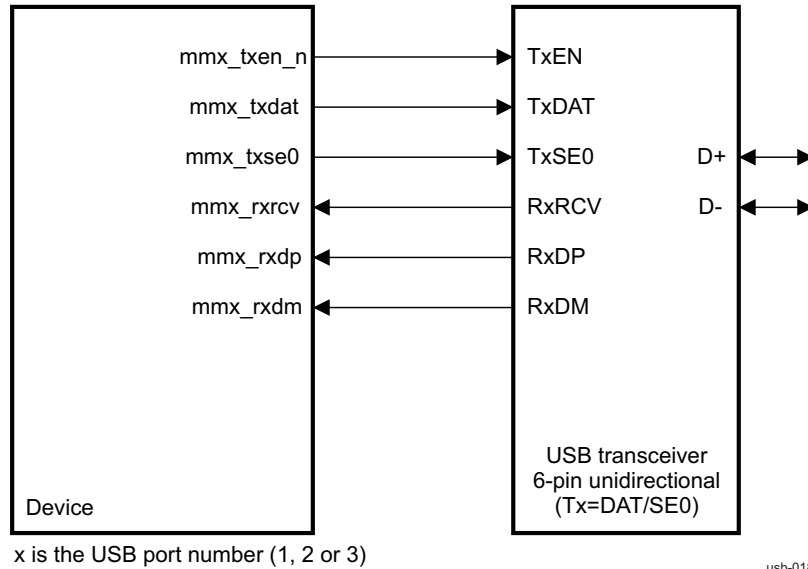

The 6-pin modes are the "natural" transceiver interface modes for the full-speed transceivers in the sense that they mirror the internal makeup of the transceivers.

Two encodings exist for TX: DAT/SE0 or DP/DM.

When a USB is connected to the device and used in 6-pin unidirectional DAT/SE0 signaling mode, the signaling described in [Table 23-72](#) is used.

[Figure 23-88](#) shows a USB port using DAT/SE0 encoding.

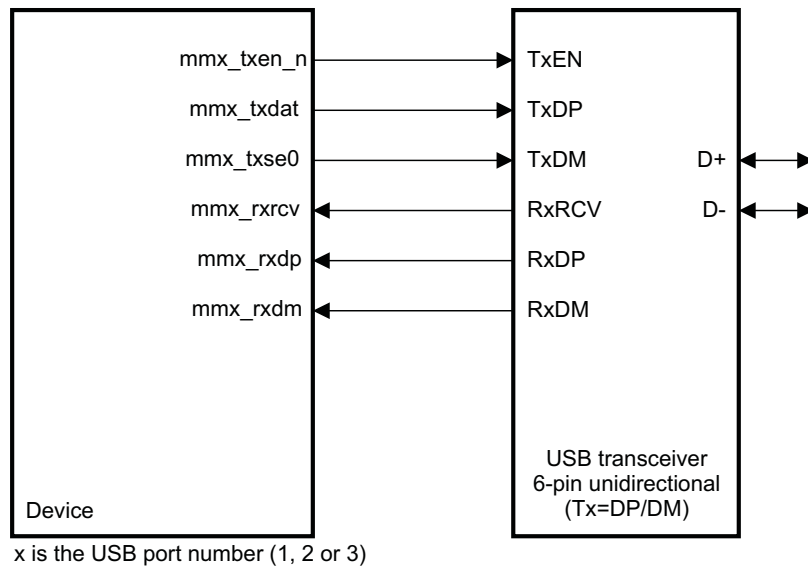

Figure 23-88. 6-Pin Unidirectional Using DAT/SE0 Signaling

When a USB is connected to the device and used in 6-pin unidirectional DP/DM signaling mode, the signaling described in [Table 23-73](#) is used.

[Figure 23-89](#) shows a USB port using DP/DM encoding.

Figure 23-89. 6-Pin Unidirectional Using DP/DM Signaling

23.2.2.4.3.2 Bidirectional Transceiver Interface Modes: 3-Pin, 4-Pin

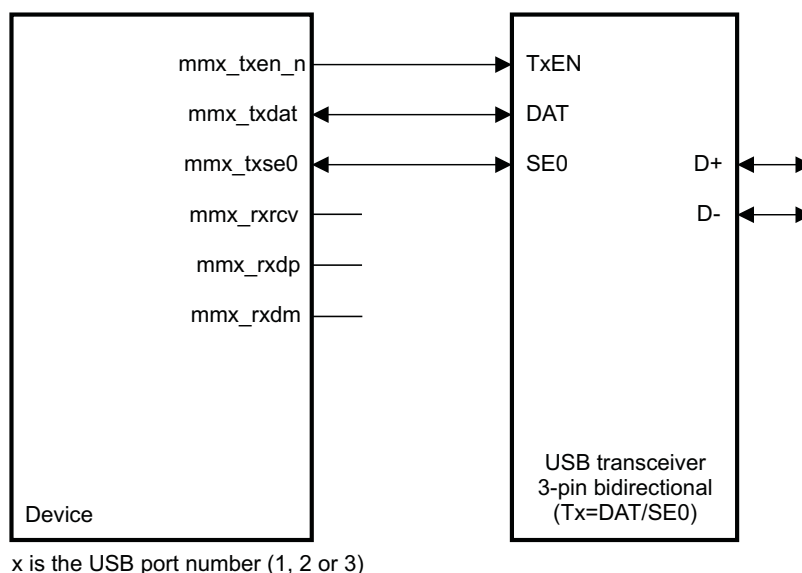

The bidirectional transceiver interface modes are pin-count optimizations of the unidirectional modes. They take advantage of the fact that a USB port is either sending or receiving at any given time, but never both. The TX and RX paths of the unidirectional mode can be multiplexed on bidirectional lines. To prevent glitches at TX/RX turnaround, the same encoding is used for both directions (DAT/SE0 or DP/DM).

The signaling listed in [Table 23-74](#) is used when a USB transceiver is connected to the device and is used in 3-pin bidirectional DAT/SE0 signaling mode.

Note: The device does not support 3-wire bidirectional signaling using DP/DM signals.

[Figure 23-90](#) shows a USB port using DAT/SE0 encoding.

Figure 23-90. 3-Pin Bidirectional Using DAT/SE0 Signaling

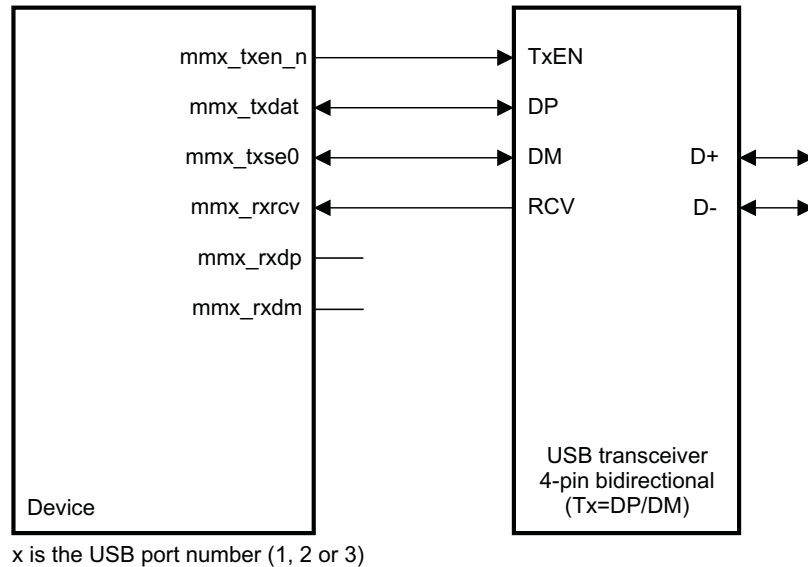

usb-020

The signaling listed in [Table 23-75](#) is used when a USB transceiver is connected to the device and is used in 4-pin bidirectional DP/DM signaling mode.

Note: The device does not support 4-pin bidirectional signaling using DAT/SE0 signals.

Figure 23-91 shows a USB port using DP/DM encoding.

Figure 23-91. 4-Pin Bidirectional Using DP/DM Signaling

108-021

23.2.2.4.4 TLL Configurations

The high-speed USB host subsystem supports unidirectional and bidirectional TLL logic interfaces on its ports. The TLL modes enable glueless interconnect to the USB device port of another device without needing a costly transceiver.

Serial interface modes are full- or low-speed only. Transceiver interface is serial (its frequency is that of the actual USB line) and combinatorial (no clock is passed).

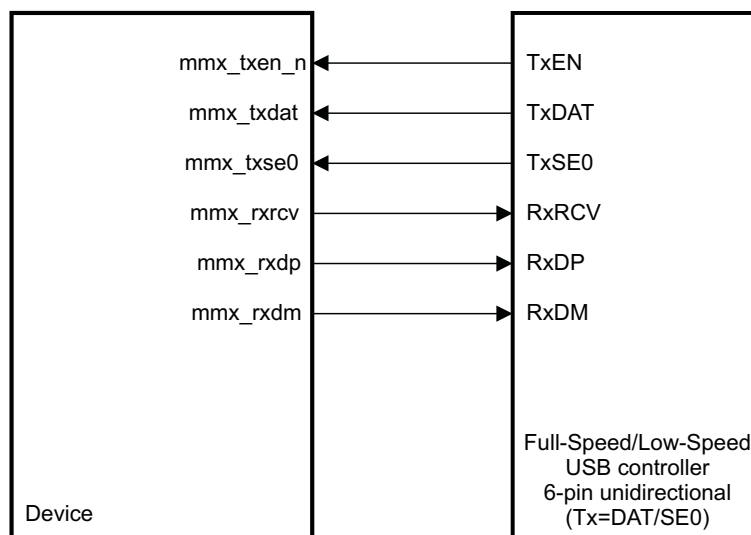

23.2.2.4.4.1 Unidirectional TLL Modes

The 6-pin TLL configurations are mirror images of the 6-pin transceiver configurations presented above. The same signals are mapped on the same physical pins, but in the opposite directions.

Two possible modes exist, depending on the TX data encoding used by the external device.

Figure 23-92 shows an external device using DAT/SE0 encoding.

Figure 23-92. 6-Pin Unidirectional TLL Using DAT/SE0 Signaling

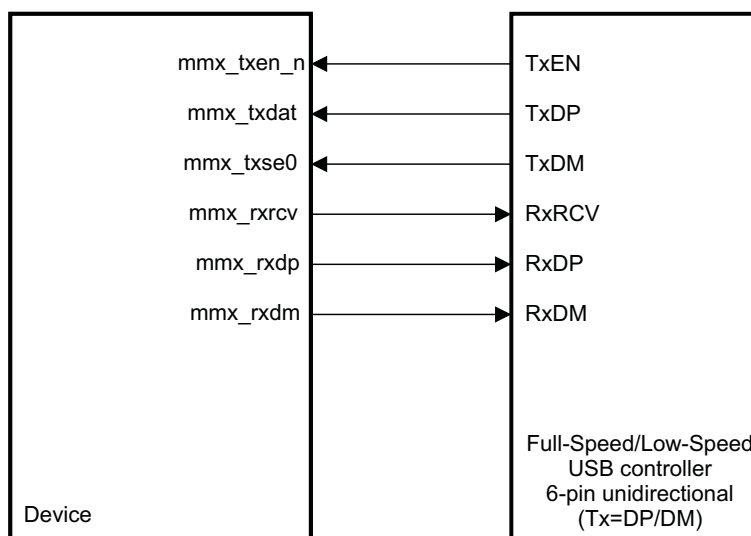

x is the USB port number (1, 2 or 3)

usb-022

Figure 23-93 shows an external device using DP/DM encoding.

Figure 23-93. 6-Pin Unidirectional TLL Using DP/DM Signaling

x is the USB port number (1, 2 or 3)

usb-023

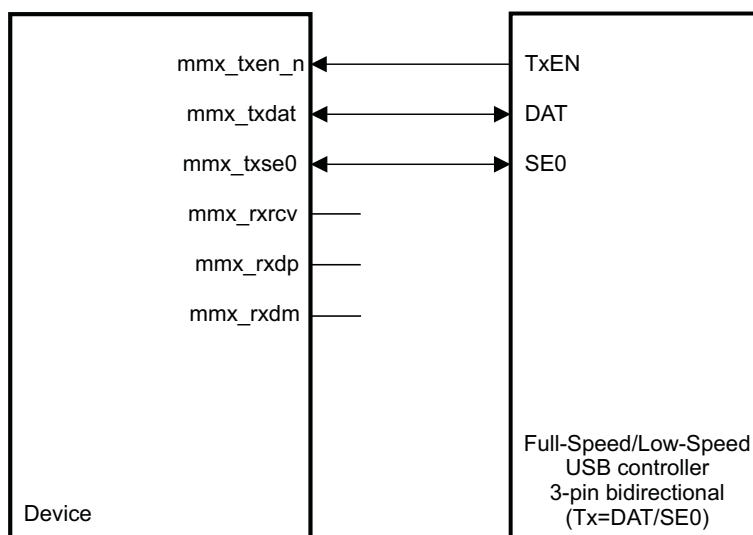

23.2.2.4.4.2 Bidirectional TLL Modes

The 3-pin/4-pin TLL configurations are mirror images of the 3-pin/4-pin transceiver configurations presented above. The same signals are mapped on the same physical pins, but in the opposite directions (bidirectional lines remain bidirectional).

Two possible modes exist, depending on the TX data encoding used by the external device.

Figure 23-94 shows an external device using DAT/SE0 encoding.

Figure 23-94. 3-Pin Bidirectional TLL Using DAT/SE0 Signaling

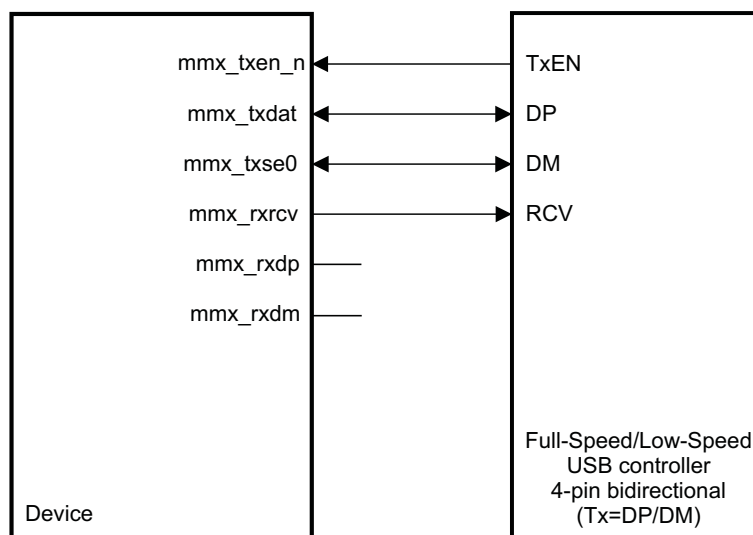

x is the USB port number (1, 2 or 3)

usb-024

Figure 23-95 shows an external device using DP/DM encoding.

Figure 23-95. 4-Pin Bidirectional TLL Using DP/DM Signaling

x is the USB port number (1, 2 or 3)

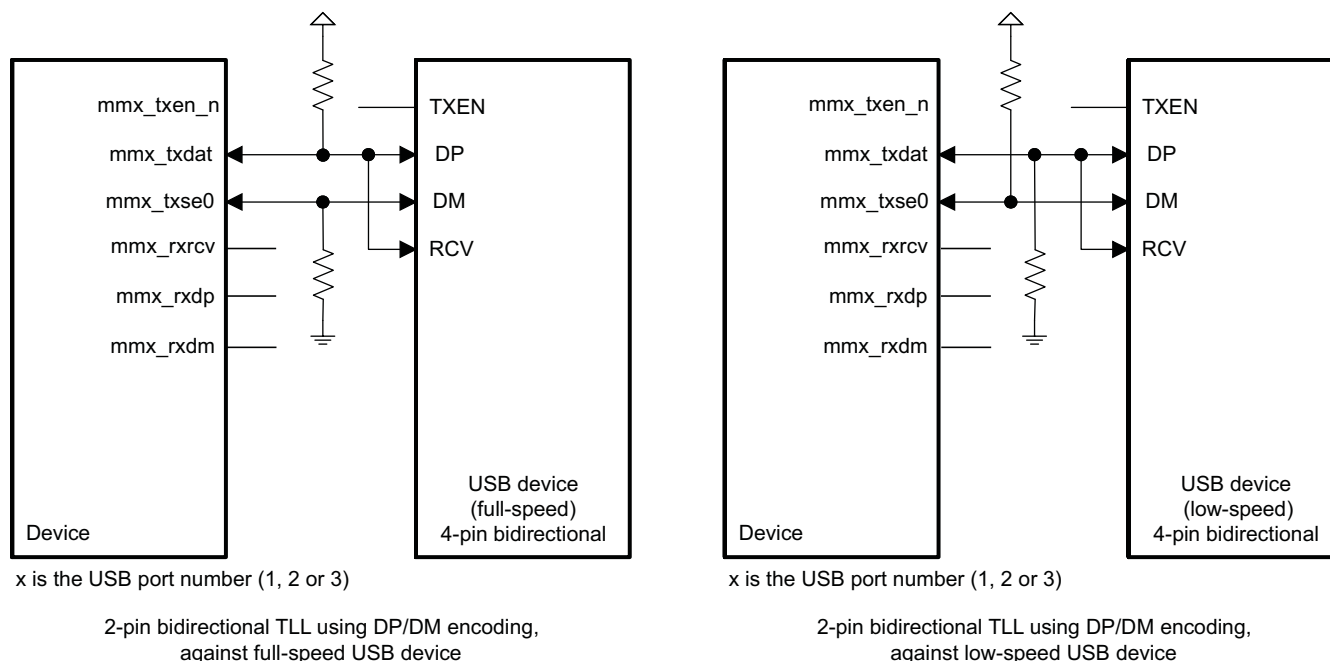

usb-025

The 2-pin TLL configurations have unique specifications:

- They require pullups/pulldowns to operate, because the bidirectional lines are not driven at all times like the other serial transceiver interfaces described above. The connection of pull resistors depends on the speed of the controller.
- The module supports explicit 2-pin TLL modes, with either DAT/SE0 or DP/DM encoding.
- Non-TLL modes (that is, transceiver configuration mode) can be used to implement the 2-pin functionality, using a specific connectivity.

Figure 23-96 shows USB port using DP/DM encoding.

23.2.3 High-Speed USB Host Subsystem Integration

This section describes the integration of the high-speed USB host subsystem.

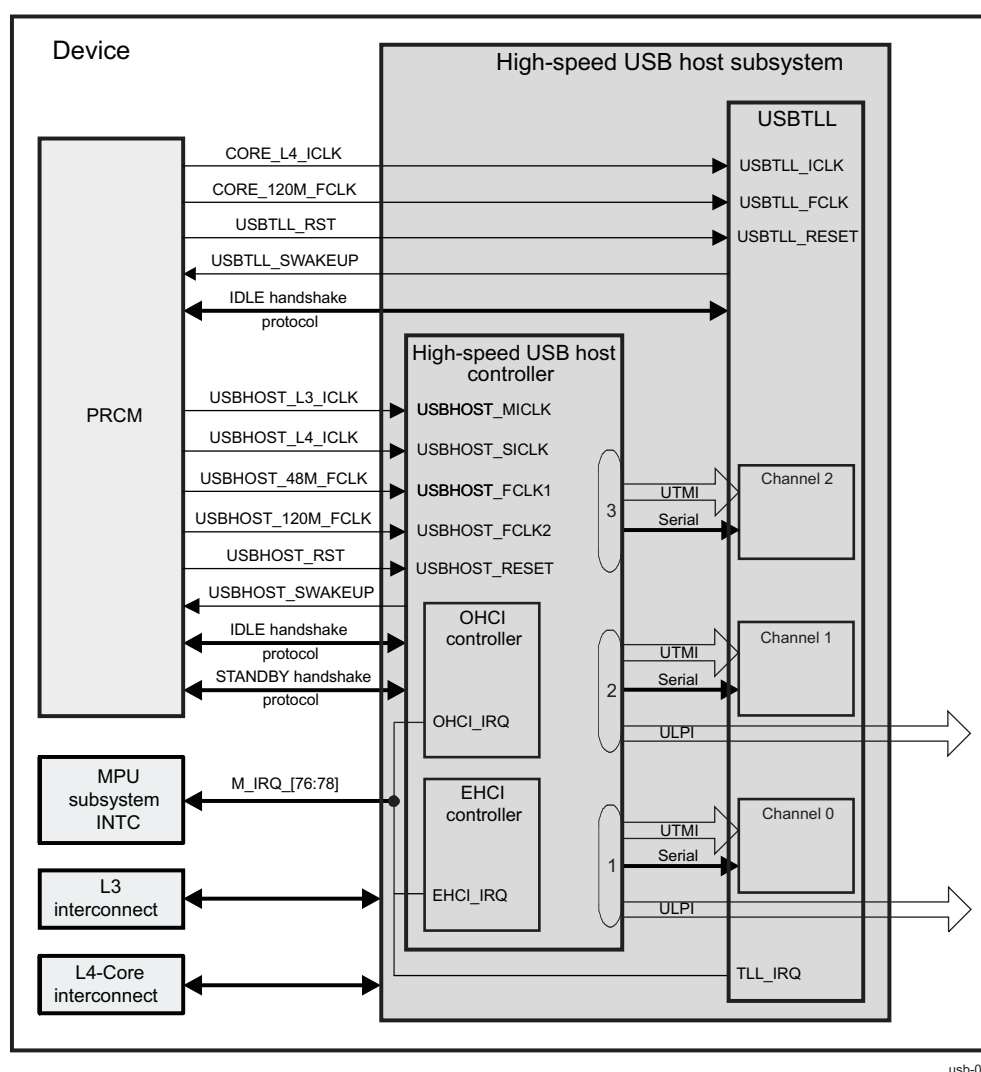

The high-speed USB host controller is connected to the L3 interconnect master (initiator) and L4-Core interconnect slave (target) interfaces. The USBTLL module is connected to the L4-Core interconnect slave (target) interface. The L3 interconnect is used to generate data traffic within the device. The L4-Core interconnect is a configuration port for register setting.

Three interrupts, M_IRQ_[78:76], are connected to the system.

The system control module (SCM) offers complementary settings for USB port connectivity modes.

Figure 23-98 highlights the high-speed USB host subsystem integration in the device.

Figure 23-98. High-Speed USB Subsystem Integration

usb-028

23.2.3.1 Reset, Clocking, and Power-Management Scheme

The high-speed USB host controller belongs to the USBHOST power domain. As part of the USBHOST power domain, it is sensible to the USBHOST_RST reset signal issued by the PRCM and to USBHOST power domain-related transitions. For further details about USBHOST power domain implementation and USBHOST_RST signal, see the *Power, Reset, and Clock Management* chapter.

The USBTLL module belongs to the CORE power domain. As part of the CORE power domain, it is sensible to the asynchronous USBTLL_RST reset signal issued by the PRCM and to CORE power domain-related transitions. For further details about CORE power domain implementation and USBTLL_RST signal, see the *Power, Reset, and Clock Management* chapter.

23.2.3.1.1 High-Speed USB Host Subsystem Resets

Table 23-79 lists and describes all the high-speed USB host subsystem resets:

Table 23-79. High-Speed USB Host Subsystem Reset Description

Type	Name	Source	Polarity	Description
Software	USBHOST.UHH_SYSCONFIG[1] SOFTRESET bit	High-speed USB host controller internal software reset	Active high	Writing 1 to the SOFTRESET bit resets the module. The bit value of 1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset.
Software	USBHOST.USBTLL_SYSCONFIG[1] SOFTRESET bit	USBTLL module internal software reset	Active high	Writing 1 to the SOFTRESET bit resets the module. The bit value of 1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset.
Hardware	USBHOST_RESET	PRCM USBHOST_RST signal	Active low	The USBHOST_RST signal resets the module. The hardware reset signal has a global reset action on the high-speed USB host controller (see the <i>Power, Reset, and Clock Management</i> chapter).
Hardware	USBTLL_RESET	PRCM USBTLL_RST signal	Active low	The USBTLL_RST signal resets asynchronously the module. The hardware reset signal has a global reset action on the USBTLL module (see the <i>Power, Reset, and Clock Management</i> chapter).

23.2.3.1.1.1 Hardware Resets

The high-speed USB host controller is attached to the USBHOST power domain: the USBHOST_RST signal resets the module. The USBTLL module is attached to the CORE power domain: the USBTLL_RST signal resets asynchronously the module (see the *Power, Reset, and Clock Management* chapter). The hardware reset signal has a global reset action on the modules.

23.2.3.1.1.2 Software Resets

The high-speed USB host controller and the USBTLL module have their own software-reset functionality through the USBHOST.UHH_SYSCONFIG[1] SOFTRESET bit (0: normal mode; 1: module is reset) for the high-speed USB host controller, and through the USBHOST.USBTLL_SYSCONFIG[1] SOFTRESET bit (0: normal mode; 1: module is reset) for the USBTLL module.

Writing 1 to the SOFTRESET bit resets the module. The bit value of 1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset.

23.2.3.1.2 High-Speed USB Host Subsystem Clocks

The high-speed USB host controller operates from four clock domains:

- USBHOST_FCLK1 is a high-speed USB host controller functional clock. It is used to clock the OHCI controller internal logic of the high-speed USB host controller. Its source is the PRCM USBHOST_48M_FCLK output clock. USBHOST_FCLK1 is controlled by the PRCM.PRCM.CM_FCLKEN_USBHOST[0] EN_USBHOST1 bit (0: disabled; 1: enabled).
- USBHOST_FCLK2 is a high-speed USB host controller functional clock. It is used to clock EHCI controller internal logic of the high-speed USB host controller. Its source is the PRCM USBHOST_120M_FCLK output clock. USBHOST_FCLK2 is controlled by the PRCM.PRCM.CM_FCLKEN_USBHOST[1] EN_USBHOST2 bit (0: disabled; 1: enabled).
- USBHOST_MICLK is the high-speed USB host controller L3 master interface clock. It is used to synchronize the high-speed USB host controller L3 port to L3 interconnect. All accesses from the interconnect are synchronous to USBHOST_MICLK. Its source is the PRCM USBHOST_L3_ICLK output clock. USBHOST_MICLK is controlled by the PRCM.CM_ICLKEN_USBHOST[0] EN_USBHOST bit (0: disabled; 1: enabled) and the PRCM.CM_AUTOIDLE_USBHOST[0] AUTO_USBHOST bit (enables/disables automatic control of the interface clock).
- USBHOST_SICLK is a high-speed USB host controller L4 slave interface clock. It is used to synchronize the high-speed USB host controller L4 port to L4 interconnect. All accesses from the interconnect are synchronous to USBHOST_SICLK. Its source is the PRCM USBHOST_L4_ICLK output clock.

The USBTLL module operates from two clock domains:

- USBTLL_FCLK is the USBTLL module functional clock. It is used to clock the USBTLL module internal logic. Its source is the PRCM CORE_120M_FCLK output clock. USBTLL_FCLK is controlled by the PRCM.CM_FCLKEN3_CORE[2] EN_USBTLL bit (0: disabled; 1: enabled).
- USBTLL_ICLK is the USBTLL module interface clock. It is used to synchronize USBTLL module L4 port to L4 interconnect. All accesses from the interconnect are synchronous to USBTLL_ICLK. Its source is the PRCM CORE_L4_ICLK output clock. USBTLL_ICLK is controlled by the PRCM.CM_ICLKEN3_CORE[2] EN_USBTLL bit (0: disabled; 1: enabled) and the PRCM.CM_AUTOIDLE3_CORE[2] AUTO_USBTLL bit (enables/disables automatic control of the interface clock).

Table 23-80 summarizes the high-speed USB host subsystem clocks.

Table 23-80. High-Speed USB Host Subsystem Clocks

Attributes	Frequency	Name	Module	Mapping	Comments
Functional clock	48 MHZ	USBHOST_FCLK1	High-speed USB Host controller	USBHOST_48M_FCLK	Source is PRCM module
Functional clock	120 MHZ	USBHOST_FCLK2	High-speed USB Host controller	USBHOST_120M_FCLK	Source is PRCM module
L3 master interface clock	Depending on PRCM register settings	USBHOST_MICLK	High-speed USB Host controller	USBHOST_L3_ICLK	Source is PRCM module
L4 slave interface clock	Depending on PRCM register settings	USBHOST_SICLK	High-speed USB Host controller	USBHOST_L4_ICLK	Source is PRCM module
Functional clock	120 MHZ	USBTLL_FCLK	USBTLL	CORE_120M_FCLK	Source is PRCM module
L4 interface clock	Depending on PRCM register settings	USBTLL_ICLK	USBTLL	CORE_L4_ICLK	Source is PRCM module

23.2.3.1.2.1 L3 Master Interface Clock

The L3 master interface clock (USBHOST_L3_ICLK) is used only by the high-speed USB host controller (USBHOST_MICLK) in the subsystem, and comes from the PRCM module. This clock is controlled by the PRCM register bits PRCM.CM_ICLKEN_USBHOST[0] (0 = disabled, 1 = enabled) and PRCM.CM_AUTOIDLE_USBHOST[0] (enables/disables automatic control of the interface clock)—see [Table 23-81](#).

Table 23-81. High-Speed USB Controller L3 Master Interface Clock

PRCM.CM_AUTOIDLE_USBHOST[0]	PRCM.CM_ICLKEN_USBHOST[0]	Interface Clock
0	0	Disabled
0	1	Enabled
1	0	Disabled
1	1	Automatic enabling/disabling

CAUTION

The L3 master interface clock shall not be less than 30 MHZ, ULPI clock divided by 2 (this can occur during DPLL3 reloading).

23.2.3.1.2.2 L4 Slave Interface Clock

The L4 slave interface clock (USBHOST_L4_ICLK) is used only by the high-speed USB host controller (USBHOST_SICLK) in the subsystem, and comes from the PRCM module.

23.2.3.1.2.3 L4 Interface Clock

The L4 interface clock (CORE_L4_ICLK) is used only by the USBTLL module (USBTLL_ICLK) in the subsystem, and comes from the PRCM module. This clock is controlled by the PRCM register bits PRCM.CM_ICLKEN3_CORE[2] (0 = disabled, 1 = enabled) and PRCM.CM_AUTOIDLE3_CORE[2] (enables/disables automatic control of the interface clock)—see [Table 23-82](#).

Table 23-82. USBTLL Module Interface Clock

PRCM.CM_AUTOIDLE3_CORE[2]	PRCM.CM_ICLKEN3_CORE[2]	Interface Clock
0	0	Disabled
0	1	Enabled
1	0	Disabled
1	1	Automatic enabling/disabling

23.2.3.1.2.4 Functional Clocks

Two functional clocks are provided by the PRCM module to the high-speed USB host controller: USBHOST_FLCK1 running at 48 MHZ (USBHOST_48M_FCLK) and USBHOST_FLCK2 running at 120 MHZ (USBHOST_120M_FCLK).

The USBHOST_FLCK1 functional clock is controlled by the PRCM register bit PRCM.CM_FCLKEN_USBHOST[0] (0 = disabled, 1 = enabled).

The USBHOST_FLCK2 functional clock is controlled by the PRCM register bit PRCM.CM_FCLKEN_USBHOST[1] (0 = disabled, 1 = enabled).

The CORE_120M_FCLK functional clock is used only by the USBTLL module (USBTLL_FCLK) in the subsystem, and comes from the PRCM module. This clock is controlled by the PRCM register bit PRCM.CM_FCLKEN3_CORE[2] (0 = disabled, 1 = enabled).

23.2.3.1.3 Power-Management Scheme

23.2.3.1.3.1 High-Speed USB Host Controller Power-Management Scheme

23.2.3.1.3.1.1 Overview

To save dynamic power consumption, an efficient idle scheme in the device is based on the following:

- An efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated/deactivated safely without complex software intervention. In both cases, the high-speed USB host controller power management is applied only to the interface clock domain.

The high-speed USB host controller has both master (initiator) and slave (target) interfaces.

- As an initiator, the high-speed USB host controller implements the standby handshake protocol to inform the PRCM module when it enters standby mode and does not generate traffic on the interconnect.
- As a target, the high-speed USB host controller implements the IDLE handshake protocol to allow the PRCM module requiring it to enter idle mode.

Table 23-83 details the high-speed USB host controller module PRCM clock control bits.

Table 23-83. High-Speed USB Host Controller PRCM Clock Control Bits

Module Clock	Associated PRCM Clock Output	Enabled Bit	Autoidle Bit
USBHOST_FCLK1	USBHOST_48M_FCLK	PRCM.CM_FCLKEN_USBHOST[0] EN_USBHOST1 bit	N/A
USBHOST_FCLK2	USBHOST_120M_FCLK	PRCM.CM_FCLKEN_USBHOST[1] EN_USBHOST2 bit	N/A
USBHOST_MICKL	USBHOST_L3_ICLK	PRCM.CM_ICLKEN_USBHOST[0] EN_USBHOST bit	PRCM.CM_AUTOIDLE_USBHOST[0] AUTO_USBHOST bit

Notes:

- The PRCM USBHOST_48M_FCLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the high-speed USB host controller is a necessary but not sufficient condition.
- The PRCM USBHOST_120M_FCLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the high-speed USB host controller is a necessary but not sufficient condition.
- The PRCM USBHOST_L3_ICLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the high-speed USB host controller is a necessary but not sufficient condition.
- The PRCM.CM_AUTOIDLE_USBHOST[0] AUTO_USBHOST bit is used to link/unlink the high-speed USB host controller from USBHOST_L3_ICLK-related clock domain transitions.
- For further details about source clocks gating and domain transitions, see the *Power, Reset, and Clock Management* chapter.

23.2.3.1.3.1.2 L3 Master Interface Power Management

The high-speed USB host controller can go to standby mode, in which case it stops generating transactions on the interconnect. The module standby leads the PRCM to disable the USB clocks to save power.

The high-speed USB host controller has a MSTANDBY/WAIT handshake mechanism with the PRCM module (see [Figure 23-98](#)).

The module is ready to enter standby mode (indicated by the MSTANDBY signal to the PRCM asserted) when there is no USB activity and the module is idle. It means the following:

- The module is committed not to start any new transaction on its master interface.
- The whole module is idle and, therefore, the power manager can start the procedure to turn off the interface clock, if needed. This procedure must be implemented using the slave power-management protocol.

The handshake mechanism lets the module go to standby mode based on the USBHOST.UHH_SYSCONFIG[13:12] MIDDLEMODE field.

Table 23-84. High-Speed USB Host Controller MIDDLEMODE Settings

MIDDLEMODE Value	Selected Mode	Description
0x0	Force-standby	The high-speed USB host controller enters standby mode unconditionally (MSTANDBY is asserted unconditionally).
0x1	No-standby	The high-speed USB host controller never enters standby mode (MSTANDBY is never asserted).
0x2	Smart-standby	The high-speed USB host controller is ready to enter standby mode (MSTANDBY is asserted) when there is no more activity on the USB master interface of the interconnect. MSTANDBY is asserted when the module is idle and deasserted when the module is activated by either an external USB event or an appropriate register access. The module then waits for MWAIT deassertion before a DMA transfer is started.

23.2.3.1.3.1.3 L4 Slave Interface Power Management

At PRCM level, when all the conditions to shut off the high-speed USB host controller output clocks are met (see the *Power, Reset, and Clock Management* chapter for details), the PRCM module automatically launches a hardware handshake protocol to ensure the high-speed USB host controller is ready to have its clocks switched off. Namely, the PRCM asserts an IDLE request to the high-speed USB host controller. Although this handshake is completely hardware and out of any software control, the way in which the high-speed USB host controller acknowledges the PRCM IDLE request is configurable through the USBHOST.UHH_SYSCONFIG[4:3] SIDLEMODE bit field. [Table 23-85](#) details SIDLEMODE settings and the related acknowledgment modes.

Table 23-85. High-Speed USB Host Controller SIDLEMODE Settings

SIDLEMODE Value	Selected Mode	Description
0x0	Force-idle	The high-speed USB host controller acknowledges unconditionally the IDLE request from the PRCM, regardless of its internal operations. Because such a mode does not prevent any loss of data when the clock is switched off, the mode must be used carefully.
0x1	No-idle	The high-speed USB host controller never acknowledges any IDLE request from the PRCM. This mode is secure from a module point of view as it ensures the clocks remain active; however, it is not efficient from a power-saving perspective because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
0x2	Smart-idle	The high-speed USB host controller acknowledges the IDLE request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs or DMA requests are treated. This is the best approach for an efficient system power management.

When configured in smart-idle mode, the high-speed USB host controller also offers an additional granularity on its interface clock gating. The USBHOST.UHH_SYSCONFIG[9:8] CLOCKACTIVITY bit is used to control the interface clock internal gating while module is idle. [Table 23-86](#) details the CLOCKACTIVITY settings.

Table 23-86. High-Speed USB Host Controller CLOCKACTIVITY Settings

CLOCKACTIVITY Value	Interface Clock Effect	Description
0	OFF	Interface clock is considered for generating the acknowledgment. This setting also means the interface clock is shut down upon PRCM IDLE request.
1	ON	Interface clock is not shut down upon PRCM IDLE request. The high-speed USB host controller can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clock.

CAUTION

The PRCM does not have any hardware means to read CLOCKACTIVITY settings. Software ensures a consistent programming between the high-speed USB host controller CLOCKACTIVITY and PRCM interface clock control bit. Indeed, if the USBTLL module is disabled in the PRCM.CM_ICLKEN_USBHOST register while CLOCKACTIVITY is set to 1, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated to the USBTLL module interface clock. This may lead to unpredictable behaviors.

23.2.3.1.3.2 USBTLL Module Device Power-Management Scheme

From a global system power-management perspective, when one or both of the USBTLL module clocks are no longer required, the USBTLL module can be deactivated at PRCM level in the corresponding registers.

Table 23-87 details the USBTLL module PRCM clock control bits.

Table 23-87. USBTLL Module PRCM Clock Control Bits

Module Clock	Associated PRCM Clock Output	Enabled Bit	Autoidle Bit
USBTLL_FCLK	CORE_120M_FCLK	PRCM.CM_FCLKEN3_CORE[2] EN_USBTLL bit	N/A
USBTLL_ICLK	CORE_L4_ICLK	PRCM.CM_ICLKEN3_CORE[2] EN_USBTLL bit	PRCM.CM_AUTOIDLE3_CORE [2] AUTO_USBTLL bit

Notes:

- The PRCM CORE_120M_CLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the USBTLL module is a necessary but not sufficient condition.
- The PRCM CORE_L4_ICLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the USBTLL module is a necessary but not sufficient condition.
- The PRCM.CM_AUTOIDLE3_CORE[2] AUTO_USBTLL bit is used to link/unlink the USBTLL module from CORE_L4_ICLK-related clock domain transitions.
- For further details about source clocks gating and domain transitions, see the *Power, Reset, and Clock Management* chapter.

At PRCM level, when all the conditions to shut off the USBTLL_FCLK or USBTLL_ICLK output clocks are met (see the *Power, Reset, and Clock Management* chapter for details), the PRCM module automatically launches a hardware handshake protocol to ensure the USBTLL module is ready to have its clocks switched off. Namely, the PRCM asserts an IDLE request to the USBTLL module. Although this handshake is completely hardware and out of any software control, the way in which the USBTLL module acknowledges the PRCM IDLE request is configurable through the USBHOST.USBTLL_SYSCONFIG[4:3] SIDLEMODE bit field. Table 23-88 details SIDLEMODE settings and the related acknowledgment modes.

Table 23-88. USBTLL Module SIDLEMODE Settings

SIDLEMODE Value	Selected Mode	Description
0x0	Force-idle	The USBTLL module acknowledges unconditionally the IDLE request from the PRCM, regardless of its internal operations. Because such a mode does not prevent any loss of data when the clock is switched off, the mode must be used carefully.
0x1	No-idle	The USBTLL module never acknowledges any IDLE request from the PRCM. This mode is secure from a module point of view as it ensures the clocks remain active; however, it is not efficient from a power-saving perspective because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
0x2	Smart-idle	The USBTLL module acknowledges the IDLE request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs or DMA requests are treated. This is the best approach for an efficient system power management.

When configured in smart-idle mode, the USBTLL module also offers an additional granularity on USBTLL_ICLK gating. The USBHOST.[USBTLL_SYSCONFIG](#)[9:8] CLOCKACTIVITY bit is used to control the USBTLL_ICLK clock internal gating while the module is idle. [Table 23-89](#) details the CLOCKACTIVITY settings.

Table 23-89. USBTLL Module CLOCKACTIVITY Settings

CLOCKACTIVITY Value	USBTLL_ICLK Effect	Description
0	OFF	USBTLL_ICLK is considered for generating the acknowledgment. This setting also means USBTLL_ICLK is shut down upon PRCM IDLE request.
1	ON	USBTLL_ICLK is not shut down upon PRCM IDLE request. The USBTLL module can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clock.

CAUTION

The PRCM does not have any hardware means to read CLOCKACTIVITY settings. Software ensures a consistent programming between the USBTLL module CLOCKACTIVITY and PRCM USBTLL_ICLK control bit. Indeed, if the USBTLL module is disabled in the PRCM.CM_ICLKEN3_CORE register while CLOCKACTIVITY is set to 1, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated to the USBTLL module interface clock. This may lead to unpredictable behaviors.

23.2.3.2 Hardware Requests

23.2.3.2.1 Interrupt Requests

Table 23-90 lists the interrupt lines that are driven out from the high-speed USB host controller to the microprocessor unit (MPU) subsystem interrupt controller (INTC).

Table 23-90. High-Speed USB Host Subsystem Interrupts

Name	Mapping	Comments
HS USB OHCI Host Controller Interrupt		
OHCI_IRQ	M_IRQ_76	Destination is MPU subsystem interrupt controller
HS USB EHCI Host Controller Interrupt		
EHCI_IRQ	M_IRQ_77	Destination is MPU subsystem interrupt controller
USBTLL Module Interrupt		
TLL_IRQ	M_IRQ_78	Destination is MPU subsystem interrupt controller

23.2.3.2.2 IDLE Handshake Protocol

The PRCM handles an IDLE handshake protocol for the high-speed USB host controller and the USBTLL module. The IDLE handshake protocol allows the PRCM requiring the high-speed USB host controller to enter idle mode. The module acknowledges when it is ready.

23.2.3.2.3 MSTANDBY Handshake Protocol

The PRCM module handles an MSTANDBY handshake protocol for the high-speed USB host controller, which initiates the MSTANDBY handshake to inform the PRCM module when it enters standby mode and does not generate traffic on interconnect.

23.2.3.2.4 Wake-Up Request

Wake-up request signal USBHOST_SWAKEUP is generated by the high-speed USB host controller to the PRCM module. Wake-up request signal USBTLL_SWAKEUP is generated by the USBTLL module to the PRCM module.

23.2.4 High-Speed USB Host Subsystem Functional Description

This section describes the functionality of the high-speed USB host subsystem by describing the high-speed USB host controller and the USBTLL module.

23.2.4.1 High-Speed USB Host Controller Functionality

The full details of the standard OHCI and EHCI host controller APIs (implemented by the current module) are not repeated here. For more information, see the following specifications:

- *Open Host Controller Interface (OHCI) specification for USB Release 1.0a*
- *Enhanced Host Controller Interface (EHCI) specification for USB Release 1.0*

23.2.4.1.1 High-Speed USB Host Controller Architecture

Figure 23-99 shows an overview of the high-speed USB host controller internal architecture: it contains two independent, 3-port host controllers that operate in parallel: EHCI and OHCI. Each of the three external ports is owned by exactly one of the controllers at any point in time. Each port can work in several modes:

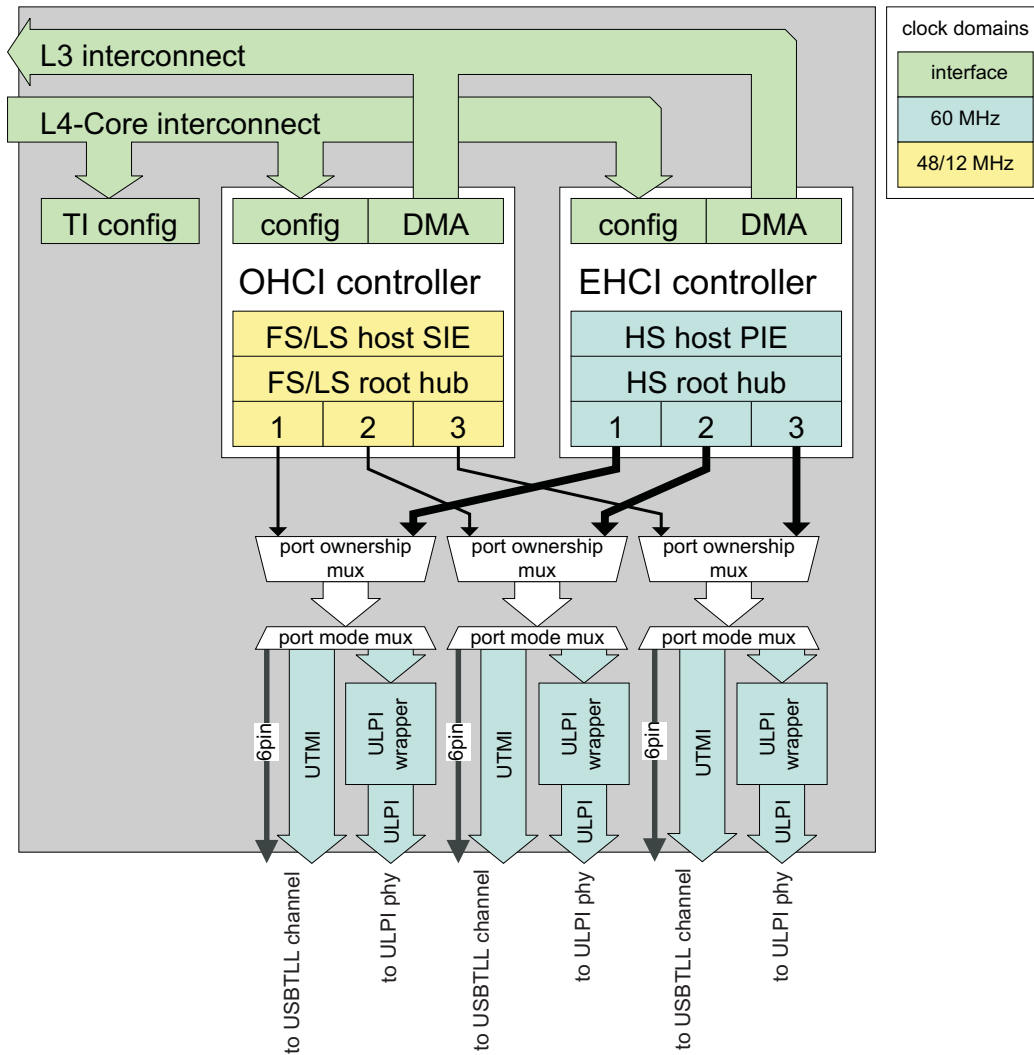

- When the port is owned by the OHCI (full-speed) host controller, the serial 6-pin interface mode is used.

- When the port is owned by the EHCI (high-speed) host controller, either the ULPI or the UTMI modes are used.

Note: If one port is connected to a high-speed ULPI transceiver, all other ports must be connected to high-speed ULPI transceivers or not used.

The L4-Core interconnect is used to configure the two controllers, as well as a general, TI-specific register bank. The L3 interconnect merges and arbitrates between the transactions generated by the controller respective DMA engines.

Figure 23-99. High-Speed USB Host Controller Architecture

usb-029

23.2.4.1.2 OHCI Implementation Specifications

Some features of the OHCI API are optional and/or implementation-specific. The choices made in the current implementation, the high-speed USB host controller, are described below, and are reflected in the register descriptions (see [Section 23.2.6.6, OHCI Registers](#)). For all standard features, see the *Open Host Controller Interface (OHCI) specification for USB Release 1.0a*.

- USBHOST.HCFMINTERVAL[30:16] FSMPS field (FullSpeedMaxPacketSize) = 0x0000: Host will stop scheduling new packets 0 bit times before the end of the frame (that is, there is no scheduling overrun protection by default). To be updated by the software driver.

- USBHOST.HCRHDESCRIPTORA[7:0] NDP field (NumberDownstreamPorts) = 0x03 = 3 ports.
- USBHOST.HCRHDESCRIPTORA[9] NPS bit (NoPowerSwitching) = 0: Ports are power-switched by default.
- USBHOST.HCRHDESCRIPTORA[8] PSM bit (PowerSwitchingMode) = 1: Per-port power switching is supported, although PPCM default setup has all ports controlled globally (default must be = OCPM).
- USBHOST.HCRHDESCRIPTORA[11] OCPM bit (OverCurrentProtectionMode) = 1: Overcurrent status is reported per port (default must be = PSM).
- USBHOST.HCRHDESCRIPTORA[12] NOCP bit (NoOverCurrentProtection) = 0: Overcurrent protection is implemented.
- USBHOST.HCRHDESCRIPTORA[31:24] POTPG field (PowerOnToPowerGood) = 0x0A = 10: Power rampup time is 10 x 2 ms = 20 ms.
- USBHOST.HCRHDESCRIPTORB[15:0] DR field (DeviceRemovable) = 0x0000: By default, no nonremovable devices (that is, devices attached to any of the ports) are removable.
- USBHOST.HCRHDESCRIPTORB[31:16] PPCM field (PortPowerControlMask) = 0x0000: By default, all ports are affected only by global power control.

23.2.4.1.3 UTMI Ports

The high-speed USB host controller supports N “downstream” ports, numbered from 1 through N. (In USB terminology, port 0 is necessarily an “upstream” port, and because the host is on “top” of the USB topological tree it has none). In the current implementation N = 3 (that is, available ports are 1, 2, 3).

The high-speed USB host controller is configured to be either in UTMI or in ULPI mode (see the USBHOST.UHH_HOSTCONFIG[0] ULPI_BYPASS bit).

In UTMI mode (see *USB 2.0 Transceiver Macrocell Interface specification Release 1.05*, and *UTMI+ specification Release 1.0*), all ports are in UTMI mode (that is, each port has its UTMI signal set broadcast the “outgoing” packets — from the host to the peripherals) and gather the “incoming” ones (that is, from the addressed peripheral to the host). ULPI signal sets are undefined/don’t care on all ports.

In the device, the UTMI ports connect to the USBTLL module. The UTMI ports between the high-speed USB host controller and the USBTLL module are on-chip and remain invisible.

23.2.4.1.4 ULPI Ports

The high-speed USB host controller supports N “downstream” ports, numbered from 1 through N. (In USB terminology, port 0 is necessarily an “upstream” port, and because the host is on “top” of the USB topological tree it has none). In the current implementation N = 3 (that is, available ports are 1, 2, 3).

The high-speed USB host controller is configured to be either in UTMI or in ULPI mode (see the USBHOST.UHH_HOSTCONFIG[0] ULPI_BYPASS bit).

In ULPI mode (see *UTMI Low-Pin Interface (ULPI) specification Release 1.1*), all ports are in ULPI mode (that is, each port has its ULPI signal set broadcast the “outgoing” packets — from the host to the peripherals) and gather the “incoming” ones (that is, from the addressed peripheral to the host). UTMI signal sets are undefined/don’t care on all ports.

When in ULPI mode, the high-speed USB host controller is in charge of generating the (nominally 60-MHZ) clock to the transceiver on the ULPI interface. This is called ULPI “input” clocking mode, because the ULPI protocol is transceiver-centric. The opposite mode, “output mode” (that is, the host receives the ULPI clock from the transceiver), is not supported and there is consequently no ULPI clock input.

In the device, the ULPI ports (only port 1 and port 2 are mapped) can only be connected directly to external transceivers. The USBTLL module is bypassed. USB traffic can be monitored directly on the USB lines.

23.2.4.1.5 Port Status

The USB port status is given through the USBHOST.UHH_HOSTCONFIG[10:8] bit field. The default value of the following bits is 1:

- USBHOST.UHH_HOSTCONFIG[8] P1_CONNECT_STATUS
- USBHOST.UHH_HOSTCONFIG[9] P2_CONNECT_STATUS
- USBHOST.UHH_HOSTCONFIG[10] P3_CONNECT_STATUS

CAUTION

These bits show the port status as connected after power on even though no USB device is connected. The USB host controller has operational status registers (for example, USBHOST.HCRHPORTSTATUS_1 for OHCI port 1) that indicate the correct port connect status. The USB driver software must read these status bits and check whether or not a port is connected. If the port is not connected, the USB driver software must reprogram the USBHOST.UHH_HOSTCONFIG bits to indicate the correct port connect status.

23.2.4.1.6 Save and Restore

The save-and-restore (SAR) mechanism can extract the hardware context of the high-speed USB host controller (after all USB activity has been suspended) before switching off (=save), save it to an external always-on memory, and reinject it later after the module has been switched on again and reset (=restore) seamlessly for the USB. Part of that context is composed of the register fields described in the current chapter. The rest of the context is composed of the “buried” flip-flops and memories (not accessible by software) like finite state-machine (FSM) states, buffer contents, and miscellaneous random logic bits.

The PRCM.PM_PWSTCTRL_USBHOSTE[4] SAVEANDRESTORE bit enables the SAR mechanism for the high-speed USB host controller (see the *Power, Reset, and Clock Management* chapter). When set, the PRCM module initiates the save and/or the restore sequences at the appropriate time. When not set, the USB host is treated as a standard module, and the save/restore sequences do not occur.

23.2.4.1.7 Burst Control

To avoid buffer underflow bursts shall be enabled by writing 0x7 in USBHOST.UHH_HOSTCONFIG[4:2] and 0x0 in USBHOST.UHH_HOSTCONFIG[5] ENA_INCR_ALIGN.

23.2.4.2 USBTLL Module Functionality

The USBTLL module implements a TLL compatible with a number of USB standard interface protocols. Once the interface protocol has been selected during an initial configuration phase, USB operation should take place seamlessly (that is, as if actual transceivers were present). To ensure maximum compatibility, as many features as possible have been included, as described in the rest of this document. The basic principle is that all the software “handles” should be available and behave in a proper way, even if there is no actual functionality underneath.

The USBTLL module is integrated with the high-speed USB host controller in the device. The transceiver interfaces (UTMI ports) between the high-speed USB host controller and the USBTLL module are on-chip and remain invisible. The other transceiver interfaces go off-chip, where they can be connected to the other controllers (for example, peripherals) on another IC.

23.2.4.2.1 Channels and Ports

Following the same convention than UTMI and ULPI, the current specification is consistently PHY-centric (that is, directions are always given with respect to the transceiver emulated here by the TLL), and not with respect to the link controller: An “input” goes from the link controller to the TLL (transceiver emulator) (that is, it is an input for the USBTLL module. Reciprocally, an “output” goes from TLL (transceiver) to the link controller (that is, it is an output for the USBTLL module).

By convention, the local link controller is the controller integrated on the same IC as the USBTLL module: This is the high-speed USB host controller in the device. The remote link controller is the other controller, located off-chip (that is, on another IC). One controller is always the USB host, the other the USB peripheral, and they communicate through the USBTLL module.

A channel is defined as a independent USB path through the USBTLL module, which always converts the UTMI+ transceiver interface protocol coming from the local link controller (the high-speed USB host controller in the device). The number of channels of the USBTLL module is three in the device.

A USB port is a set of I/O signals that carry the data and control information from/to a USB line. Several port formats exist, with different capabilities. A channel has three ports. If the channel is active, two ports are active at a time, depending on the channel configuration. The mode remains static throughout USB operation. Table 23-91 summarizes the ports features.

23.2.4.2.2 Channel Architecture

Figure 23-100 shows the architecture of a single channel (of three) of the USBTLL module, and its integration in a USB system. The ports are indicated by the circled letters (A, C, and D). See the following descriptions:

- Full arrows represent parallel, synchronous, high-speed-capable interfaces.
- Line arrows represent serial, combinatorial, full-speed/low-speed-only interfaces.
- Arrows always point toward the PHY layer (actual transceiver or TLL, in yellow), away from the link controller.
- The arrow marked ULPI* represents the entire ULPI protocol (synchronous or not) except the 3-/6-pin serial TLL modes which are reoriented toward the serial TLL block.
- The USBTLL module cannot interface with a ULPI transceiver. This functionality is provided by the high-speed USB host controller.
- Top-level multiplexing is shown only for information. It is static and does not add functionality. The figure shows ULPI and serial ports implemented on different I/O pads for clarity, but a real implementation would typically reuse the same pads, because the interfaces cannot be active simultaneously

Figure 23-100. USBTLL Channel

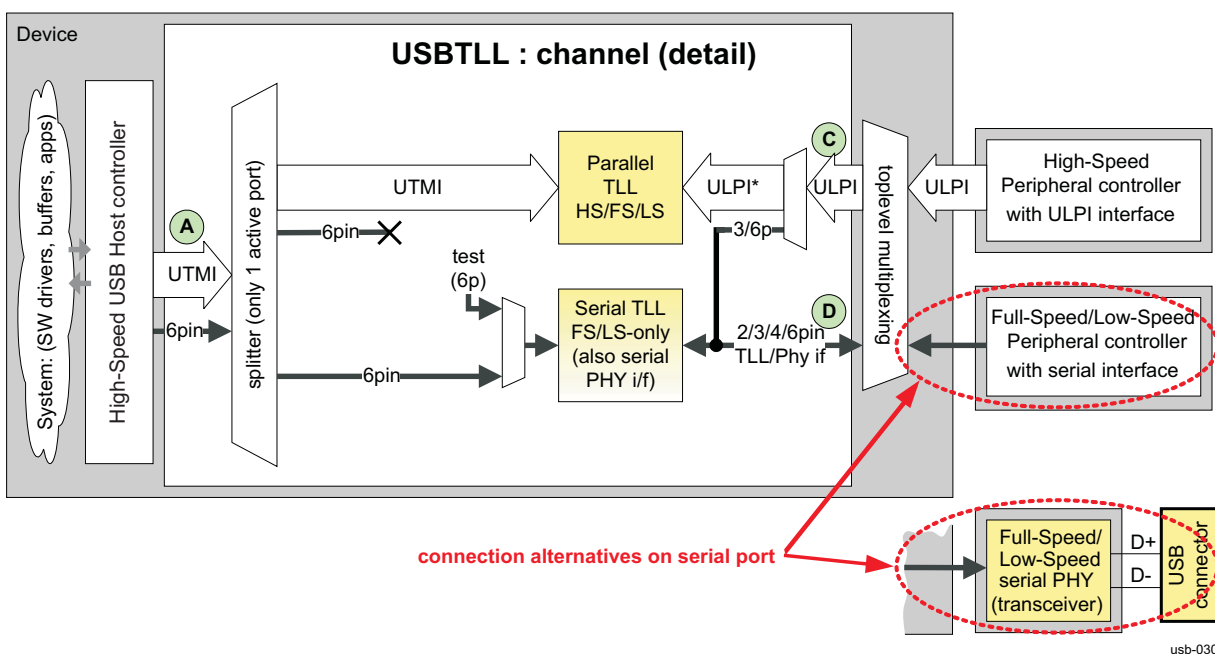

Table 23-91 summarizes the properties of each port.

Table 23-91. USBTLL Channel USB Ports

USBTLL Port	Port Description	Connect to Controller	Connect to Transceiver	Serial (Full-Speed/Low-Speed only)	Parallel (High-Speed/Full-Speed/Low-Speed)
A	PHY-side UTMI+	UTMI+ (L3)	No	6-pin	60-MHZ UTMI
C	PHY-side ULPI	ULPI TLL	No	6-pin	60-MHZ UTMI
D	Multimode Serial	6-/4-/3-/2-pin TLL	6-/4-/3-/2-pin	6-/4-/3-/2-pin TLL	No

23.2.4.2.2.1 Port A: PHY-side UTMI+ Port

Connects to the high-speed USB host controller in the device. The UTMI “local” port is used in all configurations (that is, the entire channel can be seen as a protocol converted from that port to one of the remote ports C or D).

- Compliant with UTMI+ version 1.0
- 8-data-bit, 60 MHZ UTMI (HS/FS/LS-capable)
- UTMI+ Level 3 extensions
- Vcontrol/Vstatus (from UTMI)
- Serial FS/LS “6-pin” mode

23.2.4.2.2.2 Port C: PHY-Side ULPI Port

Connects to a remote (off-chip) ULPI controller through I/O pads.

- Compliant with ULPI version 1.1
- SDR and DDR ULPI capable (respectively, 8-bit/4-bit data width modes)
- Supports optional 6-pin/3-pin serial modes
- Supports optional input clocking mode

23.2.4.2.2.3 Port D: Serial Multimode Port

Connects to either a serial controller (TLL modes) or a serial transceiver (transceiver interface modes).

- Supports 6-pin (TX: DAT/SE0 or TX: DP/DM) unidirectional, 4-pin bidirectional, 3-pin bidirectional, 2-pin bidirectional modes
- All modes are supported for TLL or transceiver interface configuration.
- Supports sideband signals (pullup/down control, speed/suspend enable, etc.)

23.2.4.2.3 Channel Configuration

A channel configuration is a set of software settings that specifies the connection of two of the channel ports through the USBTLL module. USB data and control injected on one side (or port) comes out on the other side (or port) after a certain amount of processing, depending on the mode. [Table 23-92](#), lists the modes.

All configurations connect the PHY UTMI port (attached to the high-speed USB host controller) to one of the other two ports (attached to a variety of transceivers or controllers on the pads side).

[Table 23-92](#) describes the available modes and the software settings required for each. Channel I has the following settings:

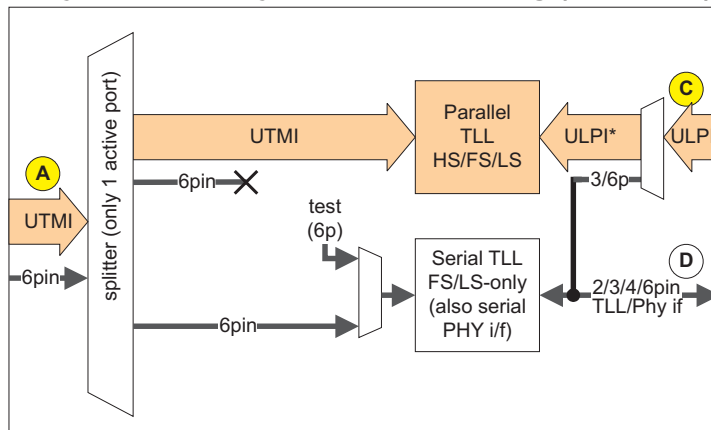

- CHANMODE: USBHOST.TLL_CHANNEL_CONF_i[2:1] CHANMODE field
- FLSMODE: USBHOST.TLL_CHANNEL_CONF_i[27:24] FLSMODE field
- FLSSEIRIALMODE_3PIN/6PIN: Either the ULPI PHY-side USBHOST.ULPI_INTERFACE_CTRL[1] FLSSEIRIALMODE_3PIN bit or the USBHOST.ULPI_INTERFACE_CTRL[0] FLSSEIRIALMODE_6PIN bit (only one can be set to 1 at a time)

Table 23-92. USBTLL Channel Configuration

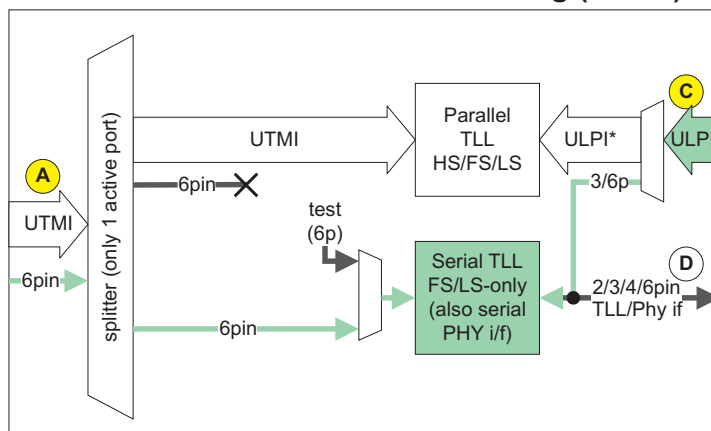

Configuration	Mode	CHAN MODE	FLSMODE	Other Settings	Ports	Speed	Remote Port Connection
2	ULPI synchronous TLL	0	N/A	FLSSEIRIALMODE_ 3PIN/6PIN = 0	A–C	HFL	ULPI link (peripheral controller)
4	Serial UTMI to serial ULPI TLL	0	N/A	FLSSEIRIALMODE_ 3PIN/6PIN = 1	A–C	FL	ULPI link (peripheral controller) supporting 3-/6-pin mode
6	Serial UTMI to serial TLL	1	0x4 to 0x7; 0xA to 0xB	-	A–D	FL	Serial link (2-/3-/4-/6-pin)
6	Serial UTMI to serial PHY	1	0x0 to 0x3	-	A–D	FL	Serial transceiver (2-/3-/4-/6-pin)

usb-031

23.2.4.2.4 VBUS Management and Emulations

In transceiver configurations, an actual USB cable is present, including an actual 5 V VBUS supply line. On the other hand, in TLL configurations, the physical USB lines are emulated and have no physical existence. This is especially true for the VBUS line, which distributes the 5-V power provided by the default host (or A-device) to the entire bus. VBUS is also used for signaling purposes, and those features must be emulated:

- A peripheral detects the presence of a host by detecting the presence of VBUS.
- USB OTG defines an elaborate voltage-sensing scheme to dynamically switch on and off VBUS (start and stop sessions). In the context of TLL, this brings no power saving compared to simple suspend.
- In particular, USB OTG uses VBUS as a wake-up source (VBUS-pulsing SRP) for the default peripheral (or B-device).

For more information on how sideband controls are integrated, see [Figure 23-86](#) and [Figure 23-87](#) and the related explanations.

23.2.4.2.4.1 VBUS Control and Status for Transceiver (Non-TLL) Configurations

In non-TLL modes, VBUS exists, and the problem is to propagate control and status to/from the actual VBUS manager IC (typically the transceiver itself).

Only serial transceiver configurations are concerned in the case of the high-speed USB host subsystem in the device.

23.2.4.2.4.1.1 VBUS Management in Serial Transceiver Configurations

VBUS management is not standardized in transceiver configurations. The chosen implementation is described below. See also [Figure 23-86](#).

- VBUS control required for host and OTG operation (VBUS drive, VBUS pullup “charge”, VBUS pulldown “discharge”) is assumed to be taken care of separately from the USBTLL module (that is, by software and straight to the power IC, which can be the transceiver itself, especially in OTG cases).
- VBUS status must be sampled by the appropriate hardware (again, most of the time the transceiver itself) and reported by software to the USBTLL module, using the USBHOST.TLL_CHANNEL_CONF_i DRVVBUS and CHRGVBUS bits, as indicated in [Table 23-93](#).

[Table 23-93](#) lists the values to write to the USBHOST.TLL_CHANNEL_CONF_i register depending on the VBUS status observed by the transceiver on the actual VBUS line. The same register fields are also used in TLL configuration, and have been named according to that second configuration. In transceiver configurations the fields’ actual signification is:

- DRVVBUS: set to 1 to report a VBUS level greater than *VBUS valid*.
- CHRGVBUS: set to 1 to report a VBUS level greater than *Session valid*

Table 23-93. VBUS Level Software Reporting for Serial Transceiver Configuration

VBUS Status	USBHOST.TLL_CHANNEL_CONF_i[16] DRVVBUS Bit	USBHOST.TLL_CHANNEL_CONF_i[15] CHRGVBUS Bit
VBUS valid	1	1
Session valid (A/B)	0	1
Session not valid	0	0
Session end	0	0

23.2.4.2.4.2 VBUS Emulation for TLL Configurations

The TLL VBUS emulation sums up all actions on the VBUS line, obtains a voltage level, reported in the VBUS status bits following the protocol. The level depends on the immediate VBUS actions and has no memory of previous levels, whereas a real VBUS line behaves like an RC circuit and takes time to charge and discharge. This causes the following differences:

- The TLL level always jumps abruptly from session valid to session end (and back) with no transient time in between (where session is neither valid nor ended) as in real life.
- The Charge feature is used for VBUS-pulsing SRP, and is enabled long enough to go over the Session valid threshold, but without reaching VBUS valid. In the TLL the transition to Session valid is immediate, and VBUS valid is never reached even if the Charge is intentionally kept active.
- The Discharge feature is used in real life to accelerate the voltage drop of an undriven VBUS towards the session-end level. For TLL, this is therefore useless (although the UTMI input/ULPI register bit do exist, for compatibility), and always a “don’t care”

23.2.4.2.4.2.1 VBUS Emulation in ULPI TLL Modes

[Table 23-94](#) summarizes the VBUS emulation in ULPI TLL modes. VBUS controls are writable, static PHY-side registers on the ULPI side, and input signals on the ULPI ports (port A). VBUS status bits are read-only, volatile PHY-side registers on the ULPI, and output signals on the ULPI ports (port A).

Table 23-94. Emulation of VBUS Levels for UTMI-to-ULPI TLL Mode

VBUS Controls (Actions)			VBUS Level		VBUS Status	
USBHOST.ULPI_OTG_CTRL[5] DRVVBUS Bit	USBHOST.ULPI_OTG_CTRL[4] CHRGVBUS Bit	USBHOST.ULPI_OTG_CTRL[3] DISCHRGVBUS Bit		USBHOST.ULPI_USB_INT_STATUS[1] VBUSVALID Bit	USBHOST.ULPI_USB_INT_STATUS[2] SESSVALID Bit	USBHOST.ULPI_USB_INT_STATUS[3] SESEND Bit
1	X	X	VBUS valid	1	1	0
0	1	X	VBUS valid	0	1	0
0	0	X	Session end	0	0	1

23.2.4.2.4.2.2 VBUS Emulation in Serial TLL Modes

In serial TLL modes, VBUS status and control is implemented with ad-hoc sideband signals. See [Figure 23-87](#).

VBUS control can be done in software, by writing to the following fields of the USBHOST.TLL_CHANNEL_CONF_i register:

- DRVVBUS: set to 1 to drive VBUS to 5 V (for A-device or host)
- CHRGVBUS: set to 1 to pullup VBUS (for SRP)
- There is no pulldown (discharge) control, because the emulated VBUS has no latency and VBUS level goes to the session end level as soon as it is neither driven nor pulled up.

Alternatively, VBUS drive can also be hardware-controlled through a dedicated input. (DRVVBUS register bit and input signal are actually ORed internally.)

VBUS status is available on dedicated output signals. If those outputs are not available at top level, a software alternative is to use the voltage status reported on the local controller (the high-speed USB host controller in the device) interface (through the standard UTMI+ sideband signals) and to pass it to the remote controller (a peripheral controller), by means of an ad hoc software-controller interface other than the USB itself. This is based on the fact that the level of VBUS is the same on both extremities of the bus (that is, it does not matter which side does the measurement).

23.2.4.2.5 Multimode Serial Port

The multimode serial port requires six bidirectional I/O pads to support all eight defined modes (selected in the USBHOST.TLL_CHANNEL_CONF_i[27:24] FSLSMODE field when field CHANMODE = 0x1 = UTMI-to-serial). Those modes are full-speed/low-speed only (that is, high-speed is not supported over a serial interface).

The pads are named TXEN, TXDAT, TXSE0, RXRCV, and RXDM after their functionality in standard 6-pin mode (mode 0). Each pad has an input, output, and output enable signal associated to it on the USBTLL entity.

Table 23-95 shows the functionality of each pad in each mode. USBTLL outputs are shown in yellow, inputs in blue, and bidirectional pads in green.

Table 23-95. Serial Mode Description, Signal Functionality

Usual Name	6-Pin Mode	6-Pin Mode (Alt)	3-Pin Mode	4-Pin Mode	6-Pin TLL Mode	6-Pin TLL (Alt) Mode	3-Pin TLL Mode	4-Pin TLL Mode	2-Pin TLL Mode	2-Pin TLL (Alt) Mode
USBHOST.TLL_CHANNEL_CONF_i[27:24] FSLSMODE field	0x0	0x1	0x2	0x3	0x4	0x5	0x6	0x7	0xA	0xB
TX encoding	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM
RX encoding	DP/DM/RCV	DP/DM/RCV	DAT/SE0	DP/DM/RCV	DP/DM/RCV	DP/DM/RCV	DAT/SE0	DP/DM/RCV	DAT/SE0	DP/DM
Pin usage	Unidirect	Unidirect	Bidirect	Bidirect	Unidirect	Unidirect	Bidirect	Bidirect	Bidirect	Bidirect
Pin count	6	6	3	4	6 or 5 ⁽¹⁾	6 or 5 ⁽¹⁾	3	4 or 3 ⁽²⁾	2	2
I/O Pad Function Per Mode										
TXEN	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	N/C	N/C
TXDAT	TX Diff Data	TX SE Plus Data	TX/RX Diff Data	TX/RX SE Plus Data	TX Diff Data	TX SE Plus Data	TX/RX Diff Data	TX/RX Diff Data	TX/RX Diff Data	TX/RX SE Plus Data
TXSE0	TX force SE0	TX SE Minus Data	TX/RX force SE0	TX/RX SE Minus Data	TX force SE0	TX SE Minus Data	TX/RX force SE0	TX/RX force SE0	TX/RX force SE0	TX/RX SE Minus Data
RXRCV	RX Diff Data	RX Diff Data	N/C	RX Diff Data	RX Diff Data	RX Diff Data	N/C	RX Diff Data	N/C	N/C
RXDM	RX SE Plus Data	RX SE Plus Data	N/C	N/C	RX SE Plus Data	RX SE Plus Data	N/C	N/C	N/C	N/C
RXDM	RX SE Minus Data	RX SE Minus Data	N/C	N/C	RX SE Minus Data	RX SE Minus Data	N/C	N/C	N/C	N/C

⁽¹⁾ RXRCV and RXDM carry the same info: RXDM can drive both inputs of the remote controller and RXRCV kept unused

⁽²⁾ Same remark on TXDAT (for outputs) and RXRCV: TXDAT only is enough

23.2.4.2.6 Attach/Connect Emulation for Serial TLL Modes

This section applies to all serial TLL modes:

- In UTMI-to-serial mode (USBHOST.TLL_CHANNEL_CONF_i[2:1] CHANMODE field = 0x1) for all TLL values of USBHOST.TLL_CHANNEL_i[27:24] FSLSMODE field (0x4 to 0x7; 0xA to 0xB)
- In UTMI-to-ULPI TLL mode (USBHOST.TLL_CHANNEL_CONF_i[2:1] CHANMODE field = 0x0) when the ULPI bus is switched to 6-pin serial or 3-pin serial modes

In those modes, the USB bus lines are emulated by USBTLL internal logic, and are never available on the outside. The pullup/pulldown actions described in the USB specification cannot be applied directly, and the USB cable cannot be physically attached.

Because serial modes do not specify a standard format for those sideband settings, a custom software-controlled one was implemented:

- USBHOST.TLL_CHANNEL_CONF_i[4] TLLATTACH bit emulates the physical attachment of the two controllers through a TLL cable.
 - When this bit is cleared, the local controller RX path only shows the local controller (the high-speed USB host controller) actions on the bus: TX driving, pullups, pulldowns (see below). The same thing applies for the remote controller RX path (except that test override is not available).
 - As soon as the bit is set, the actions of both sides are applied to the same bus and are resolved, similar to a real bus. The RX path for both sides shows the same bus state.
- USBHOST.TLL_CHANNEL_CONF_i[5] TLLCONNECT bit emulates the USB electrical connect (that is, the pullup by the USB peripheral of one of the two USB lines [by a 1.5KOhm resistor]), which causes the linestate to transition from SE0 to J, which is detected by the USB host. The register bit is ORed with a USBTLL module input signal — the connect control can be software (L4-Core interconnect write access) or hardware (input level). The speed of the connection is determined by the TLLFULLSPEED bit below.
- USBHOST.TLL_CHANNEL_CONF_i[6] TLLFULLSPEED bit determines the speed (full or low) of the USB connect to be emulated. The connect enable (controlled as defined above) results in the pulling-up of either D+ (1 = full speed) or D- (0 = low speed): see Table 23-96.
- The 15kOhm pulldowns are implicit: because they are supposed to be turned on at least on the host side of the bus, they do not require an additional control.

Note: Sideband control and status actions like pullups are included in parallel (that is, nonserial) standards (UTMI, ULPI), and do not require any custom additions.

Table 23-96. Pullup Enable Emulation in Serial TLL Modes

USBHOST.TLL_CHANNEL_CONF_i Fields		Input Signal	Resulting TLL Pullup Emulation	
TLLFULLSPEED	TLLCONNECT	USB State	D+ Pullup	D- Pullup
1	0	Full-speed unconnected	Off	Off
1	1	Full-speed connected	On	Off
0	0	Low-speed unconnected	Off	Off
0	1	Low-speed connected	Off	On

23.2.4.2.7 Save and Restore

The SAR mechanism can extract the hardware context of the USBTLL module (after all USB activity has been suspended) before switching off (=save), save it to an external always-on memory, and reinject it later after the module has been switched on again and reset (=restore) seamlessly for the USB. Part of that context is composed of the register fields described in the current chapter. The rest of the context is composed of the buried flip-flops and memories (not accessible by software) like FSM states, buffer contents, and miscellaneous random logic bits.

The PRCM.PM_PWSTCTRL_CORE[4] SAVEANDRESTORE bit enables the SAR mechanism for the USBTLL module (see the *Power, Reset, and Clock Management* chapter). When set, the PRCM module initiates the save and/or the restore sequences at the appropriate time. When not set, the USB host is treated as a standard module, and the save/restore sequences do not occur.

Table 23-97 lists the USBTLL registers impacted by the SAR context.

Note: Because all addresses give access to the same physical register (that is, to the same piece of context), the ULPI registers with multiple accesses (write, set, clear) are listed only once in the table.

Table 23-97. USBTLL Registers Impacted by the SAR Context

Register Name	Comments on SAR Policy
USBTLL_SYSCONFIG	Except the SOFTRESET bit (write-only)

23.2.5 High-Speed USB Host Subsystem Basic Programming Model

23.2.5.1 Selecting and Configuring USB Connectivity

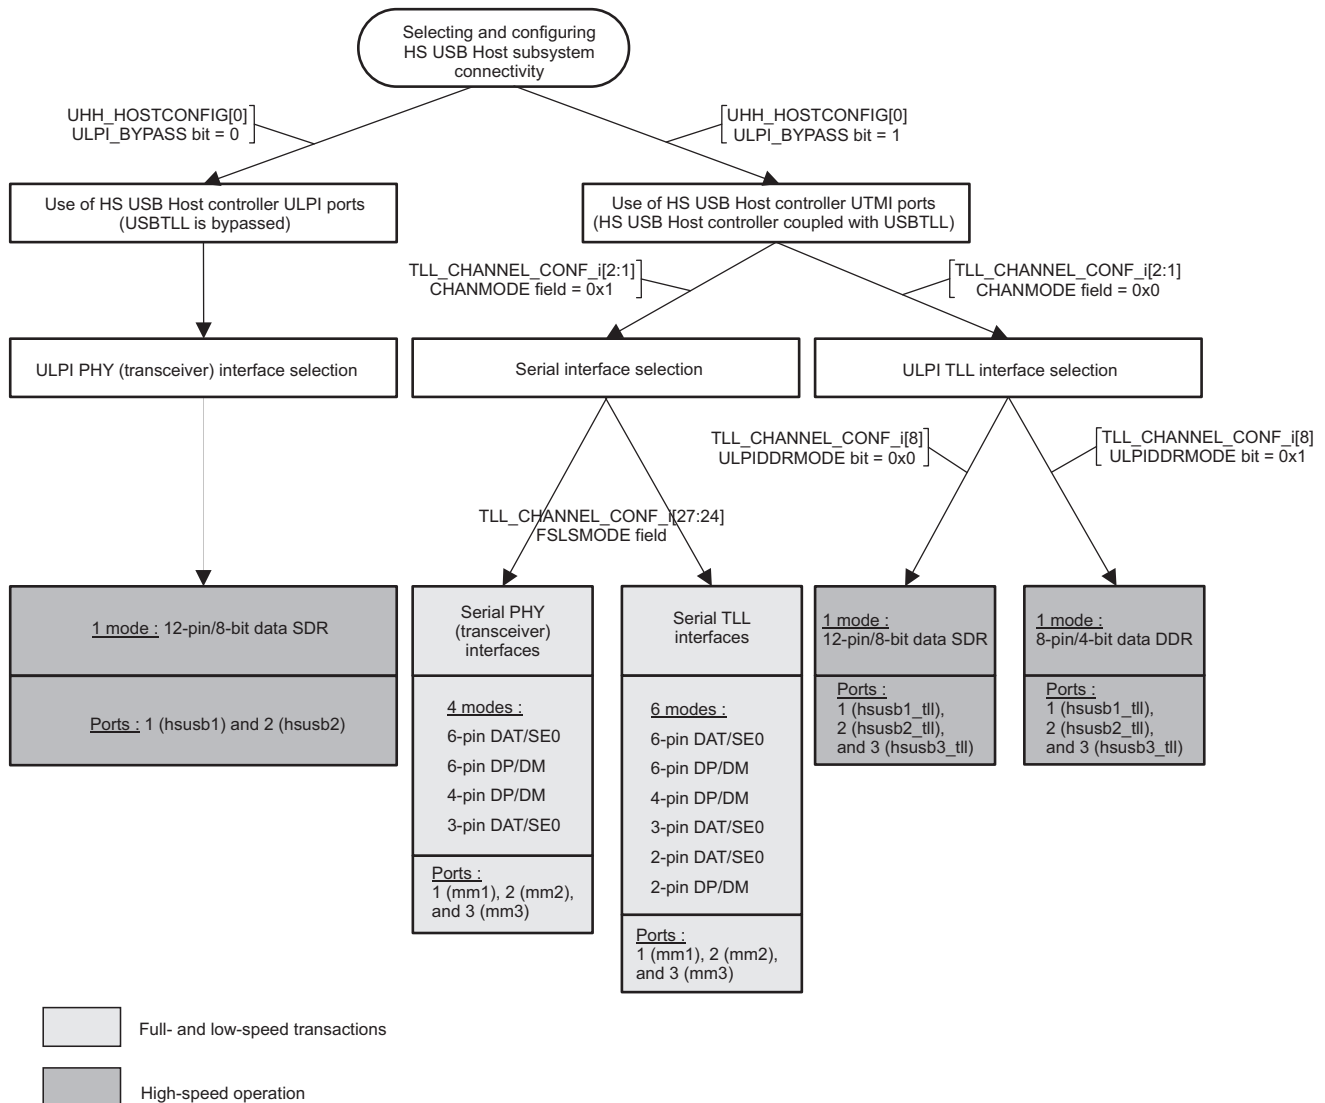

Perform the following steps to select the desired USB connectivity and configure the device accordingly.

The high-speed USB host subsystem provides three kinds of interfaces for connection:

- ULPI PHY interfaces for high-speed data transactions (up to 480 Mbps)
- Serial interfaces for full- and low-speed data transactions (up to 12 Mbps)
- ULPI TLL interfaces for high-speed data transactions (up to 480 Mbps)

Figure 23-102 shows how to select and configure the high-speed USB host subsystem connectivity.

Figure 23-102. Selecting and Configuring High-Speed USB Host Subsystem Connectivity

046 G25-033

Note: When the USBHOST.UHH_HOSTCONFIG[0] ULPI_BYPASS bit is 0 (ULPI transceiver interface selection), only the ULPI ports 1 and 2 of the high-speed USB host controller can be used. Only the 12-pin/8-bit data SDR version of the ULPI interface mode is supported.

When the USBHOST.UHH_HOSTCONFIG[0] ULPI_BYPASS bit is 1 (ULPI TLL interface selection and serial interface selection), there is no restriction and the three ports can be configured in any ULPI TLL or serial mode.

23.2.5.1.1 ULPI Interface Selection

The high-speed USB host subsystem supports the following modes with the ULPI interfaces:

- External USB transceiver
 - ULPI interfaces: 12-pin/8-bit data version supporting "input" clocking mode
- TLL
 - ULPI TLL interfaces: 12-pin/8-bit data version or 8-pin/4-bit data version

23.2.5.1.1.1 Transceiver Interfaces

The USBTLL module is bypassed and the high-speed USB host controller ports 1 and 2 are connected directly to external transceivers.

The high-speed USB host subsystem supports only the 12-pin/8-bit data SDR version of the ULPI interface mode. The high-speed USB host controller uses its ULPI ports (UTMI ports cannot be used), the USBHOST.UHH_HOSTCONFIG[0] ULPI_BYPASS bit must be cleared to 0. In ULPI mode, all ports are in ULPI mode.

23.2.5.1.1.2 TLL

The high-speed USB host controller is coupled with the USBTLL module to compose the ULPI TLL interface modes.

The high-speed USB host controller uses its UTMI ports (bypassing the ULPI ports), the USBHOST.UHH_HOSTCONFIG[0] ULPI_BYPASS bit must be set to 1. In UTMI mode, all ports of the high-speed USB host controller are in UTMI mode.

At the USBTLL module level, a channel configuration for ULPI TLL interfaces must be set (see [Section 23.2.4.2.3](#)), *Channel Configurations*.

Two configurations are supported for ULPI TLL interfaces in the device:

- Configuration 2: ULPI synchronous TLL mode
- Configuration 4: Serial UTMI to serial ULPI TLL mode

In both configurations, the USBHOST.TLL_CHANNEL_CONF_i[2:1] CHANMODE field must be cleared to 0x0 (UTMI-to-ULPI TLL mode).

The selection of the ULPI TLL interface version, 12-pin/8-bit data version (SDR mode) or 8-pin/4-bit data version (DDR mode) is done through the USBHOST.TLL_CHANNEL_CONF_i[8] ULPIDDRMODE bit (0: SDR mode; 1: DDR mode).

23.2.5.1.2 Serial Interface Selection

The high-speed USB host subsystem supports the following modes with the serial interfaces:

- External USB transceiver configurations
 - Serial 6-pin PHY (transceiver) interfaces: 6-pin unidirectional (TX: DAT/SE0 or TX: DP/DM), 4-pin bidirectional and 3-pin bidirectional modes
- TLL configurations
 - Serial 6-pin TLL interfaces: 6-pin unidirectional (TX: DAT/SE0 or TX: DP/DM), 4-pin bidirectional, 3-pin bidirectional, and 2-pin bidirectional modes

The high-speed USB host controller is coupled with the USBTLL module to compose the serial interface modes.

The high-speed USB host controller uses its UTMI ports (bypassing the ULPI ports), and the USBHOST.UHH_HOSTCONFIG[0] ULPI_BYPASS bit must be set to 1. In UTMI mode, all ports of the high-speed USB host controller are in UTMI mode.

At the USBTLL module level, a channel configuration for serial interfaces must be set (see [Section 23.2.4.2.3](#), *Channel Configurations*).

One configuration is supported for serial interfaces in the device, the Configuration 6 including two modes:

- Serial UTMI to serial TLL
- Serial UTMI to serial PHY

The multimode-mode serial interface mode selection is done through the USBHOST.TLL_CHANNEL_CONF_i[27:24] FLSMODE field only when the main channel mode is serial (USBHOST.TLL_CHANNEL_CONF_i[2:1] CHANMODE field = 0x1 = UTMI-to-serial mode).

Table 23-98. USB Connectivity Mode Description

Usual Name	6-Pin Mode	6-Pin Mode (Alt)	3-Pin Mode	4-Pin Mode	6-Pin TLL Mode	6-Pin TLL Mode (Alt)	3-Pin TLL Mode	4-Pin TLL Mode	2-Pin TLL Mode	2-Pin TLL (Alt) Mode
USBHOST.TLL_CHANNEL_CONF_i[27:24] FLSMODE field	0x0	0x1	0x2	0x3	0x4	0x5	0x6	0x7	0xA	0xB
TX encoding	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM
RX encoding	DP/DM/RCV	DP/DM/RCV	DAT/SE0	DP/DM/RCV	DP/DM/RCV	DP/DM/RCV	DAT/SE0	DP/DM/RCV	DAT/SE0	DP/DM
Pin usage	Unidirect	Unidirect	Bidirect	Bidirect	Unidirect	Unidirect	Bidirect	Bidirect	Bidirect	Bidirect
Pin count	6	6	3	4	6 or 5 ⁽¹⁾	6 or 5 ⁽¹⁾	3	4 or 3 ⁽²⁾	2	2

⁽¹⁾ RxRCV and RxDP carry the same info: RxDP can drive both inputs of the remote controller and RxRCV kept unused

⁽²⁾ Same remark on TXDAT (for outputs) and RxRCV: TXDAT only is enough

23.2.5.2 USBTLL Registers

The USBTLL module contains two types of software-programmable registers.

23.2.5.2.1 TLL Control and Status Registers

Those 32-bit registers configure the various channels. Those registers are accessed by the MPU through the L4-Core interconnect. They are used mostly before the actual USB activity starts. Those registers are:

- OCP-standard registers for revision number, IRQ, clocking management, etc.
- TLL-specific registers

23.2.5.2.2 ULPI PHY-Side Registers

Each TLL channel emulates a ULPI transceiver and accordingly contains this set of 8-bit PHY-side registers, per ULPI specification. Those registers are:

- All ULPI-mandatory standard registers and fields
- A selection of ULPI-optional standard registers and fields, when relevant to the TLL context
- Vendor-specific registers, mapped at the addresses specified for that purpose in ULPI specification

Those registers are accessed by the external (that is, off-chip) link controller over the ULPI port of each channel, in the 0x100-byte ULPI address space, using the ULPI register access protocol.

Those registers are accessible by the L4-Core interconnect: The ULPI register sets of all channels are mapped side by side in the upper part of the L4-Core interconnect address space, where they can be accessed through byte accesses. In case of conflict between the two access modes, the access over ULPI will have priority, but both accesses will eventually complete correctly. For normal USB activity, all register accesses are expected to go over ULPI, and register changes caused by L4-Core interconnect accesses could compromise proper USB operation. The L4-Core interconnect access port is intended for:

- Miscellaneous test and debug
- Nonintrusive observation of ongoing USB operations (test)
- Context restore: During USB suspend periods, the USBTLL module can be switched off to save power.

Upon resume, the ULPI register contents have been lost and can be restored over L4-Core interconnect before USB operations restarts, provided they have been saved elsewhere beforehand.

23.2.6 High-Speed USB Host Subsystem Registers

23.2.6.1 USBTLL ULPI PHY-Side Register Space

Each ULPI port emulates a separate ULPI transceiver and as such gives access to a single set of ULPI PHY-side registers, mapped in a separate ULPI register space as specified in the ULPI specification. The ULPI protocol defines two register access methods: immediate and extended.

- The immediate space maps ULPI PHY-side registers in a 0x40- (64-) byte space (address is 6 bits wide). All ULPI PHY-side registers implemented in the USBTLL implementation are in the immediate space.
- The extended register space maps all ULPI PHY-side registers in a 0x100- (256-) byte space (address is 8 bits wide). The immediate space is remapped at the bottom of the extended space (that is, the extended access method can be used to access any ULPI register).

An access is recognized as extended by first pointing to a reserved dummy address 0x2F (EXTENDED_SET_ACCESS in [Table 23-99](#)). Immediate-mode accesses to this address over the ULPI interface are forbidden by the protocol and the USBTLL behavior is then undefined. Extended accesses to this address have no effect.

Some physical registers are accessible at more than one address, where write accesses perform different actions on the register value: (over-)write, set, clear. A read to any of the addresses returns the register value. The names of the set and clear registers are the write name postfixed with respectively _SET and _CLR. The register fields are described only once, at the write address (see [Section 23.2.6.7, EHCI Register Descriptions](#)).

Note: Some ULPI registers are cleared upon read.

23.2.6.2 L4-Core Interconnect Register Space

Table 23-100 lists the base address and address space for the high-speed USB host subsystem.

Table 23-100. Instance Summary

Module Name	Base Address (hex)	Size
USBTLL	0x4806 2000	4096 bytes
UHH_CONFIG	0x4806 4000	1024 bytes
OHCI	0x4806 4400	1024 bytes
EHCI	0x4806 4800	1024 bytes

23.2.6.3 High-Speed USB Host Subsystem Register Mapping Summary

The USBTLL single L4-Core interconnect gives access to both the TLL control and status registers, and the ULPI PHY-side registers.

Table 23-101 lists all the USBTLL registers mapped by the L4-Core interconnect, for the maximum 8-channel configuration.

Table 23-102, Table 23-103, and Table 23-104 list the high-speed USB host controller registers.

CAUTION

On ULPI PHY-side register access over L4-Core interconnect:

ULPI registers are byte-sized, and can only be accessed in this size. Attempts to access them over L4-Core interconnect using any other data size (16- or 32-bit) will complete without error (or any other warning), but will result in undefined behaviors.

The following cases can cause problems:

- If the ULPI register contents are defined as static (nonvolatile) by the software, a cache update may result in a burst of 32-bit access, with unwanted consequences.
- Some registers have adjacent overwrite, set, and clear addresses. An oversized write access could clear and set the same bit, which can have several results.
- Some registers are cleared on read: oversized read accesses to adjacent memory locations could cause unwanted clears.

Bits	Field Name	Description	Type	Reset
31:30	RESERVED		R	0x0
29:28	FSLSLINESTATE	Line state for Full/Low speed serial modes Bit1 = D-/ Bit0 = D+ 0x0: Single-ended 0 0x1: Full-Speed J = differential 1 0x2: Full-Speed K = differential 0 0x3: Single-ended 1 (illegal in USB)	R	0x0
27:24	FSLSMODE	Multiple-mode serial interface's mode select. Only when main channel mode is serial. No effect in other main modes. 0x0: "6pin" unidirectional PHY I/f mode. TX encoding is Dat/Se0 (default) 0x1: "6-pin" unidirectional PHY I/f mode. TX encoding is Dp/Dm 0x2: "3-pin" bidirectional PHY I/f mode. 0x3: "4-pin" bidirectional PHY I/f mode. 0x4: "6pin" unidirectional TLL mode. TX encoding is Dat/Se0 0x5: "6pin" unidirectional TLL mode. TX encoding is Dp/Dm 0x6: "3-pin" bidirectional TLL mode. 0x7: "4-pin" bidirectional TLL mode. 0xA: "2-pin" bidirectional TLL mode. Encoding is Dat/Se0 0xB: "2-pin" bidirectional TLL mode. Encoding is Dp/Dm	RW	0x0
23:21	RESERVED		R	0x0
20	TESTTXSE0	Force-Se0 transmit override value for serial mode test Don't care if TestEn = 0 (functional mode) or = TestTxen = 1 (tx = hiz) 0x0: drive differential value on TX according to TestTXDat 0x1: drive SE0 on TX	RW	0x0

Bits	Field Name	Description	Type	Reset
19	TESTTXDAT	Differential data transmit override value for serial mode test Don't care if TestEn = 0 (functional mode) or = TestTxen = 1 (tx = hiz) or TestSe0 = 1 (tx = se0) 0x0: Drive full-speed K = differential 0 0x1: Drive full-speed J = differential 1	RW	0x0
18	TESTTXEN	Differential data transmit override value for serial mode test Don't care if TestEn = 0 (functional mode) 0x0: Drive TX according to TestTXDat/Se0 0x1: Drive TX Hiz (no drive: pullups determine line state)	RW	0x0
17	TESTEN	Enable manual test override for serial mode TX path (from local controller's UTMI port) 0x0: No override. TX is from local link controller 0x1: Override enabled	RW	0x0
16	DRVVBUS	VBUS-drive for ChanMode = serial * In TLL config, write 1 to emulate serial-side VBUS drive * In PHY config, write 1 to report "VBUS valid" status (of actual VBUS) to UTMI controller 0x0: VBUS not driven 0x1: VBUS driven to 5V	RW	0x0
15	CHRGVBUS	VBUS-drive for ChanMode = serial * In TLL config, write 1 to emulate serial-side VBUS charge / pullup (OTG) * In PHY config, write 1 to reports "session valid" status (of actual VBUS) to UTMI controller 0x0: VBUS not charged, session not valid 0x1: VBUS charged, session valid	RW	0x0
14:12	RESERVED		R	0x0
11	ULPINOBITSTUFF	Disable bitstuff emulation in ULPI TLL for ULPI ChanMode 0x0: Bitstuff enabled, following USB standard 0x1: No bitstuff or associated delays (non-standard)	RW	0x0
10	ULPIAUTOIDLE	For ChanMode = ULPI TLL only. Allow the ULPI output clock to be stopped when ULPI goes into asynchronous mode (low-power, 3-pin serial, 6-pin serial). No effect in ULPI input clock mode. 0x0: ULPI output clock always-on 0x1: ULPI output clock stops during asynchronous ULPI modes	RW	0x1
9	UTMIAUTOIDLE	For ChanMode = ULPI TLL only. Allow the UTMI clock (output) to be stopped when UTMII goes to suspended mode (suspendm = 0) 0x0: UTMI clock output always on 0x1: UTMI clock output gated upon suspend	RW	0x1
8	ULPIDDRMODE	Select single/double data rate (SDR/DDR) mode for ULPI TLL Reset value depends on hardware generics ULPI_SDR/DDR_MODE. 0x0: SDR mode (8 data bit / 12 pin) 0x1: DDR mode (4 data bit / 8 pin)	RW	0x0
7	ULPIOUTCLKMODE	ULPI clocking mode select for ULPI TLL ChanMode 0x0: ULPI clock provided by LINK (that is, off-chip). ULPI clock is input 0x1: ULPI clock provided by PHY side (that is, TLL, from functional clock). ULPI clock is output	RW	0x1
6	TLLFULLSPEED	Sets PHY speed emulation in TLL (full/slow), which determines the line to pull up upon connect. The two connect source controls are: input m(N)_tlpuen, register field TllConnect. 0x0: Connect is Low-speed: D- pullup 0x1: Connect is Full-Speed: D+ pullup	RW	0x1

Bits	Field Name	Description	Type	Reset
5	TLLCONNECT	Emulation of Full/Low-Speed connect (that is, D+ resp D- pullup) for serial TLL modes. Speed is determined by field TllSpeed. 0x0: Unconnected 0x1: Connected	RW	0x0
4	TLLATTACH	Emulates cable attach/detach for all serial TLL modes: * ChanMode = serial, in TLL mode (FsLsMode) * ChanMode = ULPI, in serial mode (6pin/3pin TLL) 0x0: cable detach emulated on serial TLL 0x1: cable attach emulated on serial TLL	RW	0x1
3	UTMIISADEV	Select the cable end "seen" by UTMI side of TLL, that is, the emulated USB cable's orientation. Note that host must always be on A side, Peripheral on B side. Reset value depends on generic DEFUTMIISHOST. 0x0: UTMI side is peripheral, ULPI side is host 0x1: UTMI side is host, ULPI side is peripheral	RW	0x1
2:1	CHANMODE	Main channel mode selection 0x0: UTMI-to-ULPI TLL mode (HS capable): to ULPI controller 0x1: UTMI-to-serial (FS/LS) mode: to serial controller (TLL) or serial PHY 0x2: Transparent UTMI mode: to UTMI PHY 0x3: No mode selected	RW	0x0
0	CHANEN	Active-high channel enable. A disabled channel is unlocked and kept under reset. 0x0: Channel #N disabled 0x1: Channel #N enabled	RW	0x0

Physical Address	0x4806 4450		
Description	HC Root Hub Status Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRWE	RESERVED														OCIC	LPSC	DRWE	RESERVED												OCI	LPS

Bits	Field Name	Description	Type	Reset
31	CRWE	Clear remote wake-up enable. Write 0x0: no effect. Write 0x1: clears the device remote wake-up enable bit.	W	0x0
30:18	RESERVED	Reserved	R	0x0000
17	OCIC	Overcurrent indication change. This bit is automatically set when the overcurrent indicator bit changes. Write 0x0: no effect. Write 0x1: clears this bit.	RW	0x0

Bits	Field Name	Description	Type	Reset
16	LPSC	Local power status change. Always reads 0x0: The Root Hub does not support the local power status feature Write 0x0: no effect. Write 0x1: Sets port power status bits for all ports, if power switching mode is 0. Sets port power status bits for ports with their corresponding port power control mask bits cleared if power switching mode is 1.	RW	0x0
15	DRWE	Device remote wake-up enable. Enables a connect status change event as a resume event, causing a USB suspend to USB resume state transition and sets the resume detected interrupt status bit. Read 0x1: connect status change is a remote wake-up event. Read 0x0: connect status change is not a remote wake-up event. Write 0x0: no effect. Write 0x1: sets the device remote wake-up enable bit.	RW	0x0
14:2	RESERVED	Reserved	R	0x0000
1	OCI	Overcurrent indicator. Reports global overcurrent indication if global overcurrent reporting is selected. If per-port overcurrent protection is implemented this bit is always 0. 0x0: all power operations are normal 0x1: an overcurrent condition exists	R	0x0
0	LPS	Local power status. Always reads 0x0. Write 0x0: no effect. Write 0x1: When in global power mode (power switching mode = 0), turns off power to all ports. If in per-port power mode (power switching mode = 1), turns of power to those ports whose corresponding port power control mask bit is 0.	RW	0x0

Bits	Field Name	Description	Type	Reset
31:20	RESERVED	Reserved	R	0x000
19:17	RESERVED	Reserved	R	0x0
16	P_INDICATOR	Port indicator support indication This bit indicates whether the ports support port indicator control. 0x1: The port status and control registers include a read/write field for controlling the state of the port indicator.	R	0
15:12	N_CC	Number of Companion Controllers This field indicates the number of companion controllers associated with this USB 2.0 host controller. 0x0: There are no companion host controllers. Port-ownership hand-off is not supported. Only high-speed devices are supported on the host controller root ports. Others: there are companion USB 1.1 host controller(s). Port-ownership hand-off is supported. High-, full-, and low-speed devices are supported on the host controller root ports.	R	0x1
11:8	N_PCC	Number of Ports per Companion Controller This field indicates the number of ports supported per companion host controller. It is used to indicate the port routing configuration to system software. For example, if N_PORTS has a value of 6 and N_CC has a value of 2, then N_PCC can have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc. The number in this field must be consistent with N_PORTS and N_CC.	R	0x3
7	PRR	Port Routing Rules The first N_PCC ports are routed to the lowest-numbered function companion host controller, the next N_PCC ports are routed to the next lowest-function companion controller, and so on.	R	0
6:5	RESERVED	Reserved	R	0x0
4	PPC	Port Power control This field indicates whether the host controller implementation includes port power control.	R	1

Bits	Field Name	Description	Type	Reset
		0x0: The ports do not have port power switches. 0x1: The ports have port power switches.		
3:0	N_PORTS	Number of downstream ports This field specifies the number of physical downstream ports implemented on this host controller.	R	0x3

RESERVED																ASS	PSS	REC	HCH	RESERVED								IAA	HSE	FLR	PCD	USBEI	USBI

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Reserved	R	0x0000
15	ASS	Asynchronous Schedule Status The bit reports the current real status of the asynchronous schedule. 0x0: The status of the asynchronous schedule is disabled. 0x1: The status of the asynchronous schedule is enabled.	R	0
14	PSS	Periodic Schedule Status The bit reports the current real status of the periodic schedule. 0x0: The status of the periodic schedule is disabled. 0x1: The status of the periodic schedule is enabled.	R	0
13	REC	Reclamation It is used to detect an empty asynchronous schedule.	R	0
12	HCH	Host Controller Halted This bit is a 0 whenever the USBHOST.USBCMD[0] RS bit is a 1. The host controller sets this bit to 1 after it has stopped executing as a result of the RS bit being set to 0, either by software or by the host controller hardware.	R	1
11:6	RESERVED	Reserved	R	0x00
5	IAA	Interrupt on Async Advance System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a 1 in the USBHOST.USBCMD[6] IAAD bit. This status bit indicates the assertion of that interrupt source.	RW	0
4	HSE	Host System Error The host controller sets this bit to 1 when a serious error occurs during a host system access involving the host controller module.	RW	0
3	FLR	Frame List Rollover The host controller sets this bit to 1 when the USBHOST.FRINDEX rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size.	RW	0
2	PCD	Port Change Detect The host controller sets this bit to 1 when any port for which the USBHOST.PORTSC_i[13] PO bit is set to 0 has a change bit transition from a 0 to a 1 or a USBHOST.PORTSC_i[6] FPR bit transition from a 0 to a 1. This bit is also set as a result of the USBHOST.PORTSC_i[1] CSC bit being set to 1 after system software has relinquished ownership of a connected port by writing a 1 to a USBHOST.PORTSC_i[13] PO bit.	RW	0
1	USBEI	USB Error Interrupt The host controller sets this bit to 1 when completion of a USB transaction results in an error condition.	RW	0
0	USBI	USB Interrupt	RW	0

Bits	Field Name	Description	Type	Reset
		<p>The host controller sets this bit to 1 on completion of a USB transaction, which results in the retirement of a transfer descriptor that had its IOC bit set.</p> <p>The host controller also sets this bit to 1 when a short packet is detected (actual number of bytes received was less than the expected number of bytes).</p>

General-Purpose I/O (GPIO) Interface

This chapter describes the general-purpose I/O (GPIO) interface for the OMAP35x Applications Processor.

24.1 General-Purpose I/O (GPIO) Interface Overview

The general-purpose interface combines six general-purpose input/output (GPIO) banks.

Each GPIO module provides 32 dedicated general-purpose pins with input and output capabilities; thus, the general-purpose interface supports up to 192 (6 x 32) pins.

These pins can be configured for the following applications:

- Data input (capture)/output (drive)
- Keyboard interface with a debounce cell
- Interrupt generation in active mode upon the detection of external events. Detected events are processed by two parallel independent interrupt-generation submodules to support biprocessor operations.
- Wake-up request generation in idle mode upon the detection of external events

These modules do not include pad control (pull up/down control, open-drain feature). For more information, see the *System Control Module* chapter.

24.1.1 Global Features

The GPIO modules include the following global features:

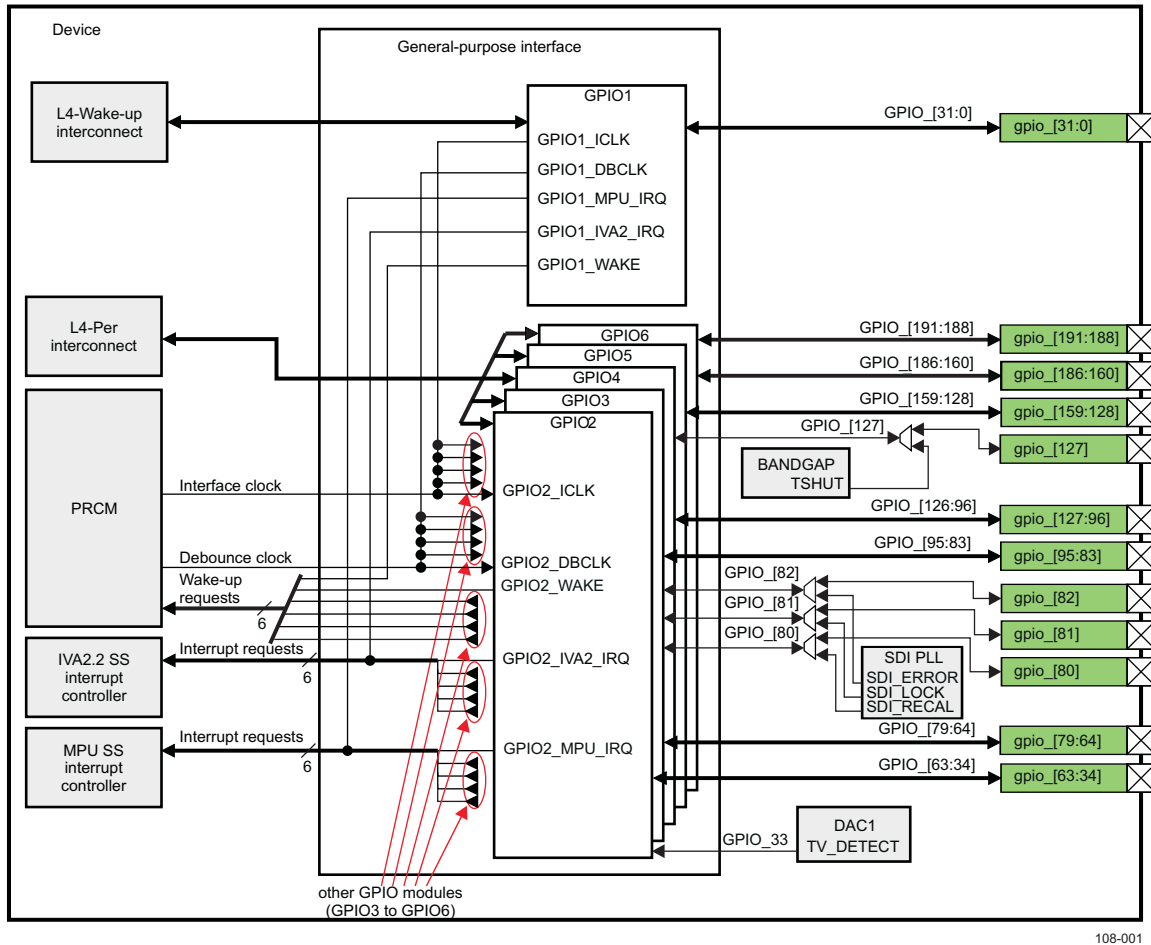

- Synchronous interrupt requests in active mode from each channel are processed by two identical interrupt generation submodules used independently by the imaging video and audio accelerator (IVA2.2) and the microprocessor unit (MPU) subsystems. One of these interrupts is mapped on the IVA2.2 subsystem interrupt controller and the other on the MPU subsystem interrupt controller.
- Asynchronous wake-up requests in idle mode from input channels are merged together to issue one wake-up signal per GPIO module.
- Data input (capture)/output (drive)
- Power management support

The general-purpose interface has 12 interrupt lines (two interrupt lines per GPIO module instance).

Each GPIO module produces a wake-up request signal to the power, reset, and clock management (PRCM) module.

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

Figure 24-1 shows an overview of the general-purpose interface.

Figure 24-1. General-Purpose Interface Overview

108-001

Each channel in the GPIO modules has the following features:

- The GPIOi.GPIO_OE register controls the output capability for each pin.
- The output line level reflects the value written in the GPIOi.GPIO_DATAOUT register through the L4 interconnect.
- The input line can be fed to the GPIO module through an optional and configurable debounce cell. (The debouncing time value is global for all ports of one GPIO module, so up to five different debouncing time values are possible.)
- The input line value is sampled into the GPIOi.GPIO_DATAIN register and can be read through the L4 interconnect.
- In active mode, the input line can be used through level and edge detectors to trigger synchronous interrupts. The edge (rising, falling, or both) or the level (logical 0, logical 1, or both) used can be configured.
- In idle mode, the input line can be used to activate the asynchronous wake-up request (on edge detection: rising edge, falling edge, or both).

The module provides an alternative to the atomic test and set operations for the following registers:

- GPIOi.GPIO_DATAOUT
- GPIOi.GPIO_IRQENABLE1
- GPIOi.GPIO_IRQENABLE2
- GPIOi.GPIO_WAKEUPENABLE

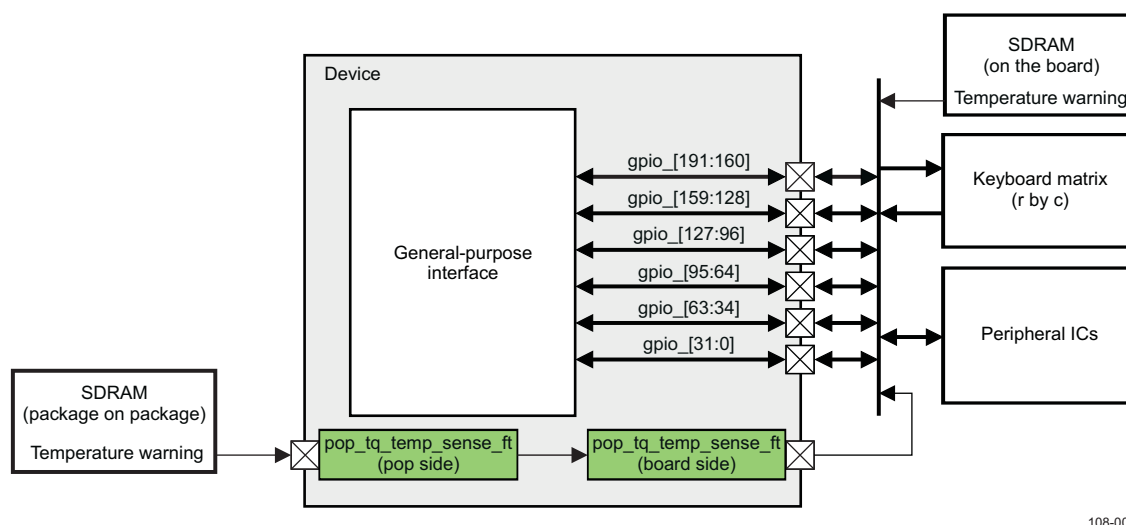

For these registers, the modules implement the set-and-clear protocol register update (see [Section 24.5.2, Set-and-Clear Instructions](#)).

24.2 General-Purpose Interface Environment

The general-purpose interface combines six GPIO modules for a flexible, user-programmable, general-purpose input/output (I/O) controller. The general-purpose interface implements functions that are not implemented with the dedicated controllers in the device and require simple input and/or output software-controlled signals. The general-purpose interface allows a variety of custom connections and expands the I/O capabilities of the system to the real world.

Figure 24-2 shows a typical application using the general-purpose interface.

Figure 24-2. General-Purpose Interface Typical Application System Overview

108-002

Note: Temperature Sensing

Most memories provide a temperature sensor to control the auto-refresh duty cycle. The device monitors the temperature of the external memory using the pop_tq_temp_sense_ft ball and a GPIO input. To do this, pop_tq_temp_sense_ft is connected to a GPIO through the customer board. This feature is application-dependent.

CAUTION

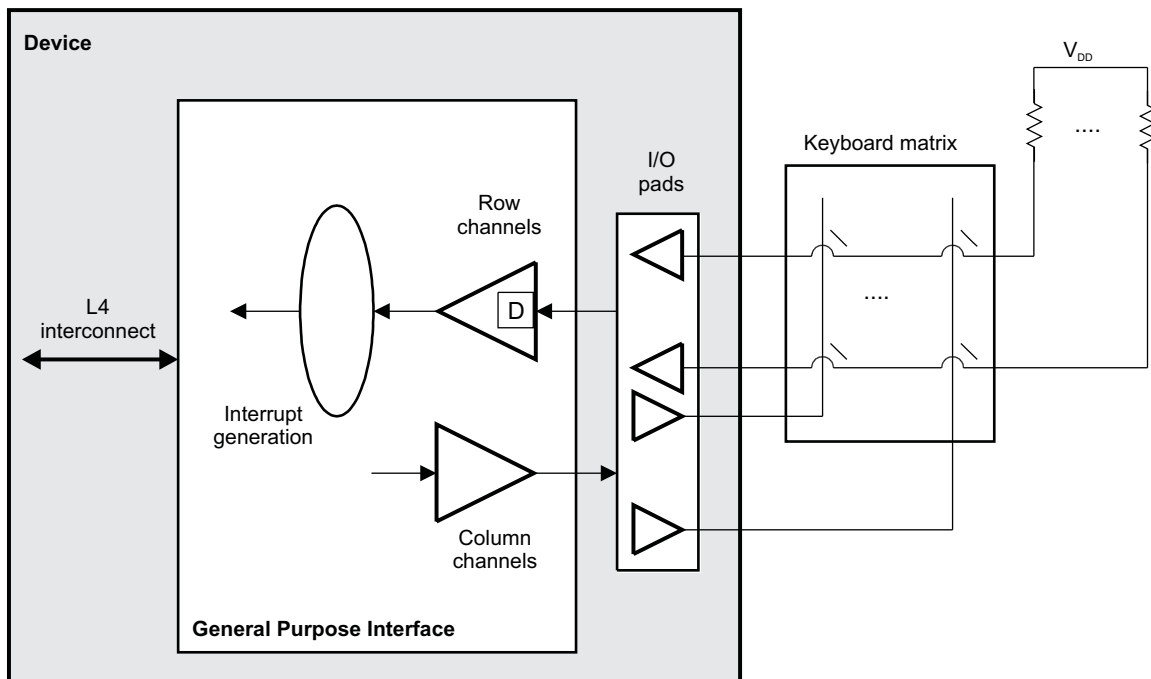

Due to buffer strength, an external serial resistor must be connected to the balls corresponding to gpio_120 to gpio_129.

The general-purpose interface can physically connect the device to a keyboard matrix and peripheral integrated circuits (ICs).

24.2.1 GPIO as a Keyboard Interface

The general-purpose interface can be used as a keyboard interface. You can dedicate channels based on the keyboard matrix = * c). Figure 24-3 shows row channels configured as inputs with the input debounce feature enabled. The row channels are driven high with an external pullup. Column channels are configured as outputs and drive a low level.

Figure 24-3. General-Purpose Interface used as a Keyboard Interface

108-003

When a keyboard matrix key is pressed, the corresponding row and column lines are shorted together and a low level is driven on the corresponding row channel. This generates an interrupt based on the proper configuration (see [Section 24.5.3, Interrupt and Wakeup](#)).

When the keyboard interrupt is received, the processor (MPU and/or IVA2.2 subsystem) can disable the keyboard interrupt and scan the column channels for the key coordinates.

- The scanning sequence has as many states as column channels: For each step in the sequence, the processor drives one column channel low and the others high.
- The processor reads the values of the row channels and thus detects which keys in the column are pressed.

At the end of the scanning sequence, the processor establishes which keys are pressed. The keyboard interface can then be reconfigured in the interrupt waiting state.

24.2.2 General-Purpose Interface Functional Interfaces

24.2.2.1 Basic General-Purpose Interface Pins

Table 24-1 lists the interface pins of the general-purpose interface.

Table 24-1. General-Purpose Interface Functional Pins Description

Signal Name	I/O ⁽¹⁾	Description ⁽²⁾	Module Reset Value
gpio_[31:0]	I/O	GPIO in configuration mode 4.	Input until software configuration
gpio_[186:34]	I/O	GPIO in configuration mode 4.	Input until software configuration
gpio_[191:188]	I/O	GPIO in configuration mode 4.	Input until software configuration

⁽¹⁾ I = Input, O = Output

⁽²⁾ See the *System Control Module* chapter, for more information about pin configuration modes.

24.3 General-Purpose Interface Integration

24.3.1 Description

Figure 24-4 highlights the general-purpose interface integration in the device.

Figure 24-4. General-Purpose Interface Integration Overview

108-004

24.3.1.1 Clocking, Reset, and Power-Management Scheme

24.3.1.1.1 Clocking

Each GPIO module uses two clocks:

- Debounce clock: The 32-KHz debounce clock, GPIOi_DBCLK, (where I = 1, 2, 3, 4, 5, and 6, with one debounce clock per module), comes from the PRCM module and is used for the debounce cell logic (without the corresponding configuration registers). This cell can sample the input line and filters the input level using a programmed delay.

For GPIO2 to GPIO6, this clock is controlled by the EN_GPIOi (where I = 2 to 6) bit PRCM.CM_FCLKEN_PER (0: disabled, 1: enabled the clock). For GPIO1, this clock is controlled by EN_GPIO1 bit PRCM.CM_FCLKEN_WKUP[3] (0: disabled, 1: enabled the clock) for GPIO1.

- Interface clock: The interface clock, GPIOi_ICLK (where I = 1, 2, 3, 4, 5, and 6), comes from the PRCM module and is used throughout the GPIO module (except within the debounce cell logic). The interface clock clocks the data exchanges between the L4 interconnect and the internal logic. The clock-gating features allow module power consumption to be adapted to the activity.

For GPIO1, this clock is controlled by the EN_GPIO1 bit PRCM.CM_ICLKEN_WKUP[3] (0: disabled, 1: enabled the clock) and AUTO_GPIO1 bit PRCM.CM_AUTOIDLE_WKUP[3] (enables/disables automatic control of the interface clock). For GPIO2 to GPIO6, this clock is controlled by the EN_GPIOi (where I = 2 to 6) bit PRCM.CM_ICLKEN_PER (0: disabled, 1: enabled the clock) and AUTO_GPIOi (where I = 2 to 6) bit PRCM.CM_AUTOIDLE_PER (enables/disables automatic control of the interface clock). Table 25-2 describes the GPIO module clocks.

Table 24-2. Clocks

Attribute	Frequency	Name	Mapping	Comments
Debounce clock	32 KHz	GPIOi_DBCLK, where I = 2 to 6	PER_32K_ALWON_F CLK	Source is PRCM module.
		GPIO1_DBCLK	WKUP_32K_CLK	
Interface clock	Depends on PRCM registers settings	GPIOi_ICLK, where I = 2 to 6	PER_L4_ICLK	
		GPIO1_ICLK	WKUP_L4_ICLK	

24.3.1.1.2 Reset

The general-purpose interface can be reset by using the domain reset (hardware reset) or by setting a dedicated configuration bit (software reset) in each GPIO module.

- Hardware reset: The GPIO2 to GPIO6 modules are attached to the PER_RST reset domain. The GPIO1 module is attached to the WKUP_RST reset domain.

The hardware reset has a global reset action on the GPIO modules of the general-purpose interface. All configuration registers and internal logic are reset when it is active (low level). In each GPIO module, the RESETDONE bit GPIOi.GPIO_SYSTATUS[0] monitors the internal reset status; it is set when the reset completes. For more information, see the *Power, Reset, and Clock Management* chapter.

- Software reset: Each GPIO module has its own software reset using the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit (where I = 1, 2, 3, 4, 5, or 6). The software reset has the same effect as the hardware reset signal, but this reset can be applied on one module or more.

Writing 1 to SOFTRESET bit GPIOi.GPIO_SYSCONFIG[1] (where I = 1, 2, 3, 4, 5, or 6) resets the module. Bit value 1 remains until the reset is complete. When the software reset is complete, the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset. The GPIOi.GPIO_SYSTATUS[0] RESETDONE is cleared during a software reset. This bit is set to 1 when the software reset is complete.

24.3.1.1.3 Power Domain

The GPIO1 module is attached to the WKUP power domain (see the *Power, Reset, and Clock Management* chapter). This domain is composed of the logic permanently supplied to manage domain power state transitions and detect wake-up events. The WKUP power domain is continuously active. The GPIO2 to GPIO6 modules are attached to the PER power domain (see the *Power, Reset, and Clock Management* chapter). The PER power domain is not active continuously.

24.3.1.1.4 Power Management

24.3.1.1.4.1 Idle Scheme

To save dynamic consumption, an efficient idle scheme is based on the following:

- An efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated and deactivated safely without requiring a complex software management.

The idle mode request, idle acknowledge, and wake-up request (GPIOi_SWAKEUP, where I = 1, 2, 3, 4, 5, and 6) are sideband signals between the PRCM module and the general-purpose interface (see [Section 24.3.1.2, Hardware Requests](#)).

24.3.1.1.4.2 Operating Modes

The following four operating modes are defined for the modules:

- Active mode: The module runs synchronously on the interface clock; interrupts can be generated based on the configuration and external signals.
- Idle mode: Power-saving mode with the module in a waiting state. The interface clock can be stopped, an interrupt cannot be generated, and a wake-up signal can be generated based on the configuration and external signals.

If the debounce clock provided by the PRCM module is active, the debounce cell can sample and filter the input to generate a wake-up event. If the debounce clock is inactive, the debounce cell gates all input signals and thus cannot be used.

- Inactive mode: The module has no activity. The interface clock can be stopped, an interrupt cannot be generated, and the wake-up feature is inhibited.
- Disabled mode: The module is not used. The internal clock paths are gated, and an interrupt or wake-up request cannot be generated.

The idle and inactive modes are configured within the module and activated on request by the PRCM module (see the *Power, Reset, and Clock Management* chapter) through sideband signals (see [Section 24.3.1.1.4.3, System Power Management and Wake-up](#)).

The disabled mode is set by software through a dedicated configuration bit, the GPIOi.GPIO_CTRL[0] DISABLEMODULE bit (0: the module is enabled and clocks are not gated; 1: the module is disabled and clocks are gated). It unconditionally gates the internal clock paths that are not used for the L4 interconnect.

24.3.1.1.4.3 System Power Management and Wake-Up

The PRCM module can require the GPIO modules to be idled for power saving purposes.

The general-purpose interface has six identical idle mode request/acknowledge (handshake) mechanisms with the PRCM module (see [Figure 24-4](#) and [Section 24.3.1.2, Hardware Requests](#)): one per GPIO module. The general-purpose interface allows the GPIO modules to enter idle mode based on the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE field.

The idle acknowledge depends on the configuration and activity of each GPIO module:

- Smart-idle mode (recommended)
When the GPIO module is configured in smart-idle mode (GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE field [10]) and receives an idle request from the PRCM module (for GPIO2 to GPIO6: the corresponding bits in the PRCM.CM_FCLKEN_PER and PRCM.CM_ICLKEN_PER registers cleared to 0 or the corresponding bit in the PRCM.CM_AUTOIDLE_PER bit set to 1 and L4 interface clock idle transitions; for GPIO1: PRCM.CM_FCLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, PRCM.CM_ICLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, or PRCM.CM_AUTOIDLE_WKUP[3] AUTO_GPIO1 bit set to 1 and L4 interface clock idle transitions), the GPIO module checks for more activity (capture of the input GPIO pins in the GPIOi.GPIO_DATAIN register is complete with no pending interrupt; all interrupt status bits are cleared) ; and there is no access to GPIO.GPIO_DEBOUNCINGTIME register pending to be synchronized.
Idle acknowledge is then asserted and the module enters in idle-mode. It waits for active system clock gating by the PRCM module (when all peripherals supplied by the same L4 interface clock domain are also ready for idle).

Idle mode (that is, when the PRCM module gates the interface clock), no interrupt occurs and the module is ready to issue a wake-up request.

When the expected transition occurs on an enabled GPIO input pin, the GPIO module exits from idle mode, if the GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP bit is set to 1 (wake-up capability enabled), and the corresponding bit in the PRCM.PM_WKEN_PER register is also set to 1 for the GPIO2 to GPIO6 modules, and/or the PRCM.PM_WKEN_WKUP[3] EN_GPIO1 bit is also set to 1 for GPIO1.

- Force-idle mode

When the GPIO module is configured in force-idle mode (GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE field [00]) and receives an idle request from the PRCM module (for the GPIO2 to GPIO6: the corresponding bits in the PRCM.CM_FCLKEN_PER and PRCM.CM_ICLKEN_PER registers cleared to 0 or the corresponding bit in the PRCM.CM_AUTOIDLE_PER bit set to 1 and L4 interface clock idle transitions; for the GPIO1: PRCM.CM_FCLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, PRCM.CM_ICLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, or PRCM.CM_AUTOIDLE_WKUP[3] AUTO_GPIO1 bit set to 1 and L4 interface clock idle transitions), the GPIO module waits unconditionally for active system clock gating by the PRCM module. (This occurs only when all peripherals supplied by the same L4 interface clock domain are also ready for idle.)

When in idle mode (that is, when the PRCM module gates the interface clock), the module (in inactive mode) has no activity, the interface clock paths are gated, an interrupt cannot be generated, and the wake-up feature is totally inhibited.

- No-idle mode

When the GPIO module is configured in no-idle mode (GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE field [01]) and receives an idle request from the PRCM module (for the GPIO2 to GPIO6: the corresponding bits in the PRCM.CM_FCLKEN_PER and PRCM.CM_ICLKEN_PER registers cleared to 0 or the corresponding bit in the PRCM.CM_AUTOIDLE_PER bit set to 1 and L4 interface clock idle transitions; for the GPIO1: PRCM.CM_FCLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, PRCM.CM_ICLKEN_WKUP[3] EN_GPIO1 bit cleared to 0 or PRCM.CM_AUTOIDLE_WKUP[3] AUTO_GPIO1 bit set to 1 and L4 interface clock idle transitions), the GPIO module does not go to the idle mode and the idle acknowledge is never sent.

Note: The GPIO2 to GPIO6 idle state can be checked by reading the corresponding status bits in the PRCM.CM_IDLEST_PER register (0: active, 1: idle) and is idle only when the GPIO2 to GPIO6 modules are configured in smart-idle mode and have asserted their idle acknowledge.

The GPIO1 idle state can be checked by the PRCM.CM_IDLEST_WKUP[3] ST_GPIO1 bit (0: idle, 1: active) and is idle only when the GPIO1 module is configured in smart-idle mode and has asserted its idle acknowledge.

The GPIO2 to GPIO6 wake-up status can be checked by accessing the corresponding bits in the PRCM.PM_WKST_PER register (read 0: no wakeup occurred; read 1: wakeup occurred; write 1: status bit reset).

The GPIO1 wake-up status can also be checked by the PRCM.PM_WKST_WKUP[3] ST_GPIO1 bit (read 0: no wakeup occurred; read 1: wakeup occurred; write 1: status bit reset).

24.3.1.1.4.4 Module Power Saving

The GPIO module has local power management by internal clock-gating features:

- Internal interface clock gating: The clock for the L4 interconnect logic can be gated when the module is not accessed, if the GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit is set. Otherwise, this logic is free-running on the interface clock.
- Clock gating for the input data sample logic: Clock for the input data sample logic can be gated when the data in register is not accessed.
- Clock gating for the event detection logic: Each GPIO module implements four clock groups used for the logic in the synchronous events detection. Each group of eight input GPIO pins has a separate enable signal depending on the edge/level detection register setting. If a group requires no detection, the corresponding clock is gated off (see [Section 24.5.1, Power Saving by Grouping the Edge/Level Detection](#)). All channels are also gated using a one-out-of-N scheme. N is the GATINGRATIO field

GPIOi.GPIO_CTRL[2:1] and can take the values 1 (b00), 2 (0b01), 4 (b10), or 8 (0b11). The interface clock is enabled for this logic one cycle every N cycles. When N is equal to 1, there is no gating and this logic is free-running on the interface clock. When N is 2, 4, or 8, this logic is running at the equivalent frequency of interface clock frequency divided by N.

- Inactive mode: In inactive mode, all internal clock paths are gated.
- Disabled mode: All internal clock paths not used for the L4 interconnect are gated. The GPIOi.GPIO_CTRL[0] DISABLEMODULE bit controls a clock-gating feature at the module level. When set to 1, this bit forces clock gating for all internal clock paths. Module internal activity is suspended. The L4 interconnect is not affected by this bit.

The interface clock gating is controlled with the GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit, which is used to save power when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits.

24.3.1.2 Hardware Requests

24.3.1.2.1 Interrupt Requests

All interrupt sources (the 32 input GPIO channels) are merged to issue two synchronous interrupt requests in each GPIO module. Thus, the general-purpose interface has 12 interrupt lines (two interrupt lines per GPIO module instance).

Synchronous interrupt request lines 1 and 2 are active depending on their respective interrupt enable 1 and 2 registers (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2).

- Synchronous interrupt request line 1 is mapped on the MPU interrupt controller.
- Synchronous interrupt request line 2 is mapped on the IVA2.2 interrupt controller.

Table 24-3 lists the interrupt lines that are driven out from the general-purpose interface to the MPU subsystem and IVA2.2 subsystem interrupt cont

Table 24-3. Interrupts

Name	Mapping	Comments
GPIO1 Module		
GPIO1_MPU_IRQ	M_IRQ_29	Destination is the MPU subsystem interrupt controller.
GPIO1_IVA2_IRQ	IVA2_IRQ[28]	Destination is the IVA2.2 subsystem interrupt controller.
GPIO2 Module		
GPIO2_MPU_IRQ	M_IRQ_30	Destination is the MPU subsystem interrupt controller.
GPIO2_IVA2_IRQ	IVA2_IRQ[29]	Destination is the IVA2.2 subsystem interrupt controller.
GPIO3 Module		
GPIO3_MPU_IRQ	M_IRQ_31	Destination is the MPU subsystem interrupt controller.
GPIO3_IVA2_IRQ	IVA2_IRQ[30]	Destination is the IVA2.2 subsystem interrupt controller.
GPIO4 Module		
GPIO4_MPU_IRQ	M_IRQ_32	Destination is the MPU subsystem interrupt controller.
GPIO4_IVA2_IRQ	IVA2_IRQ[31]	Destination is the IVA2.2 subsystem interrupt controller.
GPIO5 Module		
GPIO5_MPU_IRQ	M_IRQ_33	Destination is the MPU subsystem interrupt controller.
GPIO5_IVA2_IRQ	IVA2_IRQ[32]	Destination is the IVA2.2 subsystem interrupt controller.
GPIO6 Module		
GPIO6_MPU_IRQ	M_IRQ_34	Destination is the MPU subsystem interrupt controller.
GPIO6_IVA2_IRQ	IVA2_IRQ[43]	Destination is the IVA2.2 subsystem interrupt controller.

24.3.1.2.1.1 Wake-Up Generation

The GPIO1 module of the general-purpose interface is attached to the WKUP power domain (see the *Power, Reset, and Clock Management* chapter) and can wake up the system.

Note: The GPIO2 to GPIO6 modules belong to the PER power domain and thus have wake-up system capability only when the PER power domain is active.

All wake-up sources (the 32 input GPIO channels) are merged together to issue a single asynchronous wake-up request in each GPIO module following the expected transition(s) (based on register programming). Each GPIO module generates a wake-up signal to the PRCM module.

Note: Only gpio_1, gpio_9, gpio_10, gpio_11, gpio_30 and gpio_31 can be used to generate a direct wakeup event. The other GPIO1 pins can not be used to generate a direct wake up event because they are connected to the device I/O pad logic in the CORE power domain (VDD2). When the CORE power domain is off, the I/O pins of the GPIO1 module, which are supplied by VDD2, cannot generate a wake-up event.

The asynchronous wake-up request line is active based on the GPIOi.GPIO_WAKEUPENABLE register (where i = 1, 2, 3, 4, 5, and 6).

CAUTION

The wake-up capabilities of the GPIO2 to GPIO6 modules are operational only when the PER power domain is active.

Table 24-4 shows the wake-up signals mapping.

Table 24-4. Wake-Up Signals

Name	Mapping	Comments
GPIOi_WAKE	GPIOi_SWAKEUP	Where i = 1, 2, 3, 4, 5, and 6. Destination is the PRCM module.

Table 24-5 describes the GPIO channels.

Table 24-5. GPIO Channel Description

Channel Number	Type ⁽¹⁾	Mapping	Wake-Up Feature	Comments
GPIO1 Module				
[31:0]	I/O	gpio_[31:0]	Yes	GPIO ⁽²⁾
GPIO2 Module				
[0]	I	-	No	Not available on external balls. Read value is always 0.
[1]	I	TV_DETECT	Yes ⁽³⁾	Internal TV detection signal from the 10-bit composite/luma video DAC1
[31:2]	I/O	gpio_[63:34]	Yes ⁽³⁾	GPIO ⁽²⁾
GPIO3 Module

[30:20]	I/O	gpio_[126:116]	Yes ⁽³⁾	GPIO ⁽²⁾
[31]	I/O	gpio_127	Yes ⁽³⁾	GPIO ⁽²⁾
	I	TSHUT	Yes ⁽³⁾	Internal TSHUT signal from the BANDGAP module for the SRAMs LDOs ⁽⁴⁾
GPIO5 Module				
[31:0]	I/O	gpio_[159:128]	Yes ⁽³⁾	GPIO ⁽²⁾
GPIO6 Module				
[26:0]	I/O	gpio_[186:160]	Yes ⁽³⁾	GPIO ⁽²⁾
[27]	I	-	No	Not available on external balls. Read value is always 0.
[31:28]	I/O	gpio_[191:188]]	Yes ⁽³⁾	GPIO ⁽²⁾

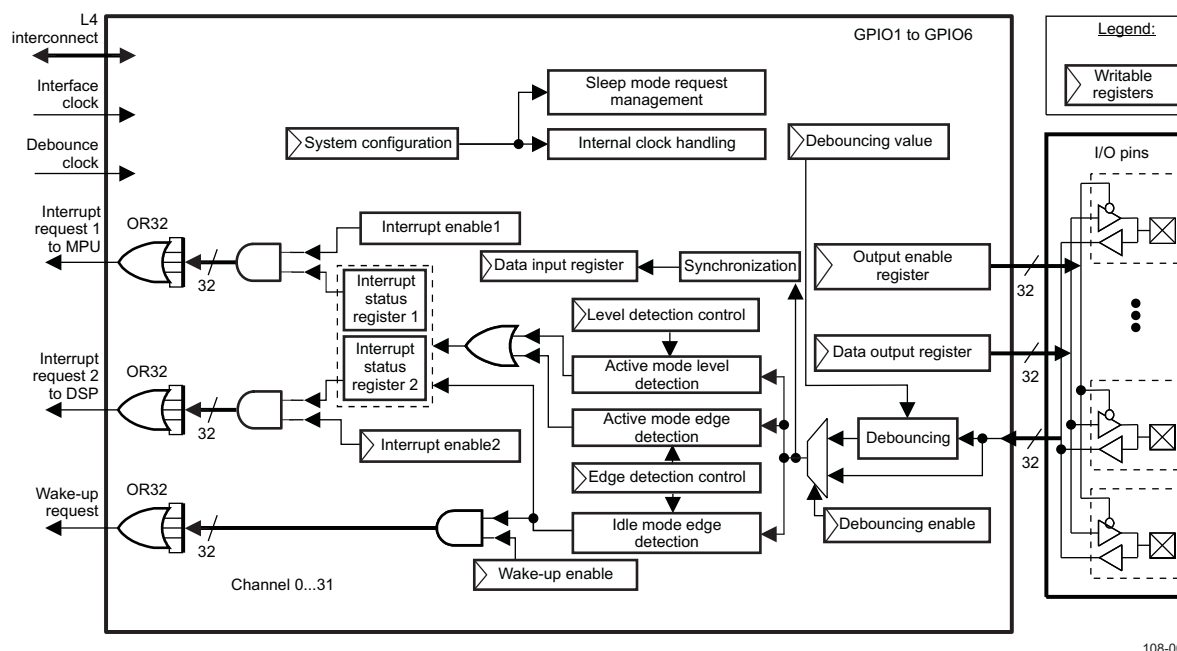

⁽⁵⁾ See Chapter 12, Camera ISP

Note: The thermal shutdown comparator output signal (TSHUT) is an output from the BANDGAP module. This signal is low during normal operation and goes high during a thermal shutdown event. When channel 31 of the GPIO4 is not connected to a ball of the device (the corresponding pin is configured in a mode different from the configuration mode 4; see \the *System Control Module* chapter, for more information about pin configuration), TSHUT is connected to channel 31 of the GPIO4, and an interrupt can be generated when a low-to-high transition occurs on TSHUT whether or not the interrupt generation for channel 31 of the GPIO4 is correctly configured.

24.4 General-Purpose Interface Functional Description

Figure 24-5 shows the general-purpose interface description.

Figure 24-5. General-Purpose Interface Description

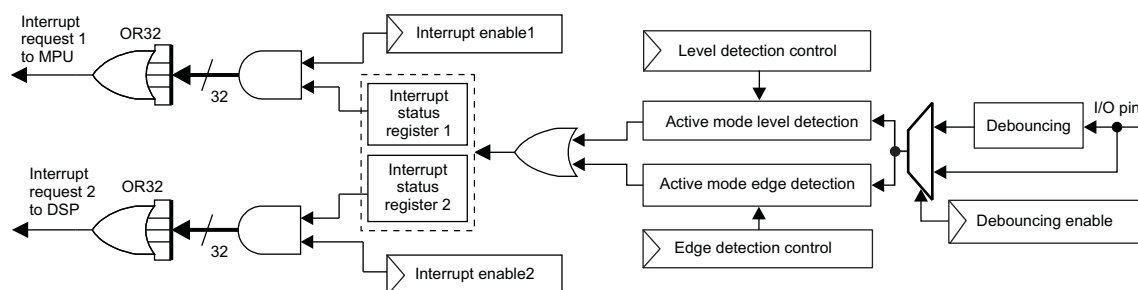

108-005

Figure 24-5 details the GPIO modules in the general-purpose interface block diagram with their configuration registers and their main functional paths:

- The synchronous path (for active mode operation) used to generate a synchronous interrupt request on expected event detection on any input GPIO; the synchronous interrupt request lines 1 and 2 are active based on their respective interrupt enable 1 and 2 registers (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2). See Figure 24-6.

Figure 24-6. Synchronous Path

108-006

- The asynchronous path (for idle mode operation) used to generate an asynchronous wake-up request on the expected edge detection on any input GPIO; the asynchronous wake-up request line is active based on the wake-up enable register. See Figure 24-7.

Figure 24-7. Asynchronous Path

- The blocks handling the internal clock (clock gating) and managing the sleep mode request/acknowledge protocol (enabling the synchronous path in active mode and the asynchronous path in idle mode).

24.4.1 Interrupt and Wake-Up Features

24.4.1.1 Synchronous Path: Interrupt Request Generation

The general-purpose interface has 12 interrupt lines (two interrupt lines per GPIO module instance). The 12 interrupt signals are GPIOi_MPU_IRQ (used by the MPU subsystem) and GPIOi_IVA2_IRQ (used by the IVA2.2 subsystem), where $i = 1, 2, 3, 4, 5$, and 6.

Synchronous interrupt requests from each channel are processed by two identical interrupt generation submodules used independently by the IVA2.2 subsystem and the MPU subsystem. Each submodule controls its own synchronous interrupt request line and has its own interrupt enable (GPIOi.GPIO_IRQENABLE1 or GPIOi.GPIO_IRQENABLE2) and interrupt status (GPIOi.GPIO_IRQSTATUS1 or GPIOi.GPIO_IRQSTATUS2) registers. The interrupt enable register selects the channel(s) considered for the interrupt request generation, and the interrupt status register determines which channel(s) activate the interrupt request. Event detection on GPIO channels is reflected in the interrupt status registers independent of the content of the interrupt enable registers.

In active mode, when the GPIO configuration registers are set to enable the interrupt generation (see [Section 24.5.3, Interrupt and Wakeup](#)), a synchronous path samples the transitions and levels on the input GPIO with the internally gated interface clock (see [Section 24.3.1.1.4.4, Module Power Saving](#)). When an event matches the programmed settings (see [Section 24.5.3, Interrupt and Wakeup](#)), the corresponding bit in the interrupt status register is set to 1 and, on the following interface clock cycle, the interrupt lines 1 and/or 2 are activated (depending on the interrupt enable registers).

Because of the sampling operation, the minimum pulse width on the input GPIO to trigger a synchronous interrupt request is two times the internally gated interface clock period (the internally gated interface clock period equals N times the interface clock period; see [Section 24.3.1.1.4.4, Module Power Saving](#)). This minimum pulse width must be met before and after any expected level transition detection. Level detection requires the selected level to be stable for at least two times the internally gated interface clock period to trigger a synchronous interrupt.

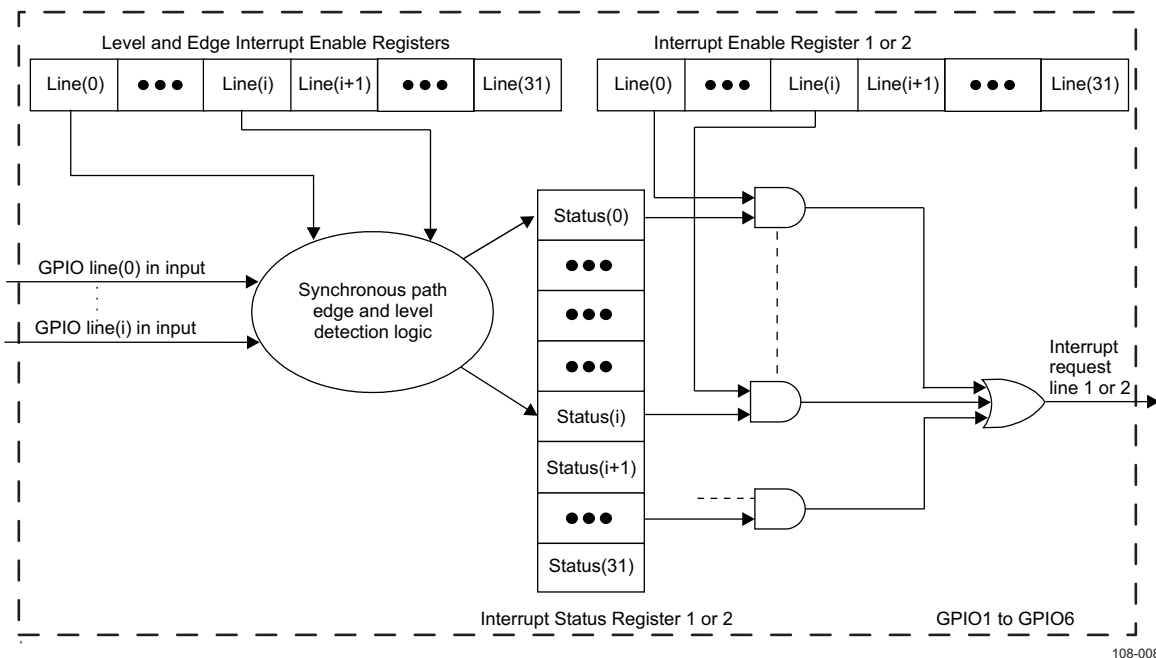

Because the module is synchronous, latency is minimal between the expected event occurrence and the activation of the interrupt line(s). This latency must not exceed four internally gated interface clock cycles + one interface clock cycle when the debounce feature is not used.

When the debounce feature is active, the latency depends on the debouncing time register (GPIOi.GPIO_DEBOUNCINGTIME) value (see [Section 24.5.5, Debouncing Time](#)) and is less than three internally gated interface clock cycles + two interface clock cycle + GPIOi.GPIO_DEBOUNCINGTIME register value debounce clock cycles + three debounce clock cycles.

Synchronous interrupt request line 1 is mapped on the MPU interrupt controller.

Synchronous interrupt request line 2 is mapped on the IVA2.2 interrupt controller.

Figure 24-8 shows an overview of the interrupt request generation.

Figure 24-8. Interrupt Request Generation

108-008

24.4.1.2 Asynchronous Path: Wake-Up Request Generation

The general-purpose interface has six wake-up lines (one wake-up line per GPIO module instance) connected to the PRCM module.

Asynchronous wake-up requests from input channels are merged to issue one wake-up signal to the system per GPIO module. The wake-up enable register (GPIOi.GPIO_WAKEUPENABLE) selects the channel(s) considered for the wake-up request generation. The asynchronous wake-up request is reflected into the synchronous interrupt status registers (GPIOi.GPIO_IRQSTATUS1 and GPIOi.GPIO_IRQSTATUS2).

In idle mode (the interface clock is shut down and the GPIO configuration registers are programmed; see Section 24.5.3, *Interrupt and Wakeup*), an asynchronous path detects the expected transition(s) on a GPIO input (based on register programming) and activates an asynchronous wake-up request by the sideband signal (GPIOi_SWAKEUP, where $i = 1, 2, 3, 4, 5$, and 6), if the wake-up enable register is set.

When the system is awakened, the interface clock is restarted and synchronously set to 1 based on the input GPIO pin triggering the wake-up request and the corresponding bit in the interrupt status registers (GPIOi.GPIO_IRQSTATUS1 and GPIOi.GPIO_IRQSTATUS2). On the following internal clock cycle, the interrupt lines 1 and/or 2 are active (active low) when the corresponding bits are set in the interrupt enable registers (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2).

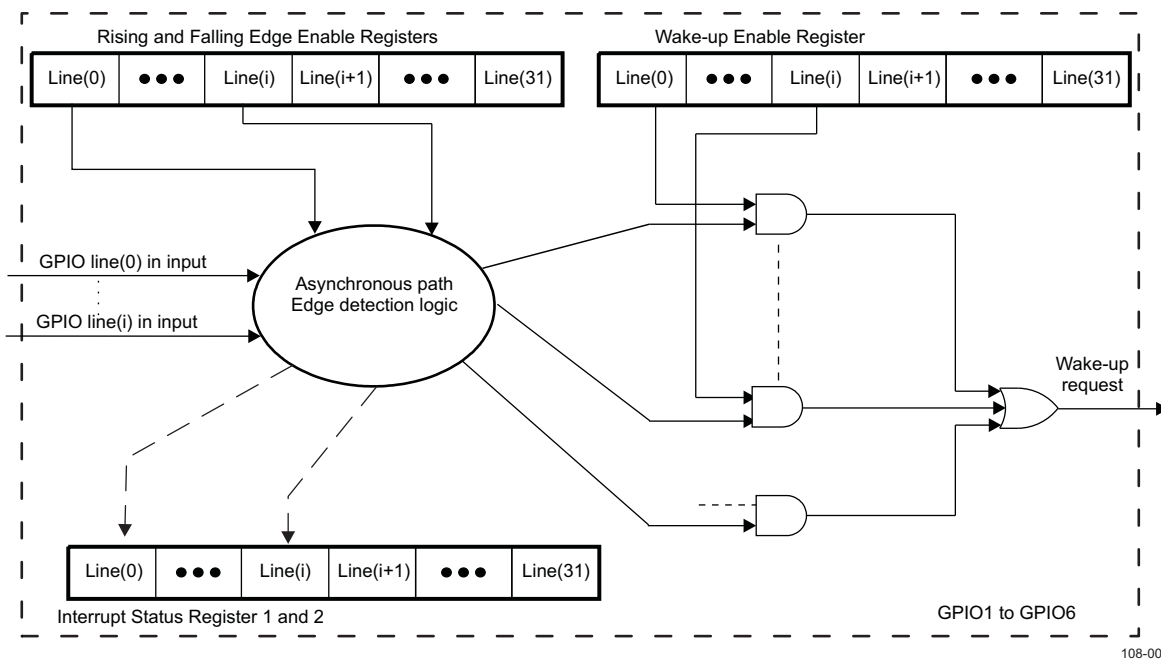

Note: When debouncing is not enabled, a minimum input pulse width does not trigger the wake-up request because there is no sampling operation.

When debouncing is enabled, the minimum pulse width is set by the specified debouncing time.

The GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP bit enables or disables the GPIO wake-up feature globally. If the bit is 0, the wake-up enable register (GPIOi.GPIO_WAKEUPENABLE) has no effect.

Figure 24-9 shows an overview of the wake-up request generation.

Figure 24-9. Wake-Up Request Generation

24.4.1.3 Interrupt (or Wake-Up) Line Release

When the host processor (the MPU and/or IVA2.2 subsystem in the device) receives an interrupt request issued by the GPIO module, it reads the corresponding interrupt status register (GPIOi.GPIO_IRQSTATUS1 or GPIOi.GPIO_IRQSTATUS2) to determine which GPIO input triggered the interrupt (or the wake-up request).

After servicing the interrupt (or acknowledging the wake-up request), the processor resets the status bit and releases the interrupt line by writing 1 in the corresponding bit of the interrupt status register. If there is still a pending interrupt request to serve (all bits in the interrupt status register that are not masked by the interrupt enable register are not cleared), the interrupt line is reasserted.

Note: The status bit must be reset to re-enter idle mode.

24.5 General-Purpose Interface Basic Programming Model

24.5.1 Power Saving by Grouping the Edge/Level Detection

Each GPIO module implements four gated clocks used by the edge/level detection logic to save power. Each group of eight input GPIO pins generates a separate enable signal depending on the edge/level detection register setting (because the input is 32 bits, four groups of eight inputs are defined for each GPIO module). If a group requires no edge/level detection, then the corresponding clock is gated (cut off). Grouping the edge/level enable can save the power consumption of the module as described in the following example.

If any of the registers:

GPIOi.GPIO_LEVELDETECT0
GPIOi.GPIO_LEVELDETECT1
GPIOi.GPIO_RISINGDETECT
GPIOi.GPIO_FALLINGDETECT

are set to 0x01 01 01 01, then all clocks are active (power consumption is high).

are set to 0x00 00 00 FF, then a single clock is active (power saving).

Note: When the clocks are enabled by writing to the GPIOi.GPIO_LEVELDETECT0, GPIOi.GPIO_LEVELDETECT1, GPIOi.GPIO_RISINGDETECT, and GPIOi.GPIO_FALLINGDETECT registers, the detection starts after five clock cycles. This period is required to clean the synchronization edge/level detection pipeline.

The mechanism is independent of each clock group. If the clock has been started before and a new setting is performed, the following is recommended: First, set the new detection required; second, disable the previous setting (if necessary). In this way, the corresponding clock is not gated and the detection starts immediately.

24.5.2 Set-and-Clear Instructions

24.5.2.1 Description

The GPIO module implements the set-and-clear protocol register update for the GPIOi.GPIO_DATAOUT, GPIOi.GPIO_IRQENABLE1, GPIOi.GPIO_IRQENABLE2, and GPIOi.GPIO_WAKEUPENABLE registers. This protocol is an alternative to the atomic test and set operations and consists of writing operations at dedicated addresses (one address for setting bit[s] and one address for clearing bit[s]). The data to write is 1 at bit position(s) to clear (or to set) and 0 at unaffected bit(s). Registers can be accessed in two ways:

- Standard: Full register read and write operations at the primary register address
- Set and clear (recommended): Separate addresses are provided to set (and clear) bits in registers. Writing 1 at these addresses sets (or clears) the corresponding bit into the equivalent register; writing a 0 has no effect.

Therefore, for these registers, three addresses are defined for one unique physical register. Reading these addresses has the same effect and returns the register value.

24.5.2.2 Clear Instruction

24.5.2.2.1 Clear Registers Addresses

Clear interrupt enable registers (GPIOi.GPIO_CLEARIRQENABLE1 and GPIOi.GPIO_CLEARIRQENABLE2).

A write operation in the clear interrupt enable1 (or enable2) register clears the corresponding bit in the interrupt enable1 (or enable2) register when the written bit is 1; a written bit at 0 has no effect.

A read of the clear interrupt enable1 (or enable2) register returns the value of the interrupt enable1 (or enable2) register

Clear wake-up enable register (GPIOi.GPIO_CLEARWКУENA).

A write operation in the clear wake-up enable register clears the corresponding bit in the wake-up enable register when the written bit is 1; a written bit at 0 has no effect.

A read of the clear wake-up enable register returns the value of the wake-up enable register.

Clear data output register (GPIOi.GPIO_CLEARDATAOUT).

A write operation in the clear data output register clears the corresponding bit in the data output register when the written bit is 1; a written bit at 0 has no effect.

A read of the clear data output register returns the value of the data output register.

24.5.2.2.2 Clear Instruction Example

Assume the data output register (or one of the interrupt/wake-up enable register) contains the binary value, 0b0000 0001 0000 0001, and you want to clear the bit 0.

With the clear instruction feature, write 0b0000 0000 0000 0001 at the address of the clear data output register (or at the address of the clear interrupt/wake-up enable register). After this write operation, a reading of the data output register (or the interrupt/wake-up enable register) returns 0b0000 0001 0000 0000; the bit 0 is cleared.

Note: Although the general-purpose interface registers are 32 bits wide, only the less-significant 16 bits are represented in this example.

Figure 24-10 shows an example of a clear instruction.

Figure 24-10. Write @GPIO_CLEARDATAOUT Register Example

108-010

24.5.2.3 Set Instruction

24.5.2.3.1 Set Registers Addresses

Set interrupt enable registers (GPIOi.GPIO_SETIRQENABLE1 and GPIOi.GPIO_SETIRQENABLE2).

A write operation in the set interrupt enable1 (or enable2) register sets the corresponding bit in the interrupt enable1 (or enable2) register when the written bit is 1; a written bit at 0 has no effect.

A read of the set interrupt enable1 (or enable2) register returns the value of the interrupt enable1 (or enable2) register.

Set wake-up enable register (GPIOi.GPIO_SETWKUENA).

A write operation in the set wake-up enable register sets the corresponding bit in the wake-up enable register when the written bit is 1; a written bit at 0 has no effect.

A read of the set wake-up enable register returns the value of the wake-up enable register.

Set data output register (GPIOi.GPIO_SETDATAOUT).

A write operation in the set data output register sets the corresponding bit in the data output register when the written bit is 1; a written bit at 0 has no effect.

A read of the set data output register returns the value of the data output register.

24.5.2.3.2 Set Instruction Example

Assume the interrupt enable1 (or enable2) register (or the data output register) contains the binary value, 0b0000 0001 0000 0000, and you want to set the bits 15, 3, 2, and 1.

With the set instruction feature, write 0b1000 0000 0000 1110 at the address of the set interrupt enable1 (or enable2) register (or at the address of the set data output register). After this write operation, a reading of the interrupt enable1 (or enable2) register (or the data output register) returns 0b1000 0001 0000 1110; the bits 15, 3, 2, and 1 are set.

Note: Although the general-purpose interface registers are 32 bits wide, only the less-significant 16 bits are represented in this example.

Figure 24-11 shows an example of a set instruction.

Figure 24-11. Write @GPIO_SETIRQENABLEx Register Example

108-011

The set wake-up enable register offers the same feature with the wake-up enable register.

24.5.3 Interrupt and Wakeup

24.5.3.1 Involved Configuration Registers

- Interrupt enable registers (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2)
The interrupt enable1 (or interrupt enable2) register allows masking of the expected transition on input GPIO to prevent the generation of an interrupt request on line1 (or line2). The interrupt enable registers are programmed synchronously with the interface clock.
These registers can be accessed with direct read/write operations or using the alternate set and clear protocol register update feature. This feature enables to set or clear specific bits of these registers with a single write access to the corresponding set interrupt enable1 (or interrupt enable2) registers (or to the clear interrupt enable1 [or interrupt enable2] registers) address (see [Section 24.5.2, Set-and-Clear Instructions](#)).
- Wake-up enable register (GPIOi.GPIO_WAKEUPENABLE)
The wake-up enable register allows masking of the expected transition on input GPIO to prevent the generation of a wake-up request. The wake-up enable register is programmed synchronously with the interface clock before any idle mode request coming from the host processor.
This register can be accessed with direct read/write operations or by using the alternate set and clear protocol register update feature. This feature allows setting or clearing specific bits of this register with a single write access to the set wake-up enable register (or to the clear wake-up enable register) address (see [Section 24.5.2, Set-and-Clear Instructions](#)).

Note: It must be a correlation between Wake-up enable and interrupt enable registers. If a GPIO pin has a Wake-up configured on it, it should also have the corresponding interrupt enabled (on one of the 2 interrupt lines). Otherwise, it is possible to have a Wake-up event, but after exiting the Idle state, no interrupt will be generated, thus the corresponding bit from the interrupt status register will not be cleared, and the module will not acknowledge a future Idle Request.

- Interrupt status registers (GPIOi.GPIO_IRQSTATUS1 and GPIOi.GPIO_IRQSTATUS2)
The interrupt status1 (or interrupt status2) register determines which of the input GPIO pins triggered

the interrupt line1 (or interrupt line2) request (or the wake-up line).

When a bit in this register is set to 1, it indicates that the corresponding GPIO pin is requesting the interrupt (or the wake-up). To reset a bit in this register, write 1 to the appropriate bit. However, an interrupt cannot be generated by writing 1 to the interrupt status1 (or interrupt status2) register.

If 0 is written to a bit in this register, the value remains unchanged. The interrupt status1 (or interrupt status2) register is synchronous with the interface clock. In idle mode, the event is detected via an asynchronous path, and the corresponding bit in the interrupt status1 and interrupt status2 registers are set when the GPIO module is awake.

Note: The wake-up capabilities of the GPIO2 to GPIO6 modules are operational only when the PER power domain is active.

24.5.3.2 Description

To generate interrupt request to a host processor (the MPU and/or DSP subsystem in the device) at a defined event (level or edge logic transition) occurring on a GPIO pin (interrupt source), the GPIO configuration registers must be programmed as follows:

1. The GPIO channel must be configured as input by the output enable register (write 1 to the corresponding bit of the GPIOi.GPIO_OE register).
2. The expected event(s) on the GPIO input to trigger the interrupt request must be selected in the low-level interrupt enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_LEVELDETECT0), and/or high-level interrupt enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_LEVELDETECT1), and/or rising-edge interrupt/wake-up enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_RISINGDETECT), and/or falling edge interrupt/wake-up enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_FALLINGDETECT).

Note: Interrupt generation on both edges on one input is configured by setting the corresponding bit to 1 in the rising detect enabling register (GPIOi.GPIO_RISINGDETECT) and falling detect enabling register (GPIOi.GPIO_FALLINGDETECT) along with the interrupt enable by setting the corresponding bit to 1 in on one or both interrupt enable registers (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2).

Enabling at the same time high level detection and low level detection for one given pin makes a constant interrupt generator.

3. Interrupts from the GPIO channel must be enabled in the interrupt 1 enable register (write 1 to the corresponding bit of GPIOi.GPIO_IRQENABLE1 register) and/or the interrupt 2 enable register (write 1 to the corresponding bit of GPIOi.GPIO_IRQENABLE2 register).

To configure a GPIO module to sent a wake-up request to the PRCM at a defined event (logic transition) occurring on a GPIO pin (wake-up source), the GPIO configuration registers must be programmed as follows:

1. The GPIO pin must be configured as input by the output enable register (write 1 to the corresponding bit of the GPIOi.GPIO_OE register).
2. The expected event(s) on the GPIO input to trigger the wake-up request must be selected in the rising-edge interrupt/wake-up enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_RISINGDETECT) and/or falling-edge interrupt/wake-up enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_FALLINGDETECT). The wake-up request can only be generated on edge transitions.
3. The GPIO channel must be enabled in the wake-up enable register (write 1 to the corresponding bit of the GPIOi.GPIO_WAKEUPENABLE).
4. The wake-up request generation on the expected transition occurring on the GPIO input pins must enable for the module (write 1 to the corresponding bit of the GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP) .

CAUTION

For each GPIO channel used, do not forget to configure the corresponding pad configuration registers in the *System Control Module* chapter.

After servicing the interrupt, the status bit in the interrupt status register (GPIOi.GPIO_IRQSTATUS1 or GPIOi.GPIO_IRQSTATUS2) must be reset and the interrupt line released (by writing 1 in the corresponding bit of the interrupt status register) before enabling an interrupt for the GPIO channel in the interrupt enable register (GPIOi.GPIO_IRQENABLE1 or GPIOi.GPIO_IRQENABLE2) to prevent the occurrence of unexpected interrupts when enabling an interrupt for the GPIO channel.

24.5.4 Data Input (Capture)/Output (Drive)

The output enable register (GPIOi.GPIO_OE) controls the output/input capability for each pin. At reset, all the GPIO-related pins are configured as input and output capabilities are disabled. This register is not used within the module. Its only function is to carry the pads configuration.

When configured as an output (the desired bit reset in the GPIOi.GPIO_OE register), the value of the corresponding bit in the GPIOi.GPIO_DATAOUT register is driven on the corresponding GPIO pin. Data is written to the data output register synchronously with the interface clock. This register can be accessed with read/write operations or by using the alternate set and clear protocol register update feature. This feature lets you set or clear specific bits of this register with a single write access to the set output data register (GPIOi.GPIO_SETDATAOUT) or to the clear output data register (GPIOi.GPIO_CLEARDATAOUT) address (see [Section 24.5.2, Set-and-Clear Instructions](#)). If the application uses a pin as an output and does not want interrupt/wake-up generation from this pin, the application must properly configure the wake-up enable (GPIOi.GPIO_WAKEUPENABLE) and the interrupt enable (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2) registers.

When configured as an input (the desired bit set to 1 in the GPIOi.GPIO_OE register), the state of the input can be read from the corresponding bit in the GPIOi.GPIO_DATAIN register. The input data is sampled synchronously with the interface clock and then captured in the data input register synchronously with the interface clock (see [Section 24.5.2, Set-and-Clear Instructions](#)). When the GPIO pin levels change, they are captured into this register after two interface clock cycles (the required cycles to synchronize and to write data). If the application uses a pin as an input, the application must properly configure the wake-up enable (GPIOi.GPIO_WAKEUPENABLE) and the interrupt enable (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2) registers to the interrupt and wake-up feature as needed.

24.5.5 Debouncing Time

To enable the debounce feature for a pin, the GPIO configuration registers must be programmed as follows:

1. The GPIO pin must be configured as input in the output enable register (write 1 to the corresponding bit of the GPIOi.GPIO_OE register)
2. The debouncing time must be set in the debouncing time register (GPIOi.GPIO_DEBOUNCINGTIME)
The debouncing value register (GPIOi.GPIO_DEBOUNCINGTIME) is used to set the debouncing time for all input lines in the GPIO module. The value is global for all the ports of one GPIO module, so up to six different debouncing values are possible. The debounce cell is running with the debounce clock (32 kHz). This register represents the number of the clock cycle(s) (one cycle is 31 microseconds long) to be used.

The following formula describes the required input stable time to be propagated to the debounced output:

Required input line stable = (GPIOi.GPIO_DEBOUNCINGTIME[7:0] DEBOUNCVAL field value + 1) x 31 s.

where GPIOi.GPIO_DEBOUNCINGTIME[7:0] field DEBOUNCVAL value is from 0 to 255.

3. The debouncing feature must be enabled in the debouncing enable register (write 1 to the corresponding bit of the GPIOi.GPIO_DEBOUNCENABLE register)

24.6 General-Purpose Interface Registers

This section summarizes the hardware interface for the GPIO product. Each module instance within the design is shown, together with the module register map and bit definitions for each bit field.

Table 24-6 shows the base address and address space for the GPIO module instances.

Table 24-6. Instance Summary

Module Name	Base Address	Size
GPIO1	0x4831 0000	4K bytes
GPIO2	0x4905 0000	4K bytes
GPIO3	0x4905 2000	4K bytes
GPIO4	0x4905 4000	4K bytes
GPIO5	0x4905 6000	4K bytes
GPIO6	0x4905 8000	4K bytes

24.6.1 General-Purpose Interface Register Mapping Summary

All module registers are 8-, 16-, or 32-bit accessible through the L4 interconnect (little endian encoding). Access to registers is direct; no shadow registers are implemented.

Table 24-7 through Table 24-8 describe the GPIO register offset addresses.

Table 24-7. GPIO1 to GPIO3 Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address (GPIO1)	Physical Address (GPIO2)	Physical Address (GPIO3)

The write latency for all the R/W registers is immediate (with respect to the interface clock)

Note: When two write accesses in the GPIOi.[GPIO_DEBOUNCINGTIME](#) register are performed in less than two debounce clock cycles (32 kHz) + four interface clock cycles, the first write access latency is immediate, but the second write access is acknowledged only after this interval ends.

In the register descriptions in this section, when one single register carries an individual configuration or setting for all the channels of the module, one bit in the register is dedicated to each channel. The bit and the corresponding channel are identified with the same number: bit 0 refers to channel 0, bit 1 refers to channel 1, and so on, up to 31.

24.6.2 Register Descriptions

Table 24-9 through Table 24-57 describe the register bits.

24.6.2.1 GPIO_SYSCONFIG

Table 24-9. GPIO_SYSCONFIG

Address Offset	0x010		
Physical Address	0x4831 0010	Instance	GPIO1
	0x4905 0010		GPIO2
	0x4905 2010		GPIO3
	0x4905 4010		GPIO4
	0x4905 6010		GPIO5
	0x4905 8010		GPIO6
Description	This register controls the various parameters of the L4 interconnect.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																												IDLEMODE	ENAWAKEUP	SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Write 0s for future compatibility. Read returns 0	RW	0x0000000
4:3	IDLEMODE	Power Management, Req/Ack control 0x0: Force-idle. An idle request is acknowledged unconditionally 0x1: No-idle. An idle request is never acknowledged 0x2: Smart-idle. Acknowledgment to an idle request is given based on the internal activity of the module 0x3: reserved do not use	RW	0x0
2	ENAWAKEUP	Wakeup capability enabled/disabled 0x0: Wakeup disable 0x1: Wakeup enable	RW	0x0
1	SOFTRESET	Software reset. This bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset	RW	0x0
0	AUTOIDLE	Internal interface clock gating strategy 0x0: interface clock is free-running 0x1: Automatic interface clock gating strategy is applied, based on the L4 interconnect activity	RW	0x0

Applications Processor Initialization

This chapter introduces the OMAP35x general-purpose device initialization.

Topic	Page
25.1 Initialization Overview	3360
25.2 Preinitialization.....	3362
25.3 Power, Clocks, and Reset Power-Up Sequence	3372
25.4 Device Initialization by ROM Code	3372
25.5 Wake-Up Booting by ROM Code	3420
25.6 Debug Configuration	3423
25.7 Revision History	3425

25.1 Initialization Overview

This chapter provides an overview of the requirements for initializing the OMAP35x Applications Processor from power-on to firmware execution. An overview of the overall initialization process is given, including hardware- and software-related steps, a general overview of the boot ROM code operational requirements, and behavior expectations.

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

25.1.1 Terminology

- **Bootstrap:** Initial software (SW) that is launched by the ROM code during the memory booting phase.
- **Certificate:** Data block plus trusted signature of the data block
- **Downloaded SW:** Initial SW that is downloaded into the internal SRAM by the ROM code during the peripheral booting phase
- **eFuse:** A one-time programmable memory location usually set at the factory
- **Flash loader:** Downloaded SW launched by the ROM code in preflashing. It also programs an image into external memories.
- **GP device:** General-purpose device. A type of device in which the security features, except the cryptographic HWA, are disabled. Intended for production.
- **Initial SW:** Software that is executed by any of the ROM code mechanisms (memory booting or peripheral booting). Initial SW is a generic term for bootstrap and downloaded SW.
- **Memory booting:** ROM code mechanism that consists of executing an Initial SW from external memory
- **Peripheral booting:** ROM code mechanism that consists of polling selected interfaces, downloading, and executing an Initial SW (in this, case called downloaded SW) in the internal RAM.
- **Permanent booting device:** Memory device containing, by default, the image to be executed during the booting sequence. It is the default memory booting device. The permanent booting device is used after warm reset if no SW booting configuration is programmed.
- **Preflashing:** A specific case of peripheral booting where the ROM code mechanism is used to program the external flash memory
- **R&D certificate:** Certificate where the data block contains development configuration parameters
- **ROM code:** The on-chip SW in OMAP ROM which implements booting and security features
- **Secure environment:** Execution and storage environment, built with hardware and SW components, whose access is enabled when the processor runs in secure mode
- **Secure mode:** MPU secure working state, active when the ARM secure state is set, and reinforced by secure state machine (SSM) policy and attack countermeasures.
- **Secure RAM:** Writable area of the OCM-RAM. Protected applications are loaded for execution and secure data is temporarily stored in this area. Can only be accessed when the processor is in secure mode, or by a secure DMA channel.
- **Secure ROM:** Read-only memory inside the chip. Programmed at the chip manufacturing phase. Can be accessed only when the processor is in secure mode.

25.1.2 Initialization Process

A brief overview of the whole initialization process and its steps are shown in the [Figure 25-1](#). Initialization consists of several steps:

- Preinitialization
- Power/clock/reset ramp sequence
- Boot ROM
- Boot loader

- OS/application

Each of these steps, up to OS/applications running, is explained in detail in the following sections.

Figure 25-1. Initialization Process

The first two steps in the initialization process are hardware oriented; however, they do require a good understanding of the process of configuring those system interface pins (balls on the device), which have SW configurable functionality. This configuration is an essential part of chip configuration and is application-dependent. This chapter refers to those pins and the associated configuration registers which are vital for proper device initialization.

See your device data manual for more information regarding the use of multiplexing configuration.

25.2 Preinitialization

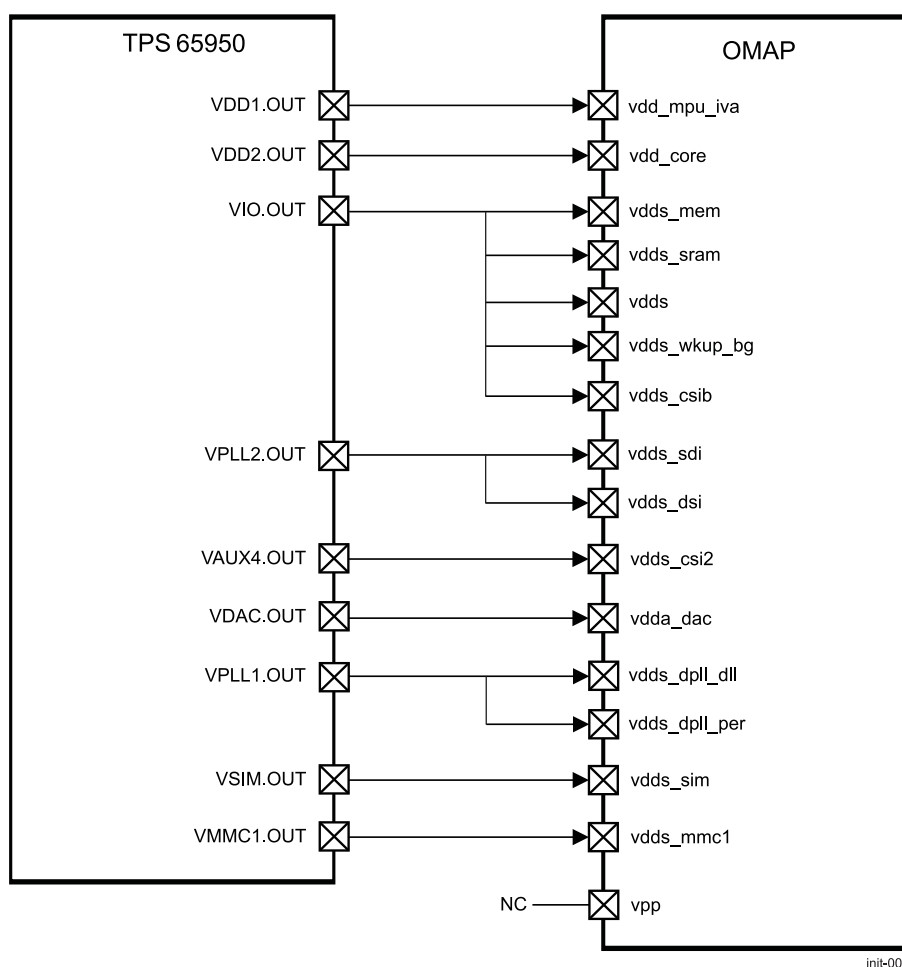

Certain hardware configuration settings must be made in order to accomplish a successful boot-up operation with a GP device. Clock, reset, and power connections, as well as pins involved in setting the boot memory space for the microprocessor unit (MPU), must be connected and driven properly for successful device initialization. The following sections detail the specific requirements for the preinitialization stage.

25.2.1 Power Connections

The device can be supplied by an external power IC. Texas Instruments provides a global solution with the OMAP35x connected to the TPS65950 power IC.

Figure 25-2 shows the power connections between the OMAP35x and the TPS65950 power IC.

Figure 25-2. OMAP35x and TPS65950 Power Connections

Note: Figure 25-2 is an example of power connections between the OMAP35x device and the TPS65950. These connections depend on the application: For example, if a serial display or camera interface is used, it must be supplied by the low-dropout (LDO) regulator (low noise).

Notes:

- The SYS_CLKOUT output clock cannot be provided to peripherals when the core is off.
- The sys_clkreq output signal switches the system clock on or off.
- After power-on reset, the hardware configuration enables the internal oscillator (assuming the input clock comes from a crystal). The decision whether to bypass the internal oscillator is controlled by the polarity of the sys_boot[6] pin.

Table 25-1 describes of the power pins.

Table 25-1. Power Pin Descriptions⁽¹⁾

OMAP35x I/O Voltage Name	Description
vdd_mpu_iva	MPU and IVA subsystem power supply
vdd_core	Core power supply
vdds	I/O power supply
vdds_mem	Memory I/O power supply
vdds_wkup_bg	Wake-up LDO and VDDA (2LDO SRAM and BG) power supply
vdds_sram	SRAM LDO power supply
vdds_dpll_dll	Power supply for 3PLL (1.8 V)
vdds_dpll_per	Peripheral DPLLs power supply
vdds_sdi	Dedicated power supply for SDI I/O cell
vdds_csi2	Dedicated power supply for CSI2 Complex I/O
vdds_csib	Dedicated power supply for CS1b Complex I/O
vdds_dsi	1.8V analog power supply
vdda_dac	Video DAC power supply
vdds_mmc1	Power supply for MMC, SD and Memory Stick interfaces
vdds_sim	power supply for USIM IO
vpp	eFuse programming

⁽¹⁾ The OMAP35x package-on-package (POP) device provides feedthroughs from the bottom of the package to the POP interface. Among these feedthroughs (FEEDTHROUGH balls), several provide power to the top memory device. The correct power supply to the feedthroughs must be provided based on memory requirements. For more information about the feedthrough interface, refer device-specific Data Manual.

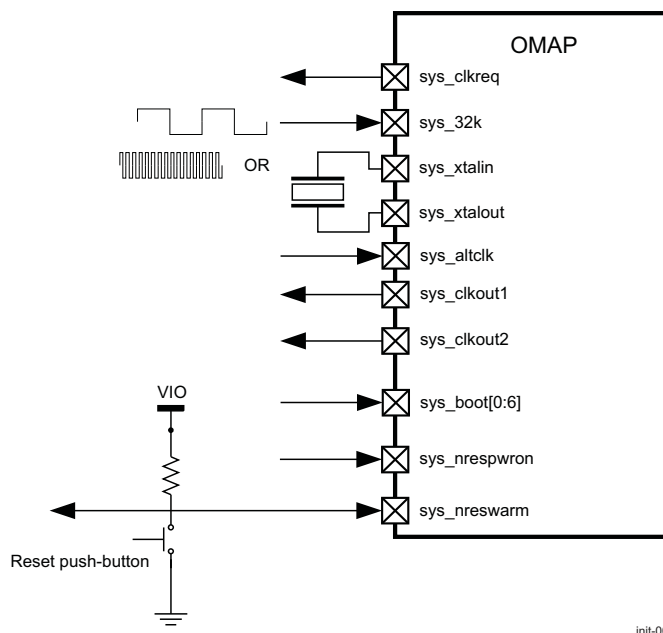

For a complete description of the power pins on the device package, see your device-specific data manual. For more information on power management, see the *Power, Reset, and Clock Management* chapter.

25.2.2 Clock and Reset

25.2.2.1 Clock and Reset Overview

Figure 25-3 shows the clock and reset environment which gathers the clocks and reset signals related at system level, as well as system expansion signals.

Figure 25-3. Clock and Reset Environment

The main features of the system interface are:

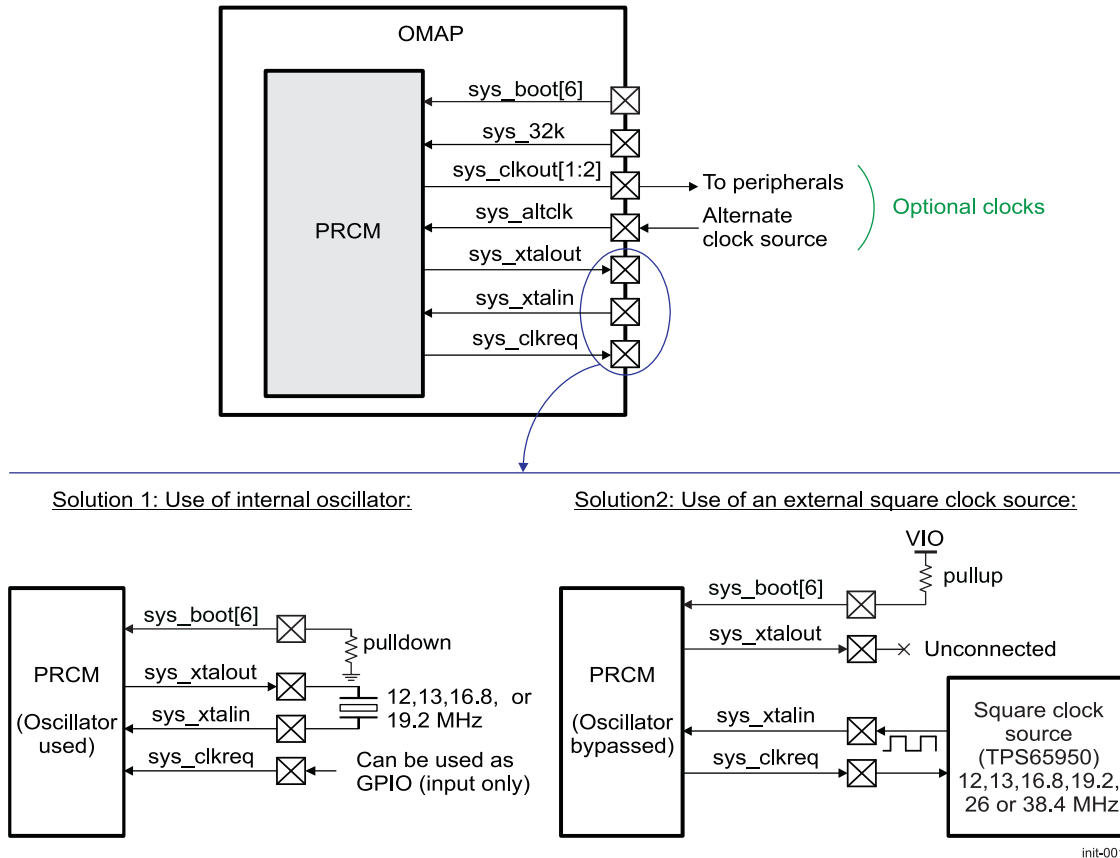

- A clock request output to an external square clock source
- 12, 13, 16.8, 19.2, 26, 38.4-MHz reference clock input from either the external crystal oscillator (only 12, 13, 16.8 or 19.2 MHz) or the digital clock input (all frequencies)
- 32-kHz CMOS clock input
- An additional clock input up to 54 MHz
- Two configurable output clocks
- Seven input signals to define the boot mode
- Two reset sources
 - Power-on reset (cold reset)
 - Bidirectional warm reset

25.2.2.2 Clock Configuration

25.2.2.2.1 Required System Input Clocks

Figure 25-4 shows the clocks interface.

Figure 25-4. Clock Interface

Notes:

- The SYS_CLKOUT output clock cannot be provided to peripherals when the core is off.
- The sys_clkreq output signal switches the system clock on or off.
- After power-on reset, the hardware configuration enables the internal oscillator (assuming the input clock comes from a crystal). The decision whether to bypass the internal oscillator is controlled by the polarity of the sys_boot[6] pin.

The device operation requires two external input clocks as follows:

- sys_32k**: The 32-kHz frequency is used for low-frequency operation.
- sys_xtal (in/out)**: The system clock is the main clock source of the device. The system clock input can be connected in either of the two following ways:
 - Crystal quartz through the SYS_XTALIN and SYS_XTALOUT pins, using an internal oscillator up to 19.2 MHz.
 - CMOS digital clock (square clock) through the SYS_XTALIN pin. The oscillator is bypassed.

Table 25-2 lists the mapping for input sources.

Table 25-2. Mapping for Input Sources

Input Source	Mapping	Frequencies	Comment
Crystal quartz	SYS_XTALIN and SYS_XTALOUT	12, 13, 16.8, or 19.2 MHz	Requires use of internal oscillator
Square clock (1.8 CMOS signal)	SYS_XTALIN (SYS_XTALOUT unconnected)	12, 13, 16.8, 19.2, 26, or 38.4 MHz	Internal oscillator is bypassed

Only one source input at a time can be used because sys_32k, SYS_XTALIN and SYS_XTALOUT have permanently assigned pin locations with no pad configuration for these pins through a system control module register.

25.2.2.2.2 Optional System Input Clock: SYS_ALTCLK

An additional clock can be provided through the SYS_ALTCLK input pin to supply internal peripherals, phase-locked loops (PLLs), a precise clock for NTSC (54 MHz), USB full-speed controller (48 MHz). If not used as a clock input, this pin can be configured as a general-purpose input/output (GPIO), using the system control module CONTROL.CONTROL_PADCONF_I2C3_SDA register. As an example, to use the SYS_ALTCLK pin, the CONTROL.CONTROL_PADCONF_I2C3_SDA[18:16] MUXMODE1 field must be set to 0x01.

25.2.2.2.3 Optional System Output Clock: SYS_CLKOUT1 and SYS_CLKOUT2

Two output clocks (SYS_CLKOUT1 and SYS_CLKOUT2 pins) are available:

- SYS_CLKOUT1 can output the oscillator clock. Its OFF state polarity is programmable.
- SYS_CLKOUT2 can output the system clock (12, 13, 16.8, 19.2, 26 or 38.4 MHz), the core clock (CORE DPLL output), 96 MHz, or 54 MHz. SYS_CLKOUT2 can be divided by 2, 4, 8, or 16, and its OFF state polarity is programmable.

CAUTION

Clock configurations depend on core voltage, and maximum clock frequencies may not be applicable to production. Please refer to your device-specific data manual for a description of the supported voltage levels and maximum clock frequencies.

The clocks can be managed by SW with the appropriate register in the power, reset, clock, management (PRCM) module:

- SYS_CLKOUT1 is managed using PRCM.PRM_CLKOUT_CTRL and PRCM.PRM_POLCTRL[2].
- SYS_CLKOUT2 is managed using PRCM.CM_CLKOUT_CTRL and PRCM.CM_CLKSEL1_PLL[28:27].

25.2.2.3 Reset Configuration

The sys_nrespwron reset pin is used to reset the entire chip during the power-on reset.

The sys_nreswarm reset pin is used to reset the entire chip when the device is supplied and operating, except for the following:

- Part of SDRC
- Part of IVA
- Part of PRCM
- Control module
- Watchdog
- 32-kHz synchronization timer
- DPLLs
- SmartReflex™ modules

CAUTION

sys_nrespwron must be driven low during a power-up sequence.

sys_nreswarm is a bidirectional reset. When an internal reset occurs, sys_nreswarm goes low and resets all the peripherals. The sys_nreswarm output is open-drain; consequently, an external pullup resistor is required.

Both sys_nrespwron and sys_nreswarm have permanently assigned pin locations.

At reset, the cause of reset is stored in the PRCM.RM_RSTST_MPU register and used by the boot ROM code.

25.2.3 Boot Configuration

Six external pins (sys_boot[5:0]) are used to select interfaces or devices used for booting. The sys_boot[6] pin is used to select whether the internal oscillator is bypassed.

These seven pins are sampled and latched onto CONTROL.CONTROL_STATUS status register following a power-on reset. After booting, these pins can optionally be used for other functions and the associated CONTROL.CONTROL_STATUS bits are not updated by the new functionality. For more information about pad multiplexing configuration, see the *System Control Module* chapter.

Note: If used as GPIOs, these pins must be used in the output mode. To ensure the sys_boot[6:0] input values are selected by the pullup and pulldown on sys_boot[6:0] pins at power-on reset, these GPIOs must be used only in output mode. As these balls have no pullup or pulldown capacity, care must be taken when choosing to use these GPIOs.

Table 25-3, Table 25-4, and Table 25-5 are decoding tables for sys_boot pins. Depending on sys_boot pin configuration during the reset (first column), the ROM code tries to boot on the first device listed. If the boot failed on this first device, the ROM code tries the second device, then the third, then the fourth.

The following names are used in the tables:

- Memory types:
 - XIP: XIP memory without wait monitoring enabled (NOR flash memories)
 - XIP wait: XIP memory with wait monitoring
 - DOC: DiskOnChip™ memory (H3 device types)
 - NAND: NAND flash memories (non XIP)
 - OneNAND: OneNAND flash memories
 - MMC1: MMC or SD flash cards with active primary partition of type FAT12/16/32 connected to the first multimedia card/secure digital/secure digital I/O (MMC/SD/SDIO1) card interface
 - MMC2: MMC or SD flash cards with active primary partition of type FAT12/16/32 connected to the second multimedia card/secure digital/secure digital I/O (MMC/SD/SDIO2) card interface
- Peripheral interfaces:
 - USB: High-speed USB
 - UART3: UART interface
- Permanent booting devices are in *italics*.

Table 25-3 and Table 25-4 list the sys_boot pin configuration after a power-on reset (POR).

CAUTION

- UART boot: UART3 is the only possible UART from which boot can be performed. Additionally, only UART3 pads that provide UART3 functionality in their MUXMODE 0 can be used. No other UART configuration allows booting from the UART.
- HS USB boot: If TPS65950 or TWL5030 processor is used as the USB transceiver, it must be connected to the OMAP35x through I2C1. No other I²C interface allows the necessary TWL processor configuration.

25.3 Power, Clocks, and Reset Power-Up Sequence

See the section *Power-Up Sequence* in the *Power, Reset, and Clock Management* chapter for the power-on sequence, including power supplies, clocks, and reset signals.

See your device data manual for more information regarding the device power-up sequence.

25.4 Device Initialization by ROM Code

This section describes the high-level booting concepts and provides basic knowledge of booting on the device.

25.4.1 Booting Overview

CAUTION

To use the level 2 (L2) cache with the OMAP35x device, the ROM code provides three primitive services. These services are implemented in monitor mode and do not use any resources outside the MPU subsystem. The services are described below. To call a service, a register r12 must be set to service ID and the SMI instruction must be executed.

- r12=1: To use the L2 cache, all L2 line data must be invalidated through the CP15 registers. This service invalidates the entire L2 cache and must be performed after a POR or a loss of L2 cache after reset. This register can also be read.
- r12=2: This service writes the value of the central processing unit (CPU) register R0 in the L2 cache auxiliary control register. This register can also be read.
- r12=3: This service writes the value of the CPU register R0 in the auxiliary control. This register can also be read. For more information about ARM L2 cache and registers, see the *Cortex-A8 Technical Reference Manual*. For more information about ARM CP15 registers, see the *ARM Architecture Reference Manual*.

25.4.1.1 Booting Types

Bootting is the process of starting a bootstrap from one of the booting memories.

The ROM code has two functionalities for booting: peripheral booting and memory booting.

- In peripheral booting, the ROM code polls a selected communication interface such as UART or USB, downloads the executable code over the interface, and executes it in internal RAM. Downloaded software from an external host can be used to program flash memories connected to the device. This special case of peripheral booting is called preflashing; software downloaded for preflashing is called the flash loader. The flash loader burns a new client application image in external flash memory. Initial software is a generic term for bootstrap, downloaded software, and flash loader. After the image is burned, a software reset can be performed.
- In memory booting, the ROM code finds the bootstrap in permanent memories such as flash memory or memory cards and executes it. This process is normally performed after cold or warm device reset.

The ROM code detects whether the device should download software from a peripheral interface (HS USB or UART 3) by using the sys_boot pin configuration. This mechanism encompasses initial flashing in production (external memory is empty) and reflashing in service (external memory is already programmed).

[Table 25-6](#) lists the pin multiplexing according to boot peripheral.

Table 25-6. Pin Multiplexing According to Boot Peripheral

Boot Device	Pins
NAND/OneNAND	General-purpose memory controller (GPMC) pins in mode 0
XIP memory	GPMC pins in mode 0
DiskOnChip	GPMC pins in mode 0
MMC/SD1	MMC1 pins in mode 0
MMC/SD2	MMC2 pins in mode 0
UART3	UART3 pins in mode 0
HS USB	HSUSB0 pins in mode 0

CAUTION

- UART boot: UART3 is the only possible UART from which boot can be performed. Additionally, only UART3 pads that provide UART3 functionality in their MUXMODE 0 can be used. No other UART configuration allows booting from the UART.
- HS USB boot: If TPS65950 or TWL5030 processor is used as the USB transceiver, it must be connected to the OMAP35x through I2C1. No other I²C interface allows the necessary TWL processor configuration.

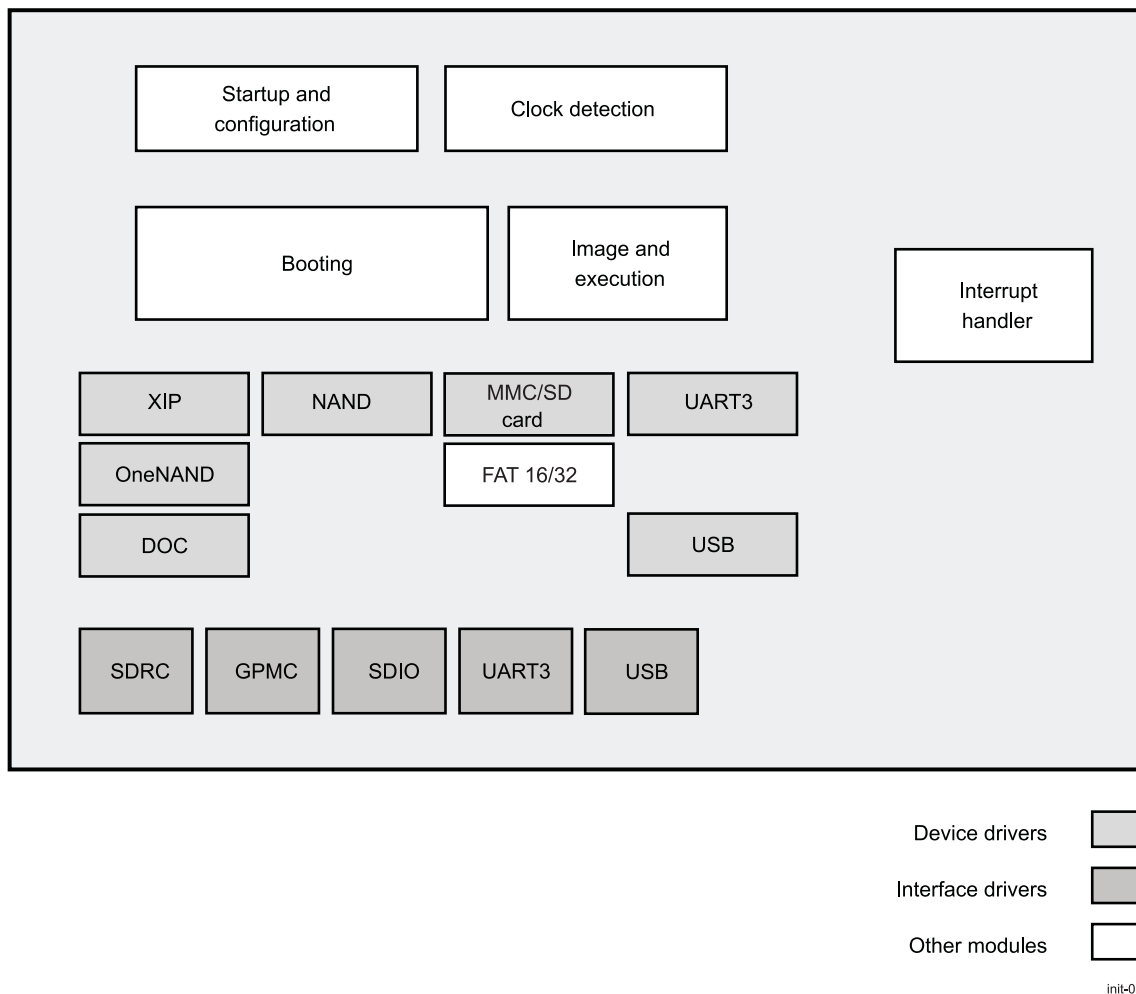

25.4.1.2 Main Features

The ROM code architecture is shown in [Figure 25-5](#). The ROM code is made up of several modules:

- The start-up module takes care of basic system configuration and dispatches control into the booting module.
- The clock detection module supports start-up by detecting the system clock frequency.
- The booting module uses several device drivers as it must boot from one of the external devices.
- The device drivers implement device protocols and perform logical operation on a device. They are abstracted from interface hardware by several interface drivers which are responsible for interacting with hardware interface facilities.
- The interrupt handler module provides services used among all modules. It allows registering interrupt service routines (ISRs) and calls them when an interrupt occurs.

[Figure 25-5](#) shows each module.

Figure 25-5. ROM Code Architecture

25.4.2 Memory Map

25.4.2.1 ROM Memory Map

Figure 25-6 shows the ROM memory map.

Figure 25-6. 32KB ROM Memory Map

- ROM exception vectors
Exceptions are redirected to ROM exception vectors (see [Table 25-7](#)). The reset exception is redirected to the public ROM code startup. Other exceptions are redirected to RAM handlers by loading appropriate addresses in the PC register.

Table 25-7. ROM Exception Vectors

Address	Exception	Content
14000h	Reset	Branch to the public ROM code startup
14004h	Undefined	PC = 4020FFC8h
14008h	Software interrupt (SWI)	PC = 4020FFCCh
1400Ch	Prefetch abort	PC = 4020FFD0h
14010h	Data abort	PC = 4020FFD4h
14014h	Unused	PC = 4020FFD8h
14018h	IRQ	PC = 4020FFDCCh
1401Ch	FIQ	PC = 4020FFE0h

- ROM code cyclic redundancy check (CRC)
The ROM code CRC is calculated as 32-bit CRC code (CRC-32-IEEE 802.3) for the address range 14000h–1BFFFh. The 4-byte CRC code is stored at location 14020h, which is filled with FFFF FFFFh before the CRC is calculated.
- Dead loops
Dead loops are branch instructions coded in ARM mode. They have multiple purposes (see [Table 25-8](#)).

Table 25-8. Dead Loops

Address	Purpose
14080h	Undefined exception default handler
14084h	SWI exception default handler

Table 25-8. Dead Loops (continued)

Address	Purpose
14088h	Prefetch abort exception default handler
1408Ch	Data abort exception default handler
14090h	Unused exception default handler
14094h	IRQ exception default handler
14098h	FIQ exception default handler
1409Ch	Validation tests Pass
140A0h	Validation tests Fail
140A4h	Booting failed: No more devices
140A8h	Image not executed or returned
140ACh	Reserved
140B0h	Reserved
140B4h	Reserved
140B8h	Reserved
140BCh	Reserved

The fixed location of these dead loops facilitates debugging and testing. The first seven dead loops are default exception handlers linked with RAM exception vectors.

Dead loops can be called directly from code, but there is also a special function called from ROM code to execute a dead loop. This function is at address 140C0h. The function is assembly code in ARM mode, which takes the dead loop address from the R0 register. The main purpose of the function is to issue a global software reset before going to a dead loop. In addition, the function clears the global cold reset status before issuing the global software reset.

- Code

This space is used to keep code.

- Code and data

This space is used to keep code and other data.

- ROM code version

The ROM code version consists of two decimal numbers: major and minor. The major number is always 14. The minor number identifies the ROM code version. The minor number is not aligned with the ROM code release number, but it can identify it. The ROM code version is coded as hexadecimal readable values (for example, ROM version 14.04 is coded as a 3-bit word: 00001404h).

25.4.2.2 RAM Memory Map

Figure 25-7 shows RAM memory map. The shown partitioning of the on-chip SRAM is only used during the booting process.

Figure 25-7. 64KB RAM Memory Map of GP Devices

- **Downloaded image**
This space is used by the public ROM code to store a downloaded booting image.
- **Public stack**
Space reserved for stacks.
- **Tracing data**
The public ROM code tracing data is described in [Table 25-9](#). More information about ROM code tracing can be found in [Section 25.4.9, Tracing](#).

Table 25-9. Tracing Data

Address	Size [bytes]	Description
0x4020FFB0	4	Current tracing vector, word 1
0x4020FFB4	4	Current tracing vector, word 2
0x4020FFB8	4	Current copy of the PRM_RSTST register (reset reasons)
0x4020FFBC	4	Cold reset run tracing vector, word 1
0x4020FFC0	4	Cold reset run tracing vector, word 2
0x4020FFC4	4	Reserved

- **RAM exception vectors**
The RAM exception vectors provide an easy way to redirect exceptions to the custom handler. [Table 25-10](#) shows the contents of the RAM space reserved for RAM vectors. The first seven addresses are ARM instructions which load into the PC the value located in the next seven addresses. These instructions are executed when an exception occurs, since they are called from ROM exception vectors. By default, all exceptions are redirected to the exception dead loops. Users can redirect an exception to other handler by writing its address to the appropriate position from 0x4020FFE4 to 0x4020FFFC, or by overriding instructions between addresses from 0x4020FFC8 to 0x4020FFE0.

Table 25-10. RAM Exception Vectors

Address	Exception	Content
0x4020FFC8	Undefined	PC = [0x4020FFE4]
0x4020FFCC	SWI	PC = [0x4020FFE8]
0x4020FFD0	Pre-fetch abort	PC = [0x4020FFEC]
0x4020FFD4	Data abort	PC = [0x4020FFF0]
0x4020FFD8	Unused	PC = [0x4020FFF4]
0x4020FFDC	IRQ	PC = [0x4020FFF8]
0x4020FFE0	FIQ	PC = [0x4020FFFC]
0x4020FFE4	Undefined	0x14080
0x4020FFE8	SWI	0x14084
0x4020FFEC	Pre-fetch abort	0x14088
0x4020FFF0	Data abort	0x1408C
0x4020FFF4	Unused	0x14090
0x4020FFF8	IRQ	0x14094
0x4020FFFC	FIQ	0x14098

25.4.3 Overall Booting Sequence

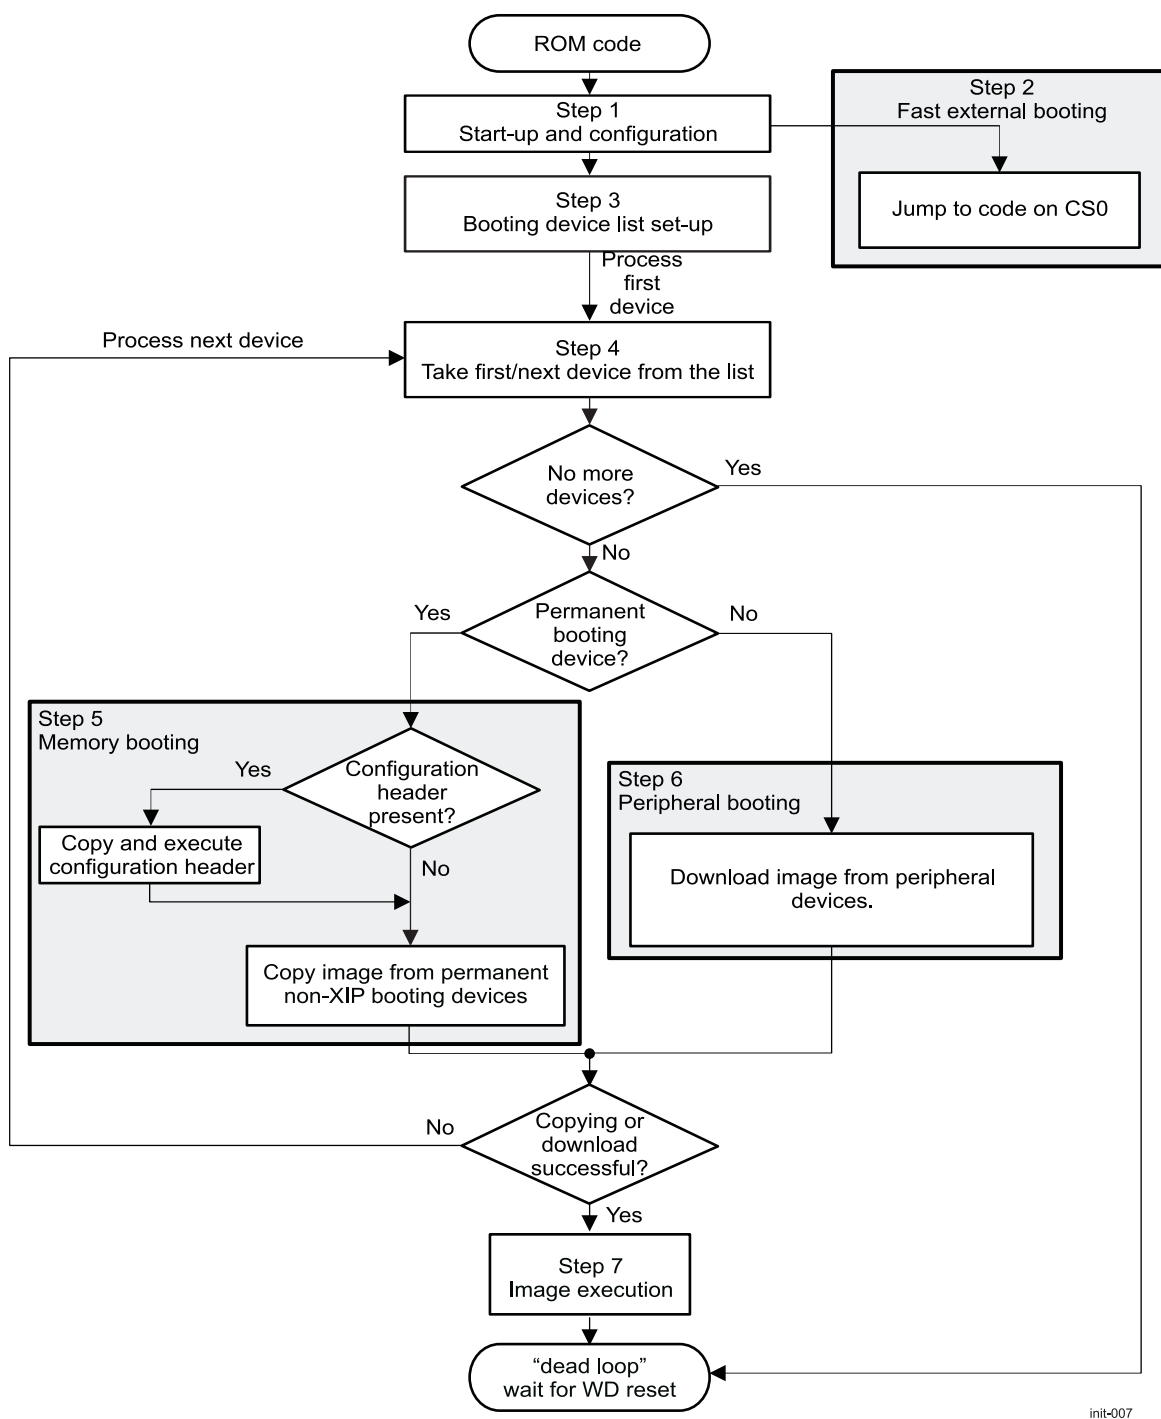

Figure 25-8 shows the ROM code flowchart.

The main loop of the booting module goes through the booting device list and tries to get an image from the currently selected booting device. The ROM code follows these steps:

- Step 1. The ROM code performs basic configurations and initializations.
- Step 2. The path named fast external boot is a special low-latency boot mode. It consists of a blind jump to the external addressable memory as soon as possible.
- Step 3. A booting device list is created (see [Section 25.4.4.3, Booting Device List Setup](#)). The list consists of all devices to be searched for a booting image. The list is created based on the sys_boot pins and the SW booting configuration described in [Section 25.4.4.4, SW Booting Configuration](#). The SW booting configuration structure is in the scratchpad memory and can be written by SW before executing a SW reset or going into the OFF or RET mode. The scratchpad memory is an internal RAM memory which keeps its contents after SW reset or wake-up, but not after POR. After a SW reset, the SW booting configuration has a priority over the sys_boot pin configuration.
- Step 4. Once the booting device list is set, the booting procedure examines the devices on the list serially and either executes memory booting or peripheral booting, depending on current booting device type:
 - Memory booting is executed when the booting device is permanent: XIP memory, NAND, DiskOnChip™, OneNAND, or MMC/SD cards.
 - The peripheral booting is executed when device is temporary: UART or USB.
- Step 5. The memory booting procedure reads data from memory type devices. The memory booting is described in detail in [Section 25.4.7, Memory Booting](#).
- Step 6. The peripheral booting procedure downloads data from communication interfaces. The ROM code uses a simple logical protocol with peripheral booting. First, the OMAP Applications Processor sends an ASIC ID structure to inform the host about peripheral booting start. Next, the host responds by sending a booting message that can have one of the following meanings: skip peripheral booting, continue peripheral booting, or change the booting device. If the message is to continue, the host sends the whole image preceded by its size. The peripheral booting is described in detail in [Section 25.4.5, Peripheral Booting](#).
- Step 7. The image is simply started.

The additional feature of the booting module is the execution of the configuration header (CH). The CH configures the system for faster and more flexible booting from selected permanent device. The CH, which is optional, is described in [Section 25.4.8.2, Configuration Header](#).

Figure 25-8. Overall Booting Sequence

25.4.4 Start-Up and Configuration

25.4.4.1 Start-Up

The ROM code starts at address 0x0001 4000.

25.4.4.2 Clocking Configuration

The ROM code detects the system input clock frequency. The supported frequencies are:

- 12 MHz
- 13 MHz
- 16.8 MHz
- 19.2 MHz
- 26 MHz
- 38.4 MHz

After detecting the input clock, the ROM code configures the clocks and DPLLs required for ROM code execution.

The configured DPLLs are:

- Peripheral DPLL, set to provide 96 MHz and 48 MHz for peripheral blocks
- MPU DPLL, set to provide 48 MHz for the Ferrari MPU
- Core DPLL, set to provide 192, 96, 48, or 24 MHz for various blocks, such as interconnect, clocked by this DPLL output

The multipliers and dividers of the DPLLs are set to values which depend on the input clock detected.

[Table 25-11](#) summarizes the ROM code default settings for key clocks.

Table 25-11. ROM Code Default Clock Settings

Clock	Frequency [MHz]	Source
CORE.CLK	192	CORE DPLL output
L3x2.CLK	192	CORE.CLK
L3.ICLK	96	CORE.CLK/2
L4.ICLK	48	L3.ICLK/2
RM clock	24	L4.ICLK/2
MPU	48	CORE.CLK/4 (MPU DPLL in bypass)

The DPLLs and other settings are configured by default after each type of reset to give the ROM code the same working conditions. However, it is possible to override the default clock settings by means of the software booting configuration; for details, see [Section 25.4.4.4, Software Booting Configuration](#).

There are three ways to change DPLLs and all related clock divider, gating, and multiplexer configurations during the boot:

- ROM code default settings, described in this paragraph
- Software booting configuration after a software reset, described in [Section 25.4.4.4, Software Booting Configuration](#)
- CH, described in [Section 25.4.8.2, CH](#). This configuration can be blocked by the software booting configuration; this is possible during the memory booting. The CH lets the user have a known configuration (about GPMC, SDRC, and clock registers) after memory booting.

25.4.4.3 Booting Device List Set-Up

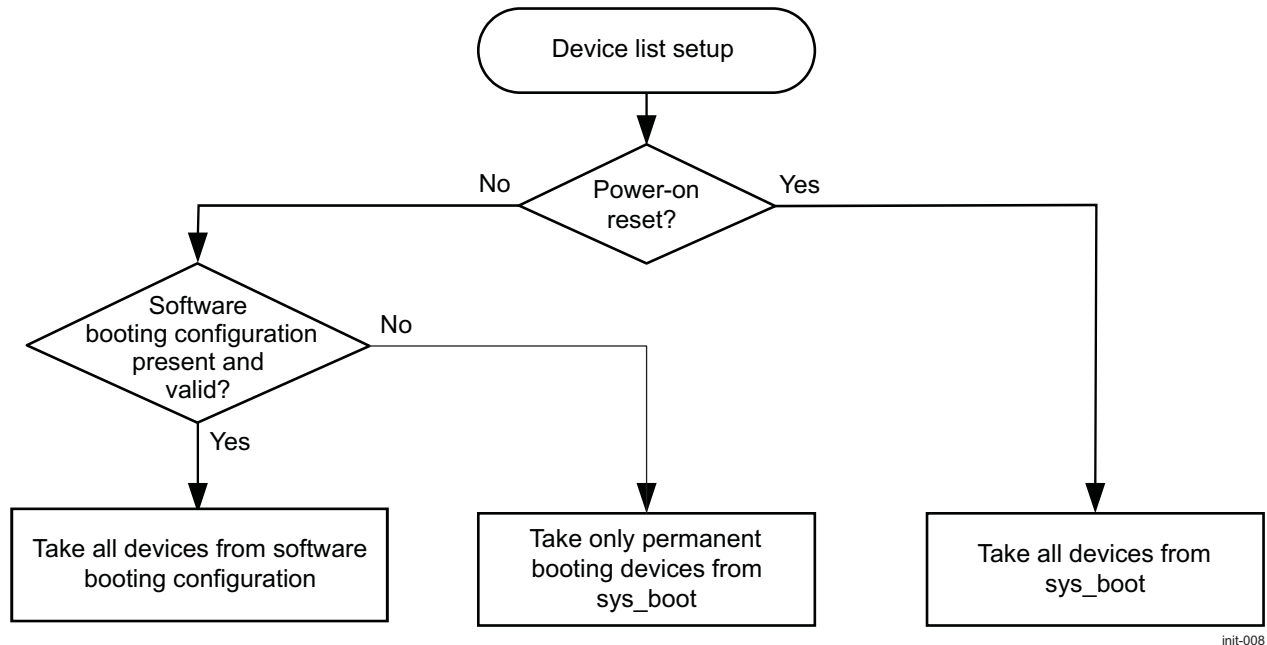

The ROM code creates device list based on two sources:

- The SW booting configuration is stored in nonvolatile RAM memory called scratchpad memory.
- The sys_boot[5:0] pins are used to index the device table from which the list of devices is extracted.

Figure 25-9 shows how the ROM code sets up the device list depending on the reset source.

Note: Only permanent booting devices are put on the list when reset is non power-on and devices are taken from the sys_boot pins. Users can force peripheral booting after SW reset using SW booting configuration.

Figure 25-9. Device List Set-Up

25.4.4.4 SW Booting Configuration

The SW booting configuration is stored in the special scratchpad memory, which is not cleared after SW resets or wake-ups. The SW booting configuration is a simple structure located at the address that is stored at the first location of available scratchpad memory: 0x48002910. The SW booting configuration structure is shown in Table 25-12. There are two sections in this structure:

- The first section provides devices for the booting device list.
- The second section provides clocking settings, which are applied before booting.

The sections are not mandatory and their order is not important. The ROM code looks for the next section at the location based on the size filled in the previous section. The clock configuration from SW booting configuration overwrites the CH settings.

Table 25-12. SW Booting Configuration Structure

Field	Size [bytes]	Description
Booting Configuration		
Section 1 key	4	Synchronization key for section 1: 0xCF00AA01
Section 1 size	4	Size of the section 1: 0x0000000C (12)

Table 25-12. SW Booting Configuration Structure (continued)

25.4.5 Peripheral Booting

25.4.5.1 Overview

The ROM code can boot from different peripherals:

- HS USB: High-speed USB Interface
- UART 3: Baud rate 115.2K bps, 8 bits, even parity, 1 stop-bit.

The purpose of booting from a peripheral is to boot from an external host, such as a PC. This booting method is mostly used for programming flash memories connected to the OMAP Applications Processor. The protocol used is common to all peripherals. Some minor exceptions are described in the following sections. The common peripheral booting protocol is shown in [Figure 25-10](#).

Figure 25-10. Common Peripheral Booting Protocol

init-009

The ROM code first initializes the interface and sends a message called ASIC ID to a host. The content of this message is summarized in [Table 25-13](#). The host uses this message to send only appropriate data to the OMAP Applications Processor according to the identification codes sent.

The ROM code waits 300 ms for an answer from the host. If a time-out occurs, the peripheral booting returns to the main booting procedure with TIMEOUT status.

Table 25-13. ASIC ID Structure

ASIC ID Item	Size [Bytes]	Description
Items	1	Number of subblocks
ID subblock	7	Device identification information
Reserved for non-GP devices	4	Reserved
ID subblock	23	Identification data
Reserved for non-GP devices	23	Reserved
Checksum subblock	11	CRC (4 bytes)

The host can send different messages as described in [Table 25-14](#). If the second or third message is not received, the ROM code stops the current peripheral booting procedure and returns to the main booting, which determines the next booting device according to the boot message received.

If the first message is received without a time-out, the image size (as a 32-bit word) and the image itself are expected to be received. The image is downloaded directly at address 0x40200000 in the internal RAM.

The ROM code waits up to one minute for completion. If the downloading procedure does not complete before this period, the peripheral booting fails. If the download passes, the peripheral booting succeeds and the image can be executed.

Table 25-14. Boot Messages

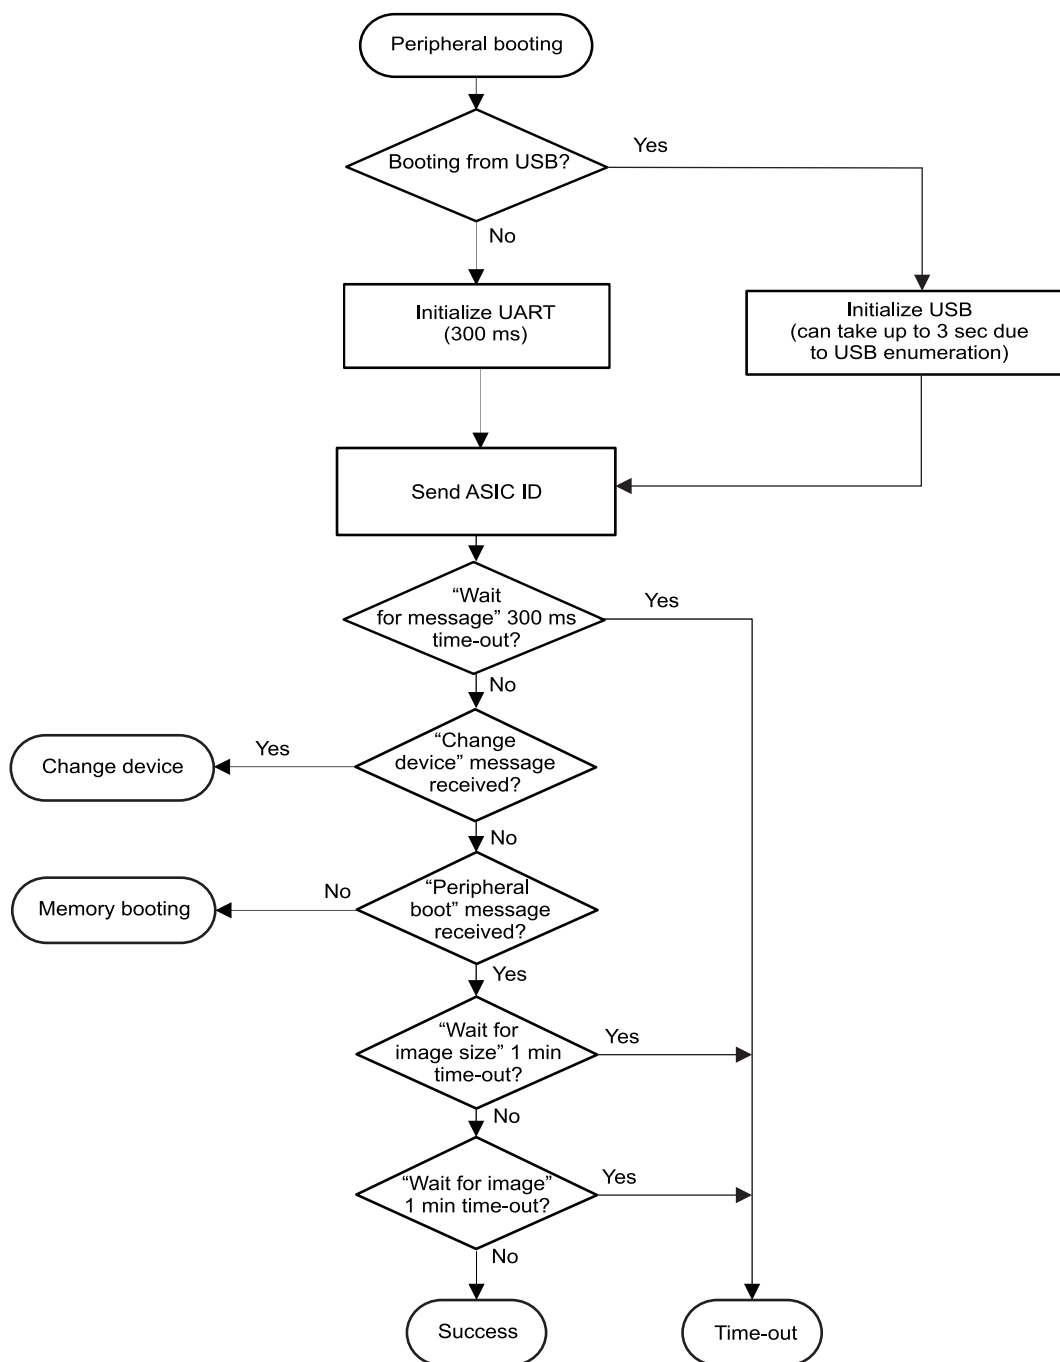

Message Name	Value	Description
Peripheral boot	0xF0030002	Continue peripheral booting.

Table 25-14. Boot Messages (continued)

Message Name	Value	Description
Change device	0xF003XX06	Skip current peripheral booting and continue booting from device type indicated by XX: 0x00 - Void, no device 0x01 - XIP memory 0x02 - NAND 0x03 - OneNAND 0x04 - DOC 0x05 - MMC/SD2 0x06 - MMC/SD1 0x07 - XIP memory with wait monitoring 0x08..0x0F - Reserved 0x10 - UART 0x11 - HS USB Others - Reserved
Next device	0xFFFFFFFF	Skip current device and move to the next device on the device list.
Memory booting	Others	Skip current peripheral booting and move to the first device for memory booting.

The peripheral booting procedure is summarized in [Figure 25-11](#).

Figure 25-11. Peripheral Booting Procedure

init-010

25.4.5.2 UART

The ROM code supports booting from a UART interface with the following characteristics:

- UART interface 3
- Communication parameters set to 115.2k baud, 8 bits, even parity, 1 stop-bit
- Two-pin interface: RX/TX with SW flow control (XON/XOFF). The other UART pins are left at their default configuration.
- The UART time-out is 300 ms.

25.4.5.3 USB

The ROM code supports booting from a USB interface with the following characteristics:

- HS USB interface
- USB 2.0 transceiver macrocell interface (UTMI)+ low pin interface (ULPI) 8-bit data transceiver support (single data rate)
- TPS65950 device detection and automatic configuration of its USB transceiver using I2C1
- The enumeration time-out is 3 seconds.

The ROM code USB driver conforms with the USB 2.0 specification and the USB on-the-go (OTG) supplement. It supports transactions at HS (that is, 480 Mbps) and FS (that is, 12 Mbps). During peripheral booting, only the USB device functionality is used. The driver resides in the on-chip memory (OCM) ROM, which is small. The driver therefore contains the minimum functionality needed as a USB device and is not a full-fledged driver. It does not contain the functionality needed for a USB host. The device functionality of the USB OTG controller is used for the peripheral booting process in the ROM code.

25.4.5.3.1 USB Driver Descriptors

USB devices report their attributes using descriptors. A descriptor is a data structure with a defined format. Each descriptor begins with a byte-wide field that contains the total number of bytes in the descriptor followed by a byte-wide field that identifies the descriptor type. Using descriptors allows concise storage of the attributes of individual configurations so that each configuration can reuse descriptors or portions of descriptors from other configurations that have the same characteristics. Where appropriate, descriptors contain references to string descriptors. String descriptors contain displayable, human-readable information that describes a descriptor. These descriptor details can be used for tool development or debugging:

- Device descriptor
A device descriptor contains general information about a USB device, including information that applies globally to the device and all device configurations. A USB device has only one device descriptor. Because the ROM code uses the HS feature of the USB core, a device-qualifier descriptor is required. [Table 25-15](#) describes the device descriptors.

Table 25-15. Device Descriptor

Field	Value	Description
bLength	0x12	Size of this descriptor in bytes
bDescriptorType	0x01	Device descriptor type
bcdUSB	0x0210	USB specification release number in binary coded decimal (BCD) format
bDeviceClass	Vendor-specific (0xFF)	Class code
bDeviceSubClass	Vendor-specific (0xFF)	Subclass code
bDeviceProtocol	Vendor-specific (0xFF)	Protocol code
bMaxPacketSize0	0x40	Maximum packet size for endpoint 0
idVendor	0x0451	Vendor ID
idProduct	0x0000	Product ID
bcdDevice	0x0000	Device release number

Table 25-15. Device Descriptor (continued)

Field	Value	Description
iManufacturer	See values in Section 25.4.5.3.2 .	Index of string descriptor describing manufacturer
iProduct	See values in Section 25.4.5.3.2 .	Index of string descriptor describing product
iSerialNumber	See values in Section 25.4.5.3.2 .	Index of string descriptor describing device serial number
bNumConfigurations	0x01	Number of possible configurations

- **Device-qualifier descriptor**

The device-qualifier descriptor contains information about a HS-capable device that changes if the device operates at its other speed. This descriptor is retrieved by the host using the GetDescriptor() request (standard device request). [Table 25-16](#) describes a device-qualifier descriptor.

Table 25-16. Device-Qualifier Descriptor

Field	Value	Description
bLength	0x0a	Size of this descriptor in bytes
bDescriptorType	0x06	Device-qualifier descriptor type
bcdUSB	0x0210	USB specification release number in BCD
bDeviceClass	0xFF	Class code
bDeviceSubClass	0xFF	Subclass code
bDeviceProtocol	0xFF	Protocol code
bMaxPacketSize0	0x40	Maximum packet size for endpoint 0
bNumConfigurations	0x01	Number of possible configurations
bReserved	0x00	Reserved for future use

- **Configuration descriptor**

This descriptor gives information about a specific device configuration. The descriptor describes the number of interfaces supported by the configuration. See [Table 25-17](#) for details.

Table 25-17. Configuration Descriptor

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x02	Configuration descriptor type
wTotalLength	–	Combined length of all descriptors
bNumInterfaces	0x01	Number of interfaces supported
bConfigurationValue	0x01	Value to use as an argument for the SetConfiguration() request
iConfiguration	Index	Index of string descriptor describing this configuration
bmAttributes	0xc0	Power setting and remote wakeup
bMaxPower	0x32	Maximum power consumption of the USB device

- **Other speed configuration descriptor**

This descriptor describes the configuration of a HS-capable device if it operates at its other possible speed. See [Table 25-18](#) for details.

Table 25-18. Other Speed Configuration Descriptor

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x07	Other speed configuration descriptor type
wTotalLength	–	Combined length of all descriptors

Table 25-18. Other Speed Configuration Descriptor (continued)

Field	Value	Description
bNumInterfaces	0x01	Number of interfaces supported
bConfigurationValue	0x01	Value to use as an argument for the SetConfiguration() request
iConfiguration	Index	Index of string descriptor describing this configuration
bmAttributes	0xc0	Power setting and remote wakeup
bMaxPower	0x32	Maximum power consumption of the USB device

- Interface descriptor

This descriptor describes a specific interface in a configuration. See [Table 25-19](#) for details.

Table 25-19. Interface Descriptor

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x04	Interface descriptor type
bInterfaceNumber	0x00	Number of this descriptor
bAlternateSetting	0x00	Value to select the alternate setting
bNumEndpoints	0x02	Number of endpoints used for this interface
bInterfaceClass	0xFF	Class code
bInterfaceSubClass	0xFF	Subclass code
bInterfaceProtocol	0xFF	Protocol code
iInterface	Index	Index of string descriptor describing this interface

- Endpoint descriptor

Each endpoint used for an interface has its own descriptor. This descriptor contains information required by the host to determine the bandwidth requirements of each endpoint. This descriptor is returned as part of the GetDescriptor(Configuration) request. See [Table 25-20](#) and [Table 25-21](#) for details.

Table 25-20. BULK IN Endpoint Descriptor

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x05	Endpoint descriptor type
bEndpointAddress	0x81 (1 IN)	Address of the endpoint on the USB device
bmAttributes	0x02 (Bulk)	Type of transfer
wMaxPacketSize	See ⁽¹⁾ .	Number of endpoints used for this interface
bInterval	0x00	Maximum NAK rate

⁽¹⁾ The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

Table 25-21. BULK OUT Endpoint Descriptor

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x05	Endpoint descriptor type
bEndpointAddress	0x01 (1 OUT)	Address of the endpoint on the USB device
bmAttributes	0x02 (Bulk)	Type of transfer
wMaxPacketSize	See ⁽¹⁾ .	Number of endpoints used for this interface
bInterval	0x00	Maximum NAK rate

⁽¹⁾ The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

- String descriptors

String descriptors use UNICODE encoding. The strings in a USB device can support multiple languages. When requesting a string descriptor, the requester specifies the desired language using a 16-bit language ID (LANGID) defined by the USB interface. String index 0 for all languages returns a string descriptor that contains an array of 2-byte LANGID codes supported by the device.

See the tables describing string descriptors:

- The language ID string descriptor ([Table 25-22](#))
- The manufacturer ID string descriptor ([Table 25-23](#))
- The product ID string descriptor ([Table 25-24](#))
- The configuration string descriptor ([Table 25-25](#))
- The interface string descriptor ([Table 25-26](#))

Table 25-22. Language ID String Descriptor

Field	Value	Description
bLength	0x04	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
wLangId	0x0409 (US English)	Language ID code

Table 25-23. Manufacturer ID String Descriptor

Field	Value	Description
bLength	0x06	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	TI	Manufacturer string

Table 25-24. Product ID String Descriptor

bDescriptorType	0x03	String descriptor type
bString	OMAP35x or specific vendor string	Product string

Table 25-25. Configuration String Descriptor

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	pbc	Configuration string

Table 25-26. Interface String Descriptor

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	pbi	Interface string

25.4.5.3.2 USB Customized Descriptors

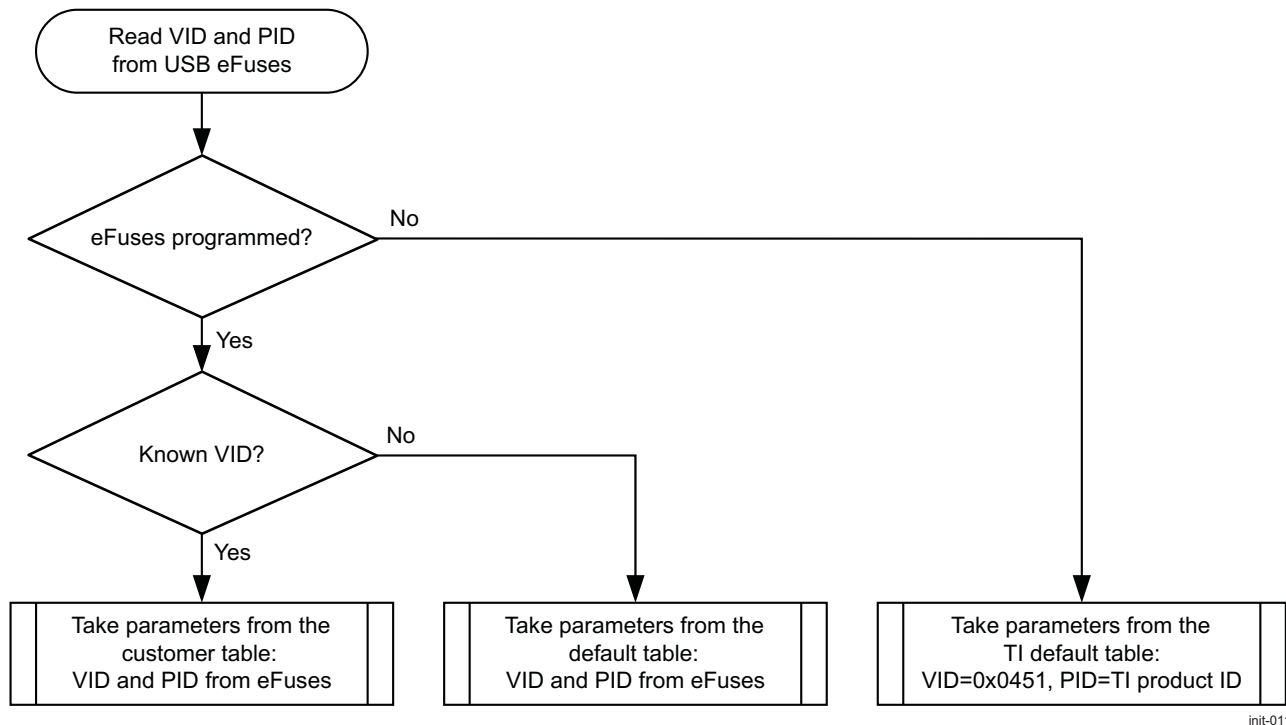

There are two parameters in USB descriptors that customers can define after the chip is created: vendor ID (VID) and product ID (PID). The ROM code uses dedicated eFuses that hold VID and PID values. Other parameters can also be changed based on VID value. The ROM code has an encoded set of parameters for customers who have defined their requirements before the ROM code has been done. [Table 25-27](#) lists the parameters that depend on VID value.

Table 25-27. Customized Descriptor Parameters

Parameter	Size [Bytes]	Default Values	TI Default Values
Device ID code	2	0x0000	0x0000
Device class	1	0xFF	0xFF
Device subclass	1	0xFF	0xFF
Device protocol	1	0xFF	0xFF
Manufacturer	String	N/A	TI
Product	String	OMAP35x or specific vendor string	OMAP35x or specific vendor string
Serial number	String	N/A	N/A

[Figure 25-12](#) describes an additional customer parameter selection method. It is based on the VID burned in the USB eFuses.

Figure 25-12. Customer USB Descriptor Selection

init-011

25.4.5.3.3 USB Driver Functionality

- Transactions supported

The following transactions are supported:

- Control transactions: Used for standard device requests
- Bulk transactions: Used for data transfer in the image downloading stage. The ASIC ID is sent on the Bulk IN endpoint and the image is transferred over the Bulk OUT endpoint from the host.

The OMAP USB device first attaches to the host as an FS device. In the reset mechanism, the USB core requests HS operation. If the HS negotiation in the reset phase is successful, further transactions are at HS; otherwise, they are at FS. After reset, the USB driver checks for the speed of the device, whether it is FS or HS. Depending on the speed configured by the host, the standard USB device requests are responded to with the corresponding descriptors.

- Standard device request restrictions

Because the USB driver is used only by the ROM code for peripheral booting, some standard device requests are not supported by the driver. [Table 25-28](#) lists the standard device requests supported by the driver.

Table 25-28. Standard Device Requests Supported

Request	Description	Support
CLEAR_FEATURE	Sets/clears a specific feature	Supported only for ENDPOINT_HALT feature
GET_CONFIGURATION	Returns the current device configuration value	Yes
GET_DESCRIPTOR	Returns the specified descriptor	Yes
GET_INTERFACE	Returns the selected alternate setting for the specified interface	Yes
GET_STATUS	Returns the status for the specified recipient	Yes
SET_ADDRESS	Sets the device address	Yes
SET_CONFIGURATION	Sets the device configuration	Yes
SET_DESCRIPTOR	Updates existing descriptors or adds new descriptors	No. Runtime updating of descriptors is not supported.
SET_FEATURE	Sets or enables a specific feature	Supported only for ENDPOINT_HALT feature
SET_INTERFACE	Selects an alternate setting in an interface	No. Runtime setting of alternate features is not supported.
SYNCH_FRAME	Sets and reports an endpoint synchronization frame	No, because isochronous transfers are not used

25.4.6 Fast External Booting

25.4.6.1 Overview

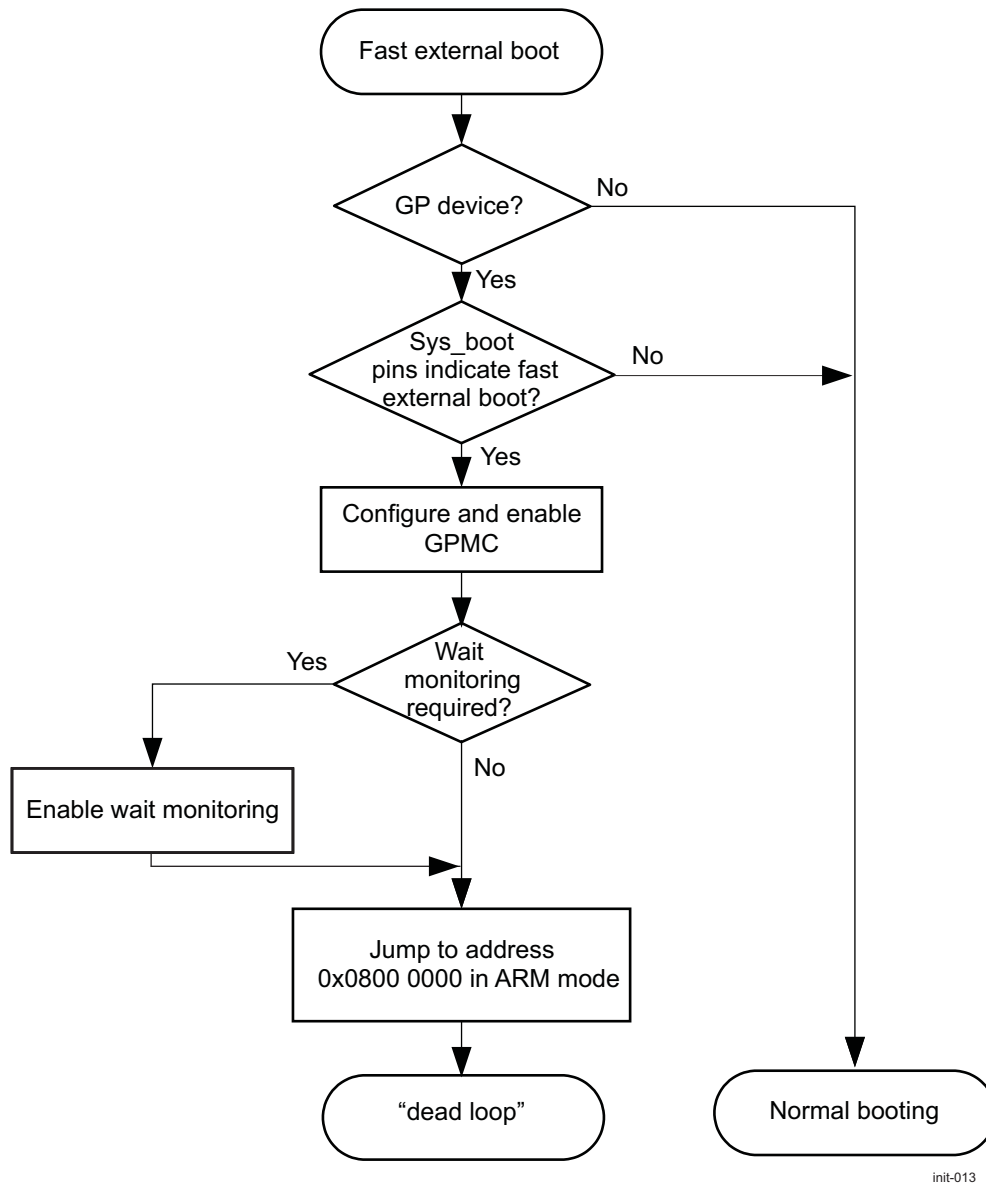

The fast external boot is a special memory booting mode. It is a blind jump to a code in an external XIP device connected to CS0. Fast external booting lets customers create their own booting code.

The jump is performed with minimum on-chip ROM code execution.

25.4.6.2 External Booting

Figure 25-13 shows the fast external boot procedure. The code is at the beginning of the public part and is written in assembly. The code does not use any RAM.

Figure 25-13. Fast External Boot

init-013

25.4.7 Memory Booting

25.4.7.1 Overview

The memory booting process takes care of starting an external code in memory type devices. These devices are called permanent booting devices because the OMAP35x Applications Processor always uses them for booting. The supported permanent booting devices are:

- NOR all devices up to 1G bit (128M bytes)
- NAND devices from 64M bits
- OneNAND devices from 512M bits

- SD/MMC flash cards with active primary partition of type FAT12/16/32
- DiskOnChip™ H3 devices

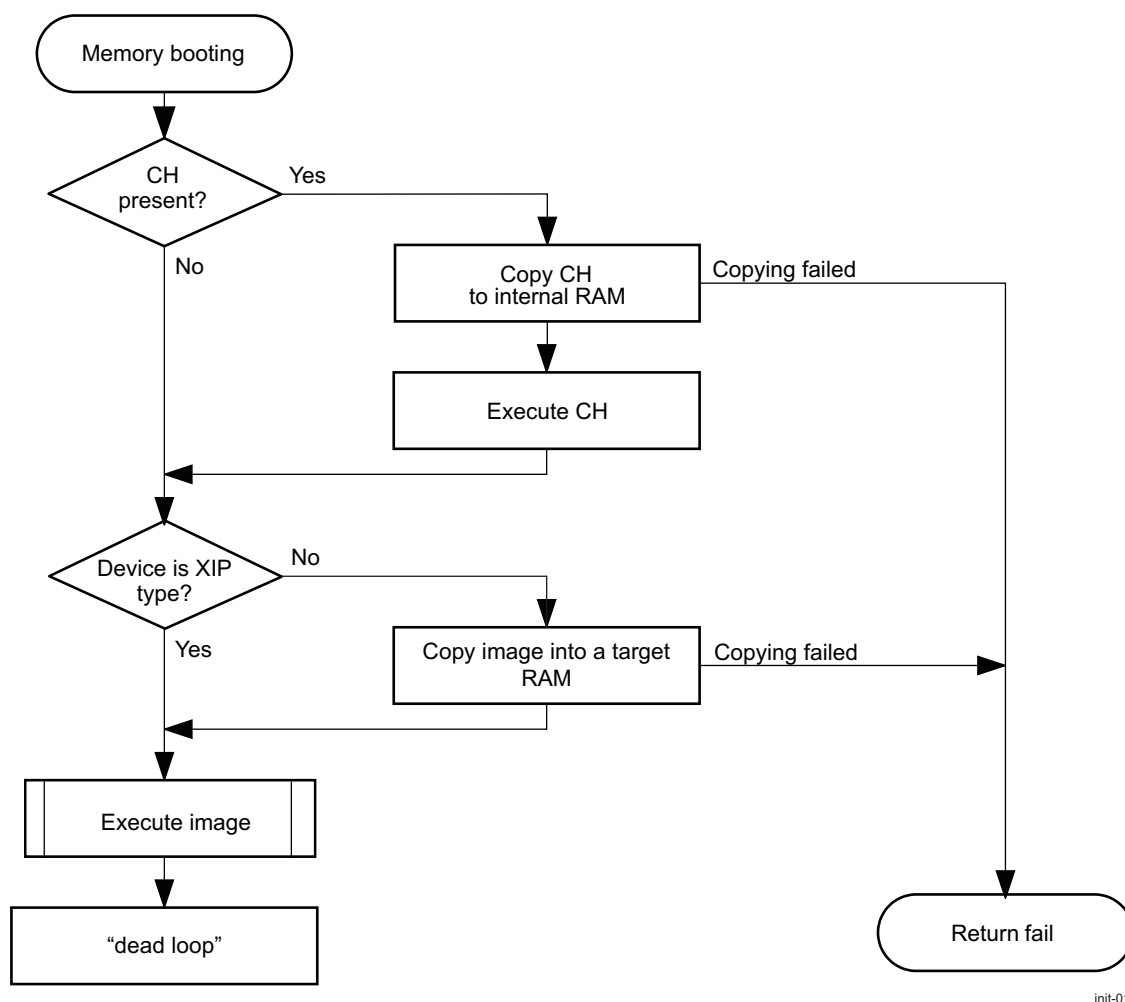

There are two main groups of permanent booting devices distinguished by code shadowing. Code shadowing means copying a code from a nondirectly addressable device (non-XIP) into RAM, where the code can be executed. Directly addressable devices are called eXecute-in-place (XIP) devices.

The memory booting flowchart shown in Figure 25-14 is an overview of common procedure for all types of devices. First, the CH is copied into internal RAM. It is copied even for XIP devices because the OMAP35x Applications Processor may lose a connection with XIP memory for a while during CH execution. The second step is to shadow the image, if the device is not XIP. The last step is image authentication and execution.

Unsuccessful authentication or return from image results in dead loop.

If CH copying or shadowing fails, memory booting returns to the main booting procedure, which selects the next device for booting.

Figure 25-14. Memory Booting

init-014

25.4.7.2 Non-XIP Memory

Figure 25-15 details the procedure used when memory booting runs with non-XIP devices. The grayed procedures are specific to each device. NAND and OneNAND devices use up to four copies of the image in the first four physical blocks. Therefore, the ROM code searches for the image in the first four physical blocks of these devices. Other devices use only one copy of the image and the block loop runs only once.

During image shadowing on a GP device, the CH is expected to be located in a separate sector preceding the Initial SW.

Figure 25-15. Detailed Memory Booting for Non-XIP Devices

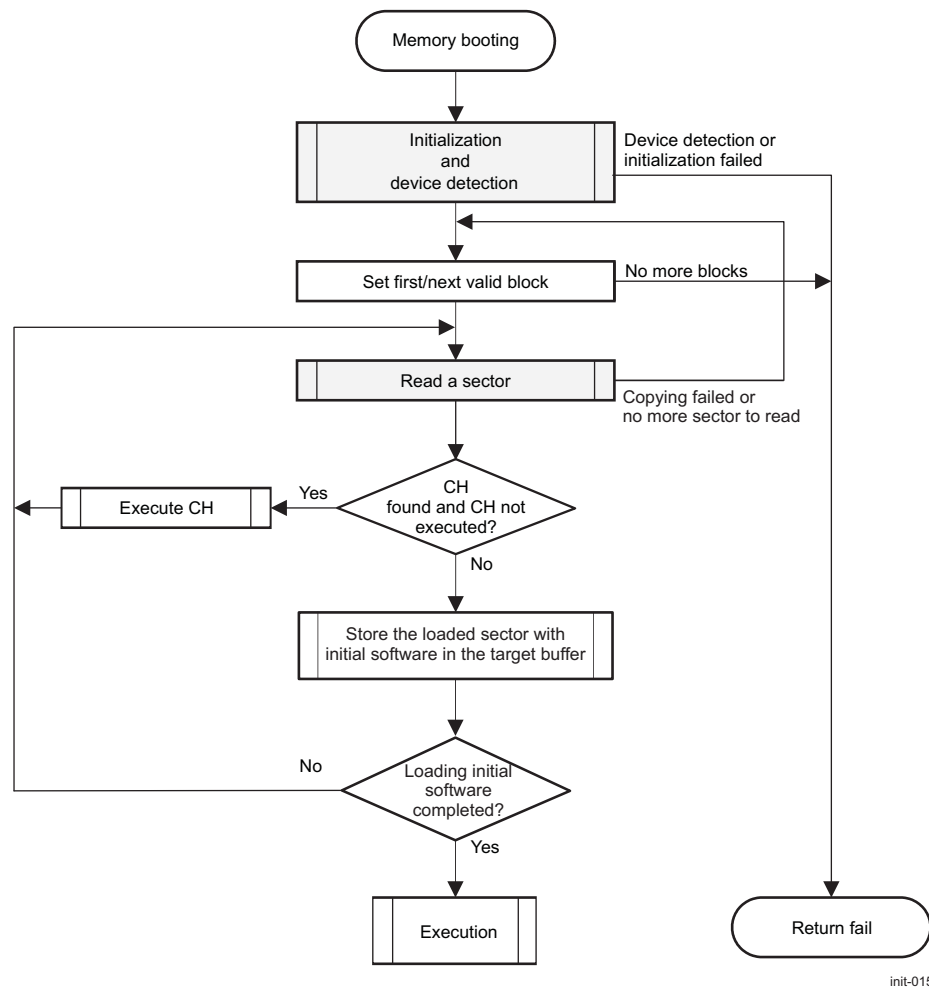

Table 25-29 summarizes numbers of blocks and sectors which are searched during the memory booting from devices requiring image shadowing. NANDs and OneNAND are organized with blocks, which are erasable units. DOC memory has only one block reserved for booting purposes, which overlaps the XIP part. MMC/SD card booting consists of reading a file. Since there is only one file read, it can be considered as one block trial.

Table 25-29. Blocks and Sectors Searched on Non-XIP Memories

Memory	Maximum Number of Checked Blocks	Number of Sectors Searched
NAND	First 4	Number of sectors in a block ⁽¹⁾
OneNAND	First 4	8
DOC ⁽²⁾	1	4
MMC/SD	One file	1

⁽¹⁾ Depends on NAND type.

⁽²⁾ DOC memory image must contain first sector filled with 0xFF or 0x00 because XIP booting always precedes DOC booting and the same data is used for XIP area. Therefore, a void sector at the beginning makes XIP booting failed and moves to DOC booting.

The following sections detail each supported device type.

For more details about the GPMC module, see the *Memory Subsystem* chapter.

25.4.7.3 XIP Memory

The ROM code can boot directly from XIP devices. Typical XIP devices are NOR flash memories. Supported XIP devices have the following characteristics:

- The GPMC is used as the communication interface.
- Memories up to 1G bit (128M bytes) can be connected.
- x16 data bus width only
- Asynchronous protocol and address/data multiplexed mode
- The GPMC clock is 48 MHz.
- The device is connected to cs0 mapped to address 0x0800 0000.
- The wait pin signal gpmc_wait0 is monitored according to the sys_boot configuration pins.

Depending on the sys_boot option, the GPMC can be configured to use the wait signal connected or not to the gpmc_wait0 pin. Wait pin polarity is set to stall accessing memory when gpmc_wait0 is low. Wait monitoring is to be used with memories that require a long time for initialization after reset, or that must pause while reading data. An example of such memory is DiskOnChip™.

For an XIP memory booting, no user intervention is needed; the following steps are described for debugging. Only the CH, which is not mandatory, lets the user change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device.

The booting from an XIP device can be described in the following points:

1. Configure the GPMC for XIP device access.
2. Verify that CH is present at address 0x0800 0000. If it is, copy the entire sector (512B) to internal RAM and execute CH.
3. Set the image location:
 - 0x0800 0000 if CH is not found.
 - 0x0800 0200 if CH (512 bytes) is found.
4. Verify that a bootable image is present at the image location.
5. Execute the image if it is found.
6. If the image is not found, return from XIP booting to the main booting loop.

25.4.7.3.1 GPMC Initialization

Table 25-30 describes the timing settings of GPMC set for XIP and other address-data accessible devices, like DiskOnChip or OneNAND. Table 25-30 is included for debug information.

Table 25-30. XIP Timing Parameters

Parameter	Value [Clock Cycles]	Register Initialization (i = 0–7)	Reset Value
Write cycle time	17	The GPMC_CONFIG5_i[12:8] WRCYCLETIME bit field is set to 0x11.	0x11
Read cycle time	17	The GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field is set to 0x11.	0x11
CS low time	1	The GPMC_CONFIG2_i[3:0] CSONTIME bit field is set to 0x1.	0x1
CS high time	16	The GPMC_CONFIG2_i[12:8] CSRDOFFTIME bit field is set to 0x10.	0x10
ADV low time	1	The GPMC_CONFIG3_i[3:0] ADVONTIME bit field is set to 0x1.	0x1
ADV high time	2	The GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field is set to 0x2.	0x2

Table 25-30. XIP Timing Parameters (continued)

Parameter	Value [Clock Cycles]	Register Initialization (i = 0–7)	Reset Value
OE low time	3	The GPMC_CONFIG4_i[3:0] OEONTIME bit field is set to 0x3.	0x3
OE high time	16	The GPMC_CONFIG4_i[12:8] OEOFFTIME bit field is set to 0x10.	0x10
WE low time	3	The GPMC_CONFIG4_i[19:16] WEONTIME bit field is set to 0x3.	0x03
WE high time	15	The GPMC_CONFIG4_i[28:24] WEOFFTIME bit field is set to 0xF.	0x10
Data latch time	15	The GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field is set to 0xF.	0x0F

25.4.7.4 NAND

NAND flash memory is not an XIP device; it requires shadowing before the code can be executed. ROM code support for the NAND flash devices has the following characteristics:

- The GPMC is the communication interface.
- Device from 64 Mb (8MB)
- x8 and x16 bus width
- Small page size (512 bytes + 16 bytes) and large page size (2048 bytes + 64 bytes)
- Chip enable (CE) don't care devices only
- Single level cell (SLC) and multilevel cell (MLC) devices
- Device identification is based on standard identification data or ID2 protocol.
- One-bit error checking and correction (ECC) is used to protect a 512-byte sector.
- GPMC timings are adjusted for NAND access.
- The GPMC clock is 48 MHz.
- The device is connected to CS0.
- The wait pin signal gpmc_wait0 is connected to the NAND BUSY output.
- Four physical blocks are searched for image. Block size depends on the device.

For NAND memory booting, no user intervention is needed; the information in the following subsections is included for debugging. Only the CH, which is not mandatory, lets the user change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device for booting.

25.4.7.4.1 Initialization and NAND Detection

The initialization routine for NAND consists of three parts: GPMC initialization, device detection with parameter determination, and bad block detection/verification.

- GPMC initialization
The GPMC interface is configured so that it can access NANDs. Because NANDs do not need the address bus, it is released. The data bus width is initially set to 8 bits. If necessary, it is changed to 16 bits after the device parameters are determined. [Table 25-31](#) shows the GPMC configuration used during NAND boot. [Table 25-31](#) is included for debug information.

Table 25-31. NAND Timing Parameters

Parameter	Value [Clock Cycles]	Register Initialization (i = 0–7)	Reset Value
Write cycle time	20	The GPMC_CONFIG5_i[12:8] WRCYCLETIME bit field is set to 0x14.	0x11
Read cycle time	20	The GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field is set to 0x14.	0x11

Table 25-31. NAND Timing Parameters (continued)

Parameter	Value [Clock Cycles]	Register Initialization (i = 0–7)	Reset Value
CS low time	0	The GPMC_CONFIG2_i[3:0] CSONTIME bit field is set to 0x0.	0x1
OE low time	5	The GPMC_CONFIG4_i[3:0] OEONTIME bit field is set to 0x5.	0x3
OE high time	16	The GPMC_CONFIG4_i[12:8] OEOFFTIME bit field is set to 0x10.	0x10
WE low time	3	The GPMC_CONFIG4_i[19:16] WEONTIME bit field is set to 0x3.	0x3
WE high time	15	The GPMC_CONFIG4_i[28:24] WEOFFTIME bit field is set to 0xF.	0x10
Data latch time	14	The GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field is set to 0xE.	0xF

- Device detection and parameters

The ROM code must first identify the NAND type connected on the GPMC interface. The GPMC is initialized using 8 bits, asynchronous mode. The NAND device is reset and its status is polled until it is ready for operation, then the Read ID command is issued. If the Read Device ID is recognized as a supported device, the device parameters are extracted from an internal ROM code table. [Table 25-32](#) lists the supported devices.

Table 25-32. Supported NAND Devices

Capacity	Device ID	Bus Width	Page Size in KB
64Mb	E6h	8	512
128Mb	33h	8	512
128Mb	73h	8	512
128Mb	43h	16	512

32Gb	A7h	8	2048
32Gb	B7h	16	2048
64Gb	A Eh	8	2048
64Gb	B Eh	16	2048

After retrieving parameters from the table, page size and block size are updated based on the fourth byte of the NAND ID data. Because of inconsistency among manufacturers, only devices recognized to be at least 2Gb have these parameters updated. Therefore, the ROM code supports 4-KB page devices, but only if their size, according to the table, is at least 2Gb. Devices smaller than 2Gb have the block size parameter set to 32KB when the page size is 512KB and to 128KB when the page size is 2048KB. [Table 25-33](#) shows the fourth ID data byte encoding used in the ROM code.

Table 25-33. Fourth NAND ID Data Byte

Item	Description	I/O Number							
		7	6	5	4	3	2	1	0
Page Size	1KB							0	0
	2KB							0	1
	4KB							1	0
	8KB							1	1
Block Size	64KB			0	0				
	128KB			0	1				
	256KB			1	0				
	512KB			1	1				

The detection procedure is described in [Figure 25-16](#). If the device ID is not recognized, the ROM code tries to read ID2 from the device; the sequence is described in [Figure 25-17](#). The description of the ID2 data content is summarized in [Table 25-34](#). If the ROM code fails to identify device ID or ID2, it returns with FAIL. When the device is successfully detected, the ROM code changes the GPMC to 16-bit bus width if necessary.

Figure 25-16. NAND Device Detection

- **Bad block detection/verification**

Invalid blocks contain invalid bits whose reliability cannot be ensured by the manufacturer. These bits are identified in the factory or during the programming and reported in the initial invalid block information in the spare area on the first and second page of each block. Because the ROM code looks for an image in the first four blocks, it detects the validity status of these blocks. Blocks detected as invalid are not accessed later. Blocks validity status is coded in the spare areas of the first two pages of a block. [Table 25-35](#) describes validity status coding for all four NAND families.

Table 25-35. Bad Block Marks Locations in NAND Spare Areas

	Small Page NAND	Large Page NAND
8 bit Device		
Block invalid when any byte not equal FFh	6th byte in 1st page 6th byte in 2nd page	1st byte in 1st page 1st byte in 2nd page
16 bit Device		
Block invalid when any word not equal FFFFh	1st word in 1st page 6th word in 1st page 1st word in 2nd page 6th word in 2nd page	1st word in 1st page 1st word in 2nd page

Section 25.4.7.4.2 depicts the invalid block detection routine. The routine consist in reading spare areas and checking data according to the conditions. The flags are used internally to convey information about each block validity.

25.4.7.4.3 Read Sector Procedure

During the booting procedure, the ROM code reads 512-byte sectors from the NAND device. The reading fails in two cases:

- The accessed sector is in a block marked as invalid.
- The accessed sector contains an error that cannot be corrected with ECC.

Pages can contain errors caused by memory alteration. To correct these errors, the ROM code uses ECC, based on Hamming codes for SLC NAND and BCH (Bose, Ray-Chaudhuri, Hocquenghem) code for multilayer ceramic capacitor (MLC) devices. The computed ECC is compared to ECC stored in the spare area of the corresponding page. If there are uncorrectable errors, the ROM code returns with FAIL.

25.4.7.5 OneNAND

ROM code support for OneNAND devices has the following characteristics:

- Devices from 512Mb
- The GPMC is the communication interface.
- x16 data bus width only
- Asynchronous protocol and address/data multiplexed mode

- GPMC reset default timings are used.
- The GPMC clock is 48 MHz.
- The device is connected to CS0 mapped to address 0x0800 0000.
- The wait pin signal gpmc_wait0 is not monitored.
- Four physical blocks are searched for image. The block size is 128KB.

The OneNAND device is a NAND matrix coupled with RAM buffers and a NOR-type interface. ECC correction handling is done automatically by the internal state-machine. The page to be accessed is first loaded in the RAM buffer using memory-mapped registers. Then, the page is read directly from the buffer using a NOR-type interface.

For OneNAND memory booting, no user intervention is needed. The information in the following subsections is included for debugging. Only the CH, which is not mandatory, lets the user change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device for booting.

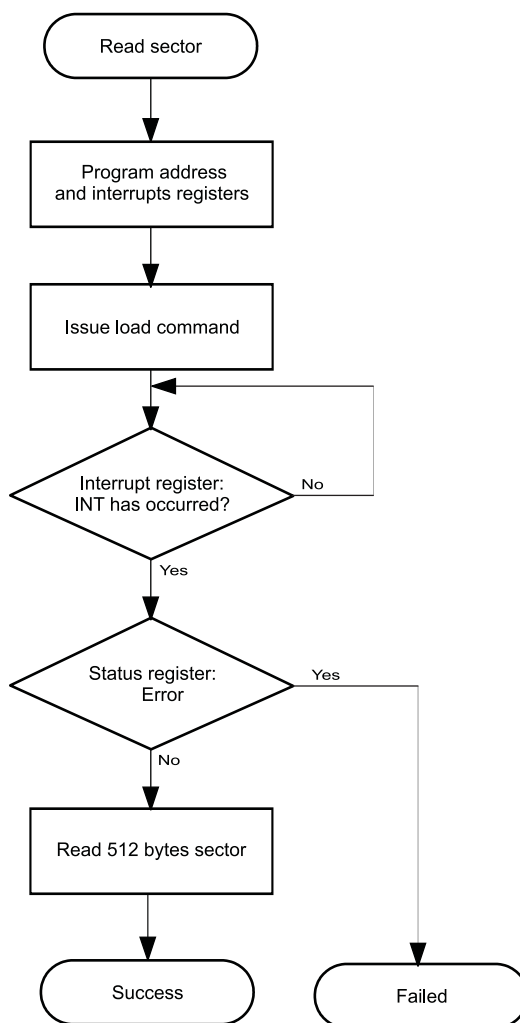

25.4.7.5.1 Initialization and OneNAND Detection

The initialization routine for OneNAND consists of two parts: GPMC initialization and device detection with parameter determination:

- GPMC initialization
The ROM code first initializes the GPMC interface the same way as for an XIP memory (that is, asynchronous 16-bit multiplexed mode). Wait signal monitoring is disabled. See [Table 25-30](#).
- Device detection and parameters
The ROM code identifies a OneNAND device by reading the device identification data. There are two ways to read identification data: using serial commands and reading from fixed memory mapped registers. The ROM code reads identification data using both methods and compares the result. When the comparison passes, the ROM code assumes that the OneNAND device is connected. If the device is successfully recognized, the ROM code reads the device configuration (amount and size of data buffers) and configures it for asynchronous mode (default).

25.4.7.5.2 OneNAND Read Sector Procedure

When booting requests a sector from the OneNAND device, the ROM code issues the load operation, which transfers the content of the requested sector to the data buffer RAM. The ROM code waits until the operation completes, polling the OneNAND interrupt register. The status register is then checked and the ROM code returns FAIL if the operation completes with an error. Otherwise, the data buffer RAM is copied to the destination buffer. [Figure 25-18](#) shows this procedure.

Figure 25-18. OneNAND Read Sector

init-025

25.4.7.6 MMC/SD Cards

The ROM code supports MMC/SD cards, with some limitations:

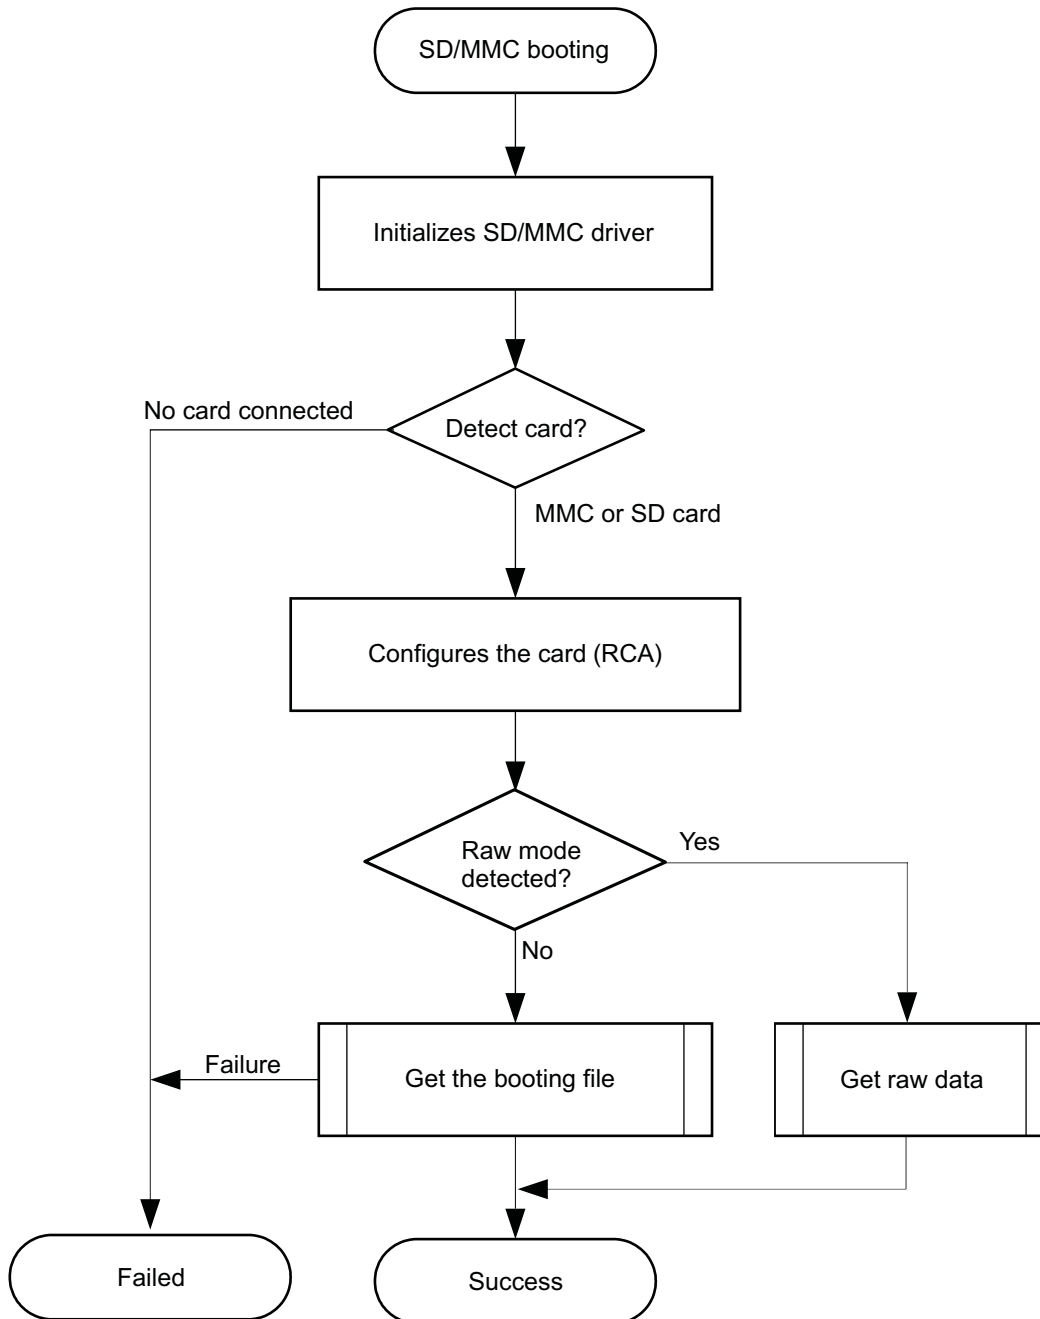

- Supports MMC/SD cards compliant with the *Multimedia Card System Specification v4.2* from the MMCA Technical Committee and the *SD I/O Card Specification v2.0* from the SD Association. Includes high-capacity (size >2GB) cards: HC-SD and HC MMC
- 3-V power supply, 3-V I/O voltage on PORT 1
- 1.8-V I/O voltage on PORT 2. External transceiver mode on PORT 2 is not supported.
- Initial 1-bit MMC mode, 4-bit SD mode
- Clock frequency:
 - Identification mode: 400 kHz
 - Data transfer mode: 20 MHz
- Only one card connected to the bus
- Raw mode, image data read directly from card sectors
- FAT12/16/32 support, with or without a master boot record (MBR).
- In case of a FAT (12/16/32) formatted memory card, the booting file must not exceed 128 KB.
- In case of a raw mode memory card, the booting image must not exceed 128 KB.

For MMC memory booting, no user intervention is needed. The information in the following subsections is included for debugging. Failure in MMC/SD card detection causes a return to the main booting procedure, which selects the next device for booting.

The HS MMC/SD/SDIO host controllers (MMCHS) handle the physical layer, while the ROM code handles the simplified logical protocol layer (read-only protocol). A limited range of commands is implemented in the ROM code. The MMC/SD specification defines two operating voltages for standard or HS cards. The ROM code supports only standard operating voltage range (3 V) (both modes supported).

The ROM code reads a booting file from the card file system and boots from it. [Figure 25-19](#) shows the complete procedure.

Figure 25-19. MMC/SD Booting

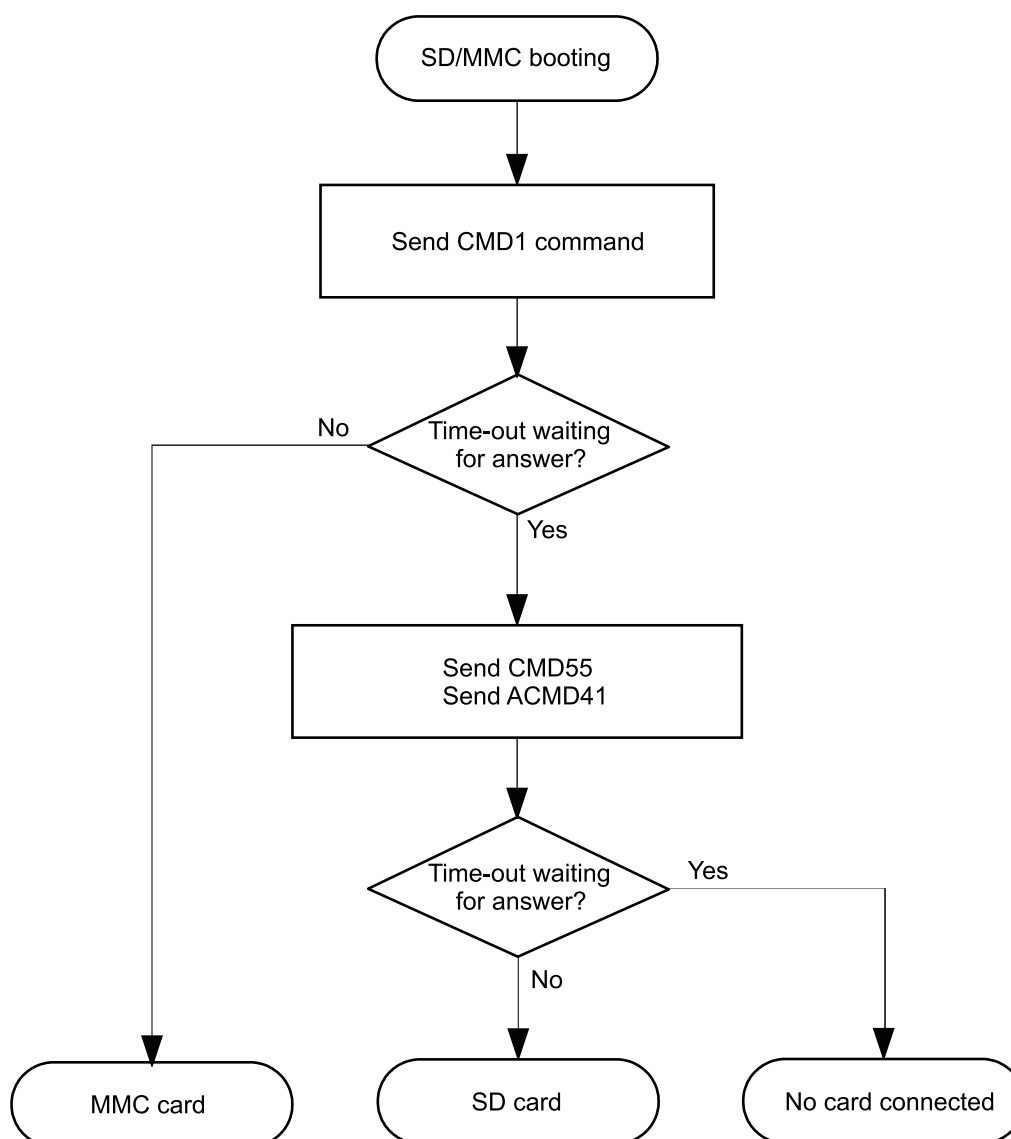

init-016

25.4.7.6.1 Initialization and MMC/SD Card Detection

The ROM code initializes the card connected on interface 1 using the standard high-voltage range (3.0 V) if a card is plugged in. If no card is present, the ROM code goes to the next booting device. The standard identification process and relative card address (RCA) assignment are used. However, the ROM code searches for only one card connected on the bus. This is done using the CMD line common to the SD and MMC cards. The MMC and SD standards describe this phase as the initialization phase. They differ in the first commands, CMD1 and ACMD41. The ROM code uses this command difference to differentiate between MMC and SD cards; that is, CMD1 is supported only by MMC and ACMD41 is supported only by SD. The ROM code first sends a CMD1 to the card and gets an answer only if an MMC card is connected. If no answer is received, ACMD41 (a combination of CMD55 and ACMD41) is sent, and an answer is expected from an SD card. If no answer is received, no cards are connected and the ROM code exits MMC/SD booting with FAIL.

Figure 25-20 shows the MMC/SD detection procedure.

Figure 25-20. MMC/SD Detection Procedure

init-026

25.4.7.6.2 Read Sector Procedure

- Raw mode

In raw mode, an image can be at offset 0 or 128KB and must not be bigger than 128KB. Raw mode is detected by reading sector 0. If a CH is in this first sector, raw mode is validated. The CH can be void, as described in [Section 25.4.8.2, CH](#). To sum up, ROM Code decides to switch into the raw mode if the first read sector contains a TOC structure with either an “MLO” or “CHSETTINGS” item. If raw mode is not detected, file system mode is assumed. Image data is read directly from continuous sectors of a card.

- File system handling

The sector read procedure uses the standard MMC/SD read data procedure. The sector address is generated based on the booting memory file map collected during initialization. Thus, the ROM code can address sectors freely in the booting file space.

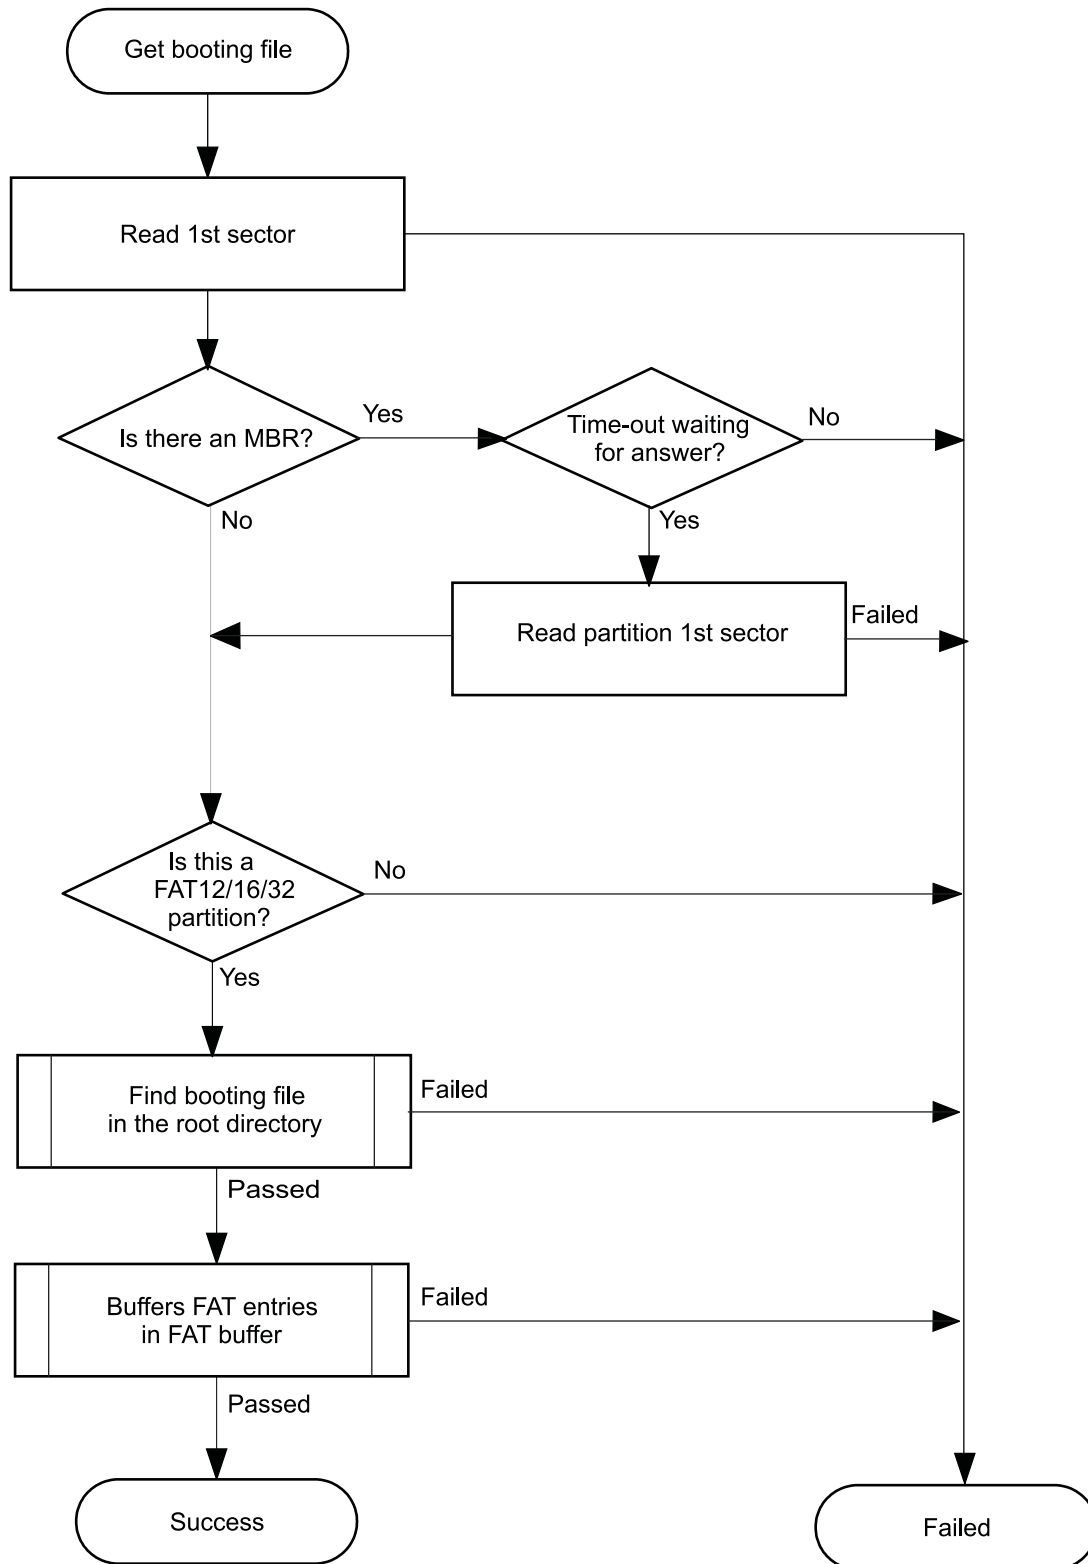

25.4.7.6.3 File System Handling

MMC/SD Cards may hold a file system which ROM Code reads. The image used by the Booting procedure is taken from a specific booting file named “MLO”. This file has to be located in the root directory on an active primary partition of type FAT12/16 or FAT32.

An MMC/SD card can be configured as floppy-like or hard-drive-like:

- When acting like a floppy, the content of the card is a single FAT12/16/32 file system without an MBR holding a partition table.
- When acting like a hard drive, an MBR is present in the first sector of the card. This MBR holds a table of partitions, one of which must be FAT12/16/32, primary, and active.

According to the *MultiMediaCard FAT16 File System Specification* from the MMCA Technical Committee, the card should always hold an MBR, except for MMC cards using a floppy-like file system. However, depending on the operating system used, the MMC/SD card is formatted with or without partition(s) (using an MBR). The ROM code supports both types: floppy-like or hard-drive-like. The ROM code retrieves a map of the booting file from the FAT table. The booting file map is a collection of all FAT table entries related to the booting file (a FAT entry points to a cluster holding part of the file). The booting procedure uses this map to access any 512-byte sector in the booting file without involving the ROM code FAT module. [Figure 25-21](#) shows the complete process.

Figure 25-21. SD/MMC Booting

init-027

- MBR and FAT file system

This paragraph describes functionalities used by the ROM code to recognize whether an MBR with a FAT is used. It is not intended to fully describe the MBR and the FAT file system detection and reading procedure. The ROM code can detect FAT12/16/32 allocation table types. It cannot boot on devices with NTFS or Linux FS partitions. Some memory devices that support file systems can be formatted with or without MBR; therefore, the first task of the ROM code is to detect whether the device is holding an MBR in the first sector.

The MBR is the first sector of a memory device. It consists of executable code, four partition entries, and one signature. The aim of such a structure is to divide the hard disk in partitions used primarily to boot different systems (for instance, Microsoft Windows™). This structure is described in [Table 25-36](#); partition table entry is described in [Table 25-37](#).

Table 25-36. Master Boot Record Structure

Offset	Length [Bytes]	Entry Description
0000h	446	Optional code
01BEh	16	Partition table entry
01CEh	16	Partition table entry
01DEh	16	Partition table entry
01EEh	16	Partition table entry
01FEh	2	Signature (= 0xAA55)

Table 25-37. Partition Table Entry

Offset	Length [Bytes]	Entry Description	Value
0000h	1	Partition state	00h: Inactive 80h: Active
0001h	1	Partition start head	Hs
0002h	2	Partition start cylinder and sector	Cs[7:0]–Cs[9:8]–Ss[5:0]
0004h	1	Partition type	01h: FAT12 04h, 06h, 0Eh: FAT16 0Bh, 0Ch, 0Fh: FAT32
0005h	16	Partition end head	He
0006h	2	Partition end cylinder and sector	Ce[7:0]–Ce[9:8]–Se[5:0]
0008h	4	First sector position relative to the beginning of media	LBAs = Cs.H.S+ Hs.S+ Ss–1
000Ch	4	Number of sectors in partition	LBAe = Ce.H.S+ He.S+ Se–1 Nb s= LBAe–LBAs + 1

1. Find the booting file

Once a partition is found, the root directory entries are searched for a specific booting file named “MLO” inside the Root Directory of the FAT12/16/32 file system. The file is not searched in any other location. For a FAT12/16 file system, the Root Directory has a fixed location which is cluster 0. For a FAT32 file system, its cluster location is given by BPB_RootClus. The general formulae to find the sector number (relative to device sector 0, not partition sector 0) of a cluster is given by:

$$\text{Cluster}_{\text{sector}} = \text{BPB_HiddSec} + \text{BPB_RsvdSecCnt} + \text{BPB_NumFATs} \times \text{BPB_FATSz} + \text{Cluster} \times \text{BPB_SecPerClus}$$

Note: BPB_FatSz is BPB_FatSz16 for FAT12/16 or BPB_FatSz32 for FAT32

Note: the BPB_HiddSec field can contain 0 even though the FAT file system is located somewhere other than on sector 0 (floppy-like). The ROM Code actually uses the partition offset taken from the MBR instead of this field which can be wrong. If no MBR was found (floppy-like) the value 0 is used. Each entry in the Root Directory is 32 bytes long and hold information about the file, i.e. filename, date of creation, rights, cluster location etc. This is described in [Table 25-38](#).

The ROM Code checks each entry in the Root Directory until either the booting file is found or the entry is empty (first byte is 00h) or when the end of the Root Directory has been reached. Entries with ATTR_LONG_NAME attribute (LFN) and with first byte at E5h (erased file) are ignored. When found, the first cluster offset of the file is read from the DIR_FstClusHi/DIR_FstClusLo fields.

There is a slight difference between FAT12/16 and FAT32 when handling the Root Directory. On FAT12/16, this directory has a fixed location (see above) and length fixed by BPB_RootEntCnt which is the total number of 32 bytes entries. Handling this directory is therefore straight forward. On FAT32, the Root Directory is like a standard file, the File Allocation Table (FAT) has to be used in order to retrieve each sector of the Directory. The way the FAT is handled is described in the next paragraph.

Table 25-38. FAT Directory Entry

Offset	Length [Bytes]	Name	Description
0000h	11	DIR_Name	Short name (8 + 3)
000Bh	1	DIR_Attr	File Attributes: ATTR_READ_ONLY 01h ATTR_HIDDEN 02h ATTR_SYSTEM 04h ATTR_VOLUME_ID 08h ATTR_DIRECTORY 10h ATTR_ARCHIVE 20h ATTR_READ_ONLY I ATTR_HIDDEN I ATTR_SYSTEM I ATTR_VOLUME_ID
000Ch	1	DIR_NTRes	Reserved, set to 00h
000Dh	1	DIR_CrtTimeTenth	Millisecond stamp at file creation
000Eh	2	DIR_CrtTime	Time file was created
0010h	2	DIR_CrtDate	Date file was created
0012h	2	DIR_LstAccDate	Last Access date
0014h	2	DIR_FstClusHi	High word of this entry's first cluster number
0016h	2	DIR_WrtTime	Time of last write
0018h	2	DIR_WrtDate	Date of last write
001Ah	2	DIR_FstClusLo	Low word of this entry's first cluster number
001Ch	4	DIR_FileSize	File size in bytes

2. Buffer FAT entries in the FAT buffer

Once the booting file is found, the ROM code reads the FAT and buffers the singly-linked chain of clusters in a FAT buffer used by booting to access the file directly, sector by sector. For FAT12/16 and for FAT32, multiple copies of the FAT exist (ROM code supports only two copies) located after the Boot Sector:

$$\text{FAT}_{\text{sector}} = \text{BPB_HiddSec} + \text{BPB_RsvdSecCnt} + \text{BPB_FatSz} \times n$$

Its size is given by BPB_FATsSz16 or BPB_FATsSz32. The ROM Code checks each copy of the FAT if identical. In case the values are different, the ROM Code uses the value from the last FAT copy. With FAT32 file system, the copy system can be disabled according to a flag located in BPB_ExtFlags[7]. If this flag is set then FAT BPB_ExtFlags[3:0] is used. In this case no verification is made by the ROM Code with other copies of FAT.

The FAT is a simple array of values each referring to a cluster located in the Data Area. One entry of the array is 12, 16 or 32 bits depending on the file system in use. The value inside an entry defines whether the cluster is being used or not and if another cluster has to be taken into account. This creates a singly-linked chain of clusters defining the file.

Note: For compatibility reasons, clusters 0 and 1 are not used for files and those entries must contain FF8h and FFFh (for FAT12); FFF8h and FFFFh (for FAT16); ?FFFFFF8h and ?FFFFFFFh (for FAT32).

Table 25-39. FAT Entry Description

FAT12	FAT16	FAT32	Description
000h	0000h	?0000000h	Free Cluster
001h	0001h	?0000001h	Reserved Cluster
002h-FEFh	0002h-FFEFh	00000002h-?FFFFFFEFh	Used Cluster; value points to next cluster
FF0h-FF6h	FFFF0h-FFFF6h	?FFFFFFF0h-?FFFFFFF6h	Reserved values
FF7h	FFFF7h	?FFFFFFF7h	Bad Cluster
FF8h-FFFh	FFF8h-FFFFh	?FFFFFFFh-?FFFFFFFh	Last Cluster in File

Note: FAT32 uses only bits [27:0], the upper 4 bits are usually 0 and should be left untouched. When accessing the Root Directory for FAT32, the ROM Code just starts from the Root Directory Cluster entry and follows the linked chain to retrieve the clusters.

When the booting file has been found, the ROM Code buffers each FAT entry corresponding to the file in a sector way. This means each cluster is translated to one or several sectors depending on how many sectors are in a cluster (BPB_SecPerClus). This buffer is used later on by the booting procedure to access the file.

25.4.7.7 DiskOnChip™

The ROM code support for DiskOnChip™ devices has the following characteristics:

- DiskOnChip™ H3
- 1.8-V power supply
- Density from 256M bits

The DiskOnChip™ contains an XIP part that can hold a boot image. In this case, the DiskOnChip™ is connected just like a regular NOR device, and uses the same procedure as for NOR described in [Section 25.4.7.3](#).

If booting determines that it must boot from DOC, the ROM code initializes the GPMC using standard asynchronous, 16-bit, multiplexed mode. The DOC device is then detected using the M-System driver. This proprietary driver handles all DiskOnChip protocols and identification. If the device cannot be identified, the ROM code returns a failed code. Otherwise, booting directly requests sectors from the M-System driver.

SD/MMC booting consists of several steps:

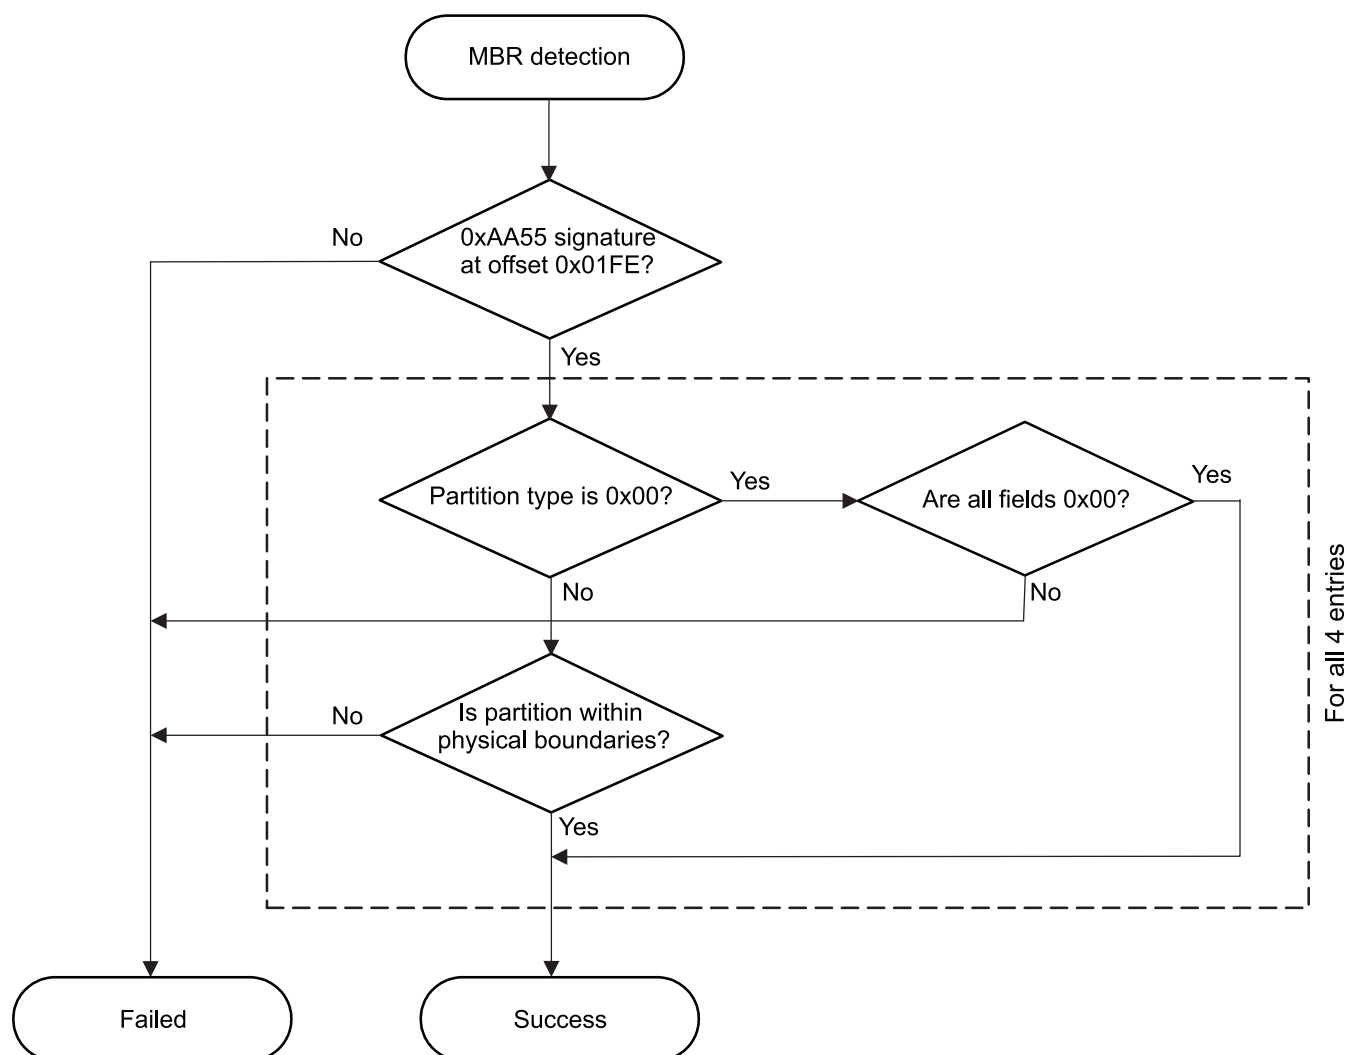

1. MBR detection

The ROM code first checks whether the MBR signature is present and then it searches an active FAT12/16/32 partition in all four MBR partition entries, based on the Type field. If the MBR entries are not valid or if no usable partition is found, the ROM code returns to the booting procedure with FAIL. The extended partitions are not checked; the booting file must reside in a primary partition. Each partition entry is checked:

- If its type is set to 00h, all fields in the entry must be 00h.
- The partition is checked to be within physical boundaries (that is, the partition is inside and it fits the total physical sectors).

See [Figure 25-22](#) for more information about MBR detection.

Figure 25-22. MBR Detection Procedure

init-028

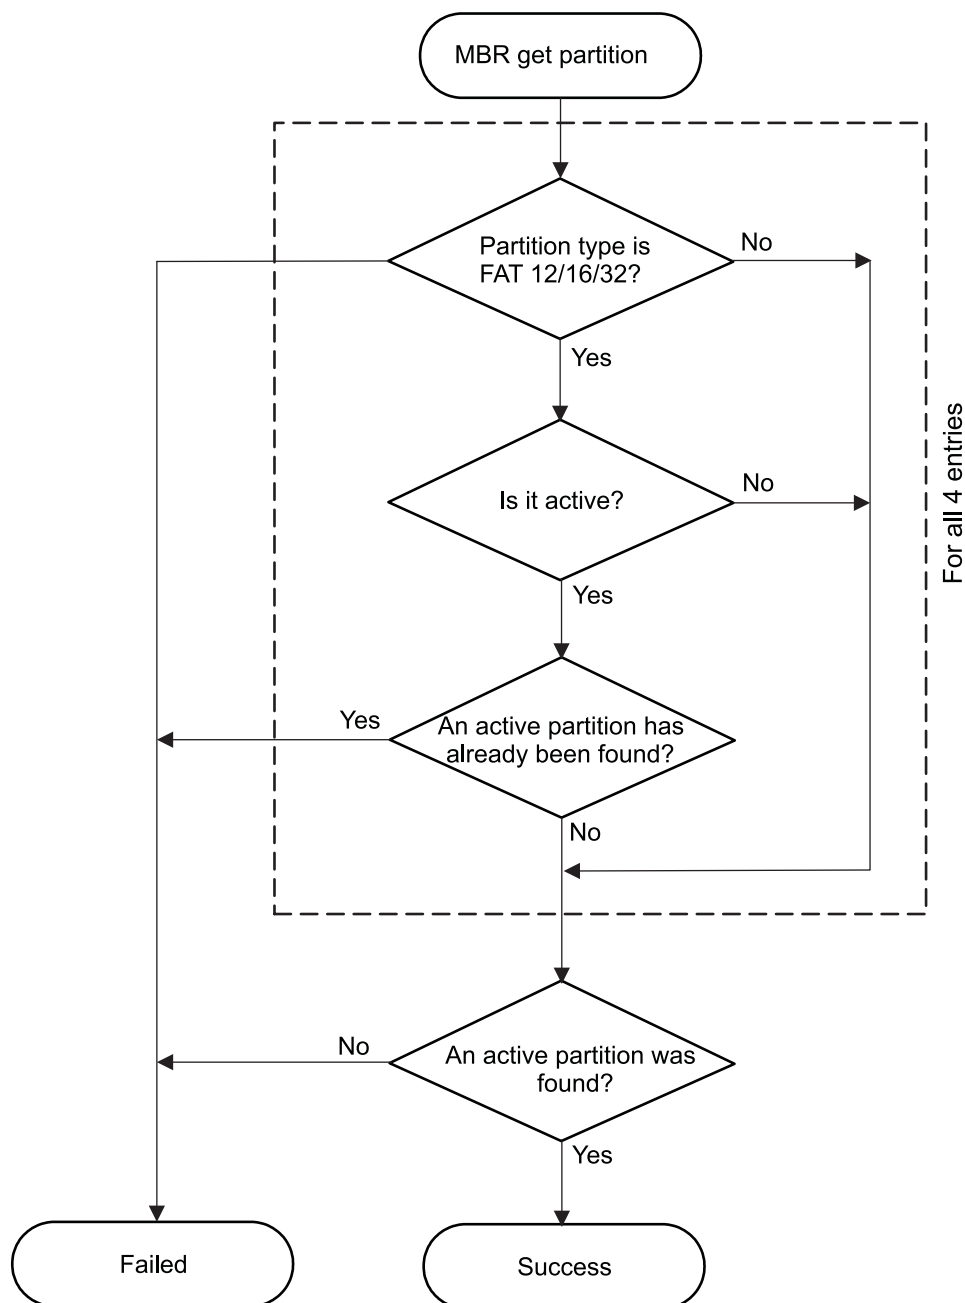

2. Get the MBR partition.

Once identified, the ROM code gets the partition using the procedure described in [Figure 25-22](#). The partition type is checked to be FAT12/16 or FAT32. Its state must be 00h (inactive) or 80h (active.) The ROM code returns with FAIL if no active primary FAT12/16/32 is found, or if there is more than one active partition, the test fails. If an active partition is found, its first sector is read and used later. If no MBR is present (in case of a floppy-like system), the first sector of the device is read and used later. The read sector is checked to be a valid FAT12/16 or FAT32 partition. If this fails, if another partition type is used (for instance, Linux® FS) or if the partition is not valid, the ROM code returns with FAIL. The FAT file system consists of several parts:

- Boot sector, which holds the BIOS parameter block (BPB). Not all are used by the ROM code.
- FAT, which describes the use of each cluster of the partition
- Data area, which holds the files, directories, and root directory (for FAT12/16, the root directory has a specific fixed location).

To check whether a sector holds a valid FAT12/16/32 partition, many fields of the boot sector (used by all FAT types) that must have specific values are checked. [Figure 25-23](#) shows more information about getting the MBR partition.

Figure 25-23. Get MBR Partition

init-029

25.4.8 Image Format

25.4.8.1 Overview

An image is basically made out of two major parts:

- An optional configuration header (CH).
- The software to execute.

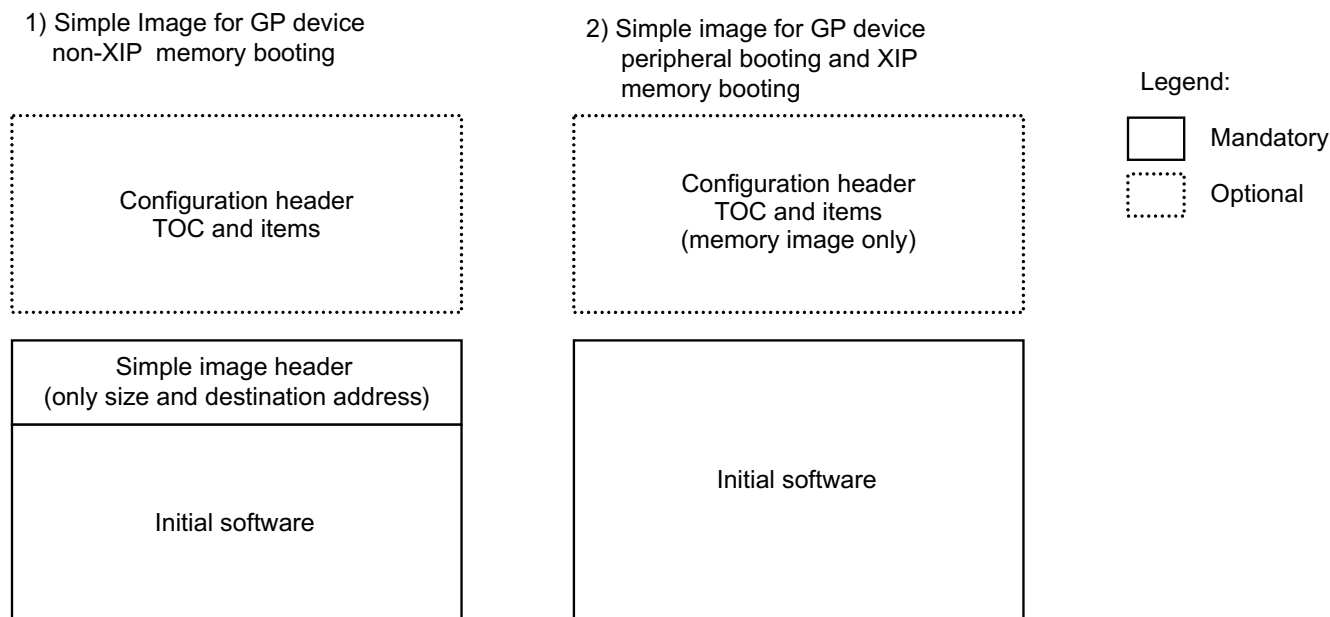

The CH, which is optional, can contain several parameters set by users to speed-up the boot process. It is further described in the next section.

The mandatory part contains the SW which is loaded into the memory and executed.

An overview of the image formats is shown in [Figure 25-24](#). There are two image types for GP devices:

1. GP non-XIP memory booting:
This image type is used for memories that require shadowing. The image must begin with a simple header that contains information on size to copy and destination. This format is detailed in [Section 25.4.8.3, Image Format for GP Devices](#).
2. GP XIP memory booting and peripheral booting:
GP image on XIP memory contains only code. Optionally, the first sector can contain CH. The GP peripheral booting image contains only code.

Figure 25-24. Image Format

init-018

25.4.8.2 Configuration Header

The CH is completely optional and is required only if the customer wants to use settings different from the ROM code defaults (for example, clock frequencies, SDRAM/DDRDRAM settings, GPMC settings.) The CH can be present only when booting from a memory-type device (for example CH is not supported when booting from UART or USB.) Therefore, the CH contains only settings for memory booting, it can contain up to four parts:

- SETTINGS: Contains various clock settings (mandatory)
- RAM: Contains settings for SDRAM/DDRDRAM interface
- FLASH: Contains settings for flash interface (GPMC)
- MMC/SD: Contains settings for the MMC/SDIO Interfaces

The beginning of the CH is a table of contents (TOC) pointing to each item. This is described in [Figure 25-25](#). Each TOC item is a simple structure described in [Table 25-40](#). The complete CH (CH TOC and items) should fit in a 512-byte sector.

The ROM code identifies the presence of a CH by reading the first TOC item if it contains a known string (CHSETTINGS, CHRAM, ...). Then, the TOC is identified and searched until a 0xFFFFFFFF offset is found. The CH is read and parameters are executed sequentially.

Figure 25-25. Configuration Header Format

Table 25-40. Configuration Header TOC Item

Offset	Field	Size [bytes]	Description
0x0000	Start	4	Offset from the start address of TOC to the actual address of a section
0x0004	Size	4	Size of a section
0x0008	reserved	4	Unused
0x000C	reserved	4	Unused
0x0010	reserved	4	Unused
0x0014	Filename	12	12-character long name of a section, including the zero (0) terminator.

25.4.8.3 Image Format for GP Devices

For a GP device, no security is enabled and, therefore, neither keys nor certificates are required. The image is simple and must contain a small header having the size of the SW to load and the destination address of where to store it when a device is other than XIP. The XIP device image is even simpler and starts with executable code. The image format is described in [Table 25-41](#). The header is used only for memory booting. The peripheral booting image does not have any header and starts directly with executable code.

Table 25-41. GP Device SW Image

Filed	Non-XIP Device		XIP Device		Size (Bytes)	Description
	Offset		Offset			
Size	0x0000	-			4	Size of the image
Destination	0x0004	-			4	Address where to store the image

Table 25-41. GP Device SW Image (continued)

Filed	Non-XIP Device		XIP Device		Size (Bytes)	Description
	Offset		Offset			
Image	0x0008	0x0000			x	The Image

25.4.8.4 Image Execution

The image is executed when the ROM code performs a branch instruction to the first executable instruction inside the Initial SW. The execution address is the first word after the image header. After the branch, the ARM runs in public ARM supervisor mode. The R0 register points to the booting parameter structure that contains some information about the booting process. [Table 25-42](#) details the booting parameters structure.

Table 25-42. Booting Parameters Structure

Offset	Field	Size [Bytes]	Description
0x00	Booting message	4	Last received Booting Message.
0x04	Current booting device	1	Code of device used for booting: 0x01: XIP memory 0x02: NAND 0x03: OneNAND 0x04: DOC 0x05: MMC/SD2 0x06: MMC/SD1 0x07: XIP memory with wait monitoring 0x10: UART 0x11: HS USB
0x05	Reserved	1	Reserved
0x06	Reset reason	1	Current reset reason bit mask (bit = 1, event present): [0]: Power-on reset [1]: Global SW reset [3]: Violation reset [4]: MPU watchdog reset [5]: Watchdog reset [6]: External warm reset Other bits: Reserved
0x07	CH Flags	1	Configuration header sections flag. Each section is described by one bit. A set bit indicates the section was executed: [0]: CHSETTINGS [1]: CHRAM [2]: CHFLASH [3]: CHMMC Other bits: Reserved
0x08	Device descriptor	4	Pointer to the device descriptor structure. This pointer is required when current booting device driver functions are called.

25.4.9 Tracing

Tracing in the public ROM code consists in a 64-bit vector in which each bit corresponds to a certain point of the ROM code execution flow. The tracing vector is divided into two 32-bit words. [Table 25-43](#) lists the location and organization of the tracing data in RAM. Tracing data is initialized at the beginning of the start-up phase.

There are two sets of tracing data: the first set is the current trace information, the second set holds tracing collected during the first ROM code run following a cold reset. This cold reset tracing is copied into its location during the tracing initialization of the second ROM code run after the cold reset run. These data can be used for debugging purposes.

Table 25-43. Tracing Vector

Bit No.	Group	Meaning
0	General	Reset
1	General	ROM code C main
2	General	ROM code runs after the cold reset
3	Boot	Booting started
4	Memory boot	Memory booting started
5	Boot	No more device to check
6	Peripheral boot	Peripheral booting started
7	Boot	Booting message change device
8	Boot	Booting message skip per. booting
9	Reserved	Reserved
10	Memory boot	CH found
11	Memory boot	Image header correct
12	Peripheral boot	Device initialized
13	Peripheral boot	ASIC ID sent
14	Peripheral boot	Booting message received
15	Peripheral boot	Image received
16	Peripheral boot	Peripheral booting failed
17	Peripheral boot	UART
18	Peripheral boot	USB
19	Reserved	Reserved
20	Reserved	Reserved
21	Peripheral boot	NULL device
22	Execute	Image executed
23	Reserved	Reserved for non-GP devices
24	Reserved	Reserved for non-GP devices
25	Reserved	Reserved for non-GP devices
26	Reserved	Reserved for non-GP devices
27	Reserved	Reserved for non-GP devices
28	Reserved	Reserved for non-GP devices
29	Boot	Software booting configuration section 1 found
30	General	Software booting configuration clocking section found
31	Reserved	Reserved
32	Memory boot	Null device
33	Memory boot	XIP
34	Memory boot	NAND
35	Memory boot	OneNAND
36	Memory boot	DOC
37	Memory boot	MMC/SD2

Table 25-43. Tracing Vector (continued)

Bit No.	Group	Meaning
38	Memory boot	MMC/SD1
39	Memory boot	XIP memory with wait monitoring

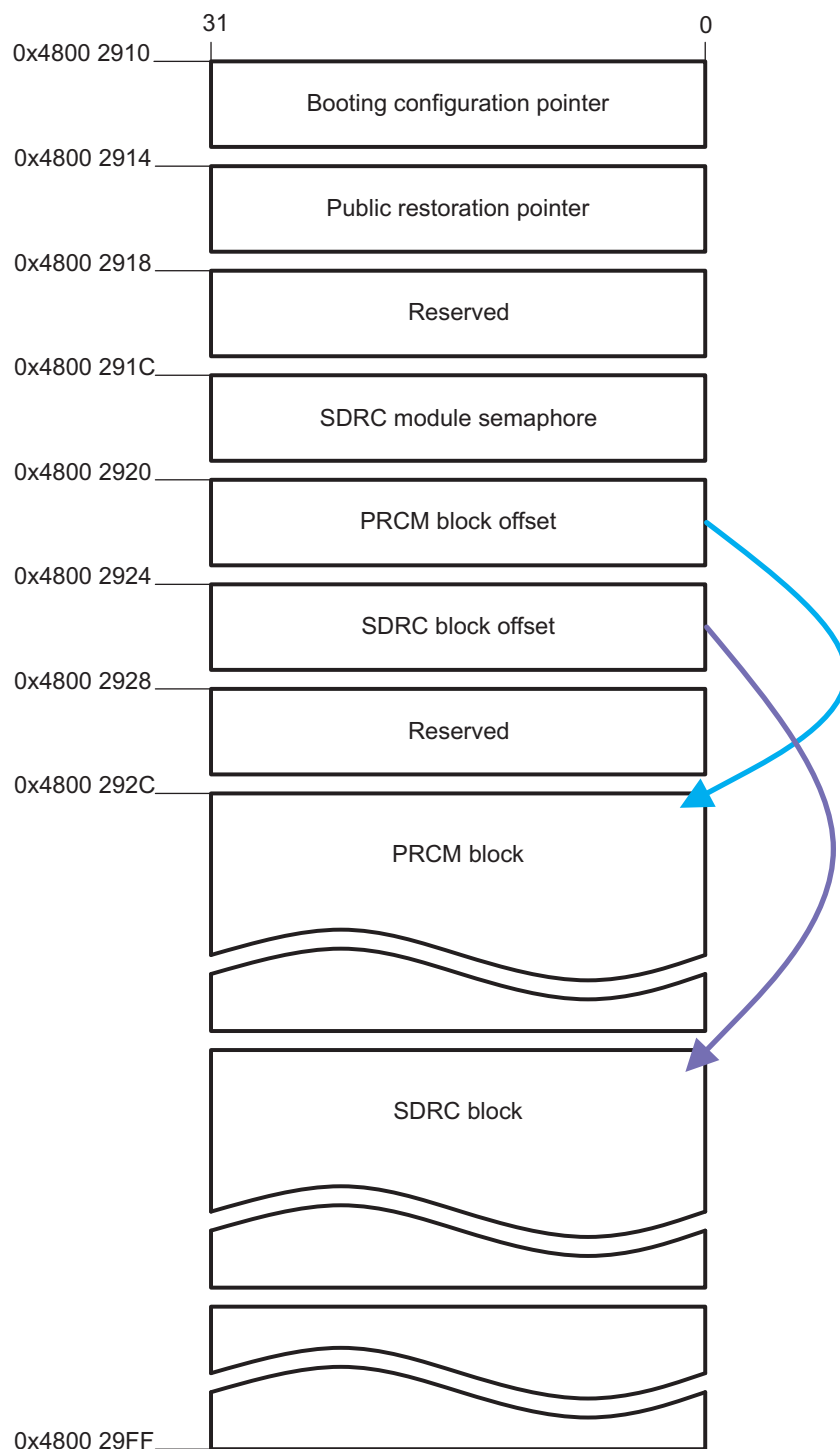

25.5 Wake-Up Booting by ROM Code

In core OFF mode, all configurations outside the wake-up domain are reset and must be restored to restart the system in the condition it was before being stopped. Following an MPU and CORE wake-up reset, the ROM code restores the SDRC and clock settings to allow a jump to a public restore function. This public restore function is specifically implemented by users to restore their own HW and SW environments. Users must set the public restore function address in the public restore pointer field of the CONTROL_SAVE_RESTORE_MEM structure (see [Figure 25-26](#)).

The CONTROL_SAVE_RESTORE_MEM memory of the system control module is used to save and restore the mandatory information to automatically reconfigure the SDRC and PRCM registers. The SDRC and clock registers must be saved by users in the respective structures (see [Table 25-45](#) and [Table 25-46](#)) in the SCM before going in OFF mode to be automatically restored on wake-up boot by the ROM code.

The size of CONTROL_SAVE_RESTORE_MEM is 239 bytes starting at the HW physical address 0x48002910 to 0x480029FF. [Figure 25-26](#) shows the memory format that must be obeyed to handle the context restoration.

Figure 25-26. CONTROL_SAVE_RESTORE_MEM Format

init-021

Table 25-44. CONTROL_SAVE_RESTORE_MEM Fields Definition

Filed Name	Size	Description
Booting Configuration Pointer	32 bits	Address of public booting information used after a SW reset

Table 25-44. CONTROL_SAVE_RESTORE_MEM Fields Definition (continued)

Filed Name	Size	Description
Public Restore Pointer⁽¹⁾	32 bits	Address of the public restore function to branch to when exiting a wake-up reset boot.
SDRC Module Semaphore⁽²⁾	32 bits	Semaphore used for accessing the SDRC module.
PRCM Block Offset⁽¹⁾	32 bits	Offset of the PRCM configuration inside the control save restore memory. Set 0x0 to not use this block.
SDRC Block Offset⁽¹⁾	32 bits	Offset of the SDRC configuration inside the Control Save Restore Memory. Set 0x0 to not use this block.

⁽¹⁾ Field to be set by users.

⁽²⁾ ROM code use only

Table 25-45 describes the PRCM context restore block.

25.6 Debug Configuration

25.6.1 Overview

This section provides information for using a debugger on the public ARM Cortex™-A8 in the OMAP35x device. The debug capability is accessible through the JTAG interface with a limited number of pins.

25.6.2 JTAG Port Signal Description

The OMAP35x target debug interface uses the five standard IEEE 1149.1 (JTAG) signals (nTRST, TCK, TMS, TDI, and TDO), a return clock (RTCK) to meet the clocking requirements of the ARM968 processor, and the two instrumentations pins (EMU0, EMU1). For more information, see [Table 25-47](#).

Table 25-47. Debug POR Signals

Pin	Type ⁽¹⁾	Name	Description
nTRST	I	Test logic reset	When asserted (active low), causes all test and debug logic in the device to be reset with the IEEE 1149.1 interface
TCK	I	Test clock	This is the test clock used to drive an IEEE 1149.1 test access port (TAP) state-machine and logic. Depending on the emulator attached to OMAP35x, this is a free-running clock or a gated clock, depending on RTCK monitoring.
RTCK	O	Returned test clock	Synchronized TCK. Depending on the emulator attached to OMAP35x, the JTAG signals are clocked from RTCK or RTCK is monitored by the emulator to gate TCK.
TMS	I	Test mode select	Directs the next state of the IEEE 1149.1 TAP state-machine
TDI	I	Test data input	Scan data input to the device.
TDO	O	Test data output	Scan data output of the device.
EMU0	I/O	Emulation 0	Channel 0 trigger: Boot mode
EMU1	I/O	Emulation 1	Channel 1 trigger: Boot mode

⁽¹⁾ I = Input, O = Output

The power domain containing the debug logic can be switched OFF in normal operating mode to reduce power consumption.

CAUTION

Before starting the debugger, the DEBUG power domain must be activated by applying a minimum of 10 TCK pulses to the OMAP35x device after nTRST is pulled high.

25.6.3 Initial Scan Chain Configuration

The general-purpose ports that can provide access to many test support functions built into the device (including the test logic defined by the IEEE 1149.1 standard) are the TAP.

The first level of the debug interface that sees the scan controller is the TAP router module.

The debugger can configure the TAP router to serially link to 16 TAP controllers or to individually scan one TAP controller without disrupting the instruction register (IR) state of the other TAPs. The initial scan chain configuration of the OMAP35x device is determined from the level of the EMU0 and EMU1 pins on the release of POR. At POR, EMU0 and EMU1 are automatically configured as inputs. The EMU0 and EMU1 pins should be pulled high at POR to configure the initial scan chain of the OMAP35x device to TAP router-only mode. In the TAP router-only configuration, no secondary TAPs are selected. The TAP router is the only TAP between the device-level TDI and TDO.

The router TAP has an IR length of 6 bits. This is the recommended boot mode. The third-party debugger must assume that the TAP router is the only TAP between TDI and TDO at boot.

25.6.4 Debugger Address Space

The CoreSight components are interfaced with the TAP router through the DAP. As recommended by the CoreSight architecture, the DAP is directly interfaced to the OMAP35x bus. The debugger can directly access the entire memory space without requiring the processor to enter debug state and be programmed with a load or store instruction. [Table 25-48](#) lists the modules that are mapped to the DAP address, and the address space detail.

Table 25-48. Debugger Address Space

Start Addr (Hex)	End Addr (Hex)	Size	Description
0xD401 0000	0xD401 0FFF	4KB	ARM embedded trace macrocell (ETM) module
0xD401 1000	0xD401 1FFF	4KB	Cortex-A8 module
0xD401 9000	0xD401 9FFF	4KB	Trace port interface unit (TPIU)
0xD401 B000	0xD401 BFFF	4KB	ARM embedded trace buffer (ETB) module

The DBGEM signal on the Cortex-A8 is driven by setting bit 13 at address 0xD401 D030 in the DAP-APB address space.

25.7 Revision History

Table 25-49 lists the changes made since the previous version of this document.

Table 25-49. Document Revision History

Reference	Additions/Modifications/Deletions
Section 25.1.1	Deleted bullets 7, 13, 14, and 17 - 21.

Section 25.4.8.1	Changed 2nd bullet and 3rd paragraph.
Section 25.4.8.4	Changed 2nd sentence and deleted 3rd sentence.
Table 25-42	Changed byte size and description.
Section 25.4.9	Changed section.
Table 25-43	Changed table.
Table 25-44	Changed table.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
