DMA4 has four interrupt lines, numbered L_j with j=0..3. Each logical channel can request an interrupt over any line. The attachment of a channel interrupt event to one of these four external lines is programmable. The software determines whether it attaches a channel interrupt to a single IRQ line or to multiple IRQ lines.

There are two different registers per interrupt line:

- SDMA.DMA4_IRQSTATUS_L_j CH_31_0_L_j field shows the status of the different sources of interrupt. If the SDMA.DMA4_IRQENABLE_L_j bit *i* is 1, the channel *i* is the source of interrupt in line *j*. In contrast to the SDMA.DMA4_CSR_i registers, the SDMA.DMA4_IRQSTATUS_L_j registers are updated regardless of the corresponding bits in the SDMA.DMA4_IRQENABLE_L_j registers.
- SDMA.DMA4_IRQENABLE_L_j CH_31_0_L_j_EN field masks/unmasks the channel interrupt. If the SDMA.DMA4_IRQENABLE_L_j bit *i* is set to 0, the channel interrupt *i* of the line *j* is masked.

Each logical channel can generate 10 different interrupt events when enabled (that is, set to 1) in the SDMA.DMA4_CICR_i register. Each status bit is updated in the SDMA.DMA4_CSR_i register only when the corresponding enable bit is enabled in the SDMA.DMA4_CICR_i register.

To determine an interrupt source when an interrupt rises on an interrupt line L_j, you must:

- Identify the channel (LCH_i) generating the interrupt.
Read the SDMA.DMA4_IRQSTATUS_L_j.LCH_i (LCH₀ to LCH₃₁). If LCH_i = 1, channel *i* is the originator of the interrupt.
- Identify the interrupt event.
Read the LCH_i SDMA.DMA4_CSR_i. For example, if the drop event (the SDMA.DMA4_CSR_i[1] DROP bit) is 1, there will be a request collision.
The interrupt event status bit in the SDMA.DMA4_CSR_i register is immediately reset after it is written to 1.
The interrupt status bit in the SDMA.DMA4_IRQSTATUS_L_j register is cleared after it is written to 1.

Table 9-2 shows how the SDMA module interrupt lines are connected to the interrupt lines of the MPU interrupt controller.

Table 9-2. SDMA Interrupt Mapping to the MPU Subsystem

IRQ	Source	Description
M_IRQ_12	SDMA_IRQ0	SDMA interrupt request 0
M_IRQ_13	SDMA_IRQ1	SDMA interrupt request 1
M_IRQ_14	SDMA_IRQ2	SDMA interrupt request 2
M_IRQ_15	SDMA_IRQ3	SDMA interrupt request 3

9.3.3.2 DMA Requests to the SDMA Controller

This section gives information about all modules and features in the high-tier device. See the *OMAP35x Family* chapter to check availability of modules and features. Ensure that DMA requests of unavailable modules and features are masked in DMA subsystems.

All peripherals internal to the device use the transition-sensitive scheme for DMA requests. For more information on the transition-sensitive scheme, see [Section 9.2.2, SDMA Request Scheme](#). [Table 9-3](#) lists the SDMA request mapping.

Table 9-3. SDMA Request Mapping

9.4 SDMA Functional Description

The SDMA module provides high-performance data transfers between memories and peripheral devices with low processor use. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

Figure 9-6 shows the SDMA controller top-level block diagram.

Figure 9-6. SDMA Controller Top-Level Block Diagram

108-005

9.4.1 Logical Channel Transfer Overview

As Figure 9-6 shows, the SDMA module has one read port and one write port operating independently of each other. Buffering is provided between the read and write ports through a FIFO queue memory pool that is shared dynamically between the active logical channels.

- Logical channel synchronization
A logical channel is described as hardware-synchronized when the DMA transfers are triggered by DMA requests from a hardware device. Alternatively, a logical channel is described as nonsynchronized when the DMA transfer is triggered by software.
- Logical channel activation
A logical channel becomes active as follows:
 - For hardware-synchronized transfers, when the logical channel is enabled and the hardware DMA

- request line is asserted
- For software-triggered (nonsynchronized) transfers, as soon as software enables the logical channel

- Logical channel transfer composition

A DMA transfer is divided automatically into a number of transactions. Depending on the logical channel context configured, transfer size, the start address alignment, the addressing mode, and the configured maximum burst size, each transaction can be either a single access or a burst of accesses.

- Logical channel scheduling

When several logical channels are active at the same time, schedulers manage the read and write ports. The scheduling of logical channel transfers is similar for both read and write ports. When a logical channel becomes active, it is added to the tail of a scheduling queue. If more than one logical channel becomes active at the same time, the one with the lower number is queued first. This mechanism provides a first-come, first-serve scheduling scheme between the concurrently active logical channels.

In addition, each read and write port has a high-priority queue and a low-priority queue. The priority bit in the logical channel SDMA.DMA4_CCRi register determines if a logical channel is queued as high or low priority. The relative weighting of the scheduling of the high-priority queue to the low priority queue is programmable from 1:1 to 1:256 through the DMA global channel register (SDMA.DMA4_GCR).

Note: The SDMA.DMA4_GCR[23:16] ARBITRATION_RATE field is not dependent on the SDMA.DMA4_GCR[13:12] HI_THREAD_RESERVED field. The ARBITRATION_RATE field is dependent on the SDMA.DMA4_CCRi[26] WRITE_PRIORITY bit and the SDMA.DMA4_CCRi[6] READ_PRIORITY bit.

- Read/write port access scheduling policy

When either the read or write port becomes available, the port access scheduler selects the next logical channel for which to perform a DMA transaction from either the high- or low-priority queue.

When the current DMA transaction (single or burst access) is complete and the full DMA transfer is not finished, the logical channel returns to the tail of the queue. Because the port access scheduling is on a per-transaction basis, a logical channel can be queued repeatedly this way several times during a single transfer.

The SDMA module can have up to four outstanding read transactions and two outstanding write transactions in the system interconnect; four read and two write thread IDs exist. For an arbitration cycle to occur, these two conditions must be met:

- At least one channel is requesting.
- At least one free thread ID is available.

On an arbitration cycle, the scheduler grants the highest priority channel that has an active request, allocates the thread ID, and tags this thread as busy. At a given time, a channel cannot be allocated for more than one thread ID.

Note: If more than one channel is active, each channel is given a thread ID for the current service only, not for the whole channel transfer.

When only one channel is active, one thread ID is allocated during the channel transfer. The access can be up to a 16 x 32-bit access (that is, 16 32-bit single access, four bursts of 16bytes, two bursts of 32bytes, or one burst of 64bytes) without rescheduling the channel at the end of each burst transfer.

When nonburst alignment is at the beginning of the transfer, the channel is rescheduled for each smaller access until burst-aligned. When the end of the transfer is not burst-aligned, the channel is rescheduled for each of the remaining smaller accesses.

For a logical channel transfer completion, when the last access is written to the destination, the logical channel becomes inactive. If enabled, an interrupt request is generated (see [Section 9.4.12, Interrupt Generation](#)).

9.4.2 FIFO Queue Memory Pool

A FIFO queue memory pool provides buffering between the read and write ports. The hardware allocates the space dynamically to a number of FIFO queues, and each queue is associated with an active logical channel.

To avoid a memory pool overflow, if there are fewer entries in the FIFO queue memory pool than are required for the maximum configured source burst size of the next logical channel to be scheduled, the logical channel is returned to the tail of the queue, and the port access scheduler continues to search the queue until it finds a logical channel that can be scheduled.

The maximum FIFO depth that can be allocated to each individual logical channel can be limited globally through the SDMA.DMA4_GCR register. This value should be configured to allow a fair allocation of the memory pool between the active channels.

A logical channel is scheduled if it has not yet reached its allocation limit, even if the access to be performed will exceed this limit. This means that the effective number of entries used by a particular logical channel is limited to the configured maximum entries per channel + channel maximum configured burst size (in words) - 1.

9.4.3 Addressing Modes

A DMA transfer block consists of a number of frames (FN). Each frame consists of a number of elements, and each element can have a size of 8, 16, or 32 bits, as follows:

transfer block size = number of frames x number of elements per frame x element size

The FN, number of elements per frame (EN), and size of elements are common for both the source and destination. However, the way in which the data is represented (addressing profile/mode) is independently programmable for the source and destination devices, using one of these four addressing modes:

- Constant: The address remains the same for consecutive element accesses.
- Post-increment: The address increases by the element size (ES), even across consecutive frames.
- Single-index: The address increases by the ES, plus the element index (EI) value minus one (even across consecutive frames).
- Double-index: The address increases by the ES, plus the EI value minus one within a frame. When a full frame is transferred, the address increases by the ES plus the frame index (FI) value minus 1.

The ES, EI, and FI values are expressed in bytes. The EI and FI values can be positive or negative.

When calculating the EI and FI values, it is critical to note that, after an element is accessed, the logical channel address pointer equals the address of the last byte (highest address) of the accessed element. The correct value for the EI or FI should be such that, when added to the logical channel address pointer, results in the address of the first byte (lowest address) of the next element to be accessed.

The EI and FI values must be configured so that the address of each element in the transfer is aligned on an ES boundary.

Consequently, the single-index addressing mode with EI = 1 or double-index addressing mode with EI = 1 and FI = 1 is equivalent to post-increment addressing.

Note: The source and destination start addresses must also be aligned on an ES boundary.

When the address of an element to be accessed is not aligned on an ES boundary, the transfer is stopped and an address error interrupt occurs, if enabled (see [Section 9.4.12, Interrupt Generation](#)).

The SDMA.DMA4_CFNi register configures the FN in a block.

The SDMA.DMA4_CENi register configures the EN.

The SDMA.DMA4_CSDPi register configures the ES.

The SDMA.DMA4_CSSAi and SDMA.DMA4_CDSAi registers configure the source and destination start addresses.

The SDMA.DMA4_CCRi register configures the source and destination addressing modes.

The SDMA.DMA4_CSEi, SDMA.DMA4_CSFi, SDMA.DMA4_CDEi, and SDMA.DMA4_CDFi registers configure the source EI, source FI, destination EI, and destination FI, respectively.

The addressing profiles are expressed as equations as follows:

Equation 1. Constant addressing:

$$A(n+1) = A(n)$$

Equation 2. Post-increment addressing:

$$A(n+1) = A(n) + ES$$

Equation 3. Single-indexed addressing:

$$A(n+1) = A(n) + ES + (EI - 1)$$

Equation 4. Double-indexed addressing:

When not at the end of a frame or transfer (that is, when the element counter $\neq 0$):

$$A(n+1) = A(n) + ES + (EI - 1)$$

When at the end of a frame but not at the end of the transfer (that is, when the element counter = 0 and the frame counter $\neq 0$):

$$A(n+1) = A(n) + ES + (FI - 1)$$

Calculate the element and frame index as follows:

Equation 5. Element index

$$EI = [(Stride\ EI - 1) * ES] + 1$$

Equation 6. Frame index

$$FI = [(Stride\ FI - 1) * ES] + 1$$

where:

A(n): Byte address of the element n within the transfer.

ES is in bytes, ES \in {1, 2, 4}.

EI is in bytes, specified in a configuration register, $-32768 \leq EI \leq 32767$.

Stride EI: The difference in the number of elements between the start of the current element, n, to the start of next element, n+1.

Element counter: A counter that is (re)initiated with the number of elements per frame or per transfer. Decreased by 1 for each element transferred. The initial value is configured in the register DMA channel element number, SDMA.DMA4_CENi.

F is in bytes, specified in a configuration register, $-2147483648 \leq FI \leq 2147483647$.

Stride FI: The difference in the number of elements between the start of the last element of the current frame and the beginning of the first element of the next frame.

Frame counter: A counter that is (re)initiated with the FN per transfer. Decreased by 1 for each frame transferred. The initial value is configured in the register DMA channel frame number, SDMA.DMA4_CFNi.

Figure 9-7 shows how a stride EI and FI are defined. When handling complex configurations, using strides can make it easier to calculate EI and FI because you can calculate in elements instead of bytes. (This approach is used in the 90Degrees clockwise image rotation example shown in Figure 9-11.) The double-index addressing example shown in Figure 9-7 has ES = 4, EN = 2, EI = 5, FI = 5, and FN = 2.

Figure 9-7 through Figure 9-10 show examples of addressing mode configurations. Table 9-4 lists parameter values for the examples.

Figure 9-7. Example Showing Double-Index Addressing, Elements, Frames, and Strides

Figure 9-8. Addressing Mode Example (a)

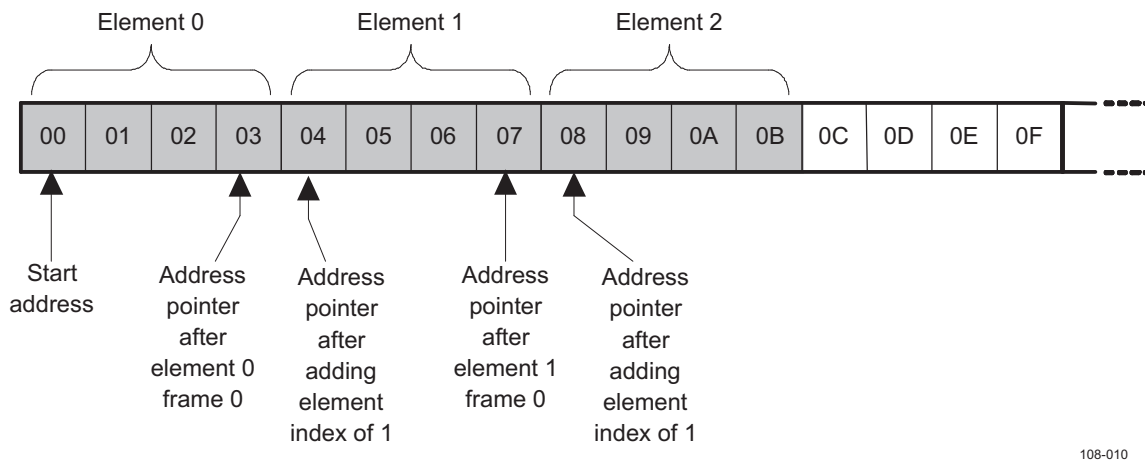

Figure 9-9. Addressing Mode Example (b)

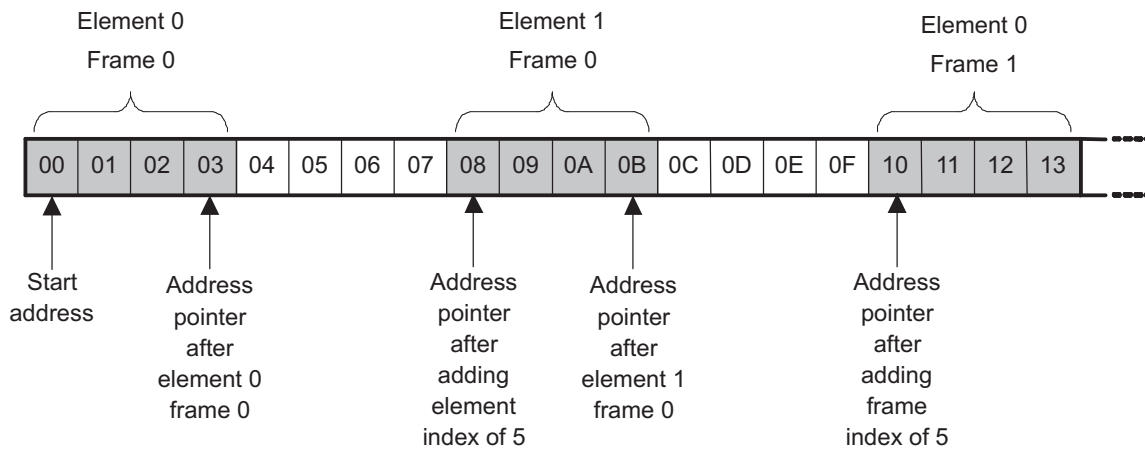

Figure 9-10. Addressing Mode Example (c)

108-008

Table 9-4. Parameter Values for Addressing Mode Examples (a), (b), and (c)

Parameter	Example (a)	Example (b)	Example (c)
Addressing mode	Single index (or post-increment)	Double index	Double index
Start address	0	0	8
ES	4 (32-bit)	4 (32-bit)	2 (16-bit)
EN	3	2	2
EI	1	5	1
FN	1	2	2
Frame index	N/A	5	-9

Double indexing can occur either on source (read) or destination (write). Equations for rotation of xx degrees on destination are obtained by taking equations for rotation of (360-xx) degrees on source, and swapping x and y in them. The opposite is also true. [Table 9-5](#) list the equations for rotation for 90, 180 and 270°.

Table 9-5. Equations for Rotation

		90° Rotation	180° Rotation	270° Rotation
Double indexing on destination (write)	Base address	$ES \cdot (y-1)$	$ES \cdot (x \cdot y - 1)$	$ES \cdot y \cdot (x-1)$
	Element index (EI)	$ES \cdot (y-1) + 1$	$1 - 2 \cdot ES$	$1 - ES \cdot (y+1)$
	Frame index (FI)	$1 - ES \cdot [(x-1) \cdot y + 2]$	$1 - 2 \cdot ES$	$1 + ES \cdot (x-1) \cdot y$
Double indexing on source (read)	Base address	$ES \cdot x \cdot (y-1)$	$ES \cdot (x \cdot y - 1)$	$ES \cdot (x-1)$
	Element index (EI)	$1 - ES \cdot (x+1)$	$1 - 2 \cdot ES$	$ES \cdot (x-1) + 1$
	Frame index (FI)	$1 + ES \cdot (y-1) \cdot x$	$1 - 2 \cdot ES$	$1 - ES \cdot [(y-1) \cdot x + 2]$

[Table 9-6](#) and [Figure 9-11](#) show the configuration required to perform a 90° clockwise image rotation of a 240 x 160 pixel, 32-bit image. The EI, frame size, and FI values are configured so that the image is rotated line by line starting at the left-hand end of the top line.

Note: The FI value for the destination is negative so that the first pixel of each subsequent line of the source image is written to the correct location at the destination.

Equation 5 and Equation 6 calculate the destination FI and EI. The example assumes that the image lines are stored at consecutive addresses in memory, meaning that both EI and FI on the source side are 1.

Rotations:

[Section 9.5.8](#), *90° Clockwise Image Rotation*, describes how to program this example.

Observe that:

- One pixel = one element
- One line = one DMA frame
- Pixel size = element size = ES

Table 9-6. Example Parameter Values for a 90° Clockwise Image Rotation

Parameter	Source Value	Destination Value
Bits per pixel	32	32
ES	4	4
Image width	SW	SH
Image height	SH	SW
Stride elements (stride EI)	1 element	SH
Stride frames (stride FI)	1 element	$-[(SW-1)*SH+1] = -38241$ elements
Start address	0x100000	$0x200000 + (SH - 1) \times ES = 0x20027C$
EN	SW	SW
EI	$[(Stride\ EI - 1) * ES] + 1 = 1$	$[(Stride\ EI - 1) * ES] + 1 = 637$
FN	SH	SH
FI	$[(Stride\ FI - 1) * ES] + 1 = 1$	$[(Stride\ FI - 1) * ES] + 1 = -152967$

Figure 9-11. Example of a 90° Clockwise Image Rotation

9.4.4 Packed Accesses

When the logical channel ES is less than the DMA module read/write port size, and the addressing profile supports it (that is, post-increment mode or single- or double-index mode with EI = 1), the number of elements to transfer in each read/write port access may be maximized by specifying that the source or destination is packed through the channel SDMA.DMA4_CSDPi register. Thus:

- For a read/write port size of 32 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (four elements per access) and 16 bits (two elements per access).

- For a read/write port size of 64 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (eight elements per access), 16 bits (four elements per access), and 32 bits (two elements per access).

Depending on the start address and transfer length, the first or last packed access might be only partially filled. This is indicated to the source or destination using the byte-enable signals.

Note: When a constant addressing mode is specified, only nonpacked accesses are used, and specifying the accesses as packed has no effect.

9.4.5 Burst Transactions

Transfer performance can be improved, where the source or destination and addressing profile supports it, by configuring the logical channel to perform burst transactions consisting of multiple instead of single accesses. The channel can be programmed to use burst sizes equivalent to 16, 32, or 64 bytes through the SDMA.DMA4_CSDPi register, with the read burst size being programmable independently of the write burst size. Typically, the optimal burst size is 64 bytes (16 accesses for a 32-bit read/write port size or 8 accesses for a 64-bit read/write port size).

To obtain the maximum benefit from burst transactions, the source and destination start addresses should be aligned with the burst size. If this is not the case, the start of the transfer can consist of a number of smaller (single or burst) transactions until the first burst size boundary is reached.

Similarly, if the end of the transfer is not aligned on a burst size boundary, the final part of the transfer can consist of a number of smaller transactions.

Note: Except in the constant addressing mode, the source or destination must be specified as packed for burst transactions to occur.

9.4.6 Endianism Conversion

The source and destination are each specified as little-endian or big-endian through the SDMA.DMA4_CSDPi register for the particular logical channel. If the endianism of the source and destination differ, and the logical channel ES is less than the SDMA module read/write port size, an endianism conversion is applied to the data before it is written to the destination.

When transferring data between a source and a destination with different endianism, it is important to specify an ES that is equal to the type of data being transferred to preserve the correct data image at the destination.

In the system, endianism conversion can be performed in more than one place. It is possible to inform the source and/or destination to lock the endianism (that is, to not perform a conversion) through the logical DMA channel SDMA.DMA4_CSDPi register.

9.4.7 Transfer Synchronization

A logical channel can be programmed for either software-triggered or hardware synchronized transfers.

9.4.7.1 Software Synchronization

A transfer is software-triggered when the logical channel is set up and started by software. To specify a software-triggered transfer, set the channel DMA register bits SDMA.DMA4_CCRi[4:0] and SDMA.DMA4_CCRi[20:19] to 0. The transfer starts as soon as the DMA register bit SDMA.DMA4_CCRi[7] is set (that is, enters the scheduling process).

9.4.7.2 Hardware Synchronization

A transfer is hardware-synchronized if the logical channel activation is driven by hardware requests from either the source or destination target. A hardware synchronized transfer is specified by configuring the DMA request line number in the channel SDMA.DMA4_CCRi register to a value that corresponds to the DMA request line from the source or destination that generates the DMA requests. The DMA request numbers to be configured are specified in the DMA request mapping (see Table 9-8).

Specify the DMA request number in the channel DMA register bits SDMA.DMA4_CCRi[4:0] and SDMA.DMA4_CCRi[20:19]. After the DMA register bit SDMA.DMA4_CCRi[7] is set, the logical channel becomes enabled but not activated (that is, it does not enter the scheduling process), which means that channel registers are not updated until the first DMA request is received.

Note: DMA Request Line

A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared between several chained logical channels.

The channel synchronization control registers are 1-based. For example, to enable the S_DMA_1 request, SDMA.DMA4_CCRi[4:0] SYNCHRO_CONTROL must be set to 0x2 (DMA request number + 1).

For hardware synchronization, the amount of data to be transferred for each assertion of the DMA request line is configured through the frame synchronization (FS) and block synchronization (BS) bits in the logical channel SDMA.DMA4_CCRi register and the DMA register bits SDMA.DMA4_CCRi[5] and SDMA.DMA4_CCRi[18], respectively.

The amount of data can be any of the following:

- A single element transfer: A complete element defined by Data_type. For example, 8/16/32 bits are transferred in response to a DMA request.
- A full frame: A complete frame of several elements is transferred in response to a DMA request.
- A full block (a full channel transfer): A complete block of several frames is transferred in response to a DMA request.
- A full packet (a full channel transfer): A complete packet of several elements is transferred in response to a DMA request.

Packets allow the size of each part of the full DMA transfer to be configured independent of the organization of the data to be transferred (typically a number of elements). This can be useful when the source or destination has a buffer (such as a FIFO queue) with a size unrelated to the frame size of the transfer. The packet size then can be set to the size of the buffer.

Packet transfer must be used only where the source or destination is addressed in constant addressing mode, because FI registers are reused to specify size of the packet.

To support the burst mode, the logical channel must also be configured to use the source-port packed access mode. The packed address mode cannot be used with a constant address mode: it must be configured to use a post-increment address mode.

The packet size is configured based on the source/destination synchronization select bit in the SDMA.DMA4_CCRi register through either the channel SDMA.DMA4_CDFi register (source synchronized) or the SDMA.DMA4_CSFi register (destination synchronized).

When the logical channel transfer block is not an exact multiple of the packet size, the final packet consists of the remaining elements in the transfer, using burst or single accesses to complete the block transfer.

The maximum transfer size, regardless of the packet size, is always as follows:

$$\text{Block_size} = \text{Number_of_Frame_in_Block} * \text{Number_of_Element_in_Frame} * \text{Element_Size}$$

- Synchronized at the source

The DMA module optimizes the transfer with respect to the number and size of burst transactions for the given source and destination addressing profiles and configured maximum burst sizes. When writing to the destination is slower than reading from the source, data is buffered in the channel FIFO queue. If the transfer is packet-synchronized at the source, the end-of-packet interrupt is disabled (see [Section 9.4.11, Reprogramming an Active Channel](#)).

For a source synchronized transfer, buffering can be enabled or disabled by setting the SDMA.DMA4_CCRin[25] BUFFERING_DISABLE bit. For a packet source synchronization with buffering disabled and the packed/burst across the packet boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the packet transfer size. However, for a packet source synchronized transfer with buffering enabled and with the packed/burst across the packet boundary, the DMA module waits for the next DMA request(s) to read enough data to issue an atomic packed/burst write transaction (assuming the address is packed/burst aligned).

Note: Regardless whether buffering is enabled or not, buffering is not performed between frames. If the packed/burst is across the frame boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the frame transfer size.

- Synchronized at the destination

The performance of a hardware-synchronized transfer can be improved by using the prefetch mode, enabled through the channel DMA register bit SDMA.DMA4_CCRi[23]. Data is prefetched on the read port side in advance of the DMA request received and buffered in the FIFO queue. Up to a full transfer block can be prefetched, although this can be limited by the specified maximum channel FIFO queue depth (see [Section 9.4.2, FIFO Queue Memory Pool](#)).

Buffering disable is not allowed for a destination-synchronized transfer.

Note: Behavior is undefined when prefetch is enabled and a transfer is synchronized to the source.

Whichever buffering is enabled or disabled, the last transaction in the frame or in the block is write nonposted (WNP) even if the write mode is specified as write last nonposted (WLNP; the WRITE_MODE bit field of the SDMA.DMA4_CSDPi register = 0x2). However, in a packet synchronization mode, the last transaction of each packet in the transfer is WNP only if the buffering disable is on (even if the write mode is specified as WLNP).

Regardless whether buffering disable is enabled or disabled, the packet interrupt is not generated in the packet source synchronized mode.

CAUTION

The BUFFERING_DISABLE bit field of the SDMA.DMA4_CCRi register must be filled with an allowed value, as specified in [Table 9-7](#).

Table 9-7. Buffering Disable

BUFFERING_DISABLE (0: buffering enable, 1: buffering disable)		
Destination synchronized	0	Allowed
	1	Not allowed
Source synchronized	0	Allowed
	1	Allowed

Synchronized transfer monitoring using CDAC (SDMA.DMA4_CDACi):

Context is restored only when the channel becomes active on a DMA request (not at software enable). The channel is software-enabled first, and then a DMA request is asserted followed by the first context restore.

The CDAC register is writable; thus, you can initialize the CDAC to monitor the transfer and determine if the transfer is started or not (see [Section 9.5.4, Synchronized Transfer Monitoring Using CDAC](#), for more information).

Note: The CDAC register must be written or read so that the least-significant byte (LSByte) is read first; otherwise, the shadow registers do not update the CDAC registers.

This is not an issue for 32-bit read-write transactions. Nevertheless, for 16-bit transactions, start reading or writing the LSByte first to enable the register update.

9.4.8 Thread Budget Allocation

When several concurrent channels are latency critical and hardware synchronized, a specific latency cannot be ensured until the target is served. This situation occurs when the concurrent channel number is superior to the number of available threads.

Note: Four threads are available on the read port, and two threads are available on the write port.

For a hardware-synchronized transfer (memory to peripheral), a minimum bandwidth for a latency-critical transfer must be ensured to avoid collisions between two hardware requests.

Because it is latency critical, the software user is responsible for the following:

- Programming the synchronized channel as a high-priority channel
- Reserving one or several threads for high-priority channels

The proposed implementation is as follows (see [Section 9.5.6](#)):

Prevent the regular channel queue from exceeding more than a programmable (3, 2, or 1) number of threads on the read port and no more than one thread on the write port. This number can be set on the global register SDMA.DMA4_GCR[13:12].

The thread reservation is programmable for maximum use of thread resources for concurrent, low-priority channel transfer. Programmability can also allow a partial throughput control by limiting in software the number of concurrent outstanding requests that break the pipelining.

Depending on the SDMA.DMA4_GCR [13:12] value, the following ThreadID on the read/write ports are allocated for a high-priority channel:

Read port priority thread reservation:

- SDMA.DMA4_GCR[13:12] = 0x0 => No ThreadID is allocated for high-priority channels.
- SDMA.DMA4_GCR[13:12] = 0x1 => Read ThreadID 0 is allocated for high-priority channels.
- SDMA.DMA4_GCR[13:12] = 0x2 => Read ThreadID 0 and Read ThreadID 1 are allocated for high-priority channels.
- SDMA.DMA4_GCR[13:12] = 0x3 => Read ThreadID 0, Read ThreadID 1, and Read ThreadID 2 are allocated for high-priority channels.

Write port priority thread reservation:

- SDMA.DMA4_GCR[13:12] = 0x0 => No ThreadID is allocated for high-priority channels
- SDMA.DMA4_GCR[13:12] = 0x1 => Write ThreadID 0 is allocated for high-priority channels.
- SDMA.DMA4_GCR[13:12] = 0x2 => Write ThreadID 0 is allocated for high-priority channels.
- SDMA.DMA4_GCR[13:12] = 0x3 => Write ThreadID 0 is allocated for high-priority channels.

Regardless whether or not the enabled channels are of high priority, only the setting of the SDMA.DMA4_GCR[13:12] value forces the thread reservation to these values. Set the appropriate value to avoid losing threads using only regular channels.

To have an independent read and write priority context, a per-channel bit SDMA.DMA4_CCRi[26] is added for write priority, and the previous priority bit becomes read priority bit SDMA.DMA4_CCRi[6].

Note: The device has one priority bit per logical channel, not one per port.

9.4.9 FIFO Budget Allocation

To avoid fully occupying the FIFO with a high-priority transfer while low-priority channels wait in the arbitration queue, two separate FIFO budgets are specified: one for high-priority channels and one for low-priority channels. This is defined in the SDMA.DMA4_GCR register, allowing the user to share the FIFO budget between the low- and high-priority channels. The amount of the FIFO allocated by the low- and high-priority channels is fixed by the value set in the SDMA.DMA4_GCR[15:14] HI_LO_FIFO_BUDGET field. The maximum channel FIFO depth is limited by the HI_LO_FIFO_BUDGET field as follows:

If the channel is low priority:

- When HI_LO_FIFO_BUDGET = 0x1, then low priority cannot exceed 75 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x2, then low priority cannot exceed 25 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x3, then low priority cannot exceed 50 percent of the total FIFO.

If channel is high priority

- When HI_LO_FIFO_BUDGET = 0x1, then high priority cannot exceed 25 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x2, then high priority cannot exceed 75 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x3, then high priority cannot exceed 50 percent of the total FIFO.

The user is responsible for performing the following equation:

- For a high-priority channel: $(\text{Per_Channel_Maximum FIFO Depth} + 1) \times \text{Number of High Channel} \leq \text{High Budget FIFO}$
- For a low-priority channel: $(\text{Per_Channel_Maximum FIFO Depth} + 1) \times \text{Number of Low Channel} \leq \text{Low Budget FIFO}$

Note: Ensure that *Number of High Channel* means *Number of Active High-Priority Channel* and that *Number of Low Channel* means *Number of Active Low-Priority Channel*.

9.4.10 Chained Logical Channel Transfers

Chaining multiple logical channels permits transfers consisting of multiple parts to be executed without repeated software intervention. This results in better performance than the alternative of software setting up and starting each transfer separately. Each part of a chained transfer can have the data addressed in a different manner that permits the programming of a variety of complex transfers. For example:

- Interlaced video data with one logical channel configured to transfer the even lines and another logical channel configured to transfer the odd lines
- Protocol headers with a separate DMA4 channel configured to transfer each field in the header

Channels can be chained through each channel SDMA.DMA4_CLNK_CTRLi register. When the transfer for the first channel completes, the next channel in the chain is enabled. The number of channels in the chain that are configured for hardware-synchronized transfers is flexible (although typically it might be all, none, or just the first one). The DMA request line number should be set to 0 to specify that any or all of the channels in a chain are software-triggered or nonsynchronized.

The last channel in a chain can be chained to the first channel to create a continuously looping chain. The continuously looping transfer can be stopped on the fly at a specific channel by disabling the SDMA.DMA4_CLNK_CTRLi[15] ENABLE_LNK bit. The looping transfer stops after the specified channel transfer is complete.

Note: DMA Request Line

A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared between several chained logical channels.

For more information on the programming model, see [Section 9.5](#), *SDMA Basic Programming Model*.

9.4.11 Reprogramming an Active Channel

A currently active logical DMA channel can be disabled through the SDMA.DMA4_CCRi[7] ENABLE bit. When any ongoing transaction is complete and the read-active and write-active bits in the SDMA.DMA4_CCRi register (SDMA.DMA4_CCRi[9] RD_ACTIVE and SDMA.DMA4_CCRi[10] WR_ACTIVE) are reset, the channel can be reprogrammed for a new transfer.

9.4.12 Interrupt Generation

The SDMA module has four interrupt request output lines, IRQ0 to IRQ3. One or more logical channels can be programmed to generate an interrupt request on any of these lines when any one of the maskable DMA events listed in [Table 9-8](#) occurs.

Table 9-8. Logical DMA Channel Events

Event	Description
End of packet	A packet transfer completed.
End of block	A block transfer completed.
End of frame	A frame transfer completed.
Half of frame	Half of the current frame transferred.
Start of last frame	The first element of the last frame transferred.
Transaction error	A transaction error returned by the interconnect in either the read or write port.
Address error	An attempt was made to perform a DMA access to an address not aligned on an ES boundary.
Secure transaction error (not available on GP device)	An attempt was made to set or modify the configuration of a channel specified as secure through a nonsecure access, or an attempt was made to perform a nonsecure DMA transfer to or from a secure region.
Supervisor transaction error	An error occurred, for example, when an unauthorized initiator (that is, neither supervisor nor secure) tries to use a supervisor transfer.
Synchronization error	A new DMA request arrived before completion of the transfer because of the previous DMA request.
Drain end	Drain is completed (SDMA.DMA4_CCRi[10] WR_ACTIVE becomes 0).
System transaction error	An error has occurred, for example, when an unauthorized initiator tries to set a normal channel to a System channel or tries to change a System channel to a normal channel or tries to access (write) any register of a System channel registers.

The logical DMA channels that generate an interrupt on a particular IRQ output are specified through the SDMA.DMA4_IRQENABLE_Lj register (where *j* is the IRQ number: 0, 1, 2, or 3). The events that generate an interrupt for a particular channel can be configured through the channel SDMA.DMA4_CICRi register.

When an interrupt is detected, the logical DMA channel generating the event can first be identified by reading the SDMA.DMA4_IRQSTATUS_Lj register. The event causing the interrupt then can be identified by reading the interrupt status via the relevant DMA channel SDMA.DMA4_CSRi register.

9.4.13 Packet Synchronization

A packet transfer notion is related to the behavior of some peripheral, which have certain buffering capability and requires to transfer the buffer content once an element number threshold is reached (a hardware DMA request is generated). To associate a frame synchronization to each DMA request is possible, but this limits the maximum transfer size. Indeed the maximum transfer size is proportional to the FIFO depth of the peripheral:

$$\text{maximum_transfer_size} = \text{peripheral_FIFO_depth} \times \text{number_of_frame_in_block}.$$

The packet synchronization allows to dissociate the transfer size from the FIFO depth of the peripheral. Only Constant addressing mode is allowed on RD port or WR port if source target or destination target is packet synchronized respectively.

Example:

Let's consider a camera interface, which have a FIFO_depth of 128 Words and a FIFO_element_number_threshold of 128 and a picture to transfer with a size 320 lines per 240 columns. If frame synchronization is associated to each DMA request then the maximum transfer size that can be performed is 128×2^{16} words. In this case, a frame is 128 words long, which does not fit the size of a line. Then it's not possible to generate an interrupt at the end of line. However with introducing the packet transfer notion, which is related to the peripheral FIFO behavior/structure, the maximum transfer size (maximum_transfer_size = $2^{24} \times 2^{16}$ words) is independent of both peripheral_FIFO_depth and FIFO_element_number_threshold. This allows, making an enough long transfer within one channel context and perform rotation operation on big image format.

The main features of DMA Packet transfer are as follows:

- DMA Packet_Data_Size for each DMA Request: typically this will be Peripheral_element_number_threshold Number of elements in a packet shares the SDMA.DMA4_CSFI and SDMA.DMA4_CDFI configuration registers. Indeed if the peripheral is the source target, respectively destination target, that means the used addressing mode is constant, consequently SDMA.DMA4_CSFI[15:0], respectively SDMA.DMA4_CDFI[15:0], is used to specify the packet data size (PKT_ELNT_NBR) and the bit fields [31:16] are unused. To specify the Packet data size in the SDMA.DMA4_CSFI or SDMA.DMA4_CDFI, the user must set the SDMA.DMA4_CCRI[24] SEL_SRC_DST_SYNC respectively to 1 or 0.

Note: The packet size can be a sub-multiple or non sub-multiple of a frame size. If DMA Packet_Data_Size is aligned on DMA channel block data size boundary, then DMA will transfer the last data in channel block boundary, and stop at block boundary for the last packet DMA Request. If the Packet_Data_size is not aligned on the block boundary then the remaining data smaller than a packet size are transferred using burst or single accesses to complete the block

- DMA Packet_Data_Transfer does not affect DMA channel capabilities in term of packing and bursting. The Packet synchronization mode is active when SDMA.DMA4_CCRI[5] FS = SDMA.DMA4_CCRI[18] BS = 1. Then
 - if SDMA.DMA4_CCRI[24] SEL_SRC_DST_SYNC=0; SDMA.DMA4_CDFI[15:0] gives the number of element in packet and SDMA.DMA4_CDFI[31:16] is unused for the packet size.
 - if SDMA.DMA4_CCRI[24] SEL_SRC_DST_SYNC=1; SDMA.DMA4_CSFI[15:0] gives the number of element in packet and SDMA.DMA4_CSFI[31:16] is unused for the packet size.

Note: The maximum transfer size, regardless to the packet size, is always: Block_size = Number_of_Frame_in_Block x Number_of_Element_in_Frame x Element_Size If DMA channel packet/burst access across packet boundary, then DMA hardware will automatically split this packing/burst access into a multiple smaller accesses, which will be aligned on packet boundary. Otherwise, DMA will transfer data as usual packing/burst access.

9.4.14 Graphics Acceleration Support

The SDMA supports two graphic acceleration features:

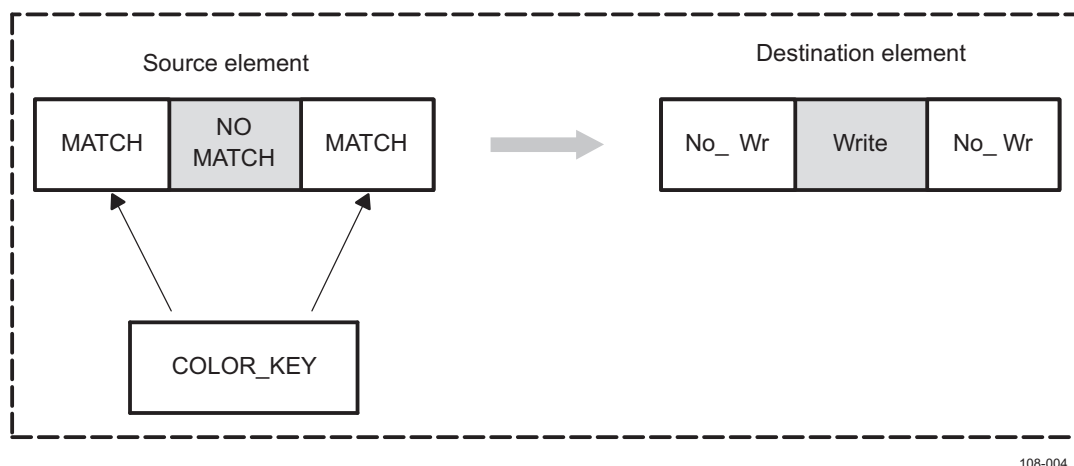

- Transparent copy
- Constant fill

Only one of these features can be enabled at any given time through the SDMA.DMA4_CCRI register for the particular logical DMA channel.

The transparent copy feature enables specification of a particular color through the SDMA.SDMA.DMA4_COLORi register, so that when it is recognized in the data from the source, it is not copied to the corresponding location in the destination, but instead leaves the data in the corresponding location in the destination as it is.

Figure 9-12 shows the 2-D graphic transparent color block diagram.

Figure 9-12. 2-D Graphic Transparent Color Block Diagram

The constant fill feature provides the ability to specify a particular color through the SDMA.SDMA.DMA4_COLORi register for every specified location in the destination. In this case, the transfer consists only of writing to the destination without reading from a source.

Both features support 8 bpp (bits per pixel), 16 bpp, and 24 bpp, depending on what is specified as the DMA transfer ES via the SDMA.SDMA.DMA4_CSDPi register. An ES of 32 bits corresponds to 24 bpp. During a 32-bit (24 bpp) transfer, the most-significant 8 bits ([31:24]) are 0. Both features are compatible with packed and burst transactions.

9.4.15 Secure (Not Available on GP Device) and Supervisor Modes

A logical DMA channel can be configured to operate either in secure mode (not available on GP device) and/or supervisor mode through the corresponding bits in the channel SDMA.DMA4_CCRi register. This must be done using secure or supervisor access. Once a channel is configured either in secure or supervisor mode, the channel configuration is protected from nonsecure or nonsupervisor accesses. All DMA transactions on a secure or supervisor channel are secure or supervisor transactions.

A supervisor transaction is possible in secure mode, but a secure transaction is not possible in supervisor mode. Secure mode is not available on GP devices.

9.4.16 Posted and nonposted Writes

A logical channel can be configured in its DMA register bits SDMA.DMA4_CSDPi[17:16] to use one of three write access handshake modes for the destination:

- nonposted write: Each write must complete before transfer can continue or complete.
- Posted write: Transfer continues without waiting for each write to complete (might improve performance with slow devices).
- Posted with final write nonposted: Transfer continues without waiting for each write to complete, but final write is completed before transfer can complete.

9.4.17 Disabling a Channel During Transfer

When a channel is disabled during a transfer, the channel will undergo an abort, except if the channel was hardware source synchronized with buffering Enabled (SDMA.DMA4_CCRi[25] BUFFERING_DISABLE='0'). In that case, the FIFO will be drained in order to avoid losing data. See [Section 9.4.18](#) for details on this feature.

9.4.18 FIFO Draining Mechanism

When a source synchronized channel is disabled during a transfer, then the current hardware request (element/packet/frame/block) service is completed and the channel SDMA.DMA4_CCRi[9] RD_ACTIVE bit is set to 0, which means the channel is not active on the read port. The remaining data in the corresponding disabled channel FIFO is drained onto the write port and transferred to the programmed destination as in normal transfer.

At the end of the draining the SDMA.DMA4_CCRi[10] WR_ACTIVE bit is set to 0 (channel is no more active on the write port) and if the SDMA.DMA4_CICRI[12] DRAIN_END_IE is set to 1, the status bit DMA4_CSRi[12] DRAIN_END is updated and an interrupt is generated.

Once a channel is disabled during a transfer, it needs to wait for SDMA.DMA4_CCRi[9] RD_ACTIVE and SDMA.DMA4_CCRi[10] WR_ACTIVE to become '0' before being re-enabled for a new transfer. The FIFO drain for a channel will happen only in the following cases:

- If the channel is a source synchronized channel and SDMA.DMA4_CCRi[25] BUFFERING_DISABLE='0' and
- If the channel is not a solid fill channel and
- If the channel is not a transparent and copy channel

Note: In case of self-linked or chain-linked channel it is user responsibility to disable the SDMA.DMA4_CLNK_CTRLi[15] ENABLE_LINK bit before disabling the channel.

In all other cases, the channel will undergo an abort.

9.4.19 Reset

Following a software or hardware reset, all fields in the logical channel registers have undefined values, except 5 bits in the SDMA.DMA4_CCRi and SDMA.DMA4_CICRI registers. Thus, when programming a channel for the first time, the remaining fields in all channel registers must be configured before enabling the channel.

Note: After a reset, the global registers take their specified reset values.

9.4.20 Power Management

The SDMA module provides two methods to reduce power consumption:

- Interconnect clock auto-idle
- Automatic standby mode

9.4.20.1 Interconnect Clock Auto-Idle

The interconnect clock auto-idle power-saving mode is enabled or disabled in DMA register bit SDMA.DMA4_OCP_SYSCONFIG[0]. When this mode is enabled and there is no activity on the interconnect interface, the interconnect clock is disabled internally to the module to reduce power consumption. When there is new activity on the interconnect interface, the interconnect clock is restarted without any latency penalty. After reset, this mode is disabled by default. Enabling this mode is recommended to reduce power consumption.

9.4.20.2 Automatic Standby Mode

As part of the system-wide power-management scheme, the module can go into a standby mode at the request of the power, reset, and clock management (PRCM) module (for more information, see the *Power, Reset, and Clock Management* chapter).

The module can be configured to one of the following standby modes using the DMA register bits `SDMA.DMA4_OCP_SYSCONFIG[13:12]`:

- No standby mode: The module never goes into standby mode.
- Force standby mode: The module goes into standby mode only when all the DMA channels are disabled.
- Smart standby mode: The module enters standby mode when:
 - All DMA channels are disabled.
 - No nonsynchronized channel is enabled, no DMA request line is asserted, and no DMA request is pending in the module.

9.5 SDMA Basic Programming Model

9.5.1 Setup Configuration

After a software or hardware reset, program all fields in the logical channel registers to default values for any channels used, because most fields are undefined following reset.

Before programming any DMA transfers, the priority arbitration rate and the maximum FIFO depth must be configured through the SDMA.DMA4_GCR register, and any required interrupts must be enabled through the SDMA.DMA4_IRQENABLE_Li registers and the logical channel SDMA.DMA4_CICRi registers.

Software clears the SDMA.DMA4_CSRI register and the IRQSTATUS bit for the different interrupt lines before enabling the channel.

9.5.2 Software-Triggered (nonsynchronized) Transfer

To program a software-triggered DMA transfer:

1. Configure the transfer parameters in the logical DMA channel registers:
 - SDMA.DMA4_CSDPi:
 - Transfer ES (8 bits, 16 bits, or 32 bits) and DMA register bits SDMA.DMA4_CSDPi[1:0]
 - Read and write port access types (single/burst), DMA register bits SDMA.DMA4_CSDPi[8:7] and SDMA.DMA4_CSDPi[15:14]
 - Source and destination endianness, DMA register bits SDMA.DMA4_CSDPi[21] and SDMA.DMA4_CSDPi[19]
 - Write mode (posted or nonposted) and DMA register bits SDMA.DMA4_CSDPi[17:16]
 - Source or destination packed or nonpacked (if the ES is less than the read/write port size), DMA register bits SDMA.DMA4_CSDPi[6] and SDMA.DMA4_CSDPi[13]
 - SDMA.DMA4_CENi: EN
 - SDMA.DMA4_CFNi: FN per transfer block
 - SDMA.DMA4_CSSAi and SDMA.DMA4_CDSAi: source and destination start address (aligned with transfer ES)
 - SDMA.DMA4_CCRi:
 - Read and write port addressing modes, DMA register bits SDMA.DMA4_CCRi[13:12] and SDMA.DMA4_CCRi[15:14]
 - Priority bit for both read and write ports, DMA register bits SDMA.DMA4_CCRi[6] and SDMA.DMA4_CCRi[26]
 - DMA request number (set to 0 for a software-triggered transfer) and DMA register bits SDMA.DMA4_CCRi[4:0] = 0 and SDMA.DMA4_CCRi[20:19] = 0
 - SDMA.DMA4_CSEi, SDMA.DMA4_CSFi, SDMA.DMA4_CDEi, and SDMA.DMA4_CDFi: source and destination element and frame indexes (depending on addressing mode)
2. Start the transfer through the enable bit in the channel SDMA.DMA4_CCRi register and DMA register bit SDMA.DMA4_CCRi[7]

The example below perform a DMA transfer on channel 10 of a 240*160 picture from RAM to RAM (0x80C00000 to 0x80F00000) :

```
UWORD32 RegVal = 0;
DMA4_t *DMA4;

DMA4 = (DMA4_t *)malloc(sizeof(DMA4_t));

/* Init. parameters */
DMA4->DataType = 0x2; // DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0; // DMA4_CSDPi[8:7]
DMA4->WritePortAccessType = 0; // DMA4_CSDPi[15:14]
DMA4->SourceEndiansim = 0; // DMA4_CSDPi[21]
DMA4->DestinationEndianness = 0; // DMA4_CSDPi[19]
DMA4->WriteMode = 0; // DMA4_CSDPi[17:16]
DMA4->SourcePacked = 0; // DMA4_CSDPi[6]
DMA4->DestinationPacked = 0; // DMA4_CSDPi[13]
DMA4->NumberOfElementPerFrame = 240; // DMA4_CENi
DMA4->NumberOfFramePerTransferBlock = 160; // DMA4_CFNi
```

```

DMA4->SourceStartAddress = 0x80C00000;    // DMA4_CSSAi
DMA4->DestinationStartAddress = 0x80F00000; // DMA4_CDSAi
DMA4->SourceElementIndex = 1;              // DMA4_CSEi
DMA4->SourceFrameIndex = 1;                // DMA4_CSFi
DMA4->DestinationElementIndex = 1;         // DMA4_CDEi
DMA4->DestinationFrameIndex = 1;           // DMA4_CDFi
DMA4->ReadPortAccessMode = 1;              // DMA4_CCRi[13:12]
DMA4->WritePortAccessMode = 1;             // DMA4_CCRi[15:14]
DMA4->ReadPriority = 0;                     // DMA4_CCRi[6]
DMA4->WritePriority = 0;                    // DMA4_CCRi[23]
DMA4->ReadRequestNumber = 0;                // DMA4_CCRi[4:0]
DMA4->WriteRequestNumber = 0;               // DMA4_CCRi[20:19]

/* 1) Configure the transfer parameters in the logical DMA registers */
/*-----*/

/* a) Set the data type CSDP[1:0], the Read/Write Port access type CSDP[8:7]/[15:14], the
Source/dest endianness CSDP[21]/CSDP[19], write mode
CSDP[17:16], source/dest packed or nonpacked CSDP[6]/CSDP[13]*/
// Read CSDP
RegVal = DMA4_CSDP_CH10;

// Build reg

// Read CCR
RegVal = DMA4_CCR_CH10;

// Build reg
RegVal = ((RegVal & ~(0x3 << 12)) | (DMA4->ReadPortAccessMode << 12));
RegVal = ((RegVal & ~(0x3 << 14)) | (DMA4->WritePortAccessMode << 14));
RegVal = ((RegVal & ~(0x1 << 6)) | (DMA4->ReadPriority << 6));
RegVal = ((RegVal & ~(0x1 << 26)) | (DMA4->WritePriority << 26));

RegVal&= 0xFFCFFFE0 ;

// Write CCR
DMA4_CCR_CH10 = RegVal;

/* f)- Set the source element index CSEI[15:0]*/
DMA4_CSEI_CH10 = DMA4->SourceElementIndex;

/* - Set the source frame index CSFI[15:0]*/
DMA4_CSFI_CH10 = DMA4->SourceFrameIndex ;

```

```

/*      - Set the destination element index CDEI[15:0]*/
DMA4_CDEI_CH10 = DMA4->DestinationElementIndex;

/*      - Set the destination frame index CDFI[31:0]*/
DMA4_CDFI_CH10 = DMA4->DestinationFrameIndex;

/* 2) Start the DMA transfer by Setting the enable bit CCR[7]=1 */
/*-----*/
//write enable bit
DMA4_CCR_CH10 |= 1 << 7; /* start */

```

9.5.3 Hardware-Synchronized Transfer

To monitor a hardware synchronized DMA transfer, initialize the SDMA.DMA4_CDACi register before the software enable.

To configure an LCh to synchronize by element, packet, frame, or block, the frame synchronization SDMA.DMA4_CCRi[5] FS bit and the block synchronization SDMA.DMA4_CCRi[18] BS bit register must be programmed. For all the following synchronized transfers (element, packet, frame or block synchronized transfers) User must set first : SDMA.DMA4_CCRi[24] SEL_SRC_DST_SYNC to 1 when the source triggers on the DMA request and SDMA.DMA4_CCRi[24] SEL_SRC_DST_SYNC to 0 when the Destination triggers on the DMA request. Note: User must take care when setting the SDMA.DMA4_CCRi[23] PREFETCH bit it is in conjunction with SDMA.DMA4_CCRi[24] SEL_SRC_DST_SYNC bit .

- To configure an LCh to transfer one element per DMA request:
 1. Set the number of DMA request associated to the current LCH in the SDMA.DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and SDMA.DMA4_CCRi[4:0] SYNCHRO bitfield
 2. Set the data type, also referenced as element size (ES), in the SDMA.DMA4_CSDPi[1:0] DATA_TYPE bitfield
 3. Set the Read Port access type (single or burst access) in the SDMA.DMA4_CSDPi[8:7] SRC_BURST_EN bitfield
 4. Set the Write Port access type (single or burst access) in the SDMA.DMA4_CSDPi[15:14] DST_BURST_EN bitfield
 5. Set the Read Port addressing mode in the SDMA.DMA4_CCRi[13:12] SRC_AMODE bitfield.
 6. Set the Write Port addressing mode in the SDMA.DMA4_CCRi[15:14] DST_AMODE bitfield
 7. Set the Read start address in the SDMA.DMA4_CSSAi[31:0] SRC_START_ADRS bitfield
 8. Set the Write start address in the SDMA.DMA4_CDSAi[31:0] DST_START_ADRS bitfield
 9. Set both FS and BS to 0 in SDMA.DMA4_CCRi[5] FS and SDMA.DMA4_CCRi[18] BS
 10. Set to 1 the channel enable bit SDMA.DMA4_CCRi[7] EN bit
- To configure an LCh to transfer one frame per DMA request:
 1. Set the number of DMA request associated to the current LCH in the SDMA.DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and SDMA.DMA4_CCRi[4:0] SYNCHRO bitfield
 2. Set the data type, also referenced as element size (ES), in the SDMA.DMA4_CSDPi[1:0] DATA_TYPE bitfield
 3. Set the number of element per frame in the SDMA.DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bitfield
 4. Set the Read Port access type (single or burst access) in the SDMA.DMA4_CSDPi[8:7] SRC_BURST_EN bitfield
 5. Set the Write Port access type (single or burst access) in the SDMA.DMA4_CSDPi[15:14] DST_BURST_EN bitfield
 6. Set the Read Port addressing mode in the SDMA.DMA4_CCRi[13:12] SRC_AMODE bitfield.
 7. Set the Write Port addressing mode in the SDMA.DMA4_CCRi[15:14] DST_AMODE bitfield
 8. Set the Read start address in the SDMA.DMA4_CSSAi[31:0] SRC_START_ADRS bitfield
 9. Set the Write start address in the SDMA.DMA4_CDSAi[31:0] DST_START_ADRS bitfield
 10. Set FS to 1 and BS to 0 respectively in SDMA.DMA4_CCRi[5] FS and SDMA.DMA4_CCRi[18] BS

11. Set to 1 the channel enable bit SDMA.DMA4_CCRi[7] EN bit
 - To configure an LCh to transfer one block per DMA request:
 1. Set the number of DMA request associated to the current LCH in the SDMA.DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and SDMA.DMA4_CCRi[4:0] SYNCHRO bitfield
 2. Set the data type, also referenced as element size (ES), in the SDMA.DMA4_CSDPi[1:0] DATA_TYPE bitfield
 3. Set the number of element per frame in the SDMA.DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bitfield
 4. Set in the SDMA.DMA4_CFNi[15:0] CHANNEL_FRAME_NBR bitfield the number of frame (transfers), to take place before the LCH gets disabled
 5. Set the Read Port access type (single or burst access) in the SDMA.DMA4_CSDPi[8:7] SRC_BURST_EN bitfield
 6. Set the Write Port access type (single or burst access) in the SDMA.DMA4_CSDPi[15:14] DST_BURST_EN bitfield
 7. Set the Read Port addressing mode in the SDMA.DMA4_CCRi[13:12] SRC_AMODE bitfield.
 8. Set the Write Port addressing mode in the SDMA.DMA4_CCRi[15:14] DST_AMODE bitfield
 9. Set the Read start address in the SDMA.DMA4_CSSAi[31:0] SRC_START_ADRS bitfield
 10. Set the Write start address in the SDMA.DMA4_CDSAi[31:0] DST_START_ADRS bitfield
 11. Set FS to 0 and BS to 1 respectively in SDMA.DMA4_CCRi[5] FS and SDMA.DMA4_CCRi[18] BS
 12. Set to 1 the channel enable bit SDMA.DMA4_CCRi[7] EN bit
 - To configure an LCh to transfer one packet per DMA request:
 1. Set the number of DMA request associated to the current LCH in the SDMA.DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and SDMA.DMA4_CCRi[4:0] SYNCHRO bitfield
 2. Set the data type, also referenced as element size (ES), in the SDMA.DMA4_CSDPi[1:0] DATA_TYPE bitfield
 3. Set the number of element per packet to transfer: If the packet requestor is in the source then set SDMA.DMA4_CCR.Sel_Src_Dst_Sync to 1 and set the packet element number in the SDMA.DMA4_CSFli register, Else if the packet requestor is in the destination then set SDMA.DMA4_CCRi[24] SEL_SRC_DST_SYNC to 0 and set the packet element number in the SDMA.DMA4_CDFli register.
 4. Set the number of element per frame in the SDMA.DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bitfield
 5. Set in the SDMA.DMA4_CFNi[15:0] CHANNEL_FRAME_NBR bitfield the number of frame (transfers), to take place before the LCH gets disabled
 6. Set the element number in the packet in the SDMA.DMA4_CSFli[15:0] PKT_ELNT_NBR, if constant addressing or post-incremented addressing modes are used in the source side. However, the number of element in the packet is set in the SDMA.DMA4_CDFli[15:0] PKT_ELNT_NBR if constant addressing mode is used in the destination side.
 7. Set the Read Port access type (single or burst access) in the SDMA.DMA4_CSDPi[8:7] SRC_BURST_EN bitfield
 8. Set the Write Port access type (single or burst access) in the SDMA.DMA4_CSDPi[15:14] DST_BURST_EN bitfield
 9. Set the Read Port addressing mode in the SDMA.DMA4_CCRi[13:12] SRC_AMODE bitfield.
 10. Set the Write Port addressing mode in the SDMA.DMA4_CCRi[15:14] DST_AMODE bitfield
 11. Set the Read start address in the SDMA.DMA4_CSSAi[31:0] SRC_START_ADRS bitfield
 12. Set the Write start address in the SDMA.DMA4_CDSAi[31:0] DST_START_ADRS bitfield
 13. Set FS to 1 and BS to 1 respectively in SDMA.DMA4_CCRi[5] FS and SDMA.DMA4_CCRi[18] BS
 14. Set to 1 the channel enable bit SDMA.DMA4_CCRi[7] EN bit

Note: It is possible to stop a transfer by disabling the channel. This is done by reset the ENABLE bit in the SDMA.DMA4_CCRi register.

9.5.4 Synchronized Transfer Monitoring using CDAC

Because the CDAC register is writable, you can initialize the CDAC to monitor a transfer in applying the following programming model:

1. Write 0 in the SDMA.DMA4_CDACi.
2. Enable the channel.
3. If Time-out.
Read SDMA.DMA4_CDACi
4. If SDMA.DMA4_CDACi != SDMA.DMA4_CDACi reset value:
Then transfer starts.
Else, if SDMA.DMA4_CDACi = SDMA.DMA4_CDACi reset value:
Then transfer does not start.

9.5.5 Synchronized Transfer Monitoring using CDAC

The SDMA.DMA4_CDACi register is writable and noninitialized (value undefined). It can be initialized to monitor a transfer by applying the following programming model:

1. Write 0 in the SDMA.DMA4_CDACi
2. Enable the channel.
3. If time-out occurs, read SDMA.DMA4_CDACi
4. If SDMA.DMA4_CDACi != SDMA.DMA4_CDACi reset value:
Then transfer starts. User can then rely on SDMA.DMA4_CCENi and SDMA.DMA4_CCFNi element and frame counters.
Else, if SDMA.DMA4_CDACi = SDMA.DMA4_CDACi reset value:
Then transfer does not start.

9.5.6 Concurrent Software and Hardware Synchronization

This section describes thread allocation only and not the entire transfer. Because synchronized transfers are latency critical, you must allocate a thread on the synchronized target side at least.

Even for multiple concurrent channels, thread reservation guarantees that as soon as an HW DMA request comes in, the read/write scheduler finds available thread(s) to initiate a channel schedule and issue a read/write transaction.

Consider these six concurrent channels:

- Channels 0/1/2/3 are dedicated to memory-memory transfer: they are software triggered and not synchronized.
 - Channel 4 is dedicated to memory→peripheral transfer, hardware triggered, and synchronized on the write side.
 - Channel 5 is dedicated to peripheral→memory transfer, hardware triggered, and synchronized on the read side.
1. Allow thread reservation for priority channel 4 and channel 5:
Reserve one thread (Read ThreadID 0) on the read port: set SDMA.DMA4_GCR[13:12] = 0x1.
Reserve one thread (Write ThreadID 0) on the write port: set SDMA.DMA4_GCR[13:12] = 0x1.
 2. Specify channel priority:
Channel 4 is a write high priority channel: set SDMA.DMA4_CCRi[26] = 1.
Channel 5 is a read high priority channel: set SDMA.DMA4_CCRi[6] = 1.

9.5.7 Chained Transfer

A chained DMA transfer can be programmed as follows:

1. Configure the transfer parameters for each logical DMA channel in the chain as in step 1 for either the synchronized or nonsynchronized transfers above.
2. For each channel in the chain, configure the SDMA.DMA4_CLNK_CTRLi register as follows:

- Next logical DMA channel number (for a looping chained transfer link last channel to first channel number), in DMA register bits SDMA.DMA4_CLNK_CTRLi[4:0].
 - Include the logical channel to the chain and enable link by setting the DMA register bit SDMA.DMA4_CLNK_CTRLi[15].
 - For a nonlooping chain, the last logical channel in the chain must have the DMA register bit SDMA.DMA4_CLNK_CTRLi[15] set to 0 to indicate the end of the chain.
3. Enable the transfer via the enable bit in the first logical channel DMA register bit SDMA.DMA4_CCRi[7]. All other channels in the chain must be configured as disabled. Each channel is enabled automatically in turn when the previous logical channel transfer completes. A nonsynchronized transfer starts immediately; a hardware-synchronized transfer starts when the DMA request line corresponding to the first DMA channel in the chain is asserted.

To stop a looping chained transfer, disable the NEXTLCH_ID bit, DMA register bit SDMA.DMA4_CLNK_CTRLi[15](ENABLE_LNK bit set to 0x0), of the final channel transfer.

In the RAM to RAM copy example, to copy in loop it's possible to link channel 10 on itself. The following line can be added in the channel configuration :

```
/* g) Set link for loop */
DMA4_CLINK_CTRL_CH10 = 0x0000800A;
```

9.5.8 90° Clockwise Image Rotation

The 90° clockwise image rotation example described in [Section 9.4.3, Addressing Modes](#), can be programmed as follows:

1. Configure the transfer parameters in the logical DMA channel registers:
 - SDMA.DMA4_CSDPi:
 - Transfer ES = 32-bit (32 bpp), DMA register bits SDMA.DMA4_CSDPi[1:0]
 - Read and write port access types = maximum burst size supported by memory device, DMA register bits SDMA.DMA4_CSDPi[8:7] and SDMA.DMA4_CSDPi[15:14]
 - Source and destination endianism, DMA register bits SDMA.DMA4_CSDPi[21] and SDMA.DMA4_CSDPi[19]
 - Write mode = posted with last element nonposted, DMA register bits SDMA.DMA4_CSDPi[17:16]
 - Source and destination packed = Yes (although destination writes will not benefit because EI>1), DMA register bits SDMA.DMA4_CSDPi[6] and SDMA.DMA4_CSDPi[13]
 - SDMA.DMA4_CENi: EN = 240
 - SDMA.DMA4_CFNi: FN per transfer block = 160
 - SDMA.DMA4_CSSAi: source start address = 0x100000
 - SDMA.DMA4_CDSAi: destination start address = 0x20013E
 - SDMA.DMA4_CCRi:
 - Read and write port addressing modes = double-index addressing mode for both or post-increment addressing on source and double-index addressing on destination, DMA register bits SDMA.DMA4_CCRi[13:12] and SDMA.DMA4_CCRi[15:14]
 - Low or high priority, DMA register bit SDMA.DMA4_CCRi[6]
 - DMA request number = 0 (for software-triggered transfer), DMA register bits SDMA.DMA4_CCRi[4:0] and SDMA.DMA4_CCRi[20:19]
 - SDMA.DMA4_CSEi: source EI = 1
 - SDMA.DMA4_CSF: source frame index = 1
 - SDMA.DMA4_CDEi: destination EI = 637
 - SDMA.DMA4_CDFi: destination frame index = -152967
2. Start the transfer via the enable bit in the channel SDMA.DMA4_CCRi register.

Below are the parameters to perform this rotation from 0x80C00000 RAM address to 0x80F00000, with the same code as in [Section 9.5.2](#):

```
/* Init. parameters */
DMA4->DataType = 0x2;           // DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0x3; // DMA4_CSDPi[8:7]
```

```

DMA4->WritePortAccessType = 0x3;           // DMA4_CSDPi[15:14]
DMA4->SourceEndiansim = 0;                 // DMA4_CSDPi[21]
DMA4->DestinationEndianism = 0;            // DMA4_CSDPi[19]
DMA4->WriteMode = 0x2;                     // DMA4_CSDPi[17:16]
DMA4->SourcePacked = 0x1;                  // DMA4_CSDPi[6]
DMA4->DestinationPacked = 0x1;             // DMA4_CSDPi[13]
DMA4->NumberOfElementPerFrame = 240;       // DMA4_CENi
DMA4->NumberOfFramePerTransferBlock = 160; // DMA4_CFNi
DMA4->SourceStartAddress = 0x80C00000;     // DMA4_CSSAi
DMA4->DestinationStartAddress = 0x80F00000; // DMA4_CDSAi
DMA4->SourceElementIndex = 1;              // DMA4_CSEi
DMA4->SourceFrameIndex = 1;               // DMA4_CSFi
DMA4->DestinationElementIndex = 637;       // DMA4_CDEi
DMA4->DestinationFrameIndex = -152967;     // DMA4_CDFi
DMA4->ReadPortAccessMode = 0x3;           // DMA4_CCRi[13:12]
DMA4->WritePortAccessMode = 0x3;          // DMA4_CCRi[15:14]
DMA4->ReadPriority = 0;                    // DMA4_CCRi[6]
DMA4->WritePriority = 0;                   // DMA4_CCRi[23]
DMA4->ReadRequestNumber = 0;              // DMA4_CCRi[4:0]
DMA4->WriteRequestNumber = 0;             // DMA4_CCRi[20:19]

```

9.5.9 Graphic Operations

- Transparent copy :
 - 1. Set the SDMA.DMA4_CCRi[17] Transparent_Copy_Enable bitfield to 1
 - 2. Set the SDMA.DMA4_CCRi[16] Constant_Fill_Enable bitfield to 0
 - 3. Set the value of key the color in the SDMA.DMA4_COLORi[15:0] color_key bitfield
 To perform this graphic operation, the following lines can be added to the example of [Section 9.5.2](#)

```

DMA4_CCR_CH10 &= ~(0x1 << 16);
DMA4_CCR_CH10 |= 0x1 << 17;
DMA4_COLOR_CH10 = 0x00000003;

```

- Solid Color fill :
 - 1. Set the SDMA.DMA4_CCRi[16] Constant_Fill_Enable bitfield to 1
 - 2. Set the SDMA.DMA4_CCRi[17] Transparent_Copy_Enable bitfield to 0
 - 3. Set the value of key the color in the DMA4_COLORi[15:0] solid_color bitfield
 To perform this graphic operation, the following lines can be added to the example of [Section 9.5.2](#)

```

DMA4_CCR_CH10 &= ~(0x1 << 17);
DMA4_CCR_CH10 |= 0x1 << 16;
DMA4_COLOR_CH10 = 0x00000003;

```

9.6 SDMA Use Cases and Tips

9.6.1 Camcorder Use Case: How to Configure SDMA to Handle Transfers with McBSP2 and MMC to External DRAM

9.6.1.1 Introduction

In this use case, the SDMA manages:

- The audio stream between the McBSP and the external DRAM
- The audio stream between the external DRAM and the MMC buffer
- The video stream between the external DRAM and the MMC buffer

The following sections describe how to configure the SDMA controller with MMC and McBSP in this use case.

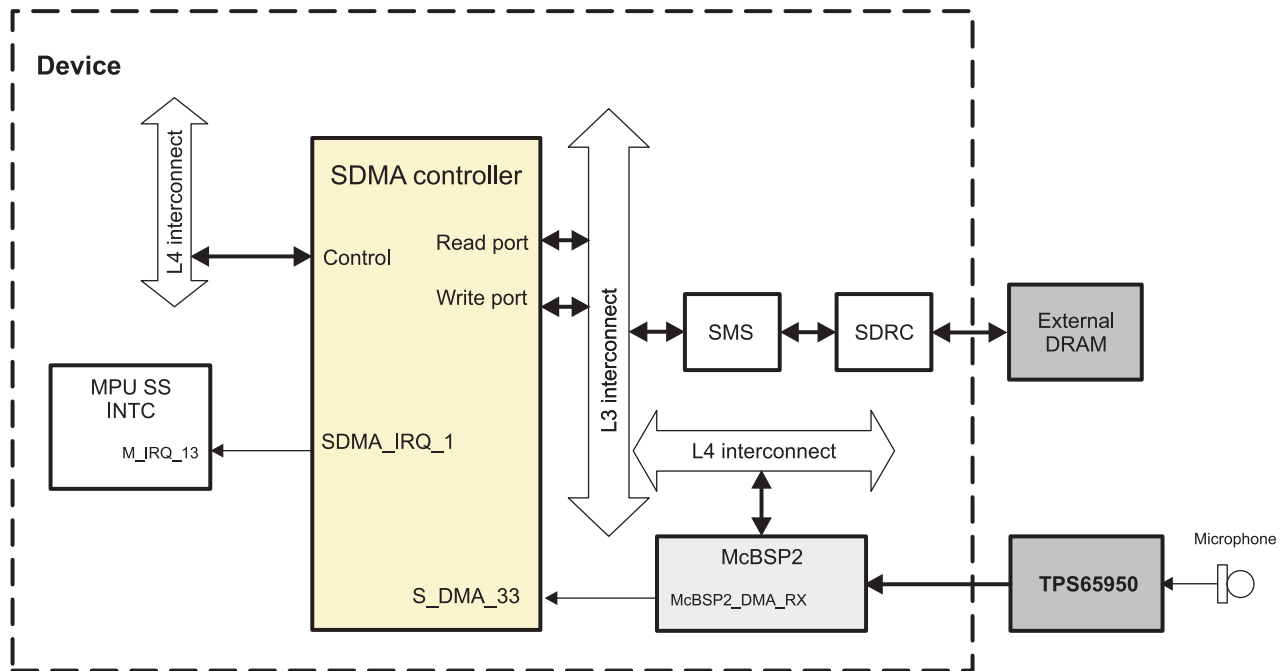

9.6.1.2 SDMA Configuration to Transfer Data Between the McBSP and External DRAM

9.6.1.2.1 Overview

The SDMA gets data from the McBSP_DRR register and copies it into three rolling buffers in the external DRAM.

Figure 9-13 is an overview of the audio path.

Figure 9-13. Overview

108-030

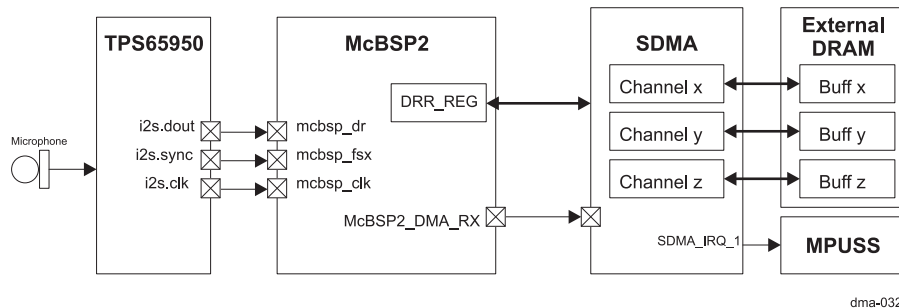

For the camcorder use case, the DMA transfer data format is:

- Frame size = 2048 x 32 bits
- Three DMA channels to manage three transfers to three memory buffers
- Interrupt generated at the end of each frame transfer
- Transfer triggered by McBSP2

9.6.1.2.2 Environment

The DMA accesses MCBSP2_DRR_REG through the interconnect and receives a DMA request from this McBSP module for driving transfers. The DMA accesses the external DRAM through the interconnect. The McBSP is directly connected to the TPS65950 device. Figure 9-14 shows the environment of this scenario.

Figure 9-14. Environment

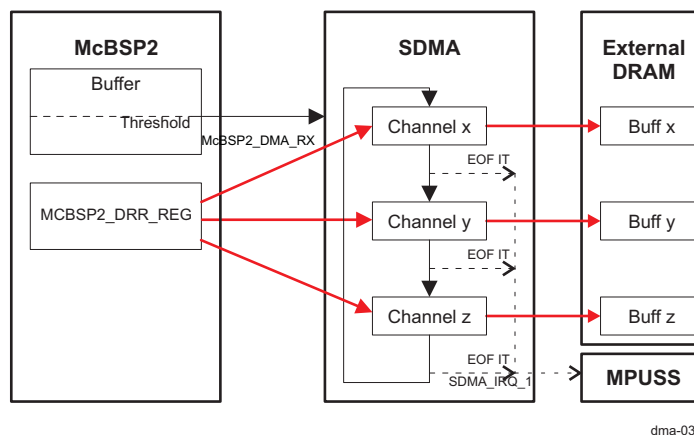

dma-032

9.6.1.2.3 Data Path

The transfer is started when the DMA transfer is enabled and the MCBSP2_DMA_REQ is asserted (that is, when the MCBSP FIFO threshold is reached). The DMA starts copying the first frame into the first memory buffer. When a whole frame has been transferred (2048 data), an interrupt is asserted to the MPU, and then the second channel is enabled and fills the second buffer, and so on. Figure 9-15 shows the data flow.

Figure 9-15. Data Flow

dma-033

9.6.1.2.4 Programming Flow

To establish a configuration for the DMA transfers, the following points have been considered.

The McBSP2_DRR_REG register is 32 bits wide, but in the camcorder use case, only the 16 LSBs are used (monophonic 16-bit-wide audio channel).

The McBSP receives data in a FIFO buffer. As long as the occupied locations level in this read buffer is greater than or equal to the threshold value + 1, the DMA request is asserted. After transferring the configured (THRSH1_REG value + 1) number of words, the receive DMA request is de-asserted and then reasserted when the conditions are met again. Therefore, the DMA can receive at least threshold value data, with a threshold maximum value = 256 elements = size of McBSP2 FIFO.

The frame synchronization transfer mode of the SDMA can be used with McBSP for frames with a size equal to the threshold. In the use case, however, the audio data frame is equal to 2048 elements, which is greater than the maximum transfer length possible with the McBSP.

Because the SDMA cannot be configured in frame synchronization mode, packet synchronization mode must be used. This mode enables to specify the maximum size of a transfer and to divide a frame into as many packet as needed. It is then possible to configure a frame of n elements and generate an interrupt at the end-of-frame transfer, while the transfer is segmented into packets.

The management of the three memory buffers is done by configuring three DMA channels linked between themselves: channel x is linked to channel y, channel y is linked to channel z, and channel z is linked to channel x. The three channels have the same configuration, except for the destination address, which corresponds to the three buffer addresses. Channels 11, 12, and 13 are used. Each channel generates the end-of-frame interrupts on the L1 interrupt line of the SDMA, to warn the MPU of the end of a frame transfer.

With these considerations, the DMA register of the three channels (i = 11, 12, and 13) is configured as follows:

1. Channel source destination parameters: [DMA4_CSDPi](#)

- [DMA4_CSDPi](#)[1:0] DATA_TYPE = 0x1: Read 16-bit elements from the McBSP_DRR_REG register.
- [DMA4_CSDPi](#)[5:2] RESERVED: Write 0's for future compatibility. Read returns 0.
- [DMA4_CSDPi](#)[6] SRC_PACKED = 0x0: Cannot pack source data
- [DMA4_CSDPi](#)[8:7] SRC_BURST_EN = 0x0: Cannot burst source
- [DMA4_CSDPi](#)[12:9] RESERVED: Write 0s for future compatibility. Read returns 0.
- [DMA4_CSDPi](#)[13] DST_PACKED = 0x1: Pack two 16-bit elements in one 32-bit packet to optimize transfer.
- [DMA4_CSDPi](#)[15:14] DST_BURST_EN = 0x3: Burst at 16x32-bit
- [DMA4_CSDPi](#)[17:16] WRITE_MODE = 0x1: Write posted
- [DMA4_CSDPi](#)[18] DST_ENDIAN_LOCK = 0x0: Endianness adapt
- [DMA4_CSDPi](#)[19] DST_ENDIAN = 0x0: Little endian type at destination
- [DMA4_CSDPi](#)[20] SRC_ENDIAN_LOCK = 0x0: Endianness adapt
- [DMA4_CSDPi](#)[21] SRC_ENDIAN = 0x0: Little endian type at source
- [DMA4_CSDPi](#)[31:22] RESERVED = 0x0: For future compatibility

2. Channel control register: [DMA4_CCRi](#)

- [DMA4_CCRi](#)[4:0] SYNCHRO_CONTROL = DmaReq & 0x1F = 0x2: 5 first bits of McBSP2_DMA_RX
- [DMA4_CCRi](#)[5] FS = 1: Packet mode with BS = 0x1
- [DMA4_CCRi](#)[6] READ_PRIORITY = 0x0: Low priority on read side
- [DMA4_CCRi](#)[7] ENABLE = 0x0: The logical channel is disabled.
- [DMA4_CCRi](#)[8] SUSPEND_SENSITIVE = 0
- [DMA4_CCRi](#)[9] RD_ACTIVE: Read status, read-only access
- [DMA4_CCRi](#)[10] WR_ACTIVE: Write status, read-only access
- [DMA4_CCRi](#)[11] RESERVED = 0: Write 0's for future compatibility.
- [DMA4_CCRi](#)[13:12] SRC_AMODE = 0x0: Constant address mode; DMA always reads McBSP2_DRR_REG.
- [DMA4_CCRi](#)[15:14] DST_AMODE = 0x1: Post-incremented address mode
- [DMA4_CCRi](#)[16] CONST_FILL_ENABLE = 0x0: Constant fill mode is disabled.
- [DMA4_CCRi](#)[17] TRANSPARENT_COPY_ENABLE = 0x0: Transparent copy mode is disabled.
- [DMA4_CCRi](#)[18] BS = 0x1: Packet mode with FS = 0x1
- [DMA4_CCRi](#)[20:19] SYNCHRO_CONTROL_UPPER = 0x1: Two MSBs of McBSP2_DMA_RX
- [DMA4_CCRi](#)[21] SECURE = 0x0: Channel secure mode is disabled.
- [DMA4_CCRi](#)[22] SUPERVISOR = 0x0: Supervisor mode is disabled.
- [DMA4_CCRi](#)[23] PREFETCH = 0x0: Prefetch mode is disabled, cannot prefetch a constant addressing source.
- [DMA4_CCRi](#)[24] SEL_SRC_DST_SYNC = 0x1: Transfer is triggered by the source. The packet element number is specified in the DMA4_CSFI register.
- [DMA4_CCRi](#)[25] BUFFERING_DISABLE = 0x0
- [DMA4_CCRi](#)[26] WRITE_PRIORITY = 0x0: Channel has low priority on Write side during the arbitration process.
- [DMA4_CCRi](#)[31:27] RESERVED = 0x0: Write 0's for future compatibility.

3. Channel parameters: [DMA4_CENi](#), [DMA4_CFNi](#), [DMA4_CSSAi](#), [DMA4_CDSAi](#), [DMA4_CSEi](#), [DMA4_CSFi](#), [DMA4_CDEi](#)

- [DMA4_CENi](#)[23:0] CHANNEL_ELMNT_NBR = 2048: 2048 elements
- [DMA4_CFNi](#)[15:0] CHANNEL_FRAME_NBR = 1: One frame
- [DMA4_CSSAi](#)[31:0] SRC_START_ADRS = 0x49022000: Channel source start address = MCBSP2_DRR_REG
- [DMA4_CDSAi](#)[31:0] DST_START_ADRS = X, Y or Z: Channel destination start address in external

- DRAM, where X, Y, and Z represent the addresses of the three buffers
 - [DMA4_CSEi\[31:0\]](#) CHANNEL_SRC_ELMNT_INDEX = 1: Channel source element index
 - [DMA4_CSF\[15:0\]](#) 16BIT_PKT_ELNT_NBR = 0x80: 16-bit Packet size = MCBSP_FIFO_THRESHOLD + 1
 - [DMA4_CDEi\[15:0\]](#) CHANNEL_DST_ELMNT_INDEX = 0x1: Channel destination element index
4. Channel linking: [DMA4_CLNK_CTRLi](#)
 - [DMA4_CLNK_CTRL11\[31:0\]](#) = 0x0000800C: Channel 11 is linked to channel 12.

 - [DMA4_CLNK_CTRL13\[31:0\]](#) = 0x0000800B: Channel 13 is linked to channel 11.
 5. Interrupt management: [DMA4_CICRi](#) and [DMA4_IRQENABLE_Lj](#)
 - [DMA4_CICRi\[31:0\]](#) = 0x00000008: Enables the end of frame interrupt and disables others (the value of these registers is unknown after a reset; it is necessary to clear other bits)
 - [DMA4_IRQENABLE_L1\[31:0\]](#) = 0x00022800; interrupts of channels 11, 12, and 13 are unmasked on IRQ line L1.
 6. Launch transfer: [DMA4_CCRi\[7\]](#) ENABLE = 0x1: Enables the three channels, starting with channel 13, then 12, and finally 11; the last one triggers the others.

[Table 9-9](#) lists the registers of DMA channel 11 after a first transfer.

Table 9-9. Registers Print

Register Name	Address	Value	Value Description
DMA4_IRQENABLE_L1	0x4805601c	0x00022800	Interrupts of channels 11, 12, and 13 are unmasked on IRQ line L1.
DMA4_CICR11	0x480564a8	0x00000008	End-of-frame interrupt enabled
DMA4_CCR11	0x480564a0	0x010c40a2	Channel control register
DMA4_CSDP11	0x480564b0	0x0001e001	Channel source destination parameters
DMA4_CEN11	0x480564b4	0x00000800	Channel element number
DMA4_CFN11	0x480564b8	0x00000001	Channel frame number
DMA4_CSSA11	0x480564bc	0x49022000	Channel source start address
DMA4_CDSA11	0x480564c0	0x81e00000	Channel destination start address
DMA4_CSF11	0x480564c8	0x00000080	Packet size
DMA4_CSAC11	0x480564d4	0x49022000	Source address counter (read only)
DMA4_CDAC11	0x480564d8	0x81e01000	Destination address counter (read only)
DMA4_CCEN11	0x480564dc	0x00000800	Channel current transferred element number in the current frame (read only)
DMA4_CCFN11	0x480564e0	0x00000001	Channel current transferred frame number in the current transfer (read only)
DMA4_CLNK_CTRL11	0x480564a4	0x0000800C	Channel link control register: Link to channel 12

Channels 12 and 13 have a similar configuration; only the destination address and channel link change.

9.6.1.3 SDMA Configuration to Transfer Data Between MMC and External DRAM

9.6.1.3.1 Overview

The SDMA gets data from the MMC.MMCHS_DATA register and copies it into the external DRAM. The SDMA accesses the MMCHS_DATA through the interconnect and receives a DMA request from the MMC module for driving transfers. The DMA accesses the external DRAM through the interconnect. The transfer is started when the DMA transfer is enabled and the MMC1_DMA_REQ is asserted (that is, when the MMC buffer is ready).

Figure 9-16 is an overview of the path.

Figure 9-16. Overview

108-031

For the camcorder use case, the DMA transfer data format is:

- Frame size = 4096 x 32 bits
- packet size = 512 x 32 bits (512 elements ready in MMC when a DMA request is asserted)
- DMA channel to manage the transfer
- Interrupt generated at the end of each frame transfer
- Transfer triggered by MMC

9.6.1.3.2 Programming Flow

To establish a configuration for the DMA transfers, the following points have been considered.

The MMCHS_DATA register is 32 bits wide.

The SDMA is configured in packet synchronization mode. This mode enables to specify the transfer of any size frame and then to divide the frame into as many packet as needed. It is therefore possible to configure a frame of n elements and generate an interrupt at the end-of-frame transfer, while the transfer is segmented into packets.

The MMC puts its received data into a 1K-byte ping-pong buffer. When 512 x 32 bits are ready in this buffer, the DMA request is asserted. Then the DMA controller transfers the defined amount of elements divided into packets of 512 x 32-bit element (PKT_ELNT_NBR) transfers.

In the use case, the size of the transfer is set at 4096 x 32 bits, chosen after performance benches.

With these considerations, the DMA register of channel i is configured as follows:

1. Channel source destination parameters: [DMA4_CSDPi](#)
 - [DMA4_CSDPi](#)[1:0] DATA_TYPE = 0x2: Read 32-bit elements from the MMCHS_DATA register.
 - [DMA4_CSDPi](#)[5:2] RESERVED: Write 0s for future compatibility. Read returns 0.
 - [DMA4_CSDPi](#)[6] SRC_PACKED = 0x0: Cannot pack source data
 - [DMA4_CSDPi](#)[8:7] SRC_BURST_EN = 0x0: Cannot burst source
 - [DMA4_CSDPi](#)[12:9] RESERVED: Write 0s for future compatibility. Read returns 0.
 - [DMA4_CSDPi](#)[13] DST_PACKED = 0x0: No packing
 - [DMA4_CSDPi](#)[15:14] DST_BURST_EN = 0x3: Burst at 16x32 bits
 - [DMA4_CSDPi](#)[17:16] WRITE_MODE = 0x1: Write posted
 - [DMA4_CSDPi](#)[18] DST_ENDIAN_LOCK = 0x0: Endianness adapt
 - [DMA4_CSDPi](#)[19] DST_ENDIAN = 0x0: Little Endian type at destination
 - [DMA4_CSDPi](#)[20] SRC_ENDIAN_LOCK = 0x0: Endianness adapt
 - [DMA4_CSDPi](#)[21] SRC_ENDIAN = 0x0: Little endian type at source
 - [DMA4_CSDPi](#)[31:22] RESERVED = 0x0: For future compatibility
2. Channel control register: [DMA4_CCRi](#)
 - [DMA4_CCRi](#)[4:0] SYNCHRO_CONTROL = DmaReq & 0x1F = 0x1E: 5 first bits of MMC1_DMA_RX(62)
 - [DMA4_CCRi](#)[5] FS = 1: Packet mode with BS = 0x1
 - [DMA4_CCRi](#)[6] READ_PRIORITY = 0x0: Low priority on read side
 - [DMA4_CCRi](#)[7] ENABLE = 0x0: The logical channel is disabled.
 - [DMA4_CCRi](#)[8] SUSPEND_SENSITIVE = 0
 - [DMA4_CCRi](#)[9] RD_ACTIVE: Read status, read-only access
 - [DMA4_CCRi](#)[10] WR_ACTIVE: Write status, read-only access
 - [DMA4_CCRi](#)[11] RESERVED = 0: Write 0's for future compatibility.
 - [DMA4_CCRi](#)[13:12] SRC_AMODE = 0x0: Constant address mode; DMA always reads the MMCHS_DATA.
 - [DMA4_CCRi](#)[15:14] DST_AMODE = 0x1: Post-incremented address mode
 - [DMA4_CCRi](#)[16] CONST_FILL_ENABLE = 0x0: Constant fill mode is disabled.
 - [DMA4_CCRi](#)[17] TRANSPARENT_COPY_ENABLE = 0x0: Transparent copy mode is disabled.
 - [DMA4_CCRi](#)[18] BS = 0x1: Packet mode with FS = 0x1
 - [DMA4_CCRi](#)[20:19] SYNCHRO_CONTROL_UPPER = 0x1: Two MSB of MMC1_DMA_RX(62)
 - [DMA4_CCRi](#)[21] SECURE = 0x0: Channel secure mode is disabled.
 - [DMA4_CCRi](#)[22] SUPERVISOR = 0x0: Supervisor mode is disabled.
 - [DMA4_CCRi](#)[23] PREFETCH = 0x0: Prefetch mode is disabled; cannot prefetch a constant addressing source.
 - [DMA4_CCRi](#)[24] SEL_SRC_DST_SYNC = 0x1: Transfer is triggered by the source. The packet element number is specified in the DMA4_CSFI register.
 - [DMA4_CCRi](#)[25] BUFFERING_DISABLE = 0x0
 - [DMA4_CCRi](#)[26] WRITE_PRIORITY = 0x0: Channel has low priority on write side during the arbitration process.
 - [DMA4_CCRi](#)[31:27] RESERVED = 0x0: Write 0's for future compatibility.
3. Channel parameters: [DMA4_CENi](#), [DMA4_CFNi](#), [DMA4_CSSAi](#), [DMA4_CDSAi](#), [DMA4_CSEi](#), [DMA4_CSFi](#), [DMA4_CDEi](#)
 - [DMA4_CENi](#)[23:0] CHANNEL_ELMNT_NBR = 4096: 4096 elements
 - [DMA4_CFNi](#)[15:0] CHANNEL_FRAME_NBR = 1: One frame
 - [DMA4_CSSAi](#)[31:0] SRC_START_ADRS = 0x4809c120: Channel source start address = MMCHS_DATA
 - [DMA4_CDSAi](#)[31:0] DST_START_ADRS = X: Channel destination start address in external DRAM
 - [DMA4_CSEi](#)[31:0] CHANNEL_SRC_ELMNT_INDEX = 1: Channel source element index
 - [DMA4_CSFi](#)[15:0] 16BIT_PKT_ELNT_NBR = 0x200: Packet size = number odd data available in MMC after DMA req
 - [DMA4_CDEi](#)[15:0] CHANNEL_DST_ELMNT_INDEX = 0x1: Channel destination element Index
4. Interrupt management: [DMA4_CICRi](#) and [DMA4_IRQENABLE_Lj](#)
 - [DMA4_CICRi](#)[31:0] = 0x00000008: Enables the end-of-frame interrupt and disables others (the value of these registers is unknown after a reset; it is necessary to clear other bits)
 - [DMA4_IRQENABLE_L0](#)[31:0] = 0xi: Interrupt of channel i is unmasked on IRQ line L0.
5. Launch transfer: [DMA4_CCRi](#)[7] ENABLE = 0x1: Enables the channel

Table 9-10 lists the DMA channel 2 registers after a first transfer.

Table 9-10. Registers Print

Register Name	Address	Value	Value Description
DMA4_IRQENABLE_L0	0x48056018	0x00000003	Interrupt of channel 2 is unmasked on IRQ line L0

DMA4_CCEN2	0x4805617c	0x00000080	Channel current transferred element number in the current frame (read only)
DMA4_CCFN12	0x48056180	0x00000000	Channel current transferred frame number in the current transfer (read only)
DMA4_CLNK_CTRL2	0x48056144	0x00000000	Channel link control register: No link

9.7 System Direct Memory Access (SDMA) Registers

This section provides a global view of the memory mapping as seen from the MPU for SDMA (also called DMA4). [Table 9-11](#) shows the DMA register base address.

Table 9-11. Instance Summary

Module Name	Base Address	Size
SDMA	0x4805 6000	4K bytes

9.7.1 DMA4 Controller Register Mapping Summary

[Table 9-12](#) lists all DMA4 controller registers and their physical addresses. [Table 9-13](#) through [Table 9-65](#) describe the individual register bits.

Index *i* represents the logical channel number (from 0 to 31 for SDMA and 23 for dDMA). The offset address for some registers is calculated from channel *c* number. For example, register SDMA.DMA4_CCR10 (channel 10) has an offset address of $10 \times 0x60 = 0x3C0$, and so a physical address of $0x4800\ A080 + 0x3C0 = 0x4800\ A440$.

Index *j* represents the interrupt line number from 0 to 3. The offset address for some registers is calculated from channel *c* number. For example, register SDMA.DMA4_IRQSTATUS_L3 (line 3) has an offset address of $3 \times 0x4 = 0xC$, and so a physical address of $0x4800\ A008 + 0xC = 0x4800\ A014$.

Table 9-12. SDMA Register Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address

9.7.2 DMA4 Register Descriptions

This section describes the registers used in the DMA4 controller.

Note: Some registers have no reset value (marked with -) because of hardware implementation in memory. Software must ensure the correct programming of these registers, if needed.

The shadow registers are used to read run time registers like CCEN, CCFN, CDAC, or CSAC. Typically, when accessed in 8-bit or 16-bit access for two consecutive access the value of the previous registers may change. This shadow register is used to hold the whole value to allow the next access recover the remaining 24-bit or 16-bit.

The CSAC, CDAC, CCEN, and CCFN registers must be written or read in a way that enables the LSByte; otherwise, the shadow registers do not update the register.

There is no issue for 32-bit read-write transactions. For 16-bit transactions, read or write the LSByte first to enable the register update.

Table 9-13 through Table 9-65 describe the DMA register bits.

Bits	Field Name	Description	Type	Reset
31:14	RESERVED	Write 0's for future compatibility, Reads return 0	RW	0x00000
13:12	MIDLEMODE	Read write power management, standby/wait control 0x0: Force-standby: MStandby is asserted only when all the DMA channels are disabled 0x1: No-Standby: MStandby is never asserted 0x2: Smart-Standby: MStandby is asserted if at least one of the following two conditions is satisfied: 1. All the channels are disabled 2. There is no nonsynchronized channel enabled and or no DMA request input is asserted and no request in the read and write port scheduler state machine. 0x3: reserved for second smart-standby mode if needed	RW	0x0
11:10	RESERVED	Reserved for clocks activities extension	RW	0x0

Bits	Field Name	Description	Type	Reset
9:8	CLOCKACTIVITY	Clocks activities during wake-up Bit 8: OCP interface clock 0 OCP clock can be switched-off Bit 9: Functional clock 0 Functional clock can be switched-off	R	0x0
7:6	RESERVED	Reserved, Write 0's for future compatibility, Read returns 0	RW	0x0
5	EMUFREE	Enable sensitivity to MSuspend 0x0: DMA4 freezes its internal logic upon MSuspend assertion 0x1: DMA4 ignores the MSuspend input	RW	0x0
4:3	SIDLEMODE	Configuration port power management, Idle req/ack control 0x0: Force-idle. An idle request is acknowledged unconditionally 0x1: No-idle. An idle request is never acknowledged 0x2: Smart-idle. Acknowledgment to an idle request is given 0x3: reserved - do not use based on the internal activity of the module	RW	0x0
2	RESERVED	Write 0's for future compatibility, Reads return 0	RW	0x0
1	SOFTRESET	Software reset. Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: No effect 0x1: Reset	RW	0x0
0	AUTOIDLE	Internal OCP clock gating strategy 0x0: OCP clock is free running 0x1: Automatic OCP clock gating strategy is applied, based on the OCP interface activity.	RW	0x0

Bits	Field Name	Description	Type	Reset
31:27	RESERVED	Reserved, Write 0's for future compatibility, Read returns 0	RW	0x00
26	WRITE_PRIORITY	Channel priority on the Write side 0x0: Channel has low priority on the Write side during the arbitration process 0x1: Channel has high priority on Write sided during the arbitration process	RW	0x0
25	BUFFERING_DISABLE	This bit allows to disable the default buffering functionality when transfer is source synchronized. 0x0: buffering is enable across element/packet when source is synchronized to element, packet, frame or blocks 0x1: buffering is disabled across element/packet when source is synchronized to element, packet, frame or blocks	RW	0x-
24	SEL_SRC_DST_SYNC	Specifies that element, packet, frame or block transfer (depending on CCR.bs and CCR.fs) is triggered by the source or the destination on the DMA request 0x0: Transfer is triggered by the destination. If synch on packet the packet element number is specified in the CDFI register 0x1: Transfer is triggered by the source. If synchronized on packet the packet element number is specified in the CSFI register	RW	0x-
23	PREFETCH	Enables the prefetch mode 0x0: Prefetch mode is disabled. When Sel_Src_Dst_Sync=1 transfers are buffered and pipelined between DMA requests 0x1: Prefetch mode is enabled. Prefetch mode is active only when destination is synchronized. It is SW user responsibility not to have at the same time Prefetch=1 when Sel_Src_Dst_Sync=1. This mode is not supported	RW	0x-
22	SUPERVISOR	Enables the supervisor mode 0x0: Supervisor mode is disabled 0x1: Supervisor mode is enabled	RW	0x0
21	SECURE	Enables or disables a secure transaction over the channel 0x0: Channel secure mode is disabled 0x1: Channel secure mode is enabled	RW	0x0
20:19	SYNCHRO_CONTROL_UPPER	Channel Synchronization control upper (used in conjunction with the 5 bits of synchro channel DMA4_CCRi[4:0]) Used in conjunction, as two msb, with the five bits of the synchro channel bitfield.	RW	0x-

System Direct Memory Access (SDMA) Registers

www.ti.com

Bits	Field Name	Description	Type	Reset
18	BS	Block synchronization This bit used in conjunction with the FS to see how the DMA request is serviced in a synchronized transfer	RW	0x-
17	TRANSPARENT_COPY_ENABLE	Transparent copy enable 0x0: Transparent copy mode is disabled 0x1: Transparent copy mode is enabled	RW	0x-
16	CONST_FILL_ENABLE	Constant fill enable 0x0: Constant fill mode is disabled 0x1: Constant fill mode is enabled	RW	0x-
15:14	DST_AMODE	Selects the addressing mode on the Write Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode	RW	0x-
13:12	SRC_AMODE	Selects the addressing mode on the Read Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode	RW	0x-
11	RESERVED	Reserved, Write 0's for future compatibility, Read returns 0	RW	0x0
10	WR_ACTIVE	Indicates if the channel write context is active or not 0x0: Channel is not active on the write port 0x1: Channel is currently active on the write port	R	0x-
9	RD_ACTIVE	Indicates if the channel read context is active or not 0x0: Channel is not active on the read port 0x1: Channel is currently active on the read port	R	0x-
8	SUSPEND_SENSITIVE	Logical channel suspend enable bit 0x0: The channel ignores the MSuspend even if EMUFree is set to 0. 0x1: If EMUFree is set to 0 and MSuspend comes in then all current OCP services (single transaction or burst transaction as specified in the corresponding CSDP register) have to be completed before stopping processing any more transactions	RW	0x-
7	ENABLE	Logical channel enable. It is SW responsibility to clear the CSR register and the IRQSTATUS bit for the different interrupt lines before enabling the channel. 0x0: The logical channel is disabled 0x1: The logical channel is enabled	RW	0x0
6	READ_PRIORITY	Channel priority on the read side 0x0: Channel has low priority on the Read side during the arbitration process 0x1: Channel has high priority on read sided during the arbitration process	RW	0x-

Bits	Field Name	Description	Type	Reset
5	FS	<p>Frame synchronization</p> <p>This bit used in conjunction with the BS to see how the DMA request is serviced in a synchronized transfer</p> <p>FS=0 and BS=0: An element is transferred once a DMA request is made.</p> <p>FS=0 and BS=1: An entire block is transferred once a DMA request is made.</p> <p>FS=1 and BS=0: An entire frame is transferred once a DMA request is made.</p> <p>FS=1 and BS=1: A packet is transferred once a DMA request is made.</p> <p>All these different transfers can be interleaved on the port with other DMA requests.</p>	RW	0x-
4:0	SYNCHRO_CONTROL	<p>Channel synchronization control</p> <p>This bitfield used in conjunction with the second_level_synchro_control_upper (as two msb) 0000000 : Is reserved for non synchronized LCH transfer xxxxxx (from 1 to 127) There are 127 possible DMA request to assign to any LCH.</p> <p>Note: The channel synchronization control registers are 1-based. For example, to enable the S_DMA_1 request, SDMA.DMA4_CCR[4:0] SYNCHRO_CONTROL must be set to 0x2 (DMA request number + 1).</p>	RW	0x--

Interrupt Controller (INTC)

This chapter gives an overview of the interrupt controllers (INTCs) and describes in detail the MPU subsystem interrupt controller (MPU_INTC) module used in the OMAP35x stand-alone Applications Processor.

Note: This chapter gives information about all modules and features in the high-tier device. See Chapter 1, *OMAP35x Family* section, to check availability of modules and features. Ensure that interrupts of unavailable modules and features are masked in MPU/IVA subsystems.

10.1 Interrupt Controller Overview

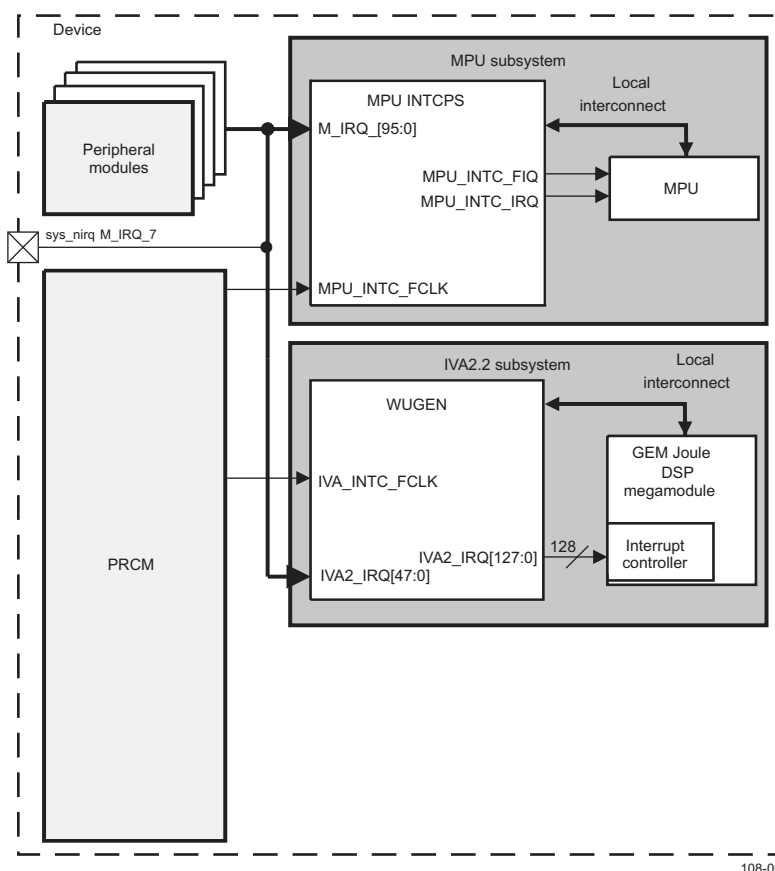

The device provides two interrupt controller (INTC) modules:

- **MPU subsystem INTC (INTCPS):** This module handles all MPU-related events, using Priority Threshold and Security Features. It communicates with the ARM Cortex-A8™ processor using a private local interconnect, and runs at half the speed of the processor.
- **IVA2.2 subsystem INTC:** This module is a specific combination of WUGEN (wake-up generator) and the GEM Joule DSP megamodule interrupt controller (IC). It is used in the device, but is not described in detail in this chapter. For detailed information about this INTC, see *IVA2.2 Subsystem* chapter.

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

Figure 10-1 shows the internal interrupt scheme.

Figure 10-1. Interrupt Controllers Highlight

10.2 Interrupt Controller Environment

The INTC can handle two types of interrupts originating from an external device:

- sys_nirq interrupt inputs:

The MPU INTC handles external interrupts through a dedicated sys_nirq interrupt line that connects the INTC module with a TPS65950 power IC. An interrupt can generate a system wake-up event.

If the system is idle and the external interrupt is masked, the interrupt cannot wake up the system. Like other interrupt lines, the external interrupt is active at low level and is acknowledged by the software according to the common programming model.

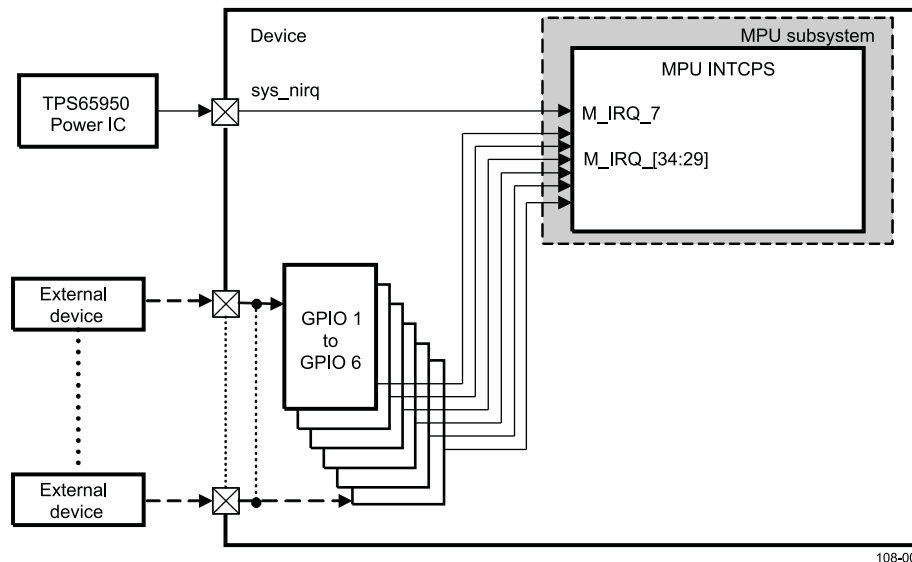

Note: If the CORE power domain is in retention or off mode, both the interrupt requests (internal or external) and the MPU INTC have no effect. The CORE power domain does not wake up, and the interrupt is not signaled to the MPU.

- GPIO interrupt inputs:

External devices can also use GPIO modules to generate interrupts to the MPU. There are six dedicated interrupt lines to the MPU INTC. One interrupt line is associated with each GPIO module. Each GPIO module can generate a single interrupt whenever there is at least one event in any one of the configured 32 GPIO inputs. For more information about GPIO features, see the *General-Purpose Interface* chapter.

Figure 10-2 shows the relationship between the device and external interrupts.

Figure 10-2. Interrupts from External Devices

The features specific to INTCPS are:

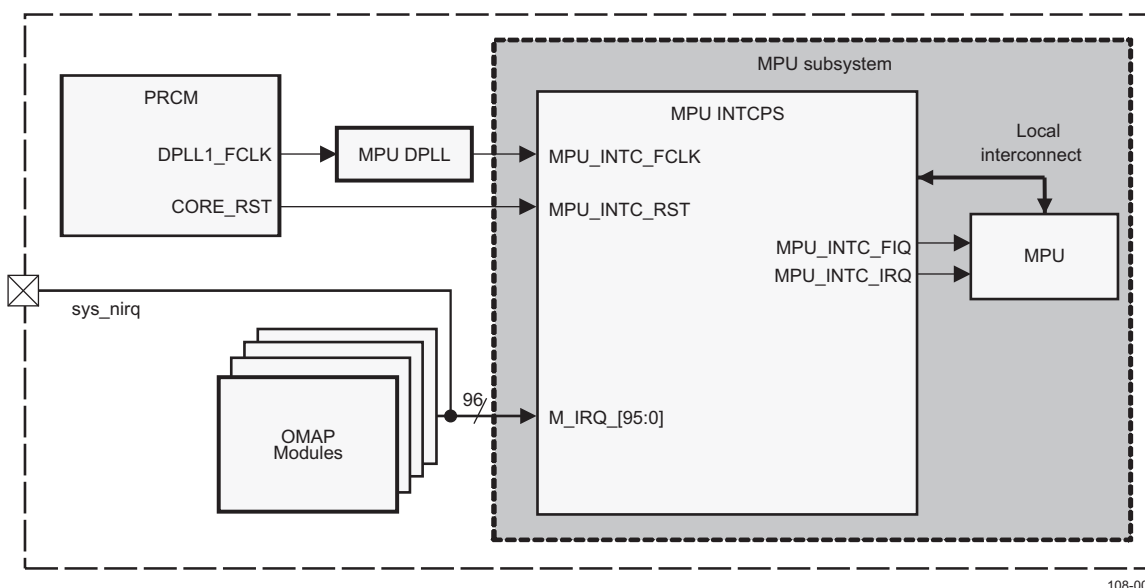

- Up to 96 level-sensitive interrupt inputs
- Individual priority (up to 64) for each interrupt input
- Interrupt lines connected to internal module interrupts
- One incoming interrupt line from an external device

10.3 MPU Subsystem INTCPS Integration

The INTCPS module is the interface between incoming interrupts and the two interrupt inputs of the MPU. It can handle up to 96 request inputs that can be configured as MPU FIQ or IRQ interrupt requests.

Figure 10-3 shows the integration of the INTCPS in the MPU subsystem.

Figure 10-3. MPU Subsystem INTCPS Integration

The MPU subsystem INTCPS is directly connected to the MPU by an MPU peripheral port. Consequently, the MPU subsystem INTCPS is accessible and visible only by the MPU.

10.3.1 Clocking, Reset, and Power Management Scheme

10.3.1.1 MPU Subsystem INTC Clocks

The MPU subsystem INTCPS runs at half the rate of the MPU functional clock (see the *MPU Subsystem* chapter).

The interface clock used for register access runs at the rate of the interconnect bus clock (equal to the rate of the MPU interface clock; see the *Power, Reset, and Clock Management* chapter).

The synchronizer clock allows external asynchronous interrupts to be resynchronized before they are masked.

Table 10-1 lists the MPU subsystem INTC clock rates.

Table 10-1. MPU Subsystem INTC Clock Rates

Clock	Frequency	Name	Comments
Functional	ARM_FCLK	MPU_INTF_FCLK	Source is the MPU DPLL.
Interface	ARM_FCLK	MPU_INTF_ICLK	Source is the PRCM module.
Synchronizer	MPU_INTF_FCLK	Synchronizer clock (module internal clock)	Source is the MPU_INTF_FCLK.

10.3.1.2 Hardware and Software Reset

Table 10-2 lists the MPU subsystem INTC resets.

Table 10-2. Hardware and Software Reset

Type	Name	Source	Activation	Domain
Hardware	CORE_RST	PRCM	Active low	CORE
Software	SOFTRESET	MPU_INTC.INTCPS_SYSCONFIG[1] SOFTRESET bit	Active at 1	MPU INTC internal

10.3.1.3 Power Management

The MPU subsystem INTC belongs to the CORE power domain. As part of CORE power domain, it is sensitive to a CORE_RST issued by the PRCM. For more information about the CORE power domain implementation and CORE_RST signal, see the *Power, Reset, and Clock Management* chapter.

The MPU INTC clocks come from the MPU DPLL. For more information about these clocks control, see the *MPU Subsystem* chapter.

10.3.2 Interrupt Request Lines

Table 10-3 lists the incoming and outgoing interrupt lines of the INTCPS.

Table 10-3. Interrupt Lines Incoming and Outgoing

Type	Number	Name	Mapping	Comments
Interrupt request inputs	Up to 96	M_IRQ_[95:0]	See Table 10-4	Inputs to INTCPS module, source from various modules.
Interrupt request outputs	2	MPU_INTC_FIQ	MPU_INTC_FIQ	Outgoing to MPU Fast Interrupt
		MPU_INTC_IRQ	MPU_INTC_IRQ	Outgoing to MPU Normal Interrupt

Note: Interrupt request signals are active at low level.

CAUTION

A single interrupt source can be physically mapped to multiple INTCs (MPU subsystem, IVA2.2 subsystem). With multiple-mapped interrupts, it is strongly recommended each interrupt source be unmasked in only one INTC at a time.

This section gives information about all modules and features in the high-tier device. See Chapter 1, *OMAP35x Family* section, to check availability of modules and features. Ensure that interrupts of unavailable modules and features are masked in MPU subsystem.

Table 10-4 lists interrupt mappings to the MPU subsystem.

Table 10-4. Interrupt Mapping to the MPU Subsystem⁽¹⁾

IRQ	Source	Description
M_IRQ_0	EMUINT	MPU emulation ⁽²⁾

10.4 Interrupt Controller Functional Description

The main features of the INTCPS are:

- Individual priority (up to 64 levels) for each interrupt input
- Ability for each interrupt to be steered to either FIQ or IRQ
- Independent priority sorting for FIQ and IRQ; FIQ sorting is processed concurrently with IRQ sorting.
- Priority masking: Interrupts can be masked based on the priority threshold register.
- Atomic bit set and clear capability for interrupt mask and software interrupt registers
- For high-security (HS) devices only:
 - Global interrupt mask
 - Protection for secure interrupts
- Power-management and wake-up support
- Auto-idle power-saving support

The INTCPS processes incoming interrupts by masking and priority sorting, then it generates the interrupt requests to the MPU.

[Figure 10-4](#) shows the top-level view of the interrupt processing.

Figure 10-4. Top-Level Block Diagram

intc-004

- (1) Public Mask = SICR[3] PUBLICINHIBIT bit OR (SICR[2] AUTOINHIBIT bit AND SICR[0] SSMFIQSTATUS bit)
- (2) The SCRN forces the interrupt priority to 0 (highest).
- (3) The SCRN forces the interrupt to FIQ.
- (4) The comparator output is TRUE only if the interrupt priority is higher than the threshold register priority. The highest priority is 0x0; the lowest priority is 0x3F (63).

10.4.1 Interrupt Processing

10.4.1.1 Input Selection

The INTCPS supports only level-sensitive incoming interrupt detection. A peripheral asserting an interrupt maintains it until software has handled the interrupt and instructed the peripheral to de-assert the interrupt.

A software interrupt is generated if the corresponding bit in the MPU_INTC.INTCPS_ISR_SETn register is set (register bank number: n = [0,2] for the MPU subsystem INTCPS, 96 incoming interrupt lines are supported). The software interrupt clears when the corresponding bit in the MPU_INTC.INTCPS_ISR_CLEARn register is written. Typical use of this feature is software debugging.

10.4.1.2 Masking

10.4.1.2.1 Individual Masking

Detection of interrupts on each incoming interrupt line can be enabled or disabled independently by the MPU_INTC.INTCPS_MIRn interrupt mask register. In response to an unmasked incoming interrupt, the INTCPS can generate one of two types of interrupt requests to the processor:

- IRQ: low-priority interrupt request
- FIQ: fast interrupt request

The type of interrupt request is determined by the MPU_INTC.INTCPS_ILRm[0] FIQNIRQ bit (m = [0,95]).

The current incoming interrupt status before masking is readable from the MPU_INTC.INTCPS_ITRn register. After masking and IRQ/FIQ selection, and before priority sorting is done, the interrupt status is readable from the MPU_INTC.INTCPS_PENDING_IRQn and MPU_INTC.INTCPS_PENDING_FIQn registers.

10.4.1.2.2 Global Masking (HS Devices Only)

Software may use global masking for security purposes, but this feature must be used with care. To determine if a HS version of your device is available and for more information on HS devices, please refer to your device-specific data manual.

10.4.1.2.3 Priority Masking

To enable faster processing of high-priority interrupts, a programmable priority masking threshold is provided (the MPU_INTC.INTCPS_THRESHOLD[7:0] PRIORITYTHRESHOLD field). This priority threshold allows preemption by higher priority interrupts; all interrupts of lower or equal priority than the threshold are masked. However, priority 0 can never be masked by this threshold; a priority threshold of 0 is treated the same way as priority 1.

PRIORITY and PRIORITYTHRESHOLD fields values can be set between 0x0 and 0x3F; 0x0 is the highest priority and 0x3F is the lowest priority.

When priority masking is not necessary, a priority threshold value of 0xFF disables the priority threshold mechanism. This value is also the reset default for backward compatibility with previous versions of the INTCPS.

10.4.1.3 Priority Sorting

A priority level (0 being the highest) is assigned to each incoming interrupt line. Both the priority level and the interrupt request type are configured by the MPU_INTC.INTCPS_ILRm register. If more than one incoming interrupt with the same priority level and interrupt request type occur simultaneously, the highest-numbered interrupt is serviced first.

When one or more unmasked incoming interrupts are detected, the INTCPS separates between IRQ and FIQ using the corresponding MPU_INTC.INTCPS_ILRm[0] FIQNIRQ bit. The result is placed in INTCPS_PENDING_IRQn or INTCPS_PENDING_FIQn

If no other interrupts are currently being processed, INTCPS asserts IRQ/FIQ and starts the priority computation. Priority sorting for IRQ and FIQ can execute in parallel.

Each IRQ/FIQ priority sorter determines the highest priority interrupt number. Each priority number is placed in the corresponding MPU_INTC.INTCPS_SIR_IRQ[6:0] ACTIVEIRQ field or MPU_INTC.INTCPS_SIR_FIQ[6:0] ACTIVEFIQ field. The value is preserved until the corresponding MPU_INTC.INTCPS_CONTROL NEWIRQAGR or NEWFIQAGR bit is set.

Once the interrupting peripheral device has been serviced and the incoming interrupt de-asserted, the user must write to the appropriate NEWIRQAGR or NEWFIQAGR bit to indicate to the INTCPS the interrupt has been handled. If there are any pending unmasked incoming interrupts for this interrupt request type, the INTCPS restarts the appropriate priority sorter; otherwise, the IRQ or FIQ interrupt line is de-asserted.

10.4.2 Secure Interrupts (HS Devices Only)

To determine if a HS version of your device is available and for more information on HS devices, please refer to your device-specific data manual.

10.4.3 Register Protection

If the MPU_INTC.INTCPS_PROTECTION[0] PROTECTION bit is set, access to the INTCPS registers is restricted to the supervisor mode. Access to the MPU_INTC.INTCPS_PROTECTION register is always restricted to privileged mode.

10.4.4 Module Power Saving

The INTCPS provides an auto-idle function in its three clock domains:

- Interface clock
- Functional clock
- Synchronizer clock

The interface clock auto-idle power-saving mode is enabled if the MPU_INTC.INTCPS_SYSCONFIG[0] AUTOIDLE bit is set to 1. When this mode is enabled and there is no activity on the bus interface, the interface clock is disabled internally to the module, thus reducing power consumption. When there is new activity on the bus interface, the interface clock restarts without any latency penalty. After reset, this mode is disabled, by default.

The functional clock auto-idle power-saving mode is enabled if the MPU_INTC.INTCPS_IDLE[0] FUNCIDLE bit is set to 0. When this mode is enabled and there is no active interrupt (IRQ or FIQ interrupt being processed or generated) or no pending incoming interrupt, the functional clock is disabled internally to the module, thus reducing power consumption. When a new unmasked incoming interrupt is detected, the functional clock restarts and the INTCPS processes the interrupt. If this mode is disabled, the interrupt latency is reduced by one cycle. After reset, this mode is enabled, by default.

The synchronizer clock allows external asynchronous interrupts to be resynchronized before they are masked. The synchronizer input clock has an auto-idle power-saving mode enabled if the MPU_INTC.INTCPS_IDLE[1] TURBO bit is set to 1. If the auto-idle mode is enabled, the standby power is reduced, but the IRQ or FIQ interrupt latency increases from four to six functional clock cycles. This feature can be enabled dynamically according to the requirements of the device. After reset, this mode is disabled, by default.

To ensure optimal power consumption, INTC_INIT_REGISTER1[0] INIT1 and INTC_INIT_REGISTER2[1] INIT2 bits must be set to 1 during initialization.

10.4.5 Interrupt Latency

The IRQ/FIQ interrupt generation takes four INTCPS functional clock cycles (plus or minus one cycle) if the MPU_INTC.INTCPS_IDLE[1] TURBO bit is set to 0. If the TURBO bit is set to 1, the interrupt generation takes six cycles, but power consumption is reduced while waiting for an interrupt.

These latencies can be reduced by one cycle by disabling functional clock auto-idle (MPU_INTC.INTCPS_IDLE[0] FUNCIDLE bit set to 1), but power consumption is increased, so the benefit is minimal. For information about power saving, see [Section 10.4.4](#).

To minimize interrupt latency when an unmasked interrupt occurs, the IRQ or FIQ interrupt is generated before priority sorting completion. The priority sorting takes 10 functional clock cycles, which is less than the minimum number of cycles required for the MPU to switch to the interrupt context after reception of the IRQ or FIQ event.

Any read of the MPU_INTC.INTCPS_SIR_IRQ or MPU_INTC.INTCPS_SIR_FIQ register during the priority sorting process stalls until priority sorting is complete and the relevant register is updated. However, the delay between the interrupt request being generated and the interrupt service routine being executed is such that priority sorting always completes before the MPU_INTC.INTCPS_SIR_IRQ or MPU_INTC.INTCPS_SIR_FIQ register is read.

10.5 Interrupt Basic Programming Model

10.5.1 Initialization Sequence

1. Program the MPU_INTC.INTCPS_SYSCONFIG register: If necessary, enable the interface clock autogating by setting the AUTOIDLE bit.
2. Program the MPU_INTC.INTCPS_IDLE register: If necessary, disable functional clock autogating or enable synchronizer autogating by setting the FUNCIDLE bit or TURBO bit accordingly.
3. Program the MPU_INTC.INTCPS_ILRm register for each interrupt line: Assign a priority level and set the FIQNFIQ bit for an FIQ interrupt (by default, interrupts are mapped to IRQ and priority is 0x0 [highest]).
4. Program the MPU_INTC.INTCPS_MIRn register: Enable interrupts (by default, all interrupt lines are masked).

Note: To program the MPU_INTC.INTCPS_MIRn register, the MPU_INTC.INTCPS_MIR_SETn and MPU_INTC.INTCPS_MIR_CLEARn registers are provided to facilitate the masking, even if it is possible for backward-compatibility to write directly to the MPU_INTC.INTCPS_MIRn register.

10.5.2 MPU INTC Processing Sequence

After the MPU_INTC.INTCPS_MIRn and MPU_INTC.INTCPS_ILRm registers are configured to enable and assign priorities to incoming interrupts, the interrupt is processed as explained in the following subsections.

IRQ and FIQ processing sequences are quite similar, the differences for the FIQ sequence are shown after a '/' character in **bold** characters in the text or the code below.

1. One or more unmasked incoming interrupts (M_IRQ_n signals) are received and IRQ or FIQ outputs (MPU_INTC_IRQ/**FIQ**) are not currently asserted.
2. If the MPU_INTC.INTCPS_ILRm[0] FIQNIRQ bit is set to 0, the MPU_INTC_IRQ output signal is generated. If the FIQNIRQ bit is set to 1, the MPU_INTC_FIQ output signal is generated.
3. The INTC performs the priority sorting and updates the MPU_INTC.INTCPS_SIR_IRQ[6:0] ACTIVEIRQ /**MPU_INTC.INTCPS_SIR_FIQ[6:0] ACTIVEFIQ** field with the current interrupt number.
4. During priority sorting, if the IRQ/**FIQ** is enabled at the host processor side, the host processor automatically saves the current context and executes the ISR as follows:

Note: The ARM host processor automatically performs the following actions in pseudo code.

```

LR = PC + 4                /* return link                */
SPSR = CPSR                /* Save CPSR before execution */
CPSR[5] = 0               /* Execute in ARM state      */
CPSR[7] = 1               /* Disable IRQ                */

```

```

CPSR[8] = 1                      /* Disable Imprecise Data Aborts */
CPSR[9] = CP15_reg1_EEbit        /* Endianness on exception entry */
if interrupt == IRQ then
    CPSR[4:0] = 0b10010          /* Enter IRQ mode */
    if high vectors configured then
        PC = 0xFFFFF018
    else
        PC = 0x00000018          /* execute interrupt vector */
else if interrupt == FIQ then
    CPSR[4:0] = 0b10001          /* Enter FIQ mode */
    CPSR[6] = 1                  /* Disable FIQ */
    if high vectors configured then
        PC = 0xFFFFF01C
    else
        PC = 0x0000001C          /* execute interrupt vector */
end if

```

5. The ISR saves the remaining context, identifies the interrupt source by reading the **ACTIVEIRQ/ACTIVEFIQ** field, and jumps to the relevant subroutine handler as follows:

CAUTION

The code in steps 5 and 7 is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

```

; INTCPS_SIR_IRQ/INTCPS_SIR_FIQ register address
INTCPS_SIR_IRQ_ADDR/INTCPS_SIR_FIQ_ADDR .word 0x48200040/0x48200044

; ACTIVEIRQ bit field mask to get only the bit field
ACTIVEIRQ_MASK .equ 0x7F

_IRQ_ISR/_FIQ_ISR:

    ; Save the critical context
    STMFD SP!, {R0-R12, LR}          ; Save working registers and the Link register
    MRS R11, SPSR                    ; Save the SPSR into R11

    ; Get the number of the highest priority active IRQ/FIQ
    LDR R10, INTCPS_SIR_IRQ_ADDR/INTCPS_SIR_FIQ_ADDR
    LDR R10, [R10]                    ; Get the INTCPS_SIR_IRQ/INTCPS_SIR_FIQ register
    AND R10, R10, #ACTIVEIRQ_MASK     ; Apply the mask to get the active IRQ number

    ; Jump to relevant subroutine handler
    LDR PC, [PC, R10, lsl #2]          ; PC base address points this instruction + 8
    NOP                                ; To index the table by the PC

    ; Table of handler start addresses
    .word IRQ0handler ;For IRQ0 of BANK0
    .word IRQ1handler
    .word IRQ2handler

```

6. The subroutine handler executes code specific to the peripheral generating the interrupt by handling the event and de-asserting the interrupt condition at the peripheral side.

```

; IRQ0 subroutine
IRQ0handler:

    ; Save working registers
    STMFD SP!, {R0-R1}

    ; Now read-modify-write the peripheral module status register
    ; to de-assert the M_IRQ_0 interrupt signal

    ; De-Assert the peripheral interrupt

```

```

MOV R0, #0x7                ; Mask for 3 flags
LDR R1, MODULE0_STATUS_REG_ADDR ; Get the address of the module Status Register
STR R0, [R1]                ; Clear the 3 flags

; Restore working registers
LDMFD SP!, {R0-R1}

; Jump to the end part of the ISR
B IRQ_ISR_end/FIQ_ISR_end

```

7. After the return of the subroutine, the ISR sets the **NEWIRQAGR/NEWFIQAGR** bit to enable the processing of subsequent pending IRQs/**FIQs** and to restore ARM context in the following code. Because the writes are posted on an Interconnect bus, to be sure that the preceding writes are done before enabling IRQs/**FIQs**, a Data Synchronization Barrier is used. This operation ensure that the IRQ/**FIQ** line is de-asserted before IRQ/**FIQ** enabling. After that, the INTC processes any other pending interrupts or de-asserts the MPU_INTC_IRQ/**MPU_INTC_FIQ** signal if there is no interrupt.

```

; INTCPS_CONTROL register address
INTCPS_CONTROL_ADDR .word 0x48200048

; NEWIRQAGR/NEWFIQAGR bit mask to set only the NEWIRQAGR/NEWFIQAGR bit
NEWIRQAGR_MASK/NEWFIQAGR_MASK .equ 0x01/0x02

IRQ_ISR_end/FIQ_ISR_end:

; Allow new IRQs/FIQs at INTC side
; The INTCPS_CONTROL register is a write only register so no need to write back others bits
MOV R0, #NEWIRQAGR_MASK/NEWFIQAGR_MASK ; Get the NEWIRQAGR/NEWFIQAGR bit position
LDR R1, INTCPS_CONTROL_ADDR
STR R0, [R1]                ; Write the NEWIRQAGR/NEWFIQAGR bit to allow new IRQs/FIQs

; Data Synchronization Barrier
MOV R0, #0
MCR P15, #0, R0, C7, C10, #4

; restore critical context
MSR SPSR, R11                ; Restore the SPSR from R11
LDMFD SP!, {R0-R12, LR}      ; Restore working registers and Link register

; Return after handling the interrupt
SUBS PC, LR, #4

```

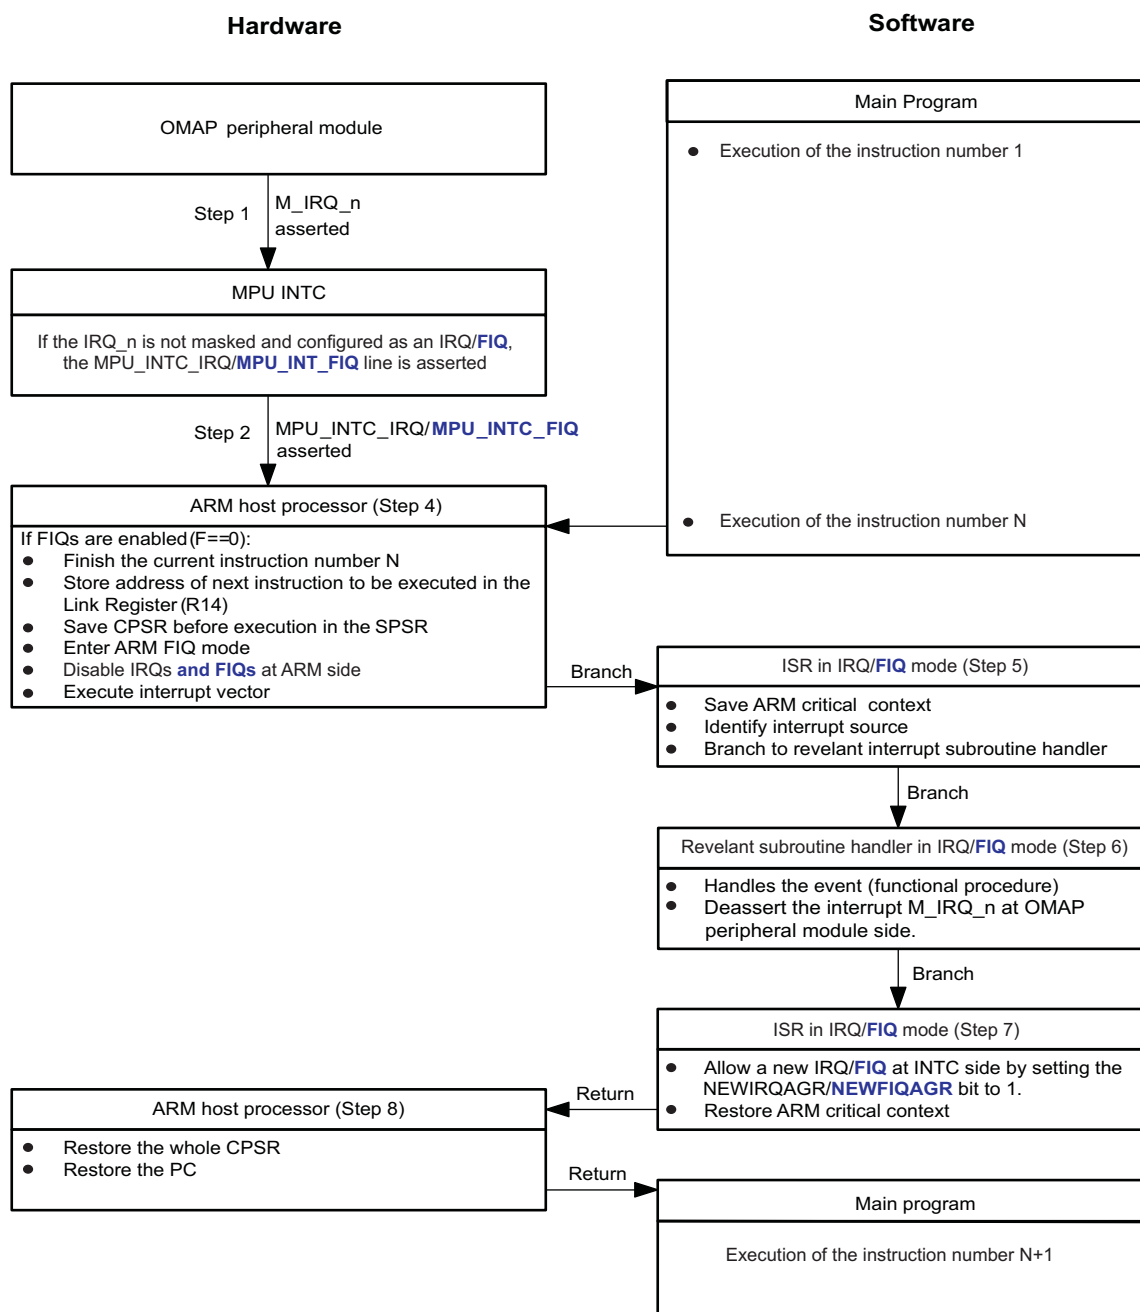

8. After the ISR return, the ARM automatically restores its context as follows:

```

CPSR = SPSR
PC = LR

```

[Figure 10-5](#) shows the IRQ/**FIQ** processing sequence from the originating device peripheral module to the main program interruption.

Figure 10-5. IRQ/FIQ Processing Sequence

108-005

Note: The differences between the IRQ and the FIQ sequence are highlighted in blue and bold characters.

The priority sorting mechanism is frozen during an interrupt processing sequence. If an interrupt condition occurs during this time, the interrupt is not lost. It is sorted when the NEWIRQAGR/**NEWFIQAGR** bit is set (priority sorting is reactivated).

10.5.3 MPU INTC Preemptive Processing Sequence

Preemptive interrupts, also called nested interrupts, can reduce the latencies for higher priority interrupts. A preemptive ISR can be suspended by a higher priority interrupt. Thus, the higher priority interrupt can be served immediately.

Nested interrupts must be used carefully to avoid using corrupted data. Programmers must save corruptible registers and enable IRQ or FIQ at ARM side.

IRQ and FIQ processing sequences are quite similar, the differences for the FIQ sequence are shown after a '/' character in **bold** characters in the text or the code below.

To enable IRQ/**FIQ** preemption by higher priority IRQs/**FIQs**, programmers can follow this procedure to write the ISR:

At the beginning of an IRQ/**FIQ** ISR:

1. Save the ARM critical context registers.
2. Save the MPU_INTC.**INTCPS_THRESHOLD** PRIORITYTHRESHOLD field before modifying it.
3. Read the active interrupt priority in the MPU_INTC.**INTCPS_IRQ_PRIORITY** IRQPRIORITY / **MPU_INTC.INTCPS_FIQ_PRIORITY** FIQPRIORITY field and write it to the PRIORITYTHRESHOLD⁽¹⁾ field.
4. Read the active interrupt number in the MPU_INTC.**INTCPS_SIR_IRQ**[6:0] ACTIVEIRQ / **MPU_INTC.INTCPS_SIR_FIQ**[6:0] ACTIVEFIQ field to identify the interrupt source.
5. Write 1 to the appropriate MPU_INTC.**INTCPS_CONTROL** NEWIRQAGR and⁽²⁾ **NEWFIQAGR** bit while an interrupt is still processing to allow only higher priority interrupts to preempt.
6. Because the writes are posted on an Interconnect bus, to be sure that the preceding writes are done before enabling IRQs/**FIQs**, a Data Synchronization Barrier is used. This operation ensure that the IRQ line is de-asserted before IRQ/**FIQ** enabling.
7. Enable IRQ/**FIQ** at ARM side.
8. Jump to the relevant subroutine handler.

The sample code below shows the previous steps:

CAUTION

The code below is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

```
; bit field mask to get only the bit field
ACTIVEPRIO_MASK .equ 0x3F

_IRQ_ISR:
; Step 1 : Save the critical context
STMFD SP!, {R0-R12, LR}           ; Save working registers
MRS R11, SPSR                     ; Save the SPSR into R11

; Step 2 : Save the INTCPS_THRESHOLD register into R12
LDR R0, INTCPS_THRESHOLD_ADDR
LDR R12, [R0]

; Step 3 : Get the priority of the highest priority active IRQ
```

- (1) The priority-threshold mechanism is enabled automatically when writing a priority in the range of 0x00 to 0x3F while reading it from the IRQPRIORITY and FIQPRIORITY fields. Writing a value of 0xFF (reset default) disables the priority-threshold mechanism. Values between 0x3F and 0xFF must not be used. When the hardware-priority threshold is in use, the priorities of interrupts selected as FIQ or IRQ become linked; otherwise, they are independent. When they are linked, all FIQ priorities must be set higher than all IRQ priorities to maintain the relative priority of FIQ over IRQ.
- (2) When handling FIQs using the priority-threshold mechanism, both NEWFIQAGR and NEWIRQAGR bits must be written at the same time to ensure that the new priority threshold is applied while an IRQ sort is in progress. This IRQ will not have been seen by the ARM, as it will have been masked on entry to the FIQ ISR. However, the source of the IRQ remains active and it is finally processed when the priority threshold falls to a priority sufficiently low to allow it to be processed. The precaution of writing to New FIQ Agreement is not required during an IRQ ISR, as FIQ sorting is not affected (providing all FIQ priorities are higher than all IRQ priorities).

```

LDR R1, INTCPS_IRQ_PRIORITY_ADDR/INTCPS_FIQ_PRIORITY_ADDR
LDR R1, [R1] ; Get the INTCPS_IRQ_PRIORITY/INTCPS_FIQ_PRIORITY register
AND R1, R1, #ACTIVEPRIO_MASK ; Apply the mask to get the priority of the IRQ
STR R1, [R0] ; Write it to the INTCPS_THRESHOLD register

; Step 4 : Get the number of the highest priority active IRQ
LDR R10, INTCPS_SIR_IRQ_ADDR/INTCPS_SIR_FIQ_ADDR
LDR R10, [R10] ; Get the INTCPS_SIR_IRQ/INTCPS_SIR_FIQ register
AND R10, R10, #ACTIVEIRQ_MASK ; Apply the mask to get the active IRQ number

; Step 5 : Allow new IRQs and FIQs at INTC side
MOV R0, #0x1/0x3 ; Get the NEWIRQAGR and NEWFIQAGR bit position
LDR R1, INTCPS_CONTROL_ADDR
STR R0, [R1] ; Write the NEWIRQAGR and NEWFIQAGR bit

; Step 6 : Data Synchronization Barrier
MOV R0, #0
MCR P15, #0, R0, C7, C10, #4

; Step 7 : Read-modify-write the CPSR to enable IRQs/FIQs at ARM side
MRS R0, CPSR ; Read the status register
BIC R0, R0, #0x80/0x40 ; Clear the I/F bit
MSR CPSR, R0 ; Write it back to enable IRQs

; Step 8 : Jump to relevant subroutine handler
LDR PC, [PC, R10, lsl #2] ; PC base address points this instruction + 8
NOP ; To index the table by the PC

; Table of handler start addresses
.word IRQ0handler ;IRQ0 BANK0
.word IRQ1handler
.word IRQ2handler

```

After the return of the relevant IRQ/FIQ subroutine handle :

1. Disable IRQs/FIQs at ARM side.
2. Restore the MPU_INTC.INTCPS_THRESHOLD PRIORITYTHRESHOLD field.
3. Restore the ARM critical context registers.

The sample code below shows the three previous steps:

CAUTION

The code below is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

IRQ_ISR_end:

```

; Step 1 : Read-modify-write the CPSR to disable IRQs/FIQs at ARM side
MRS R0, CPSR ; Read the CPSR
ORR R0, R0, #0x80/0x40 ; Set the I/F bit
MSR CPSR, R0 ; Write it back to disable IRQs

; Step 2 : Restore the INTCPS_THRESHOLD register from R12
LDR R0, INTCPS_THRESHOLD_ADDR
STR R12, [R0]

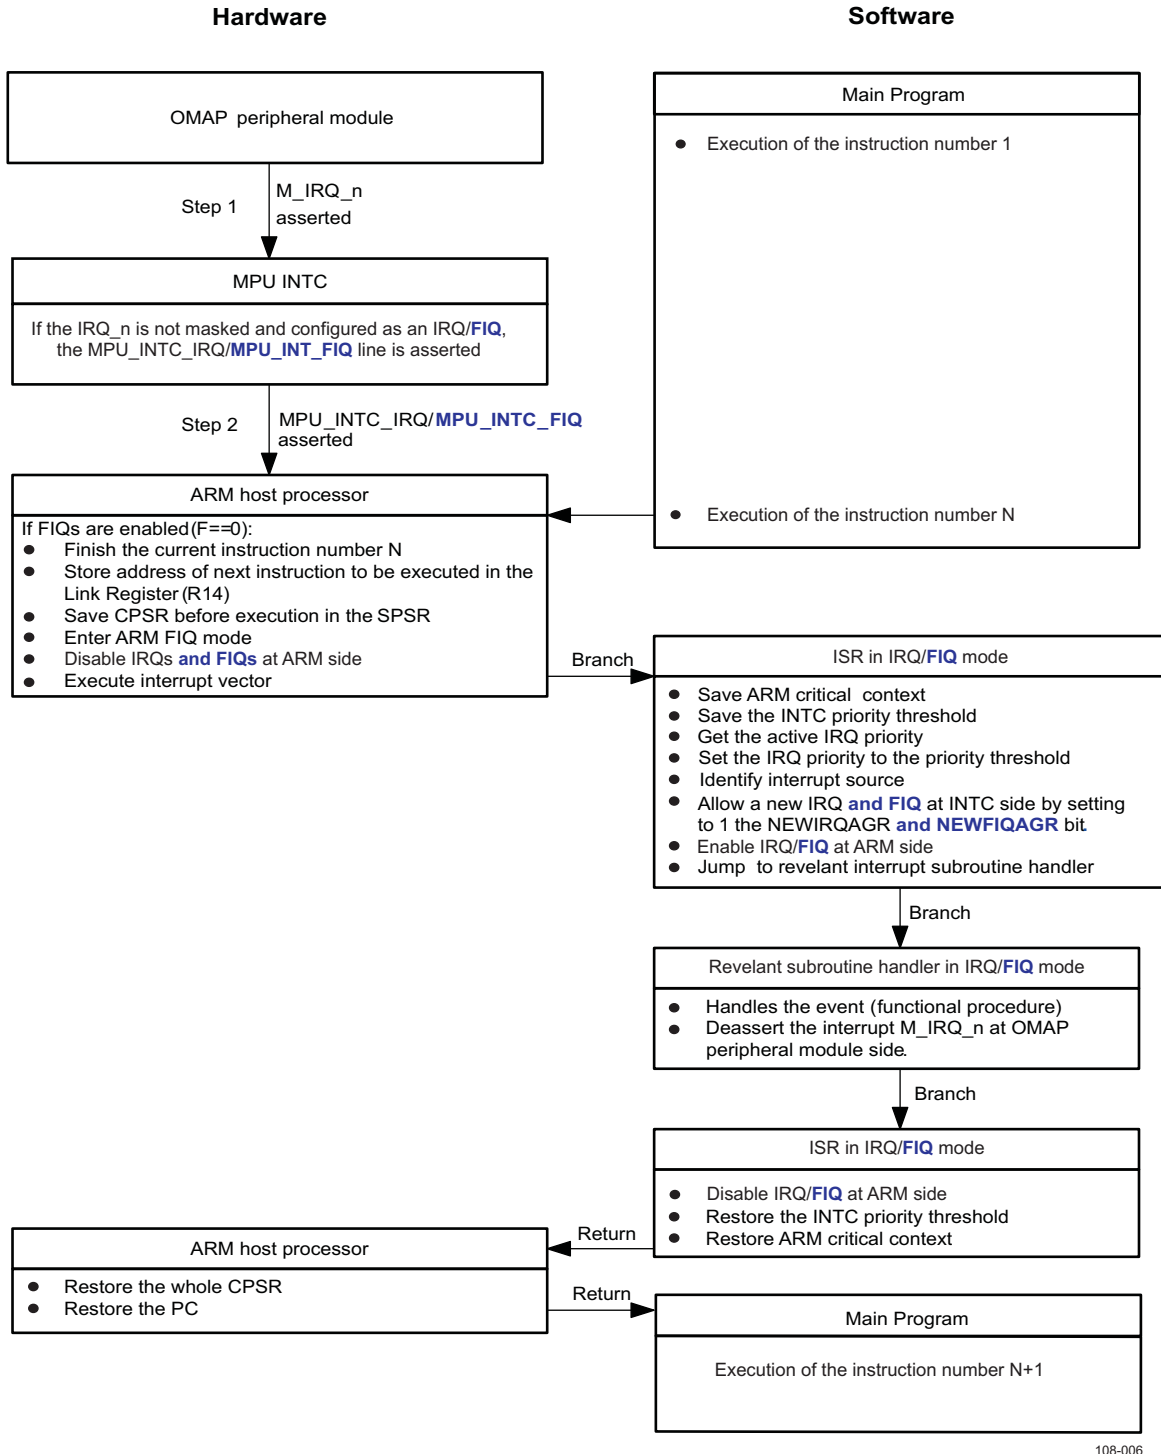

; Step 3 : Restore critical context
MSR SPSR, R11 ; Restore the SPSR from R11
LDMFD SP!, {R0-R12, LR} ; Restore working registers and Link register

; Return after handling the interrupt
SUBS PC, LR, #4

```

Figure 10-6 shows the nested IRQ/FIQ processing sequence from the originating device peripheral module to the main program interruption.

Figure 10-6. Nested IRQ/FIQ Sequence

108-006

Note: The differences between the IRQ and the FIQ sequence are highlighted in blue and bold characters.

10.5.4 MPU INTC Spurious Interrupt Handling

The spurious flag indicates whether the result of the sorting (a window of 10 INTC functional clock cycles after the interrupt assertion) is invalid. The sorting is invalid if:

- The interrupt that triggered the sorting is no longer active during the sorting.
- A change in the mask has affected the result during the sorting time.

As a result, the values in the MPU_INTC.INTCPS_MIRn, MPU_INTC.INTCPS_ILRm, or MPU_INTC.INTCPS_MIR_SETn registers must not be changed while the corresponding interrupt is asserted. If these registers are changed within the 10-cycle window after the interrupt assertion, only the active interrupt input that triggered the sort can be masked before its turn in the sort. The resulting values of the following registers become invalid:

- MPU_INTC.INTCPS_SIR_IRQ
- MPU_INTC.INTCPS_SIR_FIQ
- MPU_INTC.INTCPS_IRQ_PRIORITY
- MPU_INTC.INTCPS_FIQ_PRIORITY

This condition is detected for both IRQ and FIQ, and the invalid status is flagged across the SPURIOUSIRQFLAG (see Note 1) and SPURIOUSFIQFLAG (see Note 2) bit fields in the SIR and PRIORITY registers. A 0 indicates valid and a 1 indicates invalid interrupt number and priority. The invalid indication can be tested in software as a false register value.

Note:

1. The MPU_INTC.INTCPS_SIR_IRQ[31:7] SPURIOUSIRQFLAG field is a copy of the MPU_INTC.INTCPS_IRQ_PRIORITY[31:7] SPURIOUSIRQFLAG field.
 2. The MPU_INTC.INTCPS_SIR_FIQ[31:7] SPURIOUSFIQFLAG field is a copy of the MPU_INTC.INTCPS_FIQ_PRIORITY[31:7] SPURIOUSFIQFLAG field.
-

10.6 Interrupt Controller Registers

Table 10-5 lists the base address and address space for the INTC instances.

Table 10-5. INTC Instance Summary

Module Name	Base Address	Size
MPU INTC	0x4820 0000	4K bytes

10.6.1 Register Mapping Summary

CAUTION

MPU INTC registers are limited to 32-bit and 16-bit data accesses. 8-bit is not allowed and can corrupt register content.

In Section 10.6.2, each register from MPU_INTC.INTCPS_ITR_n to MPU_INTC.INTCPS_PENDING_FIQ_n contains 32 bits, 1 bit for each interrupt (in ascending order: bit 0 of the MPU_INTC.INTCPS_ITR0 register applies to interrupt line 0; bit 0 of the MPU_INTC.INTCPS_ITR1 register applies to interrupt line 32).

Table 10-6. MPU INTC Register Summary

Memory Subsystem

This chapter describes the memory subsystem of the OMAP35x Applications Processor.

Topic	Page
11.1 General-Purpose Memory Controller (GPMC)	1178
11.2 SDRAM Controller (SDRC) Subsystem	1295
11.3 On-Chip Memory (OCM) Subsystem	1416
11.4 Revision History	1421

11.1 General-Purpose Memory Controller (GPMC)

11.1.1 General-Purpose Memory Controller Overview

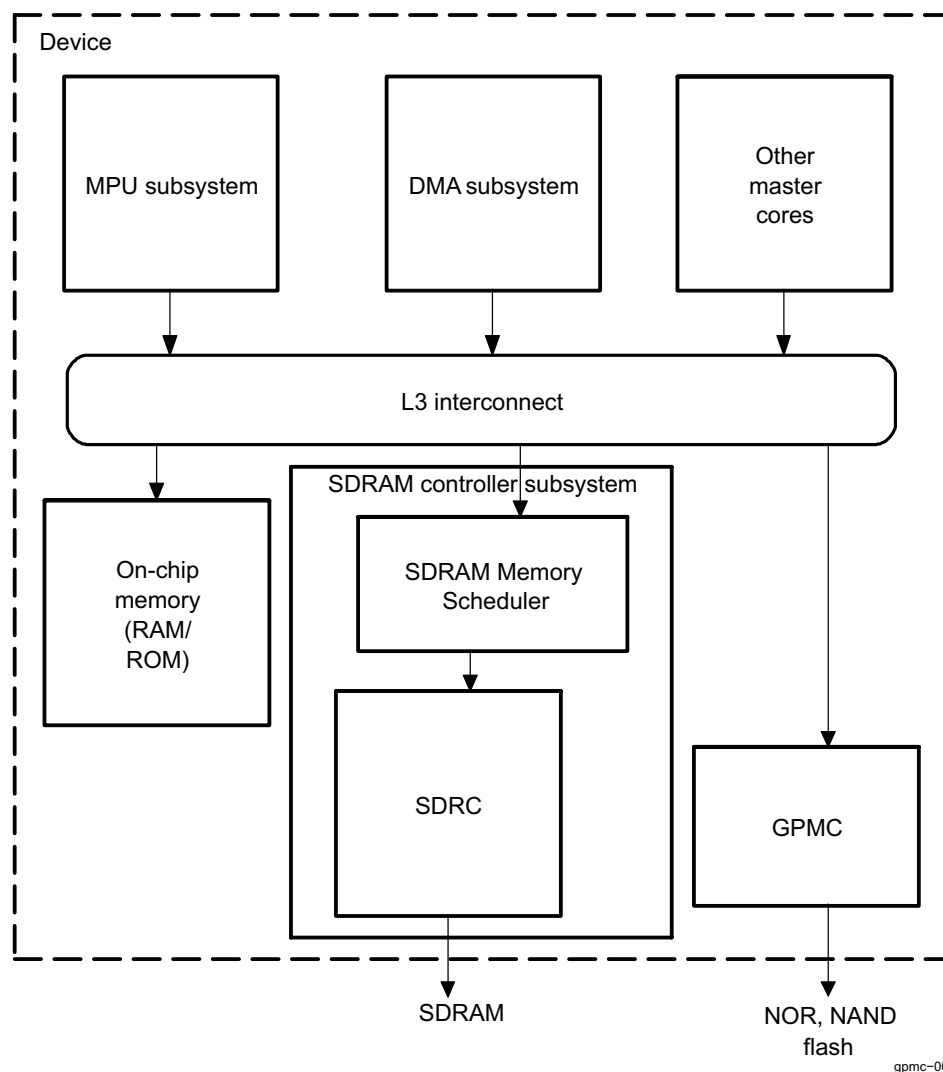

The general-purpose memory controller (GPMC) is dedicated to interfacing external memory devices:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (only available in non-muxed mode) burst NOR flash devices
- NAND flash
- Pseudo-SRAM devices

Note: Page mode is only available in non-muxed mode. The non-muxed mode is described in this chapter even though its use is very limited (address space limited to 2 KBytes).

Figure 11-1 shows the environment of the GPMC.

Figure 11-1. GPMC Environment

11.1.1.1 GPMC Features

The GPMC is a 16-bit external memory controller. The GPMC data access engine provides a flexible programming model for communication with all standard memories. The GPMC supports various accesses:

- Asynchronous read/write access
- Asynchronous read page access (4, 8, 16 Word16)
- Synchronous read/write access
- Synchronous read/write burst access without wrap capability (4, 8, 16 Word16)
- Synchronous read/write burst access with wrap capability (4, 8, 16 Word16)
- Address/data-multiplexed access
- Little- and big-endian access

The GPMC can communicate with a wide range of external devices:

- External asynchronous or synchronous 8-bit wide memory or device
- External asynchronous or synchronous 16-bit wide memory or device
- External 16-bit nonmultiplexed device with limited address range (2 Kbytes)
- External 16-bit address/data-multiplexed NOR flash device
- External 8-bit and 16-bit NAND flash device
- External 16-bit pseudo SRAM (pSRAM) device

The GPMC supports up to eight chip-select regions of programmable size, and programmable base addresses in a total address space of 1 Gbyte.

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

11.1.2 GPMC Environment

Figure 11-2 and Figure 11-3 show two GPMC external connection options:

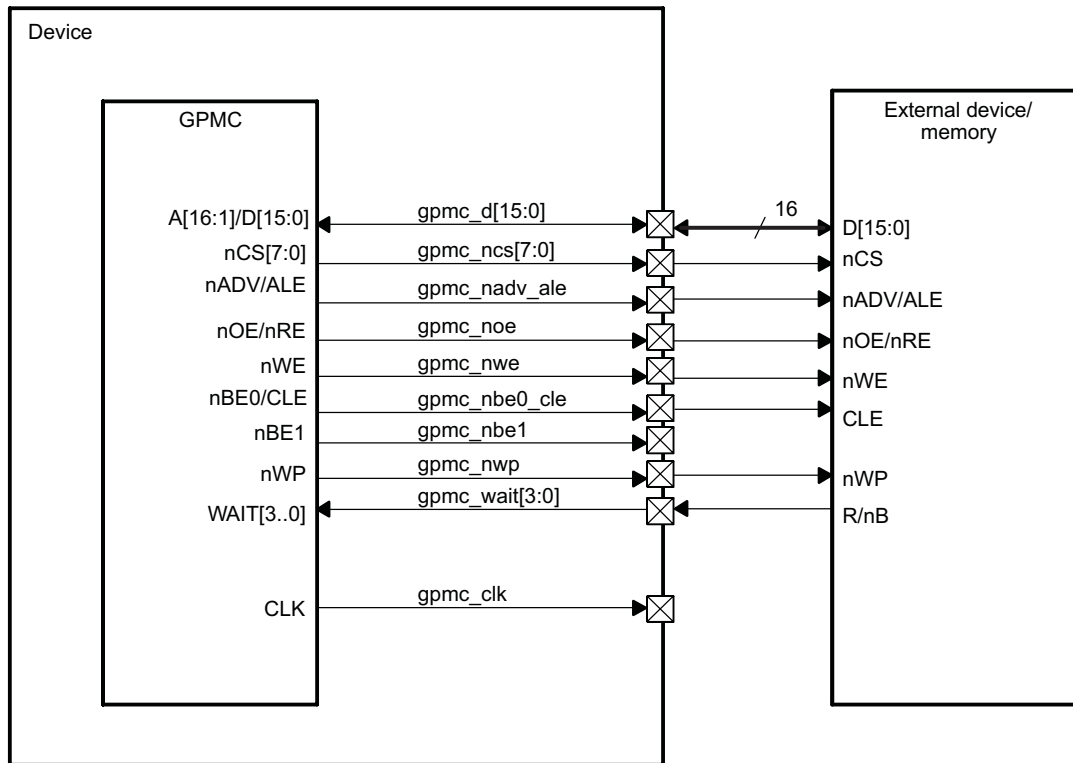

- GPMC to 16-bit address/data-multiplexed memory
Figure 11-2 shows a connection between the GPMC and a 16-bit synchronous address/data-multiplexed external memory device.
- GPMC to 16-bit NAND device
Figure 11-3 shows a connection between the GPMC and a 16-bit NAND device.

Figure 11-2. GPMC to 16-Bit Address/Data-Multiplexed Memory

Note: The OMAP device does not provide the A0 byte address line required for random-byte addressable 8-bit wide device interfacing (for multiplexed and nonmultiplexed protocol). Hence, an 8-bit device must be connected to the D[7:0] / gpmc_d[7:0] data bus (rather than D[15:8] / gpmc_d[15:8]) of the GPMC controller. This limits the use of 8-bit wide device interfacing to byte-alias access.

Figure 11-3. GPMC to 16-Bit NAND Device

gpmc-003

Note: An 8-bit NAND must be connected to the D[7:0] data bus of the GPMC.

Table 11-1 lists the GPMC subsystem I/O pins.

Table 11-1. GPMC I/O Description

Pin Name	I/O	Description
gpmc_a[10:1]	O	Address
gpmc_d[15:0]	I/O	Data
gpmc_ncs[7:0]	O	Chip-selects (active low)
gpmc_clk	I/O	Clock
gpmc_nadv_ale	O	Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories.
gpmc_noe_nre	O	Output enable (active low). Also used as read enable (active low) for NAND protocol memories.
gpmc_nwe	O	Write enable (active low)
gpmc_nbe0_cle	O	Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories.
gpmc_nbe1	O	Byte 1 enable (active low)
gpmc_nwp	O	Write protect (active low)
gpmc_wait[3:0]	I	External wait signal for NOR and NAND protocol memories
gpmc_io_dir	O	gpmc_d[15:0] signal direction control: Low during transmit (for write access: data OUT from GPMC to memory), High during receive (for read access: data IN from memory to GPMC)

Table 11-2 shows the use of address and data GPMC controller pins based on the type of external device.

Table 11-2. GPMC Pin Multiplexing Options

GPMC Pin	Multiplexed Address Data 16-Bit Device	Nonmultiplexed Address Data 16-Bit Device With LIMITED- ADDRESS Bit Enabled	16-Bit NAND Device	8-Bit NAND Device
gpmc_a[10]	A26	A10	Not used	Not used
gpmc_a[9]	A25	A9	Not used	Not used
gpmc_a[8]	A24	A8	Not used	Not used
gpmc_a[7]	A23	A7	Not used	Not used
gpmc_a[6]	A22	A6	Not used	Not used
gpmc_a[5]	A21	A5	Not used	Not used
gpmc_a[4]	A20	A4	Not used	Not used
gpmc_a[3]	A19	A3	Not used	Not used
gpmc_a[2]	A18	A2	Not used	Not used
gpmc_a[1]	A17	A1	Not used	Not used
gpmc_d[15]	A16/D15	D15	D15	Not used
gpmc_d[14]	A15/D14	D14	D14	Not used
gpmc_d[13]	A14/D13	D13	D13	Not used
gpmc_d[12]	A13/D12	D12	D12	Not used
gpmc_d[11]	A12/D11	D11	D11	Not used
gpmc_d[10]	A11/D10	D10	D10	Not used
gpmc_d[9]	A10/D9	D9	D9	Not used
gpmc_d[8]	A9/D8	D8	D8	Not used
gpmc_d[7]	A8/D7	D7	D7	D7
gpmc_d[6]	A7/D6	D6	D6	D6
gpmc_d[5]	A6/D5	D5	D5	D5
gpmc_d[4]	A5/D4	D4	D4	D4
gpmc_d[3]	A4/D3	D3	D3	D3
gpmc_d[2]	A3/D2	D2	D2	D2
gpmc_d[1]	A2/D1	D1	D1	D1
gpmc_d[0]	A1/D0	D0	D0	D0

Enabling the GPMC.GPMC_CONFIG[1] LIMITEDADDRESS bit forces A[26:11] to 1 on the GPMC I/O side. Thus, only devices with 2 Kbytes of addressing space can be accessed using gpmc_a[10:1].

With all device types, the GPMC does not drive unnecessary address lines. They stay at their reset value of 0x00.

Address mapping supports address/data-multiplexed 16-bit wide devices:

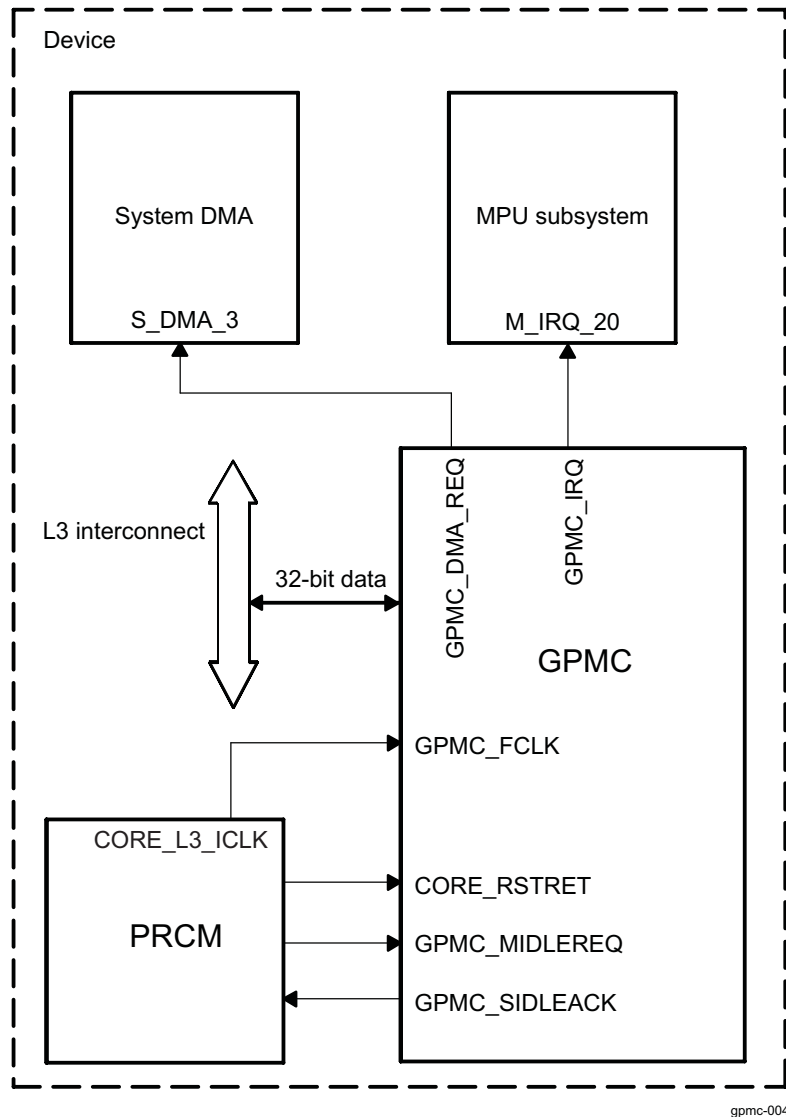

- To minimize the number of IC pins required for the external memory connection, the NOR flash memory controller supports multiplexed address and data memory devices without adding logic externally.
- Multiplexing mode can be selected through the GPMC.GPMC_CONFIG1_i[9] MUXADDDATA bit (I = 0 to 7).
- Asynchronous page mode is not supported for multiplexed address and data devices.

11.1.3 GPMC Integration

11.1.3.1 Description

Figure 11-4 shows how the GPMC interacts with other modules in the OMAP Applications Processor.

Figure 11-4. GPMC Integration in the OMAP Applications Processor

11.1.3.2 Clocking, Reset, and Power Management Scheme

11.1.3.2.1 Clocking

The GPMC use a single clock, GPMC_FCLK, which comes internally from the power, reset, and clock-management (PRCM) module and runs at the L3 interconnect frequency. Its source is the PRCM module, CORE_L3_ICLK output. CORE_L3_ICLK belongs to the L3 interconnect clock domain.

For details, see the *Power, Reset, and Clock Management* chapter.

GPMC_CLK is the external clock provided to the attached synchronous memory or device. The GPMC_CLK clock frequency is the GPMC_FCLK clock frequency divided by 1, 2, 3, or 4, depending on the GPMC.GPMC_CONFIG1_i[1:0] GPMC_FCLKDIVIDER bit field (where i = 0 to 7).

Note: When the GPMC is configured for synchronous mode, the GPMC_CLK signal (which is an output) must also be set as an input (CONTROL.CONTROL_PADCONF_GPMC_NCS7[24] INPUTENABLE1 = 1). GPMC_CLK is looped back through the output and input buffers of the corresponding GPMC_CLK pad at the OMAP boundary. The looped-back clock is used to synchronize the sampling of the memory signals.

11.1.3.2.2 Hardware Reset

A global reset of the GPMC occurs through activation of the CORE_RSTRET signal (CORE power domain) controlled by the Power, Reset and Clock Management module (see the *Power, Reset, and Clock Management* chapter).

The CORE_RSTRET signal is activated during IC global power-on and global warm reset, and it resets the controller state machine and configuration registers.

11.1.3.2.3 Software Reset

GPMC modules can be reset under software control through the GPMC.GPMC_SYSCONFIG[1] SOFTRESET bit. When software reset bit is set, all registers and the finite state-machine (FSM) are reset immediately and unconditionally. The GPMC_SYSCONFIG[0] RESETDONE bit can be polled to check reset status.

11.1.3.2.4 Power Domain, Power Saving, and Reset Management

GPMC power is supplied by the CORE power domain, and GPMC power management complies with system power-management guidelines.

The GPMC reduces power consumption through auto-idle mode and the idle request/acknowledge process, both of which are configurable:

- Dynamic auto-idle (configurable through the GPMC.GPMC_SYSCONFIG[0] AUTOIDLE bit): To reduce power consumption, the GPMC internally disables the functional clock when no requests are pending and no accesses are ongoing.
- Idle request/acknowledge (one of three idle modes configurable through the GPMC.GPMC_SYSCONFIG[4:3] IDLEMODE field):
 - Force-idle: Immediately on receiving an idle request from the PRCM module, the GPMC sends an idle request/acknowledge to let the PRCM module correctly cut the GPMC source clock.
 - No-idle: The GPMC never goes to idle mode.
 - Smart-idle (strongly recommended): The GPMC goes to idle mode when all ongoing transactions are complete.

For detailed information about power management, see the *Power, Reset, and Clock Management* chapter.

11.1.3.2.5 Hardware Requests

The GPMC uses two hardware requests as shown in [Figure 11-4](#) :

- One interrupt request goes from GPMC (GPMC_IRQ) to the microprocessor unit (MPU) subsystem : M_IRQ_20.
- One DMA request goes from GPMC (GPMC_DMA_REQ) to the system DMA (sDMA) : S_DMA_3.

11.1.3.3 GPMC Address and Data Bus

The current application supports GPMC connection to address/data-multiplexed memory and a NAND device. Connection to a nonmultiplexed address/data memory is supported with an address range of only 2 Kbytes.

Depending on the GPMC configuration on each chip-select, address and data-bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

The current application supports GPMC connection to address/data-multiplexed memory, address/data-nonmultiplexed memory with limited address (2 Kbytes), and a NAND device:

- When the GPMC.GPMC_CONFIG[1] LIMITEDADDRESS bit is set to 1, only gpmc_a[10:1] address lines are used. This limits the memory support to 2K-byte addressable memories.
- For address/data-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit wide NOR devices do not use GPMC I/O: gpmc_d[15:8] for data (they are used for address if needed).
- 16-bit wide NAND devices do not use GPMC I/O: gpmc_a[10:1].
- 8-bit wide NAND devices do not use GPMC I/O: gpmc_a[10:1] and GPMC I/O: gpmc_d[15:8].

CAUTION

Before trying to access a chip-select configured with a nonmultiplexed protocol, set the LIMITEDADDRESS bit control.

11.1.3.3.1 GPMC I/O Configuration Setting (In Default Pinout Mode 0)

Note: In this section, the I in [GPMC_CONFIG1_i](#) stands for the GPMC chip-select I where I = 0 to 7.

The address/data-nonmultiplexed device, which is limited to a 2K-byte address range, is selected by programming the following register fields:

- GPMC.GPMC_CONFIG1_i[11:10] DEVICETYPE field = 0x00
- GPMC.GPMC_CONFIG1_i[9] MUXADDDATA bit = 0
- GPMC.GPMC_CONFIG[1] LIMITEDADDRESS bit = 1

Note: The LIMITEDADDRESS field applies only to address/data-nonmultiplexed devices; it has no effect on other device types (address/data-multiplexed, NAND).

To select the address/data-multiplexed device, program the following register fields:

- GPMC.GPMC_CONFIG1_i[11:10] DEVICETYPE field = 0b00
- GPMC.GPMC_CONFIG1_i[9] MUXADDDATA bit = 1

To select the NAND device, program the following register field:

- GPMC.GPMC_CONFIG1_i[11:10] DEVICETYPE field = 0b10
- GPMC.GPMC_CONFIG1_i[9] MUXADDDATA bit = 0

11.1.3.3.2 GPMC CS0 Default Configuration at IC Reset

To ensure a correct external boot with a GPMC access from IC reset time on CS0, several external pins are sampled:

- The sys_boot[4:0] pins (OMAP Applications Processor boundary) define the sequence of interfaces and devices to use for booting.
- The sys_boot[5] pin defines which group of booting sequences is preferred: memory booting (sys_boot[5] = 0) or peripheral booting (sys_boot[5] = 1).
- Three additional pins are used to configure reset values in the GPMC.GPMC_CONFIG1_i register (where I = 0):
 - The bootwaiten input pin (GPMC boundary) enables the monitoring on chip-select 0 of the WAIT pin at IC reset release time for read accesses. The input pin is used to configure the GPMC.GPMC_CONFIG1_i[22] WAITREADMONITORING bit (where I = 0). Its value comes from the BOOT_WAIT_ENABLE signal generated by the system control module (SCM). When sys_boot[5:0] = 0b111111, the BOOT_WAIT_ENABLE signal is activated, causing the wait pin to be monitored for read access.
 - The bootdevicesize input pin (GPMC boundary) defines the size of the attached device on chip-select 0 and is used to configure the GPMC.GPMC_CONFIG1_i[13:12] DEVICESIZE bits (where I = 0). A BOOT_DEVICE_SIZE signal is propagated from the SCM. Its value is fixed at 0x1 at IC reset, causing a 16-bit wide external memory to be used.
 - The cs0muxdevice input pin (GPMC boundary) selects whether the attached device to chip-select 0 is a multiplexed address and data device or not. The input pin is used to configure the GPMC.GPMC_CONFIG1_i[9] MUXADDDATA bit (where I = 0). A CS0_MUX_DEVICE signal is propagated from the SCM. Its value is fixed at 0x1 at IC reset, causing the attached device to be address/data-multiplexed.
 - The waitselectpin input pin selects the WAIT signal at IC reset release time between WAIT0 input pin or WAIT1 input pin. At IC reset release time, these two pins have different polarity.

CAUTION

Using the internal boot code, the entire CS0 configuration can be modified before the first CS0 access. This modification of internal boot code is necessary for two external devices:

- NAND device attached to CS0
- Nonmultiplexed 2 Kbyte address range device attached to CS0

At reset time, the IC may boot from the internal ROM or from the memory attached to the GPMC chip-select 0. This selection is made outside the GPMC.

Reset values of the timing control parameters are defined to cope with direct boot on address and data multiplexed NOR Flash device, on non-multiplexed NOR Flash device or on any asynchronous device with large timing margins assuming a low GPMC_FCLK frequency (for example, 19.2Mhz) at boot time.

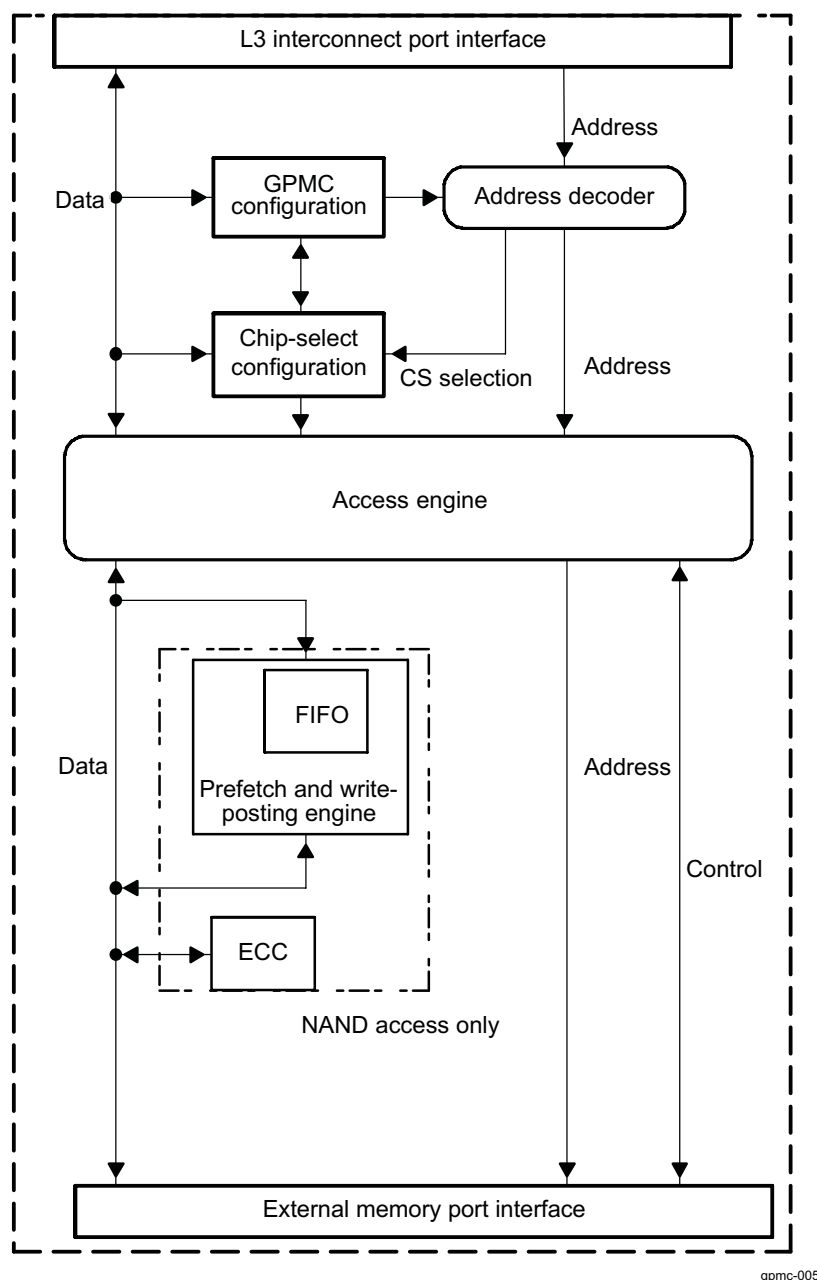

11.1.4 GPMC Functional Description

11.1.4.1 Description

As Figure 11-5 shows, the GPMC consists of six blocks:

- L3 interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

Figure 11-5. GPMC Functional Diagram

gpmc-005

The GPMC can access various external devices through the L3 Interconnect. The flexible programming model allows a wide range of attached device types and access schemes.

Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC is able to generate all control signals timing depending on the attached device and access type.

Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate device type control signals timing.

11.1.4.2 L3 Interconnect Interface

The GPMC L3 interconnect interface is a pipelined interface including an 8×32 -bit word write buffer.

Any OMAP system host can issue external access requests through the GPMC.

The OMAP system can issue the following requests through this interface:

- One 8-bit / 16-bit / 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2×32 , 4×32 , or 8×32 with the burst base address aligned on the total burst size are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line, for specific event control.

It is recommended to program the ATTACHEDDEVICEPAGELENGTH field ([GPMC_CONFIG1_i\[24:23\]](#)) according to the effective attached device page length and to enable WRAPBURST bit ([GPMC_CONFIG1_i\[31\]](#)) if the attached device supports wrapping burst.

However, it is possible to emulate wrapping burst on a non-wrapping memory by providing relevant addresses within the page or splitting transactions. Bursts larger than the memory page length are chopped into multiple bursts transactions. Due to the alignment requirements, a page boundary is never crossed.

11.1.4.3 Address Decoder, GPMC Configuration, and Chip-Select Configuration Register File

Address-decoding logic selects for chip-selects according to the address request and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and eight sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file should be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated). [Section 11.1.7](#) of this chapter provides the GPMC register locations. For the map of GPMC memory locations, see the *Memory Mapping* chapter.

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

11.1.4.4 Error Correction Code Engine (ECC)

The GPMC includes an ECC calculation engine that allows ECC calculation during data read or data program (write) operations. Two ECC algorithms are available depending on [GPMC_ECC_CONFIG\[16\]](#) ECCALGORITHM settings: Hamming code or BCH code (Bose-Chaudhuri-Hocquenghem).

The GPMC does not directly handle the error code correction itself. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (row and column) bit parity accumulation. This parity accumulation is either accomplished on the programmed number of bytes or Word16s read from the memory device, or written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the GPMC. [GPMC_ECC_CONFIG\[3:1\]](#) ECCCS bit field.

Refer to [Section 11.1.5.14.3](#), for more information on ECC Calculation.

11.1.4.5 Prefetch and Write-Posting Engine

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the L3 interface; as a default the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

For more information about prefetch and write-posting engine programming, see [Section 11.1.5.14.4](#), *Prefetch and Write-Posting Engine*.

11.1.4.6 External Device/Memory Port Interface

The external port interface controls all address, data, and control signals required for communication with GPMC-supported devices and memories.

11.1.5 GPMC Basic Programming Model

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the eight configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and the data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, Word16, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single-synchronous or asynchronous read or write mode.
- To simulate a programmable internal-wait state, an external wait pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC_FCLK) is used as a time reference to specify the following:

- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

11.1.5.1 Chip-Select Base Address and Region Size Configuration

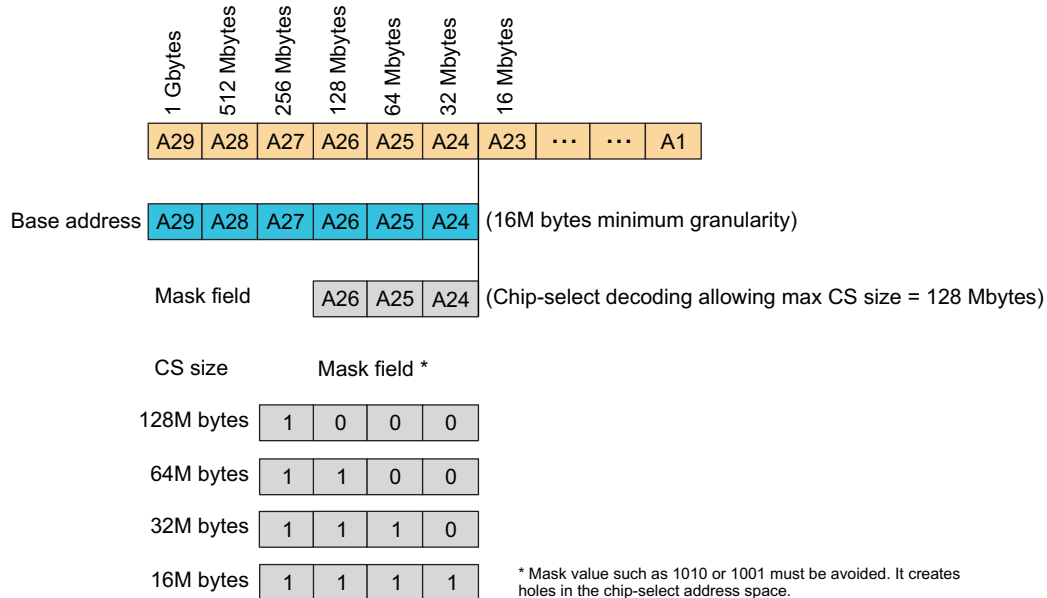

Any external memory or ASIC device attached to the GPMC external interface can be accessed by any OMAP system host within the GPMC 1 Gbyte contiguous address space. For details, see the *Memory Mapping* chapter.

The GPMC 1 Gbyte address space can be divided into a maximum of eight chip-select regions with programmable base address and programmable CS size. The CS size is programmable from 16 MBytes to 256 MBytes (must be a power-of-2) and is defined by the mask field. Attached memory smaller than the programmed CS region size is accessed through the entire CS region (aliasing).

Each chip-select has a 6-bit base address encoding and a 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-2 address value. During access decoding, the register base address value is used for address comparison with the address-bit line mapping as described in [Figure 11-6](#) (with A0 as the OMAP system byte-address line). Base address is programmed through the [GPMC_CONFIG7_i\[5:0\]](#) BASEADDRESS bit field
- The register mask is used to exclude some address lines from the decoding. A register mask bit field set to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The register mask value must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the [GPMC_CONFIG7_i\[11:8\]](#) MASKADDRESS bit field.

Figure 11-6. Chip-Select Address Mapping and Decoding Mask

gpmc-006

Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the GPMC.GPMC_CONFIG7_I[6] CSVALID bit (where I stands for the GPMC chip-select value, I = 0 to 7). In addition, a chip-select configuration can only be disabled if there is no ongoing access to that chip-select. This requires activity monitoring of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Conversely, before trying to access a chip-select, software must ensure that the chip-select is enabled. To account for prefetch engine effects, after the chip-select-enable instruction, an NOP instruction (equivalent to 64 bits) must be executed before the chip-select is accessed.

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of chip-selects overlapping, an error is generated and no access will occur on either chip-select.

Chip-select 0 is the only chip-select region enabled after either a power-up or a GPMC reset.

CAUTION

Although the GPMC interface can drive up to 8 chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers, to allow the slowest device to maintain the total load on the lines at the value specified in your OMAP device-specific data manual. To have access to the device-specific data manual, please contact your TI representative.

11.1.5.2 Access Protocol Configuration

11.1.5.2.1 Supported Devices

The access protocol of each chip-select can be independently specified through the GPMC.GPMC_CONFIG1_I[11:10] DEVICETYPE parameter (where I = 0 to 7) for:

- Random-access synchronous or asynchronous memory like NOR flash, SRAM

- NAND flash asynchronous devices

Note: NAND flash interfacing requires the parameter settings of generic chip-select 0. For more information about the NAND flash GPMC basic programming model and NAND support, see [Section 11.1.5.14, NAND Device Basic Programming Model](#), and [Section 11.1.5.14.1, NAND Memory Device in Byte or Word 16 Stream Mode](#).

11.1.5.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the GPMC.GPMC_CONFIG1_i[13:12] DEVICESIZE field (I = 0 to 7) to interface with a 16-bit wide device or an 8-bit wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to both the external device data-bus width and little-endian data organization.

Note: The OMAP Applications Processor does not provide the A0 byte address line required for random-byte addressable 8-bit wide device interfacing (for both multiplexed and nonmultiplexed protocol). It limits the use of 8-bit wide device interfacing to byte-alias accesses. This limitation is not applicable to NAND device interfacing (8-bit wide or 16-bit wide devices).

11.1.5.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 0b00), an address- and data-multiplexing protocol can be selected through the GPMC.GPMC_CONFIG1_i[9] MUXADDDATA bit (I = 0 to 7). The nADV signal must be used as the external device address latch control signal. For the associated chip-select configuration, nADV assertion and deassertion time and nOE assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device. See [Section 11.1.3, GPMC Integration](#).

Note: This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data multiplexing protocol. See [Section 11.1.5.14, NAND Device Basic Programming Model](#).

11.1.5.2.4 Address and Data Bus

See [Section 11.1.3.3, GPMC Address and Data Bus](#).

11.1.5.2.5 Asynchronous and Synchronous Access

For each chip-select configuration, the read access can be specified as either asynchronous or synchronous access through the GPMC.GPMC_CONFIG1_i[29] READTYPE bit (I = 0 to 7). For each chip-select configuration, the write access can be specified as either synchronous or asynchronous access through the GPMC.GPMC_CONFIG1_i[27] WRITETYPE bit (I = 0 to 7).

Asynchronous and synchronous read (write) access time and related control signals are controlled through timing parameters that refer to GPMC_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface (GPMC_CLK) to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For details about asynchronous and synchronous access, see the descriptions of GPMC_CLK, RdAccessTime, WrAccessTime, and wait-pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

Note: The address bus and nBE[1:0] are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

11.1.5.2.6 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The [GPMC_CONFIG1_i\[30\]](#) READMULTIPLE and [GPMC_CONFIG1_i\[28\]](#) WRITEMULTIPLE bits (I = 0 to 7) are associated with the READTYPE and WRITETYPE parameters.

Notes:

- Asynchronous write page mode is not supported.
 - 8-bit wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are don't care).
 - Not applicable to NAND device interfacing.
-

11.1.5.2.7 System Burst Versus External Device Burst Support

The OMAP system can issue the following requests to the GPMC:

- Byte, Word16, Word32 requests (byte enable controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two words, four words, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length burst. The maximum length that can be issued is defined per CS by the [GPMC_CONFIG1_i\[24:23\]](#) ATTACHEDDEVICEPAGELENGTH field (I = 0 to 7). When the ATTACHEDDEVICEPAGELENGTH value is less than the system burst request length (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple burst beats. Within the specified 4-, 8-, or 16-word value, the ATTACHEDDEVICEPAGELENGTH field value must correspond to the maximum-length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the [GPMC_CONFIG1_i\[31\]](#) WRAPBURST bit (I = 0 to 7) must be set to 1. Similarly DEVICESPAGELENGTH is set to 4 and 8 for memories supporting respectively 4 and 8 Word16-length-wrapping burst.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the ATTACHEDDEVICEPAGELENGTH value.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed burst length mode and a continuous burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPCM behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the [GPMC_CONFIG1_i\[24:23\]](#) ATTACHEDDEVICEPAGELENGTH field is set accordingly to 4 or 8 words.

The OMAP system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-words boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the ATTACHEDDEVICEPAGELENGTH value. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait states between data accesses. If the memory does not behave this way (nonzero wait state burstable memory), wait-pin monitoring must be enabled to dynamically control data-access completion within the burst beat.

Note: When the system burst request length is less than the ATTACHEDDEVICEPAGELENGTH value, the GPMC proceeds with the required accesses.

11.1.5.3 Timing Setting

The GPMC is a signal generator that offers the maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For example, the timing diagram in Figure 11-7 shows an asynchronous single-read access performed on an asynchronous device. For more information on GPMC_CLK and GPMC_FCLK refer to Section 11.1.5.3.6.

Figure 11-7. Asynchronous Single Read on a Nonmultiplexed Address/Data Device

gpmc-007

11.1.5.3.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME / WRCYCLETIME)

The GPMC.GPMC_CONFIG5_i[4:0] RDCYCLETIME and GPMC.GPMC_CONFIG5_i[12:8] WRCYCLETIME fields (I = 0 to 7) define the address bus and byte enables valid times for read and write accesses. To ensure a correct duty cycle of GPMC_CLK between accesses, RDCYCLETIME and WRCYCLETIME are expressed in GPMC_FCLK cycles and must be multiples of the GPMC_CLK cycle.

When either RDCYCLETIME or WRCYCLETIME completes, if they are not already deasserted, all control signals (NCS, nADV/ALE, nOE/RE, nWE, and BE0/CLE) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitchy transition. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

If no inactive cycles are required between successive accesses to the same or to a different chip-select (GPMC.GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSN = 0 or GPMC.GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSN = 0, where I = 0 to 7), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals (nCS, nADV/ALE, nBE0/CLE, nWE, and nOE/RE) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses, that is, CYCLE2CYCLESAMECSN = 1 or CYCLE2CYCLEDIFFCSN = 1, the control signals are forced to their respective default reset values for the number of GPMC_FCLK cycles defined in CYCLE2CYCLEDELAY:

- The RDCYCLETIME and WRCYCLETIME bit fields are programmable in the GPMC.GPMC_CONFIG5_i register, I = 0 to 7.
- The RDCYCLETIME and WRCYCLETIME bit fields can be set from 0 to 31 GPMC_FCLK cycles with a granularity of 1 for GPMC.GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY set to 0.
- The RDCYCLETIME and WRCYCLETIME bit fields can be set from 0 to 62 GPMC_FCLK cycles with a granularity of 2 for GPMC.GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY set to 1.

11.1.5.3.2 nCS: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME / CSWROFFTIME / CSEXTRADELAY)

The GPMC.GPMC_CONFIG2_i[3:0] CSONTIME field (where I = 0 to 7) defines the nCS signal-assertion time relative to the start access time. It is common for read and write accesses.

For a read access, the GPMC.GPMC_CONFIG2_i[12:8] CSRDOFFTIME field defines the nCS signal deassertion time relative to start access time.

For a write access, the GPMC.GPMC_CONFIG2_i[20:16] CSWROFFTIME field defines the nCS signal deassertion time relative to start access time.

CSONTIME, CSRDOFFTIME and CSWROFFTIME parameters are applicable to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte enable hold time after chip-select deassertion.

nCS signal transitions as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC.GPMC_CONFIG2_i[7] CSEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on the nCS assertion and deassertion time to guarantee proper setup and hold time relative to GPMC_CLK. CSEXTRADELAY is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If asserted, CSEXTRADELAY applies to all parameters controlling nCS transitions.

The CSEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the nCS signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

11.1.5.3.3 nADV/ALE: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME / ADVEXTRADELAY)

The GPMC.GPMC_CONFIG3_i[3:0] ADVONTIME field (where I = 0 to 7) defines the nADV/ALE signal-assertion time relative to start access time. It is common to read and write accesses.

For a read access, the GPMC.GPMC_CONFIG3_i[12:8] ADVRDOFFTIME field defines the nADV/ALE signal-deassertion time relative to start access time.

For a write access, the GPMC.GPMC_CONFIG3_i[20:16] ADVWROFFTIME field defines the nADV/ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte enable valid setup time control before nADV/ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte enable valid hold time control after nADV/ALE de-assertion. ADVRDOFFTIME and ADVWROFFTIME are applicable to both synchronous and asynchronous modes.

nADV/ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC.GPMC_CONFIG3_i[7] ADVEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on nADV/ALE assertion and deassertion time to guarantee proper setup and hold time relative to GPMC_CLK. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If asserted, ADVEXTRADELAY applies to all parameters controlling nADV/ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than nADV/ALE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

Refer to [Section 11.1.5.14](#) for more details on ADVONTIME, ADVRDOFFTIME and ADVWROFFTIME usage for CLE and ALE (Command / Address Latch Enable) usage for a NAND Flash interface.

11.1.5.3.4 nOE/nRE: Output Enable / Read Enable Signal Control Assertion / Deassertion Time (OEONTIME / OEOFFTIME / OEEXTRADELAY)

The GPMC.GPMC_CONFIG4_i[3:0] OEONTIME field (where I = 0 to 7) defines the nOE/nRE signal assertion time relative to start access time. It is applicable only to read accesses.

The GPMC.GPMC_CONFIG4_i[12:8] OEOFFTIME field defines the nOE/nRE signal deassertion time relative to start access time. It is applicable only to read accesses.

OEONTIME and OEOFFTIME parameters are applicable to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before nOE/nRE assertion. OEOFFTIME can be used to control an address and byte enable valid hold time control after nOE/nRE assertion.

The nOE/RE signal transitions as controlled through OEONTIME, and OEOFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC.GPMC_CONFIG4_i[7] OEEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on nOE/RE assertion and deassertion time to guaranty proper setup and hold time relative to GPMC_CLK. If asserted, OEEXTRADELAY applies to all parameters controlling nOE/nRE transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than nOE/RE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

nOE/nRE is not asserted during a write cycle.

Note: When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until nOE assertion time.

11.1.5.3.5 nWE: Write Enable Signal Control Assertion / Deassertion Time (WEONTIME / WEOFFTIME / WEEXTRADELAY)

The GPMC.GPMC_CONFIG4_i[19:16] WEONTIME field (where I = 0 to 7) defines the nWE signal-assertion time relative to start access time. It applies only to write accesses.

The GPMC.GPMC_CONFIG4_i[28:24] WEOFFTIME field defines the nWE signal-deassertion time relative to start access time. It applies only to write accesses.

WEONTIME can be used to control an address and byte enable valid setup time control before nWE assertion. WEOFFTIME can be used to control an address and byte enable valid hold time control after nWE assertion.

nWE signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC.GPMC_CONFIG4_i[23] WEEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on nWE assertion and deassertion time to guaranty proper setup and hold time relative to GPMC_CLK. If asserted, WEEXTRADELAY applies to all parameters controlling nWE transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the nWE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

nWE is not asserted during a read cycle.

11.1.5.3.6 GPMC_CLK

GPMC_CLK is the external clock provided to the attached synchronous memory or device.

- The GPMC_CLK clock frequency is the GPMC_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the GPMC.GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field (where I = 0 to 7), with a guaranteed 50-percent duty cycle.
- The GPMC_CLK clock is only activated when the access in progress is defined as synchronous (read or write access).
- The GPMC.GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME field (I = 0 to 7) defines the number of GPMC_FCLK cycles from start access time to GPMC_CLK activation.
- The GPMC_CLK clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC_CLK clock is kept low when access is defined as asynchronous.
- When cycle time completes, the GPMC_CLK may be high because of the GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC_CLK clock within the 50-percent required duty cycle, it is the user's responsibility to extend the RDCYCLETIME or WRCYCLETIME value.
- When the GPMC is configured for synchronous mode, the GPMC_CLK signal (which is an output) must also be set as an input (CONTROL.CONTROL_PADCONF_GPMC_NCS7[24] INPUTENABLE1 = 1). GPMC_CLK is looped back through the output and input buffers of the corresponding GPMC_CLK pad at the OMAP boundary. The looped-back clock is used to synchronize the sampling of the memory signals.

Note: To ensure a correct external clock cycle, the following rules must be applied:

- (RDCYCLETIME CLKACTIVATIONTIME) must be a multiple of (GPMCFCLKDIVIDER + 1).
 - The PAGEBURSTACCESSTIME value must be a multiple of (GPMCFCLKDIVIDER + 1).
-

11.1.5.3.7 GPMC_CLK and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC_CLK edge can be controlled in the following ways:

- For the GPMC_CLK signal, the GPMC.GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME field (I = 0 to 7) allows setup and hold control of control-signal assertion time.

- The use of a divided GPMC_CLK allows setup and hold control of control-signal assertion and deassertion times.
- When GPMC_CLK runs at the GPMC_FCLK frequency so that GPMC_CLK edge and control-signal transitions refer to the same GPMC_FCLK edge, the control-signal transitions can be delayed by half of a GPMC_FCLK period to provide minimum setup and hold times. This half-GPMC_FCLK delay is enabled with the CSEXTRADelay, ADVEXTRADelay, OEEXTRADelay, or WEEXTRADelay parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC_FCLK cycle.

11.1.5.3.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read access time and write access time durations can be programmed independently allowing nOE and GPMC data capture timing parameters to be independent of nWE and memory device data capture timing parameters.

RDACCESSTIME is programmed in the GPMC.GPMC_CONFIG5_i[20:16] bit field (I = 0 to 7).

WRACCESSTIME is programmed in the GPMC.GPMC_CONFIG6_i[28:24] bit field (I = 0 to 7).

RDACCESSTIME and WRACCESSTIME can be set from 0 to 31 GPMC_FCLK cycles with a granularity of one (GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY = 0).

RDACCESSTIME and WRACCESSTIME can be set from 0 to 62 GPMC_FCLK cycles with a granularity of two (GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY = 1).

11.1.5.3.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, RDACCESSTIME field (I = 0 to 7) defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater GPMC_FCLK cycle value of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge corresponding to the GPMC_CLK rising edge used for the first data capture.

GPMC_CLK which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. RDCYCLETIME must be greater than RDACCESSTIME in order to let the GPMC latch the last return data using the internally retimed GPMC_CLK.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access in both asynchronous mode and synchronous mode. For details about wait monitoring, see [Section 11.1.5.4](#).

11.1.5.3.8.2 Access Time on Write Access

In asynchronous write mode, the GPMC_CONFIG6_i[28:24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a WAIT invalid timing window, and must be set to a correct value so that the gpmc_wait pin is at a valid state two GPMC_CLK cycles before WRACCESSTIME completes. For details about wait monitoring, see [Section 11.1.5.4](#).

In synchronous write mode, for single or burst accesses, WRACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_CLK rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data capture GPMC_CLK edge for a synchronous write access. For details about wait monitoring, see [Section 11.1.5.4](#).

11.1.5.3.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

PAGEBURSTACCESSTIME is programmed in the GPMC.GPMC_CONFIG5_i[27:24] bit field (I = 0 to 7).

PAGEBURSTACCESSTIME can be set from 0 to 15 GPMC_FCLK cycles with a granularity of one (GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY set to 0), or from 0 to 30 GPMC_FCLK cycles with a granularity of two (TIMEPARAGRANULARITY set to 1).

11.1.5.3.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater GPMC_FCLK cycle value of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data capture GPMC_FCLK edge on read access. For details about wait monitoring, see [Section 11.1.5.4](#).

11.1.5.3.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory-device data capture GPMC_CLK edge in synchronous write mode. For details about wait monitoring, see [Section 11.1.5.4](#).

11.1.5.3.10 Bus Keeping Support

At the end-cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completion time to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

11.1.5.4 WAIT Pin Monitoring Control

GPMC access time can be dynamically controlled using an external gpmc_wait pin when the external device access time is not deterministic and cannot be defined and controlled only using the GPMC internal RDACCESSTIME, WRACCESSTIME and PAGEBURSTACCESSTIME wait state generator.

The GPMC four input wait pins: gpmc_wait3, gpmc_wait2, gpmc_wait1, and gpmc_wait0. These four pins allow direct plugin and control of external devices with different wait-pin polarity. They also allow the overlap of wait-pin assertion from different devices without affecting access to devices for which the wait pin is not asserted.

- The GPMC.GPMC_CONFIG1_i[17:16] WAITPINSELECT field (i = 0 to 7) selects which input gpmc_wait pin is used for the device attached to the corresponding chip-select.
- The polarity of the wait pin is defined through the WAITxPINPOLARITY bit of the GPMC.GPMC_CONFIG register. A wait pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When WAIT is inactive, data is valid.

The GPMC access engine can be configured by CS to monitor the wait pin of the external memory device or not, based on the access type: read or write.

- The GPMC.GPMC_CONFIG1_i[22] WAITREADMONITORING bit defines whether the wait pin should be monitored during read accesses or not.
- The GPMC.GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit defines whether the wait pin should be monitored during write accesses or not.

The GPMC access engine can be configured to monitor the wait pin of the external memory device asynchronously or synchronously with the GPMC_CLK clock, depending on the access type: synchronous or asynchronous (the GPMC.GPMC_CONFIG1_i[29] READTYPE and GPMC.GPMC_CONFIG1_i[27] WRITETYPE bits).

11.1.5.4.1 Wait Monitoring During an Asynchronous Read Access

When wait-pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with wait-pin monitoring enabled, the wait pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through wait-pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a WAIT invalid timing window and is set to such a value that the wait pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait-monitoring pipelining is also applicable to multiple accesses (access within a page).

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

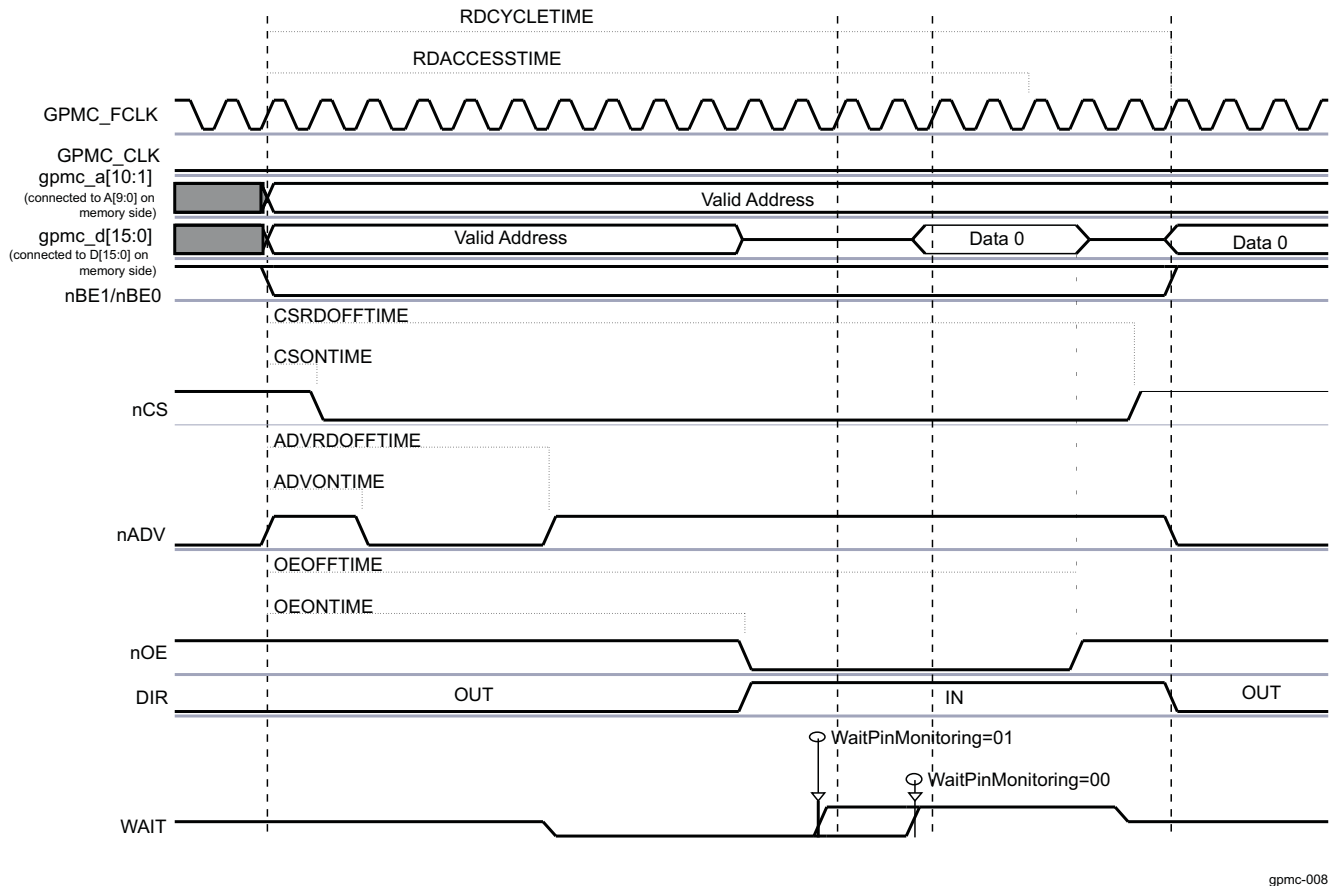

When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the GPMC.GPMC_CONFIG1_I[19:18] WAITMONITORINGTIME field (I = 0 to 7).

Notes:

- The WAITMONITORINGTIME parameter does not delay the wait-pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and no GPMC_CLK clock is provided to the external device. Still, GPMCFCLKDIVIDER is used as a divider for the GPMC clock, so it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 11-8 shows wait behavior during an asynchronous single read access.

Figure 11-8. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)

gpmc-008

Note: The WAIT signal is active low. WAITMONITORINGTIME = 00, 01.

11.1.5.4.2 Wait Monitoring During an Asynchronous Write Access

When wait-pin monitoring is enabled for write accesses (GPMC.GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit = 0x1), the WAIT-invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the wait pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- WAIT monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the GPMC.GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME fields (I = 0 to 7).

Notes:

- The WAITMONITORINGTIME parameter does not delay the wait-pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as synchronous, and even though no clock is provided to the external device. Still, [GPMC_CONFIG1_i\[1:0\]](#) GPMCFCLKDIVIDER is used as a divider for the GPMC clock and so it must be programmed to define the correct WAITMONITORINGTIME delay.

11.1.5.4.3 Wait Monitoring During a Synchronous Read Access

During synchronous accesses with wait-pin monitoring enabled, the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle it is captured in. Alternatively, it can be sampled one or two GPMC_CLK cycles ahead of the clock cycle it applies to. This pipelining is applicable to the entire burst access, and to all data phase in the burst access. This WAIT pipelining depth is programmed in the GPMC.[GPMC_CONFIG1_i\[19:18\]](#) WAITMONITORINGTIME field (where $i = 0$ to 7), and is expressed as a number of GPMC_CLK clock cycles.

In synchronous mode, when wait-pin monitoring is enabled (GPMC.[GPMC_CONFIG1_i\[22\]](#) WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the WAIT deasserted-state detection.

Depending on the programmed WAITMONITORINGTIME value, the wait pin should be at a valid level, either asserted or deasserted:

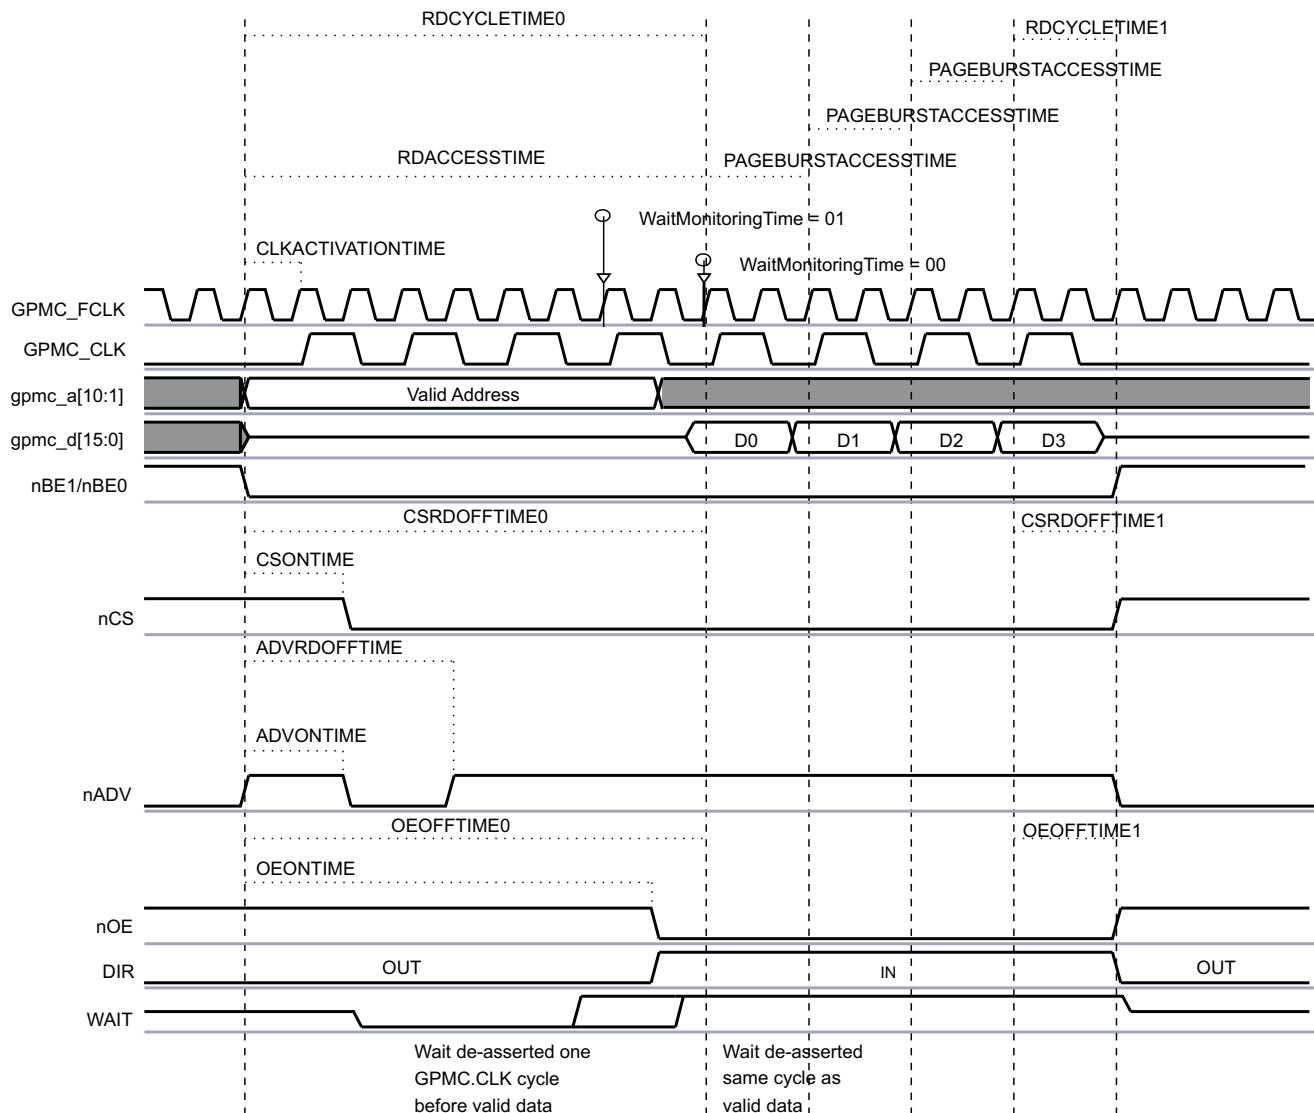

- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 (at RDACCESSTIME completion)
- In the WAITMONITORINGTIME \times (GPMCFCLKDIVIDER + 1) GPMC_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME $\neq 0$

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-inactive state. The Wait pipelining depth programming applies to the whole burst access.

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), WAIT monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), WAIT monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

[Figure 11-9](#) shows wait behavior during a synchronous read burst access.

Figure 11-9. Wait Behavior During a Synchronous Read Burst Access

gpmc-009

Note: The WAIT signal is active low. WAITMONITORINGTIME = 00, 01.

11.1.5.4.4 Wait Monitoring During a Synchronous Write Access

During synchronous accesses with wait-pin monitoring enabled (the WAITWRITEMONITORING bit), the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

If enabled, external wait-pin monitoring can be used in combination with WRACCESSTIME to control the effective memory device GPMC_CLK capture edge.

Wait-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- The WAITMONITORINGTIME × (GPMCFCLKDIVIDER + 1) GPMC_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME ≠ 0.

Wait-monitoring pipelining definition applies to whole burst accesses:

- WAIT monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as active indicates that the data bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

Note: Wait monitoring is supported for all configurations except for [GPMC_CONFIG1_i\[19:18\]](#) WAITMONITORINGTIME = 0x 0 (where I = 0 to 7) for write bursts with a clock divider of 1 or 2 ([GPMC_CONFIG1_i\[1:0\]](#) GPMCFCLKDIVIDER field equal to 0x0 or 0x1 respectively).

11.1.5.4.5 WAIT with NAND Device

For details about the use of the wait pin for communication with a NAND flash external device, see [Section 11.1.5.14.2, NAND Device-Ready Pin](#).

11.1.5.4.6 Idle Cycle Control between Successive Accesses

11.1.5.4.6.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device (that is, control the nCS/nOE de-assertion to data bus in high-impedance delay) must be delayed.

The bus turnaround is a time-out counter starting after nCS or nOE de-assertion time (whichever occurs first) and delays the next access start-cycle time. It is programmed through the [GPMC.GPMC_CONFIG6_i\[3:0\]](#) BUSTURNAROUND bit field (where I = 0 to 7).

After a read access to a chip-select with a non zero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

- A write access to any chip-select (same or different from the chip-select data was read from)
- A read access to a different chip-select from the chip-select data was read access from
- A read or write access to a chip-select associated with an address/data-multiplexed device

Another way to prevent bus contention is to define an earlier nCS or nOE deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but affects all accesses of this specific chip-select.

11.1.5.4.6.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMEECSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The [GPMC.GPMC_CONFIG6_i\[7\]](#) CYCLE2CYCLESAMEECSEN bit (I = 0 to 7) enables insertion of a minimum number of GPMC_FCLK cycles, defined by the [GPMC.GPMC_CONFIG6_i\[11:8\]](#) CYCLE2CYCLEDELAY field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMEECSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during Word32 or burst accesses split into successive single accesses when the single-access mode is used ([GPMC_CONFIG1_i\[30\]](#) READMULTIPLE = 0 or [GPMC_CONFIG1_i\[28\]](#) WRITEMULTIPLE = 0).

All control signals are kept in their default states during these idle GPMC_FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

11.1.5.4.6.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals (nCS, nADV/ALE, nBE0/CLE, nOE/RE, nWE) assertion and de-assertion timing parameters and on the IC timing parameters, some control signals assertion times may overlap between the successive accesses to different CS. Similarly, some control signals (WE, OE/RE) may not respect required transition times.

To work around the overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

If [GPMC_CONFIG6_i](#)[6] CYCLE2CYCLEDIFFCSEN is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC_FCLK cycles.

Note: CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN should be set in [GPMC_CONFIG6_i](#) registers to respectively get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. It should be noted that BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, since bus turnaround does not apply to all access types. See [Section 11.1.5.4.6.1](#) for more details on bus turnaround.

[Table 11-3](#) describes the configuration required for idle cycle insertion.

Table 11-3. Idle Cycle Insertion Configuration

1st Access Type	BUSTURN AROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	= 0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Different	Nonmuxed	0	0	BTA cycles are inserted.
R	> 0	R/W	Any	Muxed	0	0	BTA cycles are inserted.
R	> 0	W	Any	Any	0	0	BTA cycles are inserted.
W	> 0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	= 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	= 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.
R/W	> 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).

Table 11-3. Idle Cycle Insertion Configuration (continued)

1st Access Type	BUSTURN AROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	> 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

11.1.5.4.7 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the GPMC.GPMC_CONFIG1_I[4] TIMEPARAGRANULARITY bit (where I stands for the GPMC chip-select value, I = 0 to 7). Increasing all access timing parameters allows support of slow devices.

11.1.5.5 gpmc_io_dir Pin

The gpmc_io_dir pin is used to control I/O direction on the GPMC data bus gpmc_d[15:0]. Depending on top-level pad multiplexing, this signal can be output and used externally to the OMAP35x Applications Processor, if required.

The gpmc_io_dir pin is low during transmit (OUT) and high during receive (IN).

For write accesses, the gpmc_io_dir pin stays OUT from start-cycle time to end-cycle time.

For read accesses, the gpmc_io_dir pin goes from OUT to IN at nOE assertion time and stays IN until:

- BUSTURNAROUND is enabled:
 - The gpmc_io_dir pin goes from IN to OUT at end-cycle time plus programmable bus turnaround time.
- BUSTURNAROUND is disabled:
 - After an asynchronous read access, the gpmc_io_dir pin goes from IN to OUT at RDACCESSTIME + 1 GPMC_FCLK cycle or when RDCYCLETIME completes, whichever occurs last.
 - After a synchronous read access, the gpmc_io_dir pin goes from IN to OUT at RDACCESSTIME + 2 GPMC_FCLK cycles or when RDCYCLETIME completes, whichever occurs last.

Because of the bus-keeping feature of the GPMC, after a read or write access and with no other accesses pending, the default value of the gpmc_io_dir pin is OUT (see [Section 11.1.5.3.10, Bus Keeping Support](#)).

To prevent unnecessary toggling, the gpmc_io_dir pin stays IN between two successive read accesses to a nonmultiplexed device (address mapping supports nonmultiplexed 16-bit wide devices with limited address (2 Kbytes)).

[Figure 11-10](#) shows address mapping in nonmultiplexed mode with a limited address range (A[10:1]).

11.1.5.6 Reset

No reset signal is sent to the external memory device by the GPMC. The PRCM specifications provide more information about external-device reset.

The PRCM module provides an input pin, global_rst_n, to the GPMC:

- The global_rst_n pin is activated during OMAP warm reset and cold reset.
- The global_rst_n pin initializes the internal state-machine and the internal configuration registers.

11.1.5.7 Write Protect (nWP)

When connected to the attached memory device, the WRITE PROTECT signal can enable or disable the lockdown function of the attached memory.

The gpmc_nwp output pin value is controlled through the GPMC.GPMC_CONFIG[4] WRITEPROTECT bit, which is common to all CS.

11.1.5.8 Byte Enable (nBE1/nBE0)

BYTE ENABLE signals (nBE1/nBE0) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

11.1.5.9 Asynchronous Access Description

In asynchronous operations:

- GPMC_CLK is not provided outside the GPMC.
- GPMC_CLK is kept low.

11.1.5.9.1 Asynchronous Single Read

11.1.5.9.1.1 Asynchronous Single Read Operation on a Nonmultiplexed Device

Figure 11-10 shows an asynchronous single read operation on a nonmultiplexed device.

Figure 11-10. Asynchronous Single Read on an Address/Data-Nonmultiplexed Device

gpmc-010

In the following section I stands for the chip-select number, I = 0 to 7.

- GPMC.GPMC_CONFIG[1] LIMITEDADDRESS set to 1 (A26-A11 are not modified during an external memory access)
- GPMC.GPMC_CONFIG1_i register settings:
 - GPMC_CONFIG1_i[30] READMULTIPLE bit at 0 (read single access)
 - GPMC_CONFIG1_i[29] READTYPE bit at 0 (asynchronous read)
 - GPMC_CONFIG1_i[9] MUXADDDATA bit at 0 (non multiplexed device)
- Chip-select signal nCS:
 - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CS ONTIME field. It controls the address setup time to nCS assertion.
 - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12:8] CSRD OFFTIME field. It controls the address hold time from nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADV ONTIME field.
 - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADV RD OFFTIME field.

- Output enable signal nOE:
 - nOE assertion indicates a read cycle.
 - nOE assertion time is controlled by the [GPMC_CONFIG4_i\[3:0\] OEONTIME](#) field.
 - nOE deassertion time is controlled by the [GPMC_CONFIG4_i\[12:8\] OEOFFTIME](#) field.
- Read data is latched when RDACCESSTIME completes. Access time is defined in the [GPMC.GPMC_CONFIG5_i\[20:16\] RDACCESSTIME](#) field.
- The end of the access is defined by the RDCYCLETIME parameter. The read cycle time is defined in the [GPMC.GPMC_CONFIG5_i\[4:0\] RDCYCLETIME](#) field.
- Direction signal DIR: DIR goes from OUT to IN at the same time that nOE is asserted.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 11.1.5.3.10, Bus Keeping Support](#) for more details.

11.1.5.9.1.2 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

[Figure 11-11](#) shows an asynchronous single read operation on an address/data-multiplexed device.

Figure 11-11. Asynchronous Single Read on an Address/Data-Multiplexed Device

gpmc-011

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For details, see [Section 11.1.5.2.3, Address/Data-Multiplexing Interface](#).

GPMC.[GPMC_CONFIG1_i](#) register settings (I = 0 to 7):

- READMULTIPLE bit at 0 (read single access)
- READTYPE bit at 0 (read asynchronous)
- MUXADDDATA bit at 1 (address/data-multiplexed device)

Address bits ([16:1] from a GPMC perspective, [15:0] from an external device perspective) are placed on the address/data bus, and the remaining address bits [25:16] are placed on the address bus. The address phase ends at nOE assertion, when the DIR signal goes from OUT to IN.

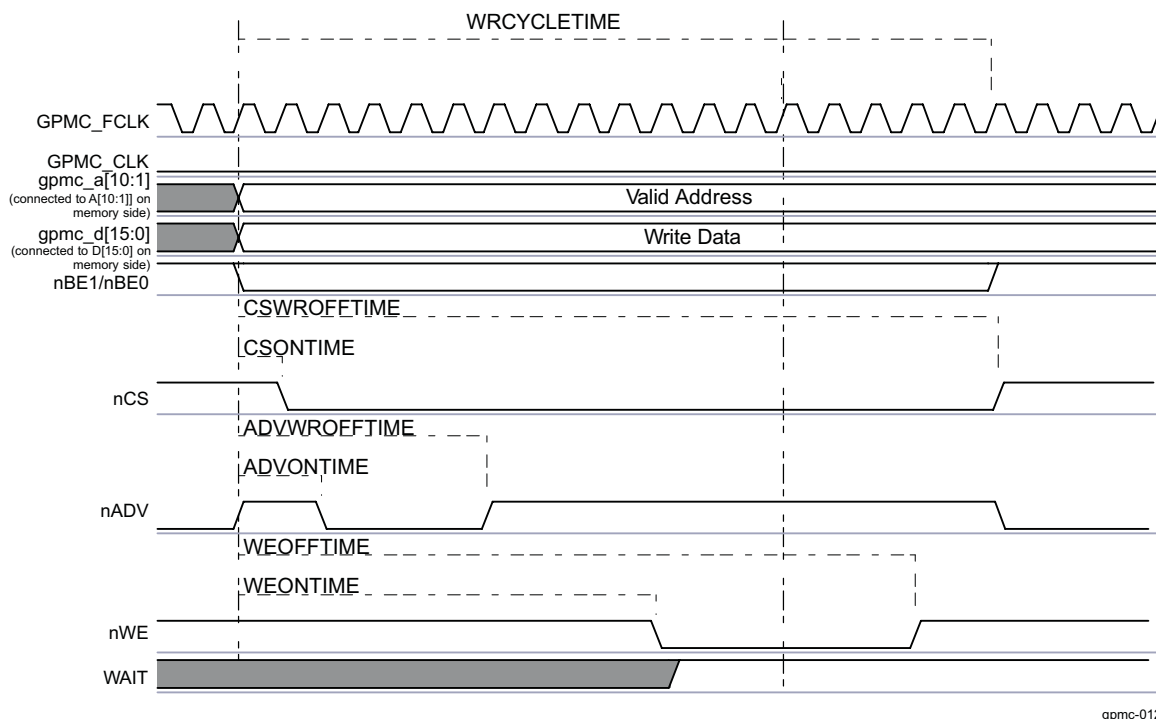

The nCS, nADV, nOE, and DIR signals are controlled in the same way as nonmultiplexed accesses.

11.1.5.9.2 Asynchronous Single Write

11.1.5.9.2.1 Asynchronous Single Write Operation on a Nonmultiplexed Device

Figure 11-12 shows an asynchronous single write operation on a nonmultiplexed device.

Figure 11-12. Asynchronous Single Write on an Address/Data-Nonmultiplexed Device

In the following section *I* stands for the chip-select number, *I* = 0 to 7.

- GPMC.GPMC_CONFIG[1] LIMITEDADDRESS set to 1 (A26-A11 are not modified during an external memory access)
- GPMC.GPMC_CONFIG1_i register settings:
 - WRITEMULTIPLE bit at 0 (write single access)
 - WRITETYPE bit at 0 (write asynchronous)
 - MUXADDDATA bit at 0 (nonaddress/data-multiplexed device)
- Chip-select signal nCS:
 - nCS assertion time is controlled by the GPMC.GPMC_CONFIG2_i[3:0] CSONTIME field and ensures address setup time to nCS assertion.
 - nCS deassertion time is controlled by the GPMC.GPMC_CONFIG2_i[20:16] CSWROFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the GPMC.GPMC_CONFIG3_i[3:0] ADVONTIME field.
 - nADV deassertion time is controlled by the GPMC.GPMC_CONFIG3_i[20:16] ADVWROFFTIME field.

Address and data are driven on their corresponding buses at start-of-cycle time.

- Write enable signal nWE:
 - nWE assertion indicates a write cycle.
 - nWE assertion time is controlled by the GPMC.GPMC_CONFIG4_i[19:16] WEONTIME field.
 - nWE deassertion time is controlled by the GPMC.GPMC_CONFIG4_i[28:24] WEOFFTIME field.
- Direction signal DIR:
 - DIR signal is OUT during the entire access.

- The end of the access is defined by the WRCYCLETIME parameter.
This write-cycle time is defined in the GPMC.GPMC_CONFIG5_i[12:8] WRCYCLETIME field.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See [Section 11.1.5.3.10, Bus Keeping Support](#).

In the GPMC, when a 16-bit wide device is attached to the controller, a Word32 write access is split into two Word16 write accesses. For more information about GPMC access size and type adaptation, see [Section 11.1.5.2.7, System Burst Versus External Device Burst Support](#).

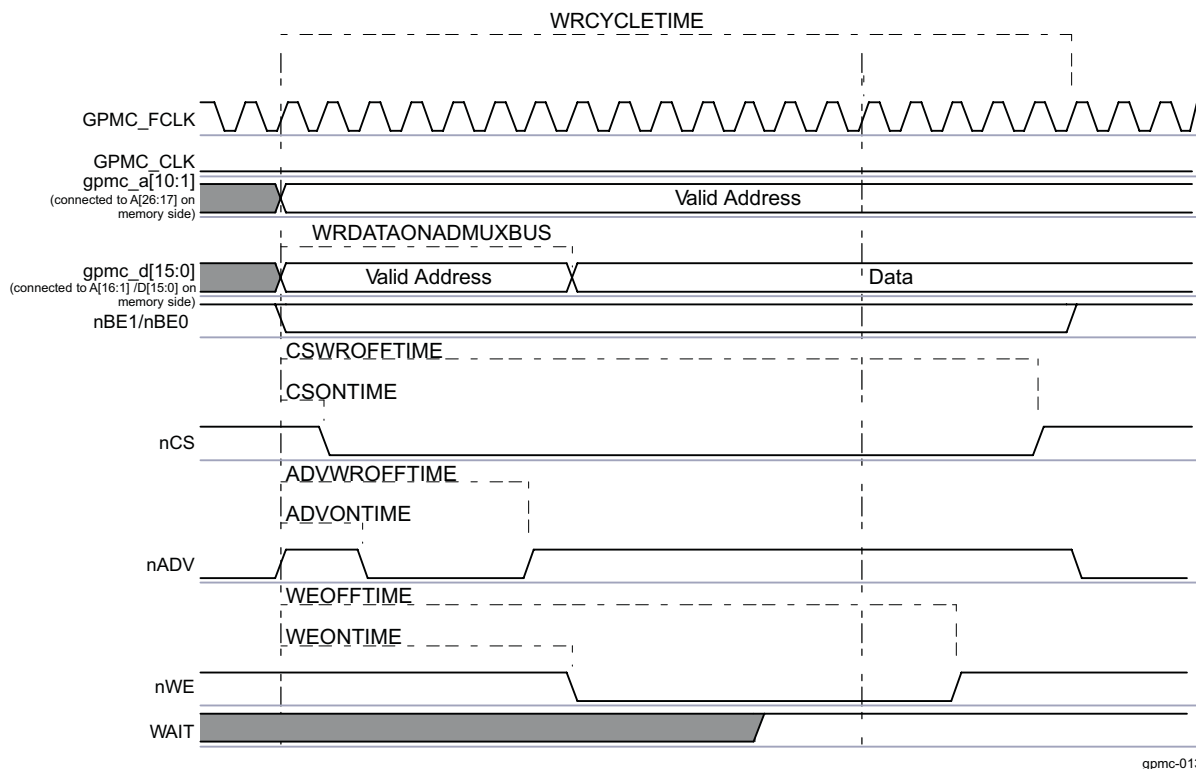

Between two successive accesses, if an nCS pulse is needed:

- The GPMC.GPMC_CONFIG6_i[11:8] CYCLE2CYCLEDELAY field can be programmed with GPMC.GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSSEN enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

11.1.5.9.2.2 Asynchronous Single Write Operation on an Address/Data-Multiplexed Device

[Figure 11-13](#) shows an asynchronous single write operation on an address/data-multiplexed device.

Figure 11-13. Asynchronous Single Write on an Address/Data-Multiplexed Device

When the GPMC generates a write access to an address/data-multiplexed device, it drives the address on the address/data muxed bus until WRDATAONADMUXBUS time, and then it drives the data. For more information, see [Section 11.1.5.2.3, Address/Data-Multiplexing Interface](#).

GPMC.GPMC_CONFIG1_i register settings (I = 0 to 7):

- WRITEMULTIPLE bit at 0 (write single access)
- WRITETYPE bit at 0 (write asynchronous)
- MUXADDDATA bit at 1 (address/data-multiplexed device)

Address bits [16:1] are placed on the address/data bus at the start of cycle time, and the remaining address bits [26:17] are placed on the address bus.

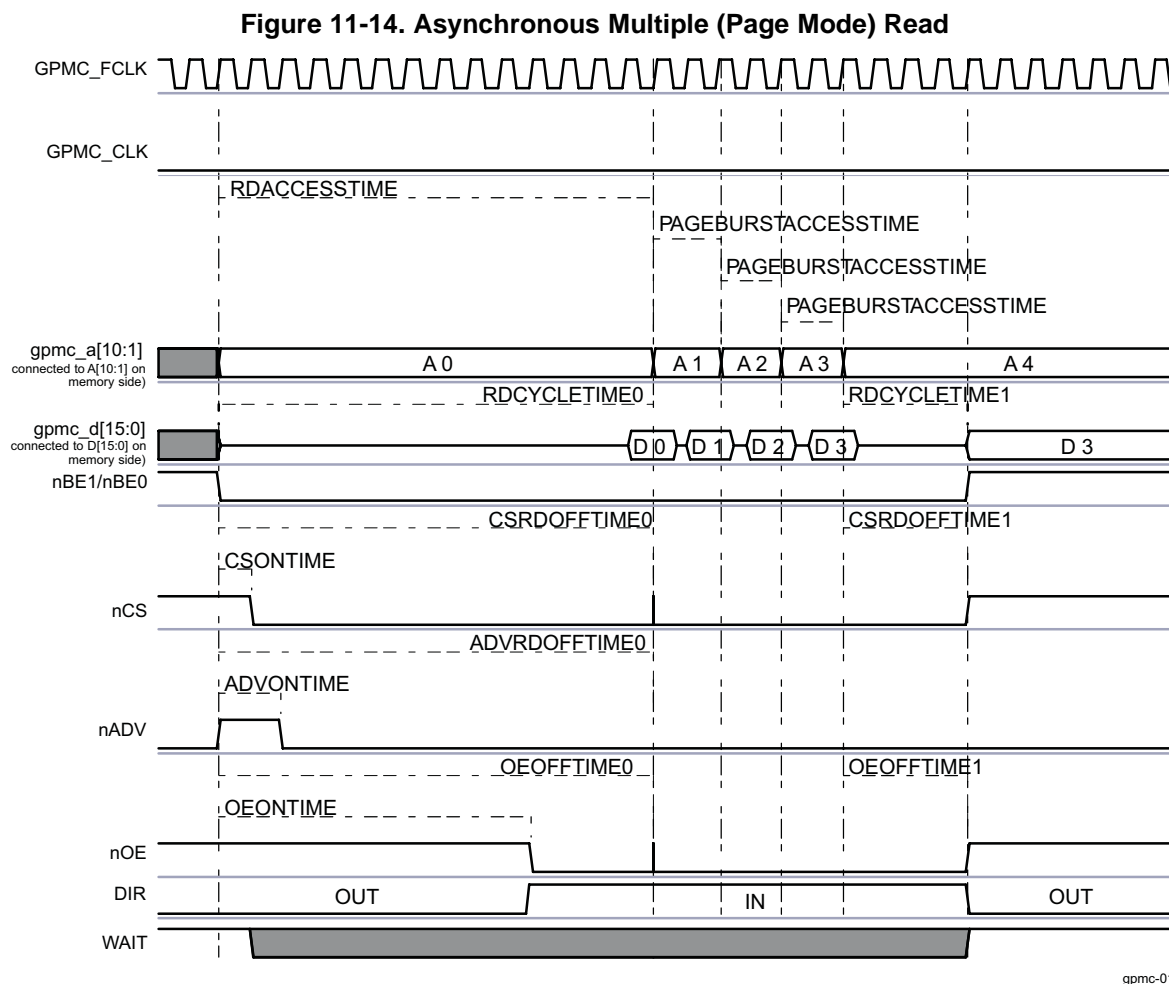

The nCS, nADV, and nWE signals are controlled in the same way as nonmultiplexed accesses.

Data is driven on the address/data bus at a [GPMC_CONFIG6_i\[19:16\]](#) WRDATAONADMUXBUS time.

Note: Write multiple access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

11.1.5.9.3 Asynchronous Multiple (Page Mode) Read

Figure 11-14 shows an asynchronous multiple read operation.

Note: The WAIT signal is active low.

In the following section *I* stands for the chip-select number, *I* = 0 to 7.

For read access with GPMC.[GPMC_CONFIG1_i](#) register settings:

- READMULTIPLE bit at 1 (read multiple access)
- READTYPE bit at 0 (read asynchronous)
- MUXADDDATA bit at 0 (non-address/data-multiplexed device). The page mode is not supported by address/data-multiplexed devices.

In [Figure 11-14](#), two Word32 read host accesses on the GPMC configured with READMULTIPLE = 1, READTYPE = 0, and MUXADDDATA = 0 are merged into one multiple-read access (page mode of four Word16) on the attached device.

When RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

- Chip-select signal nCS:
 - nCS assertion time is controlled by the GPMC.GPMC_CONFIG2_i[3:0] CSONTIME field and ensures the address setup time to nCS assertion.
 - nCS deassertion time is controlled by the GPMC.GPMC_CONFIG2_i[12:8] CSRDOFFTIME field and ensures the address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the GPMC.GPMC_CONFIG3_i[3:0] ADVONTIME field.
 - nADV deassertion time is controlled by the GPMC.GPMC_CONFIG3_i[12:8] ADVRDOFFTIME field.
- Output enable signal nOE:
 - nOE assertion indicates a read cycle.
 - nOE assertion time is controlled by the GPMC.GPMC_CONFIG4_i[3:0] OEONTIME field.
 - nOE deassertion time is controlled by the GPMC.GPMC_CONFIG4_i[12:8] OEOFFTIME field.
- Initial latency for the first read data is controlled by the RDACCESSTIME parameter.
The access time is defined in the GPMC.GPMC_CONFIG5_i[20:16] RDACCESSTIME field.

During consecutive accesses, the GPMC increments the address after each data read completes.

- Delay between successive read data in the page is controlled by the PAGEBURSTACCESSTIME parameter:
 - This timing is defined in the GPMC.GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME field.
 - Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Note that page crossing is only possible with a new burst access, meaning a new initial access phase is initiated.
- Total access time (RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time starting from the nCS deassertion plus the time from RDACCESSTIME to CSRDOFFTIME.
 - The read cycle time is defined in the GPMC.GPMC_CONFIG5_i[4:0] RDCYCLETIME field.
 - In [Figure 11-14](#), the RDCYCLETIME programmed value equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).
- Direction signal DIR:
 - DIR goes from OUT to IN at the same time as nOE assertion time.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 11.1.5.3.10](#), *Bus Keeping Support*.

11.1.5.10 Synchronous Access

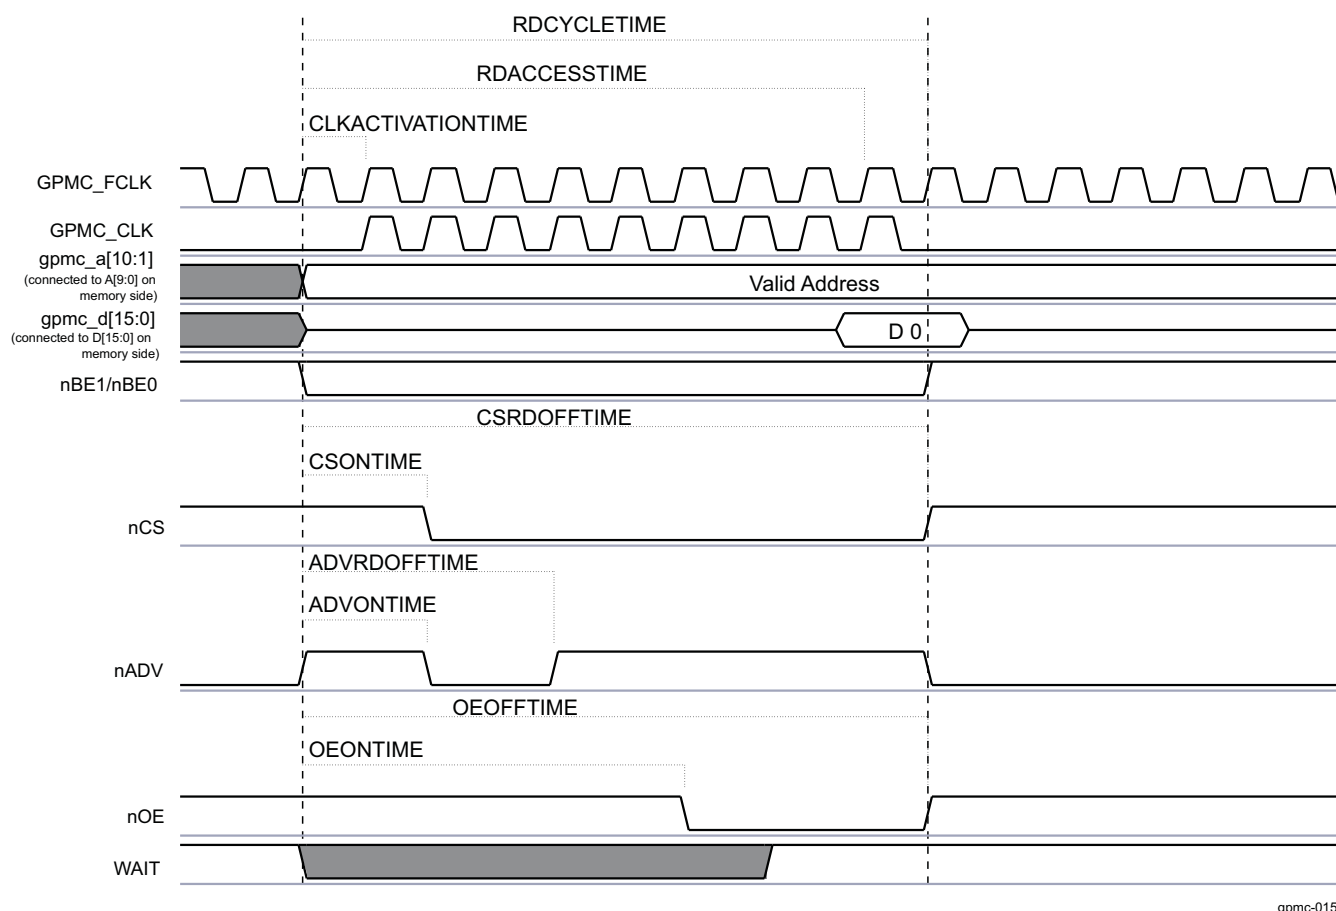

In synchronous operations:

- The GPMC_CLK clock is provided outside the GPMC when accessing the memory device.
- The GPMC_CLK clock is derived from the GPMC_FCLK clock using the GPMC.GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER field (where I = 0 to 7).
- The GPMC.GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME field specifies that the GPMC_CLK is provided outside the GPMC 0, 1, or 2 GPMC_FCLK cycles after start access time until CycleTime completes.
- When the GPMC is configured for synchronous mode, the GPMC_CLK signal (which is an output) must also be set as an input (CONTROL.CONTROL_PADCONF_GPMC_NCS7[24] INPUTENABLE1 = 1). GPMC_CLK is looped back through the output and input buffers of the corresponding GPMC_CLK pad at the OMAP boundary. The looped-back clock is used to synchronize the sampling of the memory signals.

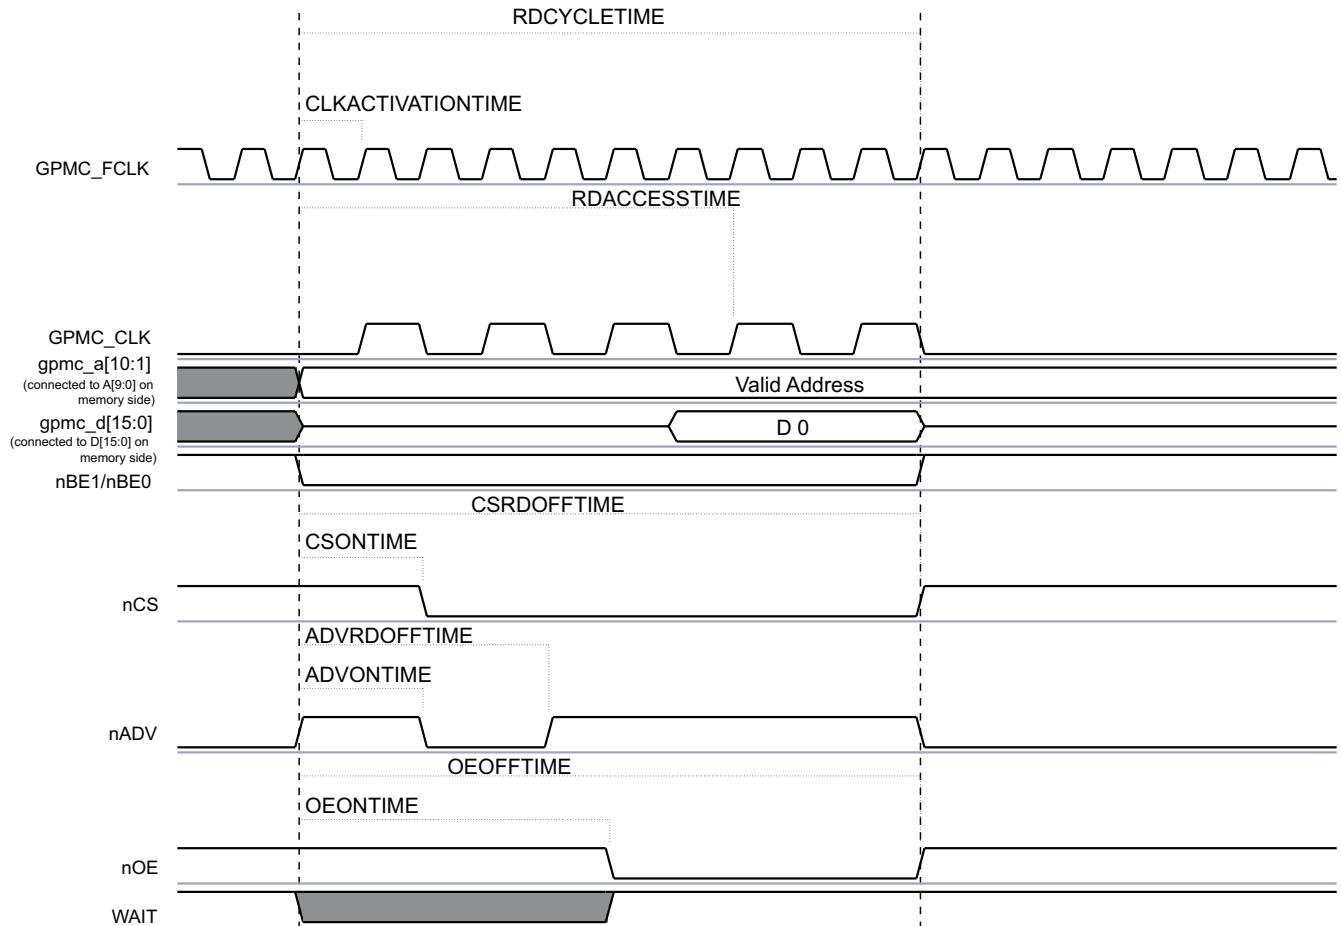

11.1.5.10.1 Synchronous Single Read

Figure 11-15 and Figure 11-16 show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

Figure 11-15. Synchronous Single Read (GPMCFCLKDIVIDER = 0)

gpmc-015

Figure 11-16. Synchronous Single Read (GPMCFCLKDIVIDER = 1)

gpmc-016

In the following section *I* stands for the chip-select number, *I* = 0 to 7.

- GPMC.GPMC_CONFIG1_i register settings:
 - READMULTIPLE bit at 0 (read single access)
 - READTYPE bit at 1 (read synchronous)
 - MUXADDDATA bit at 0 (non-address/data-multiplexed device)
- Chip-select signal nCS:
 - nCS assertion time is controlled by the GPMC.GPMC_CONFIG2_i[3:0] CSOFTIME field and ensures address setup time to nCS assertion.
 - nCS deassertion time is controlled by the GPMC.GPMC_CONFIG2_i[12:8] CSRDOFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the GPMC.GPMC_CONFIG3_i[3:0] ADVONTIME field.
 - nADV deassertion time is controlled by the GPMC.GPMC_CONFIG3_i[12:8] ADVRDOFTIME field.
- Output enable signal nOE:
 - nOE assertion indicates a read cycle.
 - nOE assertion time is controlled by the GPMC.GPMC_CONFIG4_i[3:0] OEONTIME field.
 - nOE deassertion time is controlled by the GPMC.GPMC_CONFIG4_i[12:8] OEOFTIME field.
- Initial latency for the first read data is controlled by GPMC.GPMC_CONFIG5_i[20:16]

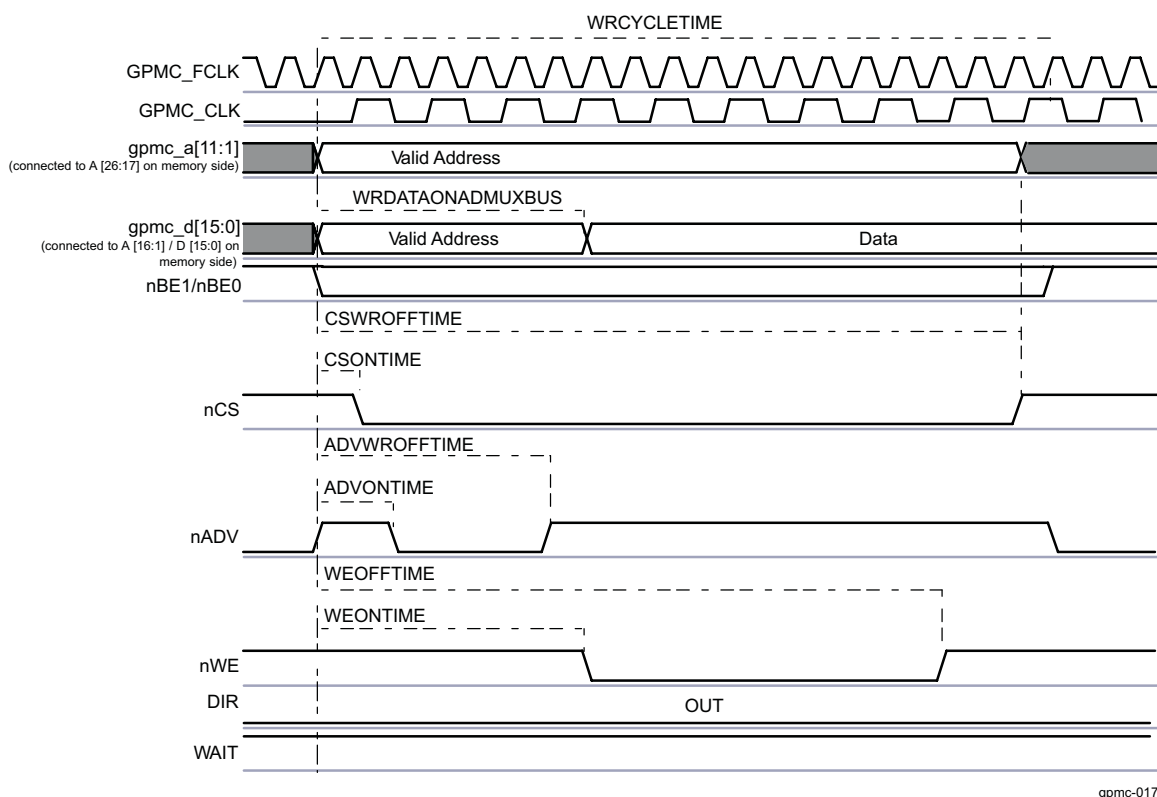

RDACCESSTIME or by monitoring the WAIT signal.

- Total access time (GPMC.GPMC_CONFIG5_i[4:0] RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus time from RDACCESSTIME to CSWROFFTIME.
- Direction signal DIR:
DIR goes from OUT to IN at the same time as nOE assertion.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 11.1.5.3.10, Bus Keeping Support](#).

11.1.5.10.2 Synchronous Single Write

Figure 11-17. Synchronous Single Write on an Address/Data-Multiplexed Device

gpmc-017

Note: The WAIT signal is active low.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus until WRDATAONADMUXBUS time (GPMC_CONFIG6_i[19:16]).

The GPMC.GPMC_CONFIG1_i register settings (I = 0 to 7) are as follows:

- WRITEMULTIPLE bit at 0 (write single access)
- WRITETYPE bit at 1 (write synchronous)
- MUXADDDATA bit at 1 (address/data-multiplexed device)

Address bits [16:1] are placed on the address/data bus at cycle-start time, and the remaining address bits [26:17] are placed on the address bus.

The address phase ends at WRDATAONADMUXBUS.

The nCS, nADV, and nWE signals are controlled in the same way as nonmultiplexed accesses.

First data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

11.1.5.10.3 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word 16 Burst with Wraparound Capability)

Figure 11-18 and Figure 11-19 show a synchronous multiple read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

Figure 11-18. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)

Note: The WAIT signal is active low.

Figure 11-19. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)

NOTE: The WAIT signal is active low.

In the following section *I* stands for the chip-select number, *I* = 0 to 7.

- GPMC.GPMC_CONFIG1_ *i* register settings:
 - READMULTIPLE bit at 1 (read multiple access)
 - READTYPE bit at 1 (read synchronous)
 - MUXADDDATA bit at 0 (nonaddress/data-multiplexed device)

When RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

- Chip-select signal nCS:
 - nCS assertion time is controlled by the GPMC.GPMC_CONFIG2_ *i*[3:0] CSOFTIME field and ensures address setup time to nCS assertion.
 - nCS deassertion time is controlled by the GPMC.GPMC_CONFIG2_ *i*[12:8] CSRDOFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the GPMC.GPMC_CONFIG3_ *i*[3:0] ADVONTIME field.
 - nADV deassertion time is controlled by the GPMC.GPMC_CONFIG3_ *i*[12:8] ADVRDOFTIME field.
- Output enable signal nOE:
 - nOE assertion indicates a read cycle.
 - nOE assertion time is controlled by the GPMC.GPMC_CONFIG4_ *i*[3:0] OEONTIME field.
 - nOE deassertion time is controlled by the GPMC.GPMC_CONFIG4_ *i*[12:8] OEOFTIME field.
- Initial latency for the first read data is controlled by GPMC.GPMC_CONFIG5_ *i*[20:16] RDACCESSTIME or by monitoring the WAIT signal.
- Successive read data are provided by the memory device each one or two GPMC_CLK cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Depending on the device page length, the GPMC can control device page crossing during a new burst request and purposely insert initial latency.

- Total access time (RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus the time from RDACCESSTIME to CSRDOFFTIME.
 - RDCYCLETIME is defined in the GPMC.GPMC_CONFIG5_i register.
 - In Figure 11-19, the RDCYCLETIME programmed value equals RDCYCLETIME0 + RDCYCLETIME1.
- Direction signal DIR:
 - DIR goes from OUT to IN at the same time as nOE assertion.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 11.1.5.3.10, *Bus Keeping Support*.

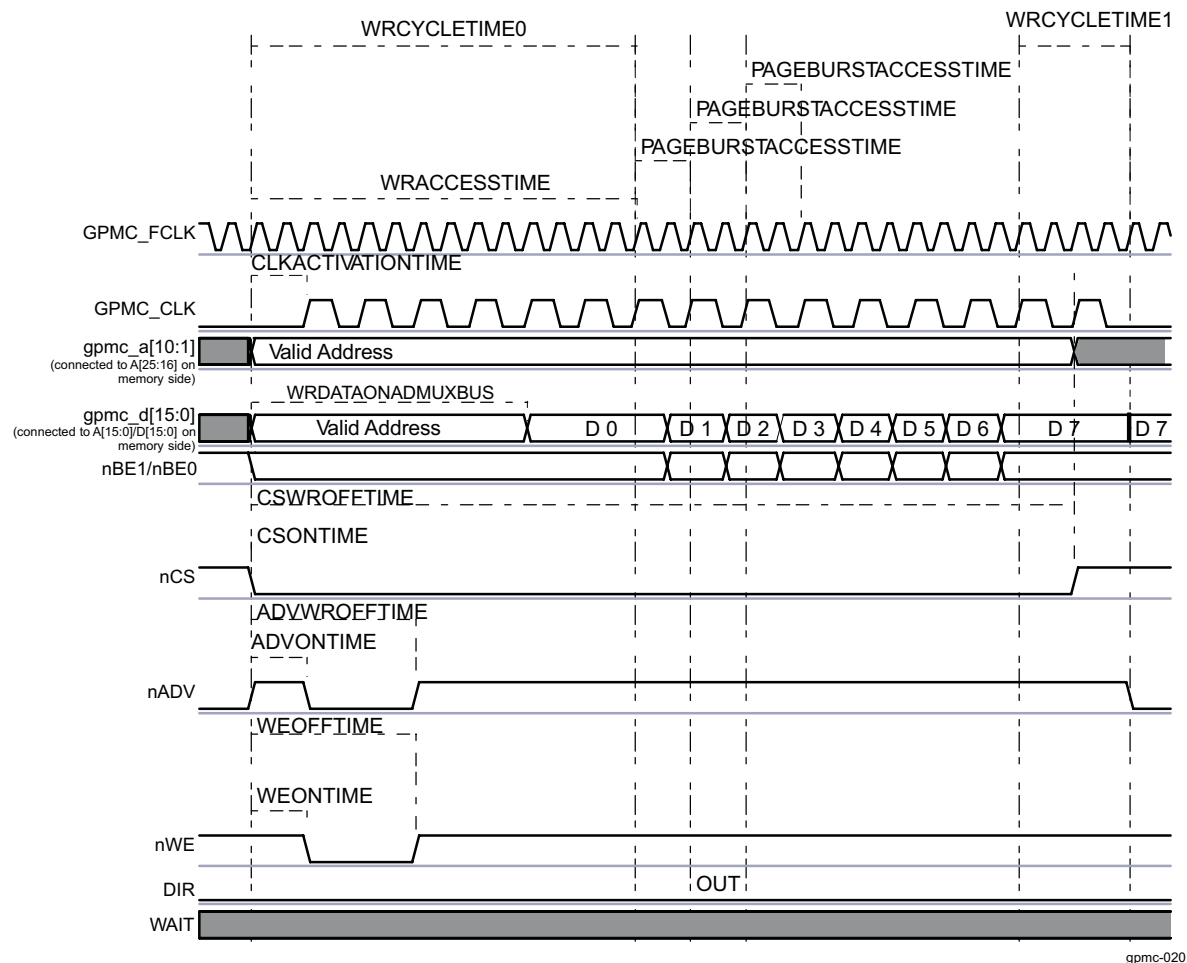

- Burst wraparound
 - The GPMC.GPMC_CONFIG1_i[31] WRAPBURST bit allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary.

11.1.5.10.4 Synchronous Multiple (Burst) Write

Burst write mode provides synchronous single or consecutive accesses.

Figure 11-20 shows a synchronous multiple (burst) write.

Figure 11-20. Synchronous Multiple (Burst) Write

NOTE: The WAIT signal is active low.

In the following section I stands for the chip-select number, I = 0 to 7.

- GPMC.GPMC_CONFIG1_i register settings:
 - WRITEMULTIPLE bit at 1 (write multiple access)
 - WRITETYPE bit at 1 (write synchronous)
 - MUXADDDATA bit at 1 (address/data-multiplexed device)

When WRACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

- Chip-select signal nCS:
 - nCS assertion time is controlled by the GPMC.GPMC_CONFIG2_i[3:0] CSONTIME field and ensures address setup time to nCS assertion.
 - nCS deassertion time controlled by the GPMC.GPMC_CONFIG2_i[20:16] CSWROFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the GPMC.GPMC_CONFIG3_i[3:0] ADVONTIME field.
 - nADV deassertion time is controlled by the GPMC.GPMC_CONFIG3_i[20:16] ADVWROFFTIME field.
- Write enable signal nWE:
 - nWE assertion indicates a write cycle.
 - nWE assertion time is controlled by the GPMC.GPMC_CONFIG4_i[19:16] WEONTIME field.
 - nWE deassertion time is controlled by the GPMC.GPMC_CONFIG4_i[28:24] WEOFFTIME field.

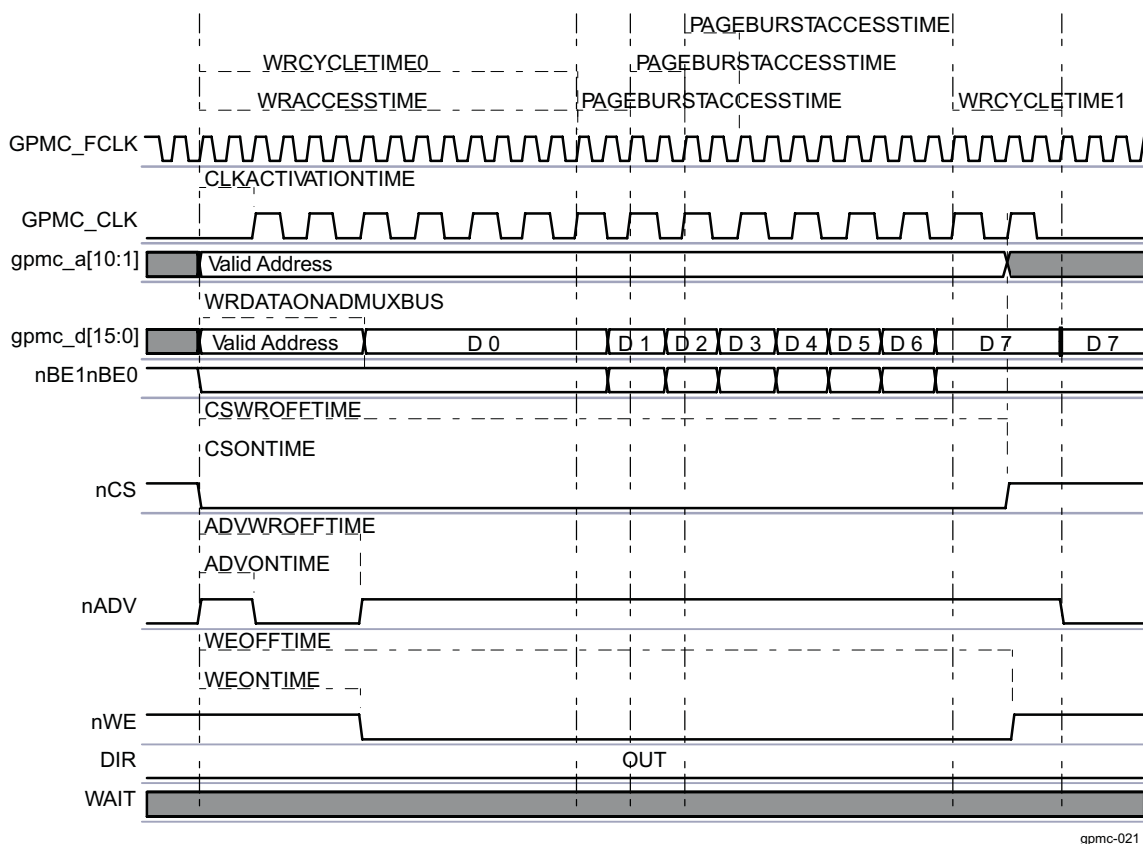

Note: The nWE falling edge must not be used to control the time when the burst first data is driven in the address / data bus because some new devices require the nWE signal at low during the address phase.

- First write data is driven by the GPMC at WRDATAONADMUXBUS (GPMC_CONFIG6_i[19:16]), when in address/data mux configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during PAGEBURSTACCESSTIME GPMC_FCLK cycles. The last data of the synchronous burst write is driven until WRCYCLETIME completes.
 - WRACCESSTIME is defined in the GPMC.GPMC_CONFIG5_i register.
 - The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.
- Total access time (WRCYCLETIME) corresponds to WRACCESSTIME plus the address hold time from nCS deassertion, plus time from WRACCESSTIME to CSWROFFTIME.
 - WRCYCLETIME is defined in the GPMC.GPMC_CONFIG5_i register.
 - In Figure 11-20, the WRCYCLETIME programmed value equals WRCYCLETIME0 + WRCYCLETIME1.
- Direction signal DIR:
 - DIR is OUT during the entire access.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See Section 11.1.5.3.10, *Bus Keeping Support*.

Figure 11-21 shows the same synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

Figure 11-21. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode

The first data of the burst is driven on the a/d bus at [GPMC_CONFIG6_i\[19:16\]](#) WRDATAONADMUXBUS.

11.1.5.11 pSRAM Basic Programming Model

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. These devices can be accessed by the GPMC with the GPMC.[GPMC_CONFIG1_i\[11:10\]](#) DEVICETYPE field (I = 0 to 7).

The pSRAM devices support the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can either automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or pSRAM devices automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum nCS high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

In both pSRAM cases, the GPMC configuration for this chip-select must be set according to the specifications of the attached device.

11.1.5.12 Error Handling

When an error occurs in the GPMC, the error information is stored in the GPMC.GPMC_ERR_TYPE register and the address of the illegal access is stored in the GPMC.GPMC_ERR_ADDRESS register. The GPMC only keeps the first error abort information until the GPMC.GPMC_ERR_TYPE register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the GPMC.GPMC_ERR_TYPE[0] ERRORVALID bit.

- ERRORNOTSUPPADD occurs when an incoming system request address decoding does not match any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1 Kbyte.
- ERRORNOTSUPPMCMD occurs when an unsupported command request is decoded at the L3 interconnect interface.
- ERRORTIMEOUT: A time-out mechanism prevents the system from hanging. The start value of the 9-bit time-out counter is defined in the GPMC.GPMC_TIMEOUT_CONTROL register and enabled with the GPMC.GPMC_TIMEOUT_CONTROL[0] TIMEOUTENABLE bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. True abort to the MPU or interrupt generation is handled at interconnect level.

11.1.5.13 Boot Configuration

See [Section 11.1.3.3.2, GPMC CS0 Default Configuration at IC Reset](#).

11.1.5.14 NAND Device Basic Programming Model

NAND (8-bit and 16-bit) memory devices using a classical NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings.

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices.

This interleaved capability limits the system to chip enable don't care NAND devices since the chip-select allocated to the NAND device has to be de-asserted if accesses to other chip-selects are requested.

11.1.5.14.1 NAND Memory Device in Byte or Word16 Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data-stream-oriented (byte or Word16).

The GPMC NAND programming model relies on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the nADV/ALE signal as Address Latch Enable (ALE active high, default state value at low) during address program access, and the nBE0/CLE signal as Command Latch Enable (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

11.1.5.14.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC.GPMC_CONFIG7_i register (where I = 0 to 7) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16 Mbytes, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND Flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

CAUTION

To allow correct command, address, and data-access controls, the GPMC.GPMC_CONFIG1_i register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters shown in Table 11-4. Failure to comply with these settings corrupts the NAND interface protocol.

Table 11-4. Chip-Select Configuration for NAND Interfacing

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1_i[31] ⁽¹⁾	0	No wrap
READMULTIPLE	GPMC_CONFIG1_i[30]	0	Single access
READTYPE	GPMC_CONFIG1_i[29]	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1_i[28]	0	Single access
WRITETYPE	GPMC_CONFIG1_i[27]	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1_i[26:25]	00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1_i[24:23]	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1_i[22]	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1_i[21]	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1_i[19:18]	Don't care	Wait not monitored by GPMC access engine
WAITPINSELECT	GPMC_CONFIG1_i[17:16]		Select which wait is monitored by edge detectors
DEVICESIZE	GPMC_CONFIG1_i[13:12]	0b00 or 0b01	8- or 16-bit interface
DEVICETYPE	GPMC_CONFIG1_i[11:10]	0b10	NAND device in stream mode
MUXADDDATA	GPMC_CONFIG1_i[9]	0	Nonmultiplexed mode
TIMEPARAGRANULARITY	GPMC_CONFIG1_i[4]	0	Timing achieved with best GPMC clock granularity
GPMCFCLKDIVIDER	GPMC_CONFIG1_i[1:0]	Don't care	Asynchronous mode

⁽¹⁾ I = 0 to 7

The GPMC.GPMC_CONFIG1_i to GPMC.GPMC_CONFIG4_i register (where I = 0 to 7) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

11.1.5.14.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The CPU software driver is responsible for issuing the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC.GPMC_NAND_COMMAND_i and GPMC.GPMC_NAND_ADDRESS_i register locations (I = 0 to 7) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with nOE and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC.GPMC_NAND_COMMAND_i register location and to the GPMC.GPMC_NAND_ADDRESS_i register location must be posted for faster operations (I = 0 to 7). The GPMC.GPMC_CONFIG[0] NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- An GPMC.GPMC_STATUS[0] EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

GPMC.GPMC_NAND_COMMAND_i and GPMC.GPMC_NAND_ADDRESS_i (I = 0 to 7) are Word32 locations, which means any Word32 or Word16 access is split into 4- or 2-byte accesses if an 8-bit wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use Word32 or Word16 access to these registers, but it must account for the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to GPMC.GPMC_NAND_COMMAND_i and GPMC.GPMC_NAND_ADDRESS_i can be used, and any of the four byte locations of the registers are valid.

The same applies to a GPMC.GPMC_NAND_COMMAND_i and a GPMC.GPMC_NAND_ADDRESS_i (I = 0 to 7) Word32 write access to a 16-bit wide NAND device (split into two Word16 accesses). In the case of a Word16 write access, the MSByte of the Word16 value must be set according to the NAND device requirement (usually 0). Either Word16 location or any one of the four byte locations of the registers is valid.

11.1.5.14.1.3 Command Latch Cycle

Writing data at the GPMC.GPMC_NAND_COMMAND_i location (i = 0 to 7) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- nCE is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE and nRE (nOE) are maintained inactive.

Figure 11-22 shows the NAND command latch cycle.

Figure 11-22. NAND Command Latch Cycle

Note: CLE is shared with the nBE0 output signal and has an inverted polarity from BE0. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, nBE0 (also nBE1) must not toggle, because it is shared with CLE.

NAND Flash memories do not use byte enable signals at all.

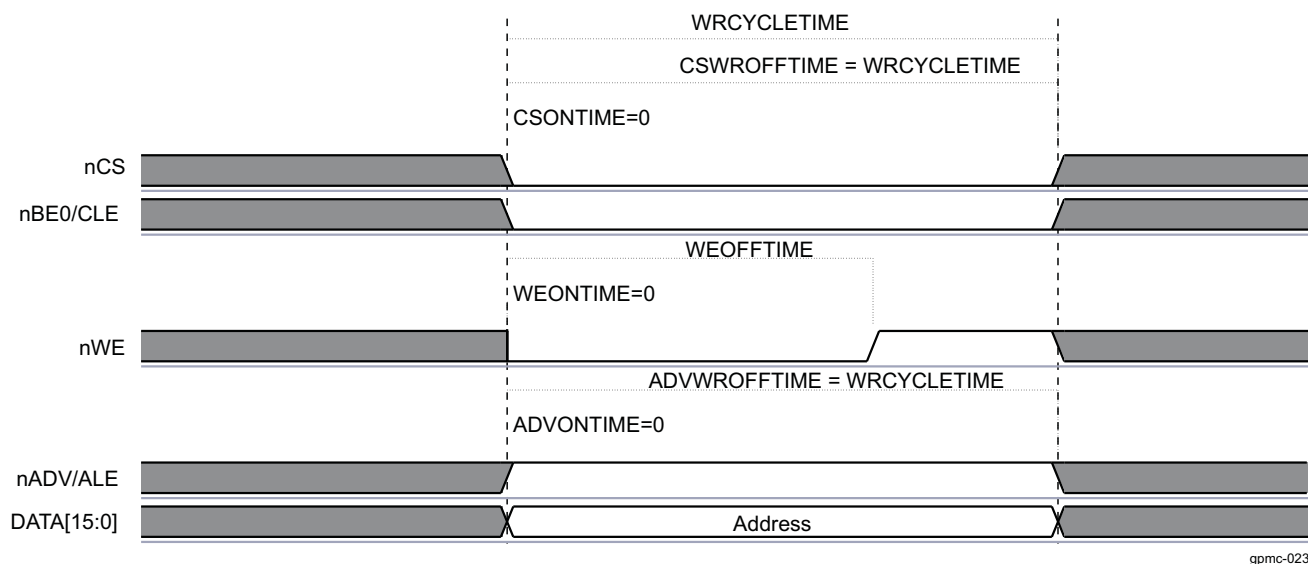

11.1.5.14.1.4 Address Latch Cycle

Writing data at the GPMC.GPMC_NAND_ADDRESS_i location (i = 0 to 7) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and nRE (nOE) are maintained inactive.

Figure 11-23 shows the NAND address latch cycle.

Figure 11-23. NAND Address Latch Cycle

Note: ALE is shared with the nADV output signal and has an inverted polarity from ADV. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

11.1.5.14.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC.GPMC_NAND_DATA_i location (I = 0 to 7) mapped in the chip-select-associated control register region. GPMC.GPMC_NAND_DATA_i is not a true register, but an address location to enable nRE or nWE signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Reading data from the GPMC.GPMC_NAND_DATA_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

- nCS is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- nRE is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of nRE high-to-data invalid minimum timing value, the RDACCESSTIME can be set so that data are effectively captured after nRE deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and OMAP IC timing parameters.

ALE, CLE, and nWE are maintained inactive.

Figure 11-24 shows the NAND data read cycle.

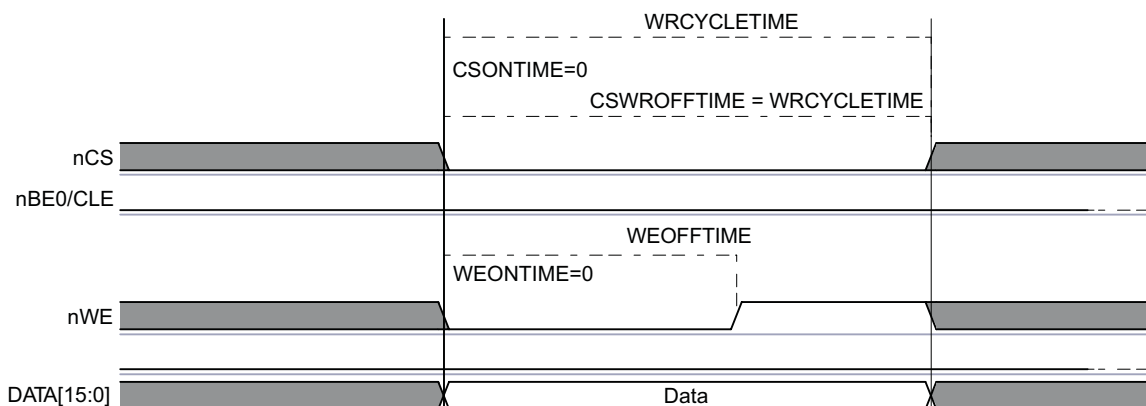

Figure 11-24. NAND Data Read Cycle

Writing data to the GPMC.GPMC_NAND_DATA_i location or to any location in the associated chip-select memory region activates an asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and nRE (nOE) are maintained inactive.

Figure 11-25 shows the NAND data write cycle.

Figure 11-25. NAND Data Write Cycle

gpmc-025

11.1.5.14.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by nCS-to-data-valid timing and has faster nRE-to-data-valid timing. Successive accesses with nCS deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that nCS always stays low between two accesses to the same chip-select. Moreover, an nCS deassertion time between the same chip-select NAND accesses is likely to be required as follows: the nCS deassertion requires programming CYCLETIME and RDACCESSTIME according to the nCS-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSRDOFFTIME, CSWROFFTIME, ADVRDOFFTIME, ADVWROFFTIME, OEOFFTIME, and WEOFFTIME on back-to-back NAND accesses (to the same memory) and suppress the minimum nCS high pulse width between accesses. For more information about optimal prefetch engine access, see [Section 11.1.5.14.4, Prefetch and Write-Posting Engine](#).

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum nCS high pulse width must be set. For this, CYCLE2CYCLESAMECSSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important nRE high to data bus in tristate mode. This requires a bus turnaround setting (BUSTURNAROUND = 1), so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND Flash are not affected by the programmed bus turnaround delay.

11.1.5.14.1.7 Read and Write Access Size Adaptation

11.1.5.14.1.7.1 8-bit Wide NAND Device

Host Word16 and Word32 read and write access requests to a chip-select associated with an 8-bit wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the chip-select is associated with an 8-bit wide NAND device.

11.1.5.14.1.7.2 16-bit Wide NAND Device

Host Word32 read and write access requests to a chip-select associated with a 16-bit wide NAND device are split into successive read and write Word16 accesses to the NAND memory device. Word16 access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit wide NAND devices. This means that the NAND device address pointer is incremented on a Word16 basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or Word16 read access gets the next Word16 NAND location. For a write access, the invalid byte part of the Word16 is driven to FF, and the next byte or Word16 write access programs the next Word16 NAND location.

Generally, byte access to a 16-bit wide NAND device should be avoided, especially when ECC calculation is enabled. 8-bit or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

11.1.5.14.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the four WAIT GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMINITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 s) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

Note: If a read access to a NAND flash is done using the wait monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the wait pin monitoring for read and write accesses (that is, set the GPMC.GPMC_CONFIG1_I[21] WAITWRITEMONITORING and GPMC.GPMC_CONFIG1_I[22] WAITREADMONITORING bits to 0, where I = 0 to 7), and use one of the following methods instead:

- Use software to poll the WAITnSTATUS bit (n = 0 to 3) of the GPMC_STATUS register.
- Configure an interrupt that is generated on the WAIT signal change (through the GPMC.GPMC_IRQENABLE register bits[11:8]).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed WAIT bit in the GPMC_STATUS register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

11.1.5.14.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the GPMC.GPMC_STATUS WAITxSTATUS bit (x = 0 to 3). The software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

11.1.5.14.2.2 Ready Pin Monitored by Hardware Interrupt

Each gpmc_wait input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the GPMC.GPMC_CONFIG WAITxPINPOLARITY bits (x = 0 to 3) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1

to the WAITxEDGEDETECTIONSTATUS bit ($x = 0$ to 3) of the GPMC.GPMC_IRQSTATUS register according to the gpmc_wait pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the GPMC.GPMC_IRQENABLE register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the GPMC.GPMC_IRQSTATUS register is set.

The WAITMONITORINGTIME field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the GPMC.GPMC_IRQSTATUS register according to the gpmc_wait pin used for the NAND device ready signal monitoring.

11.1.5.14.3 ECC Calculator

The General Purpose Memory Controller includes an Error Code Correction (ECC) calculator circuitry that enables on the fly ECC calculation during data read or data program (that is, write) operations.

The user can choose from two different algorithms with different error correction capabilities, Hamming code (for 1-bit error code correction) and BCH code (for 4- or 8-bit error correction) through the GPMC_ECC_CONFIG[16] ECCALGORITHM bit. Only one ECC context can be active at any given time through the GPMC_ECC_CONFIG[3:1] ECCCS bit. Even if two CS use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

11.1.5.14.3.1 Hamming Code

All references to Error Code Correction (ECC) in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a two-dimensional (row and column) bit parity accumulation known as Hamming Code. The parity accumulation is done for a programmed number of bytes or Word16 read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and it is the software NAND driver responsibility to read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time and parallel computations on different chip-selects are not possible. Since it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. It is the software responsibility to make sure only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is completed.

11.1.5.14.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (GPMC.GPMC_ECCj_RESULT, $j = 1$ to 9) to store ECC computation results when the specified number of bytes or Word16s has been computed.

The ECC result registers are used sequentially; one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The GPMC.GPMC_ECCj_RESULT register value is valid only when the programmed number of bytes or Word16s has been accumulated, which means that the same number of bytes or Word16s has been read from or written to the NAND device in sequence.

The GPMC.GPMC_ECC_CONTROL[3:0] ECCPOINTER field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The GPMC.GPMC_ECCj_RESULT register value ($j = 1$ to 9) can be considered valid when ECCPOINTER equals $j + 1$. When GPMC.GPMC_ECCj_RESULT (where $j = 9$) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The GPMC.GPMC_ECC_CONTROL[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each GPMC.GPMC_ECCj_RESULT register, $j = 1$ to 9), the number of bytes or Word16s used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSIZE bits ($j = 1$ to 9) in the GPMC.GPMC_ECC_SIZE_CONFIG register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in GPMC.GPMC_ECCj_RESULT).

The ECCSIZE0 and ECCSIZE1 fields allow selection of the number of bytes or Word16s used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or Word16s used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 Word16, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2 Kbyte data page 8-bit wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine GPMC.GPMC_ECCj_RESULT registers (j) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1:8]RESULTSIZE bits are set to 0, and the ECC9RESULTSIZE bit is set to 1.

11.1.5.14.3.1.2 ECC Enabling

The GPMC.GPMC_ECC_CONFIG[3:0] ECCCS field selects the allocated chip-select. The GPMC.GPMC_ECC_CONFIG[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The ECCPOINTER, ECCCLEAR, ECCSIZE, ECCjRESULTSIZE (where $j = 1$ to 9), ECC16B, and ECCCS fields must not be changed or cleared while an ECC computation is in progress.

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

Table 11-5 describes the ECC enable settings.

Table 11-5. ECC Enable Settings

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0-7	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0/1	Selects column number for ECC calculation
ECCCLEAR	GPMC_ECC_CONTROL	0-7	Clears all ECC result registers
ECCPOINTER	GPMC_ECC_CONTROL	0-7	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.
ECCSIZE1	GPMC_ECC_SIZE_CONFIG	0x00-0xFF	Defines ECCSIZE1
ECCSIZE0	GPMC_ECC_SIZE_CONFIG	0x00-0xFF	Defines ECCSIZE0
ECCkRESULTSIZE (j from 1 to 9)	GPMC_ECC_SIZE_CONFIG	0/1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

11.1.5.14.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word 16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 11-26 and Figure 11-27. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream

P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream

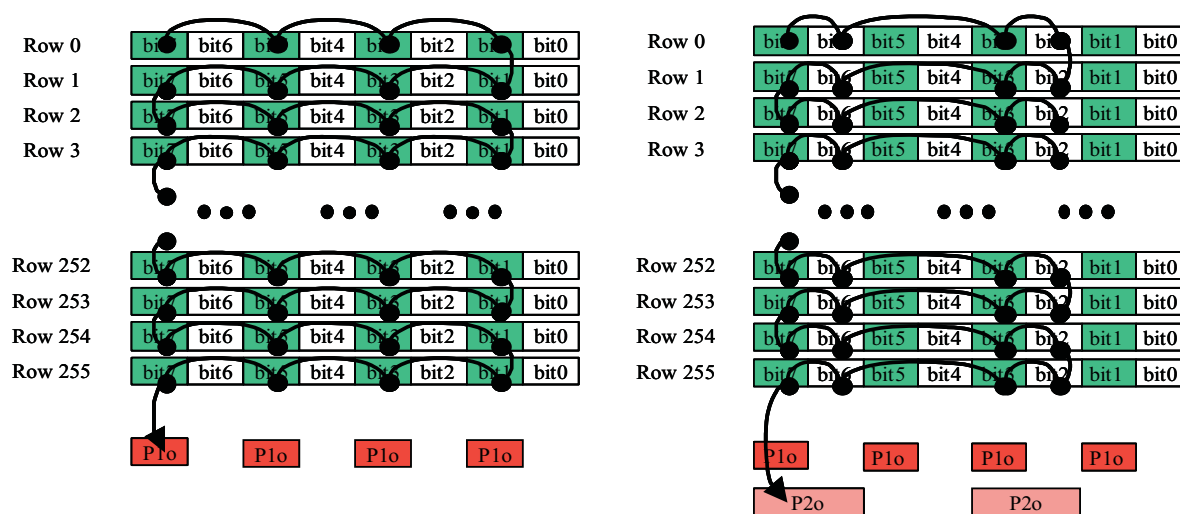

P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream

P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

Figure 11-26. Hamming Code Accumulation Algorithm ()

gpmc-026

For line parities, the bits of each new data are XORed together, and line parity bits are computed as described below:

P8e = row0 XOR row2 XOR row4 XOR XOR row254

P8o = row1 XOR row3 XOR row5 XOR XOR row255

P16e = row0 XOR row1 XOR row4 XOR row5 XOR XOR row252 XOR row 253

P16o = row2 XOR row3 XOR row6 XOR row7 XOR XOR row254 XOR row 255

Figure 11-27. Hamming Code Accumulation Algorithm (2/2)

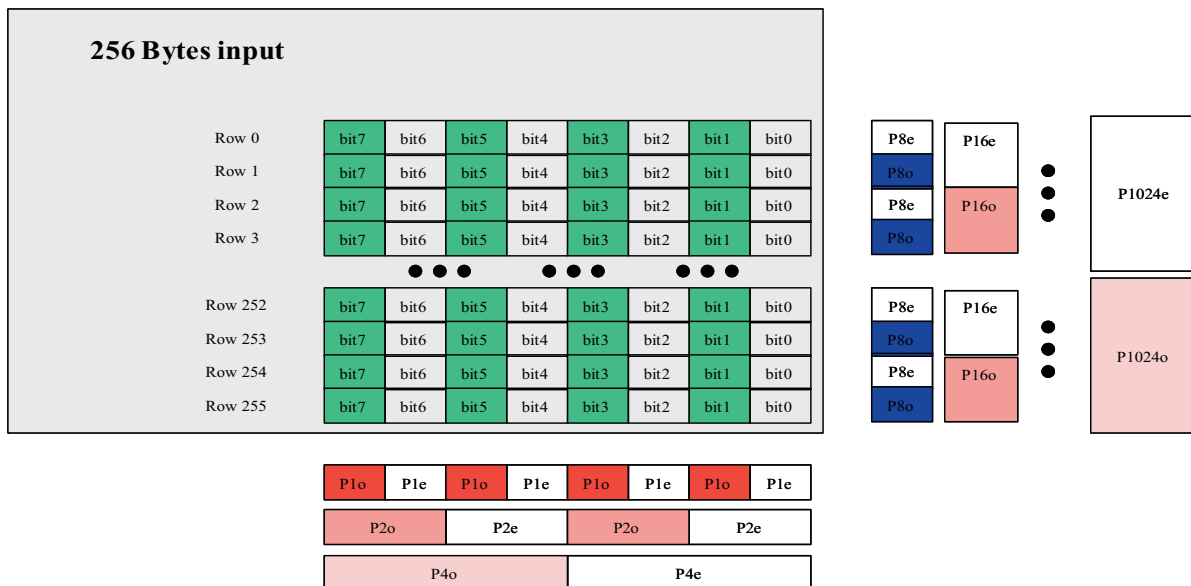

gpmc-027

Unused parity bits in the result registers are set to 0.

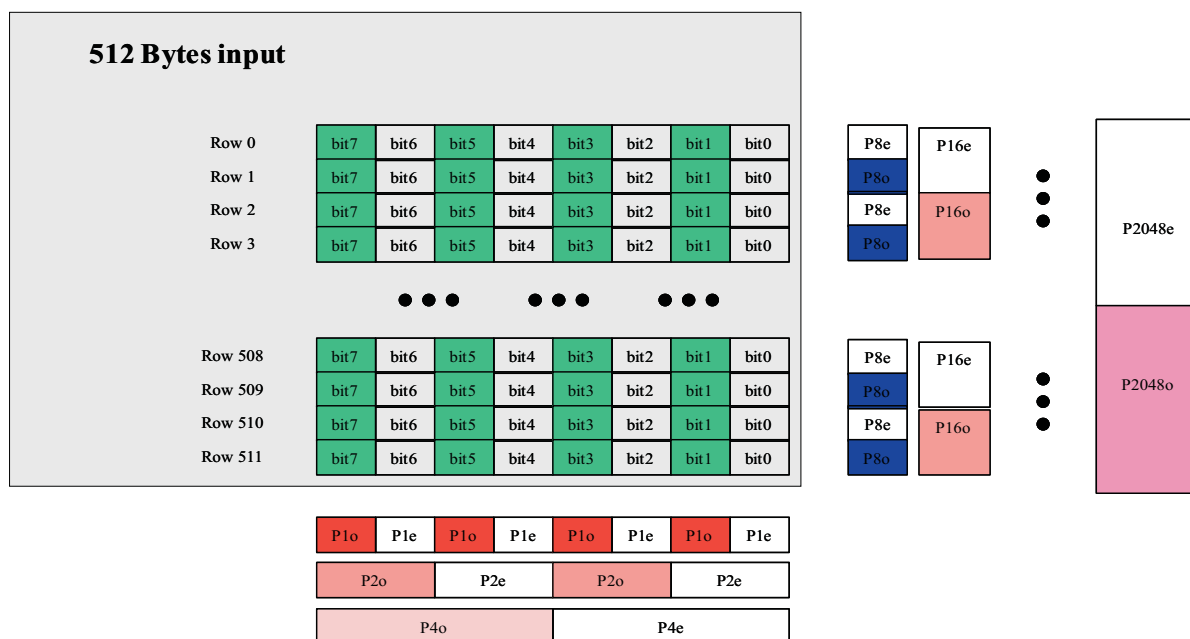

Figure 11-28 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

Figure 11-28. ECC Computation for a 256-Byte Data Stream (Read or Write)

gpmc-028

Figure 11-29 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o- - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

Figure 11-29. ECC Computation for a 512-Byte Data Stream (Read or Write)

gpmc-029

For a 2 Kbytes page, four 512 bytes ECC calculations plus one for the spare area are required. Results are stored in the [GPMC_ECCj_RESULT](#) registers ($j = 1$ to 9).

11.1.5.14.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, one bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). The software must correct the corresponding bit.
- If only one bit in the parity result is 1, it is an ECC error and the read data is correct.

11.1.5.14.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit based ECC computation is used for 8-bit wide NAND device interfacing.

The 8-bit based ECC computation can be used for 16-bit wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit wide NAND devices. In this case, the 16-bit wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the least significant bit (LSB) of the 16-bit wide data is ordered first in the byte stream used for 8-bit based ECC computation.

11.1.5.14.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on a 16-bit word is used for 16-bit wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit wide NAND device, and the [GPMC.GPMC_ECC_CONFIG\[7\]](#) ECC16B bit must be set to 0 when interfacing an 8-bit wide NAND device.

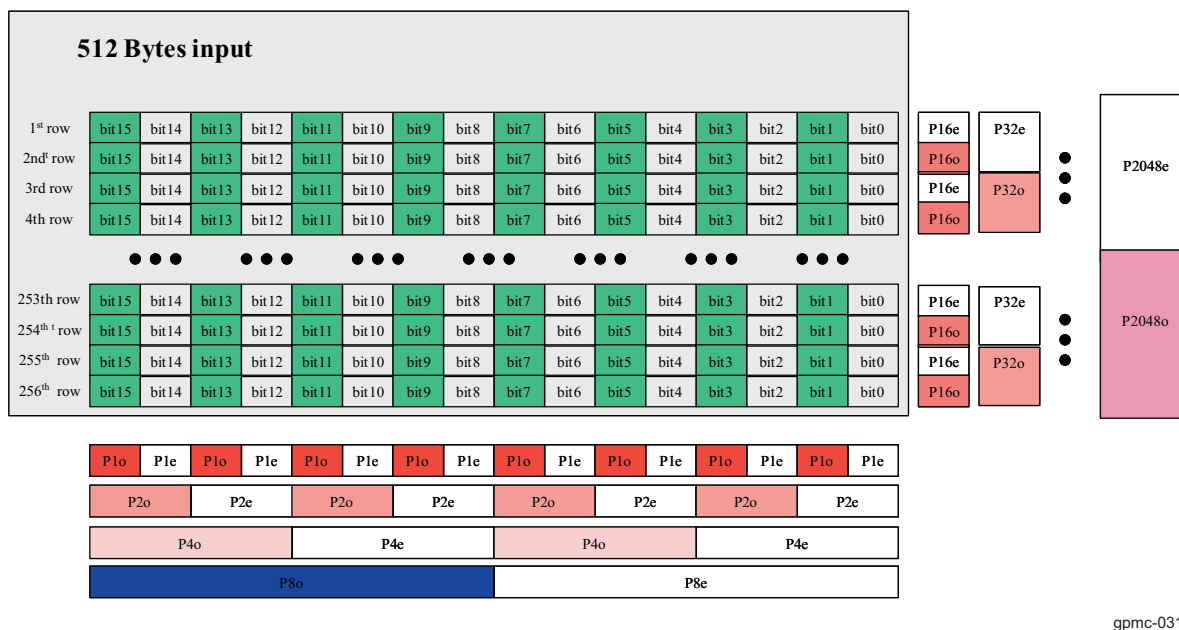

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit based ECC while there are computed on columns for a 16-bit based ECC. [Figure 11-30](#) and [Figure 11-31](#) show a 128 Word 16 ECC computation scheme and a 256 Word16 ECC computation scheme.

11.1.5.14.3.2 BCH Code

All references to Error Code Correction (ECC) in this subsection refer to the 4- or 8-bit error correction BCH code.

11.1.5.14.3.2.1 Requirements

1. Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, then some spare bytes, including the BCH ECC (and other information). The NAND IC can cache a full page, including spares, for read and write accesses. Typical page write sequence:
 - Sequential write to NAND cache of main data + spare data, for a page. ECC is calculated on the fly. Calculated ECC may be inserted on the fly in the spares, or replaced by dummy accesses.
 - When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a

- second, separate phase. The ECC module is disabled during that time.
 - NAND writes its cache line (page) to the array.
- Typical page read sequence:
- Sequential read of a page. ECC is calculated on the fly.
 - ECC module buffers status determines the presence of errors.
2. Accesses to several memories may be interleaved by the GPMC, but only one of those memories can be a NAND using the BCH engine at a time; in other words, only one BCH calculation (for example, for a single page) can be on-going at any time. Note also that the sequential nature of NAND accesses guarantees that the data is always written / read out in the same order. BCH-relevant accesses are selected by the GPMCs chip-select.
 3. Each page may hold up to 4 Kbytes of data, spare bytes not included. This means up to 8×512 -byte BCH messages. Since all the data is written / read out first, followed by the BCH ECC, this means that the BCH engine must be able to hold 8 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.
The BCH module has the capacity to store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.
 4. NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least 4 cycles of the GPMCs internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least 4 clock cycles after optimization when using the BCH calculator.
 5. The spare area is assumed to be large enough to hold the BCH ECC, that is, to have at least a message of 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (maximum codeword is 1023-byte long, ECC included, which leaves a lot of space to cover some spares bytes).

11.1.5.14.3.2.2 Memory-Mapping of the BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message $M(x)$. In our standard case, 512 bytes of data (that is, 2^{12} bits = 4096 bits) are seen as a polynomial of degree $2^{12} - 1 = 4095$, with parameters ranging from M_0 to M_{4095} . For 512 bytes of data, 52 bits are required for 4-bit error correction, and 104 bits are required for 8-bit error correction. The ECC is a remainder polynomial $R(x)$ of degree 103 (or 51, depending on the selected mode). The complete codeword $C(x)$ is the concatenation of $M(x)$ and $R(x)$ as shown in [Table 11-6](#).

Table 11-6. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)

	Message $M(x)$			ECC $R(x)$		
Bit number	M_{4095}	...	M_0	R_{103}	...	R_0

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message $M(x)$ of degree $((512 + 3) * 8) - 1 = 4119$, for a total of $3 + 13 = 16$ spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in [GPMC_BCH_RESULT0_i](#), [GPMC_BCH_RESULT1_i](#), [GPMC_BCH_RESULT2_i](#), and [GPMC_BCH_RESULT3_i](#) (where $i = 0$ to 7).

11.1.5.14.3.2.2.1 Memory-Mapping of the Data Message

The data message mapping shall follow the following rules:

- Bit endianness within a byte is little-endian, that is, the bytes LS bit is also the lowest-degree polynomial parameter: a byte b_7 - b_0 (with b_0 the LS bit) represents a segment of polynomial $b_7 * x^{(7+i)} + b_6 * x^{(6+i)} + \dots + b_0 * x^i$
- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.

- Byte endianness within the NANDs 16-bit words is big endian. This means that the same message mapped in 8- and 16-bit memories has the same content at the same byte address.

Note: The BCH module has no visibility over actual addresses. The most important point is the sequence of data word the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, and this produces the mapping patterns described below.

The following tables represent the mapping of the same 512-byte vector (typically a BCH message) in the NANDs memory space. Note that the byte 'address' is only an offset modulo 512 (0x200), since the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are respectively the bits M0 and M(2¹²-1) of the codeword mapping given above. In both cases the data vectors are aligned, that is, their boundaries coincide with the RAMs data word boundaries.

Table 11-7. Aligned Message Byte Mapping in 8-bit NAND

Byte offset	8-bit word
0x000	(msb) Byte 511 (0x1FF)
0x001	Byte 510 (0x1FE)
...	...
0x1FF	Byte 0 (0x0) (lsb)

Table 11-8. Aligned Message Byte Mapping in 16-bit NAND

Byte offset	16-bit words MSB	16-bit words LSB
0x000	Byte 510 (0x1FE)	(msb) Byte 511 (0x1FF)
0x002	Byte 508 (0x1FC)	Byte 509 (0x1FD)
...
0x1FE	Byte 0 (0x0)	(lsb) Byte 1 (0x1)

The following tables show the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on another sectors ECC).

Table 11-9. Aligned Nibble Mapping of Message in 8-bit NAND

Byte offset	8-bit word	
	4-bit most significant Nibble	4-bit less significant Nibble
1	(msb) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...
S/2 - 2	Nibble 3	Nibble 2
S/2 - 1	Nibble 1	Nibble 0 (lsb)

Table 11-10. Misaligned Nibble Mapping of Message in 8-bit NAND

Byte offset	8-bit word	
	4-bit most significant Nibble	4-bit less significant Nibble
1	(msb) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...
$(S+1)/2 - 2$	Nibble 2	Nibble 1
$(S+1)/2 - 1$	Nibble 0 (lsb)	

Table 11-11. Aligned Nibble Mapping of Message in 16-bit NAND

Byte offset	16-bit word			
	4-bit most significant Nibble		4-bit less significant Nibble	
0	Nibble S-3	Nibble S-4	(msb) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...
$S/2 - 4$	Nibble 5	Nibble 4	Nibble 7	Nibble 6
$S/2 - 2$	Nibble 1	Nibble 0 (lsb)	Nibble 3	Nibble 2

Table 11-12. Misaligned Nibble Mapping of Message in 16-bit NAND (1 Unused Nibble)

Byte offset	16-bit word			
	4-bit most significant Nibble		4-bit less significant Nibble	
0	Nibble S-3	Nibble S-4	(msb) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...
$(S+1)/2 - 4$	Nibble 4	Nibble 3	Nibble 6	Nibble 5
$(S+1)/2 - 2$	Nibble 0 (lsb)		Nibble 2	Nibble 1

Table 11-13. Misaligned Nibble Mapping of Message in 16-bit NAND (2 Unused Nibbles)

Byte offset	16-bit word			
	4-bit most significant Nibble		4-bit less significant Nibble	
0	Nibble S-3	Nibble S-4	(msb) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...
$(S+2)/2 - 4$	Nibble 3	Nibble 2	Nibble 5	Nibble 4
$(S+2)/2 - 2$			Nibble 1	Nibble 0 (lsb)

Table 11-14. Misaligned Nibble Mapping of Message in 16-bit NAND (3 Unused Nibbles)

Byte offset	16-bit word			
	4-bit most significant Nibble		4-bit less significant Nibble	
0	Nibble S-3	Nibble S-4	(msb) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...
$(S+3)/2 - 4$	Nibble 2	Nibble 1	Nibble 4	Nibble 3
$(S+3)/2 - 2$			Nibble 0 (lsb)	

Note that many other cases exist than the ones represented above, for example, where the message does not start on a word boundary.

11.1.5.14.3.2.2 Memory-Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. It is up to the software to fetch those 13 bytes (or 6 ½ bytes) from the module's interface, then store them to the NAND's spare area (page write) or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is a software-controlled operation.

However, it is advised to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error has been detected. The creation of this codeword should be made as straightforward as possible.

There are cases where the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on-the-fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on-the-fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

11.1.5.14.3.2.3 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections, as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described below. To get a better understanding and see the real-life read and write sequences implemented with each mode, see [Section 11.1.5.14.3.2.3](#).

For each mode:

- a sequence describes the mode in pseudo-language, with for each section the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0 and size1.
- a checksum condition is given. If the checksum condition is not respected for a given mode, the module's behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

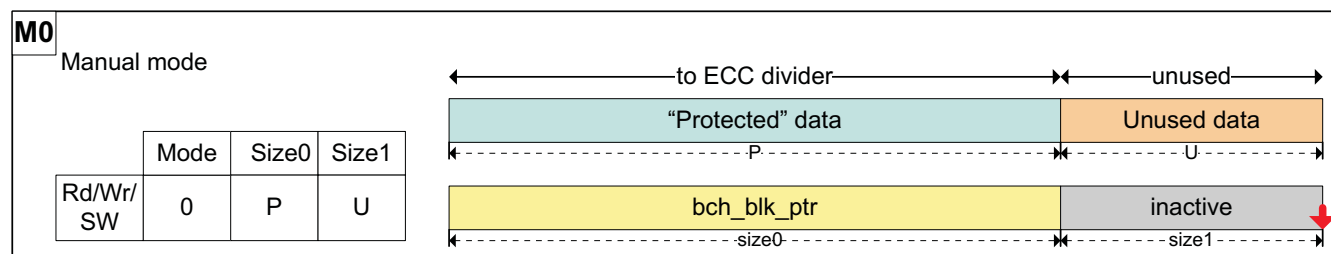

Note that wrapping modes 8, 9, 10, and 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for $t = 4$ ECC, where ECC is 6 ½ bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

11.1.5.14.3.2.3.1 Manual Mode (0x0)

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port shall be made, containing the appropriate data. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles need to be skipped, a number of unused nibbles shall be programmed in size1 (in the same example: 5 nibbles to process + 3 to discard = 8 nibbles = exactly 2 x 16-bit accesses: we must program size0 = 5, size1 = 3).

Note: In the following figures size and size0 are the same parameter.

Figure 11-32. Manual Mode Sequence and Mapping

gpmc-032

Section processing sequence:

- One time with buffer
 - size0 nibbles of data, processing ON
 - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

11.1.5.14.3.2.3.2 Mode 0x1

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + size1)

11.1.5.14.3.2.3.3 Mode 0xA (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
 - 1 nibble pad spare, processing OFF
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + 1 + size1)

11.1.5.14.3.2.3.4 Mode 0x2

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + size1)

11.1.5.14.3.2.2.3.5 Mode 0x3

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - size1)

11.1.5.14.3.2.2.3.6 Mode 0x7

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = size0 + (S - size1)

11.1.5.14.3.2.2.3.7 Mode 0x8

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - (1+size1))

11.1.5.14.3.2.2.3.8 Mode 0x4

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time (no buffer used)
 - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - size1)

11.1.5.14.3.2.2.3.9 Mode 0x9

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time (no buffer used)
 - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - (1+size1))

11.1.5.14.3.2.2.3.10 Mode 0x5

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + size1)

11.1.5.14.3.2.2.3.11 Mode 0xB (11)

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + 1 + size1)

11.1.5.14.3.2.2.3.12 Mode 0x6

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + size1)

11.1.5.14.3.2.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply throughout the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in [Section 11.1.5.14.3.2.2.1](#).

Each one of the following sections shows a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

A table on the left summarizes the mode, size0, size1 parameters to program for respectively write and read processing of a page, with the given mapping, where :

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC itself (in nibbles)
- S is the number of Sectors per page (2 in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. Note that the processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1kByte + spares, that is, S = 2 sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can only happen in the codeword that was actually written to the NAND, and not in the mathematical codeword of $n = 2^{13} - 1 = 8191$ bits. That codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, on the programmed sizes and on the sector number (all sizes in nibbles):

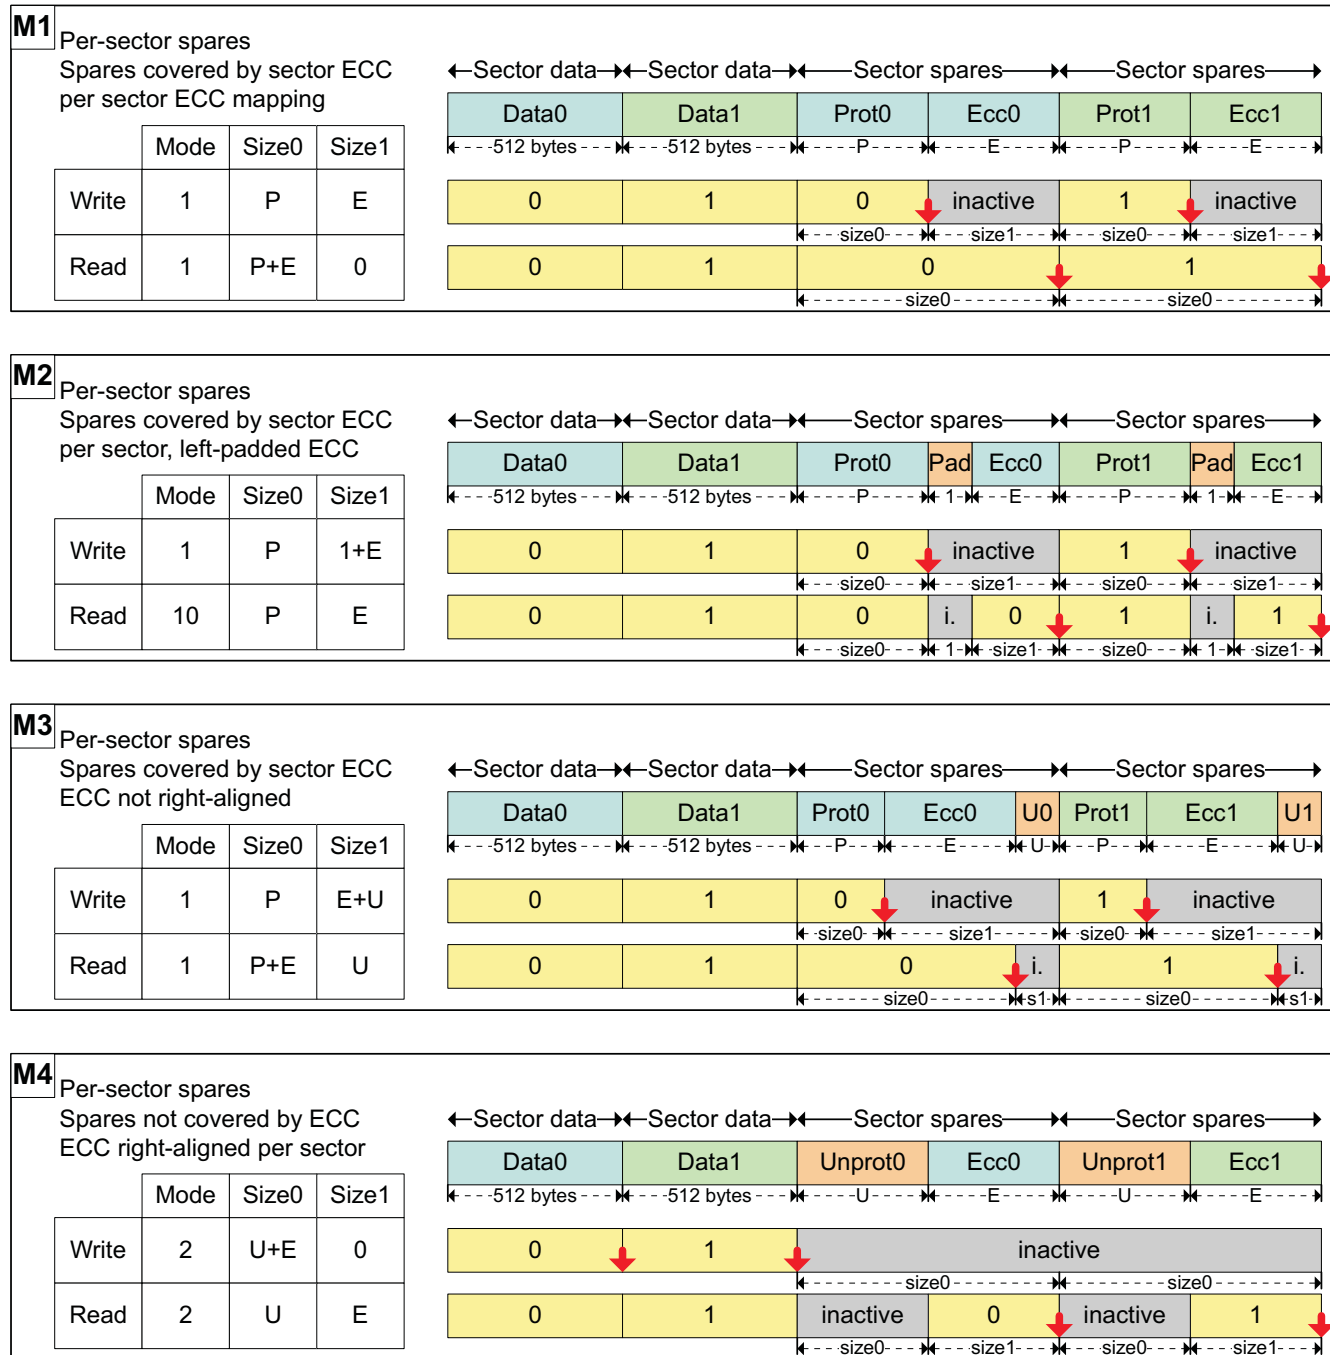

- Spares mapped and protected per sector (below: see M1-M2-M3-M9-M10):
 - all sectors: $(512) + P + E$
- Spares pooled and protected by sector 0 (below: see M5-M6):
 - sector 0 codeword: $(512) + P + E$
 - other sectors: $(512) + E$
- Unprotected spares (below: see M4-M7-M8-M11-M12):
 - all codewords $(512) + E$

11.1.5.14.3.2.3.1 Per-Sector Spare Mappings

In these schemes, each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of :

- ECC, which must be located after the data it protects
- other data, which may or may not be protected by the sectors ECC

Figure 11-33. NAND Page Mapping and ECC: Per-Sector Schemes

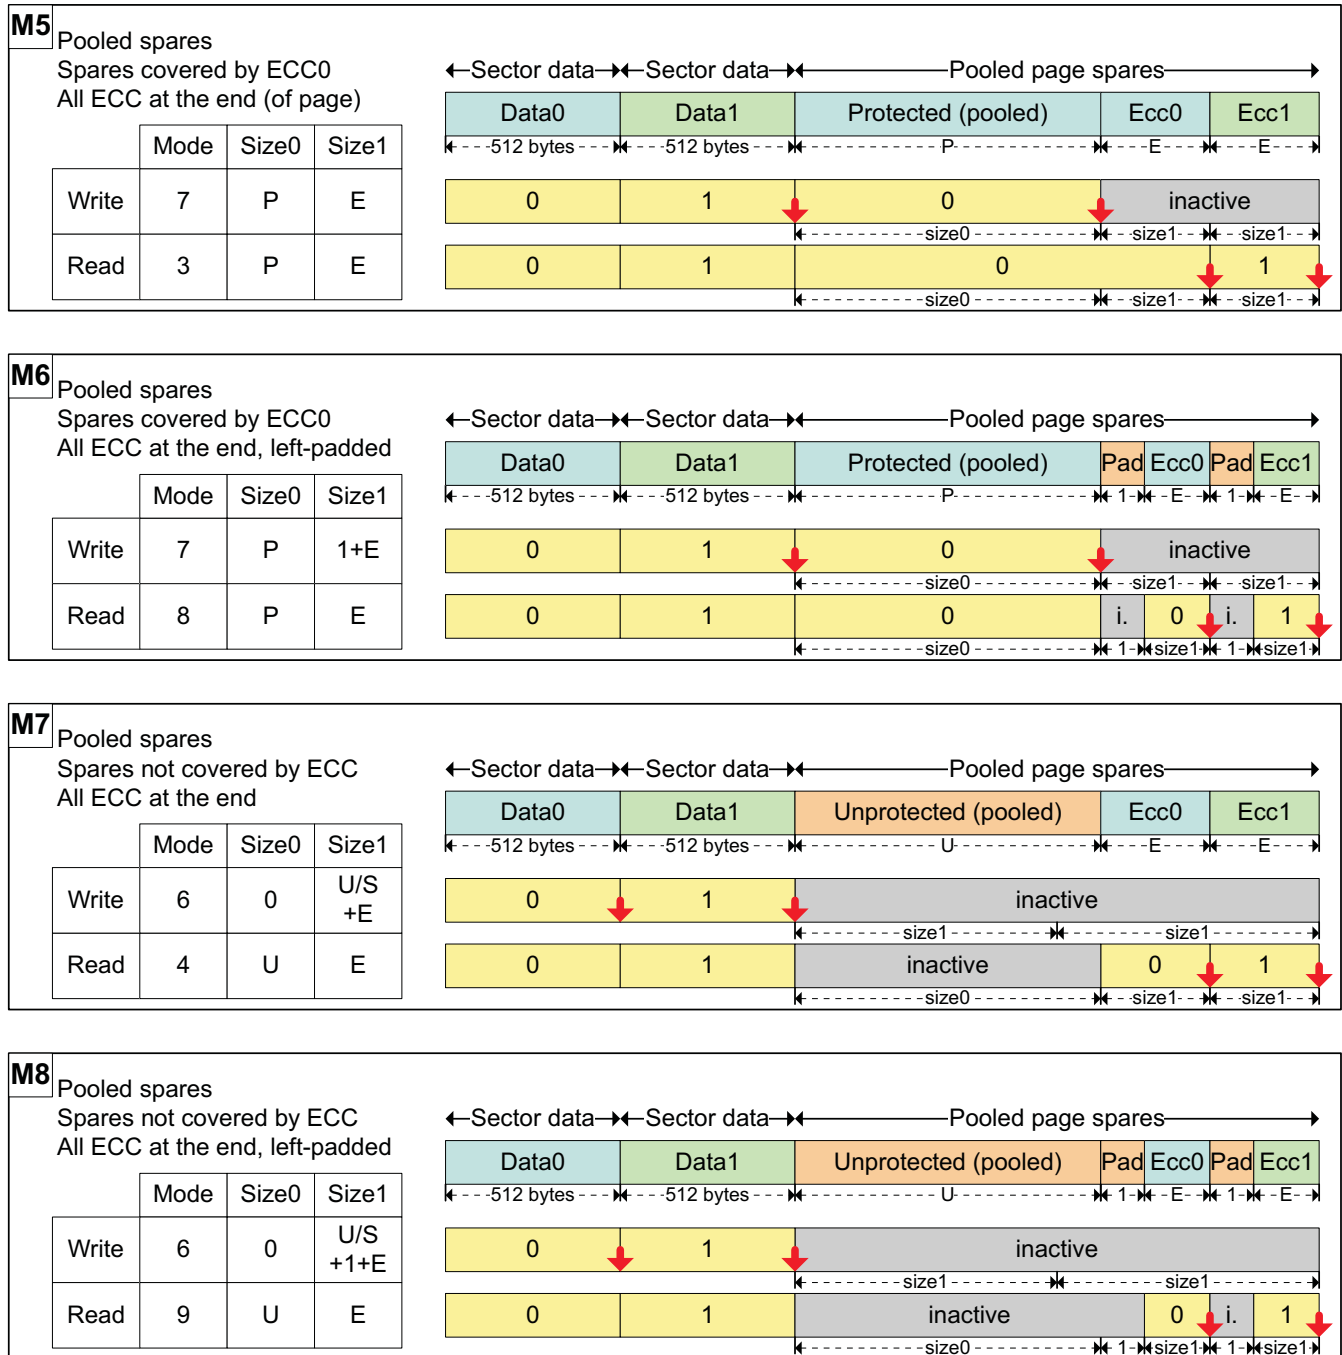

gpmc-033

11.1.5.14.3.2.3.2 Pooled Spare Mapping

In the schemes below, the spare area is pooled for the page.

- The ECC of each sector is aligned at the end of the spare area.
- The non-ECC spare data may or may not be covered by the ECC of sector 0

Figure 11-34. NAND Page Mapping and ECC: Pooled Spare Schemes

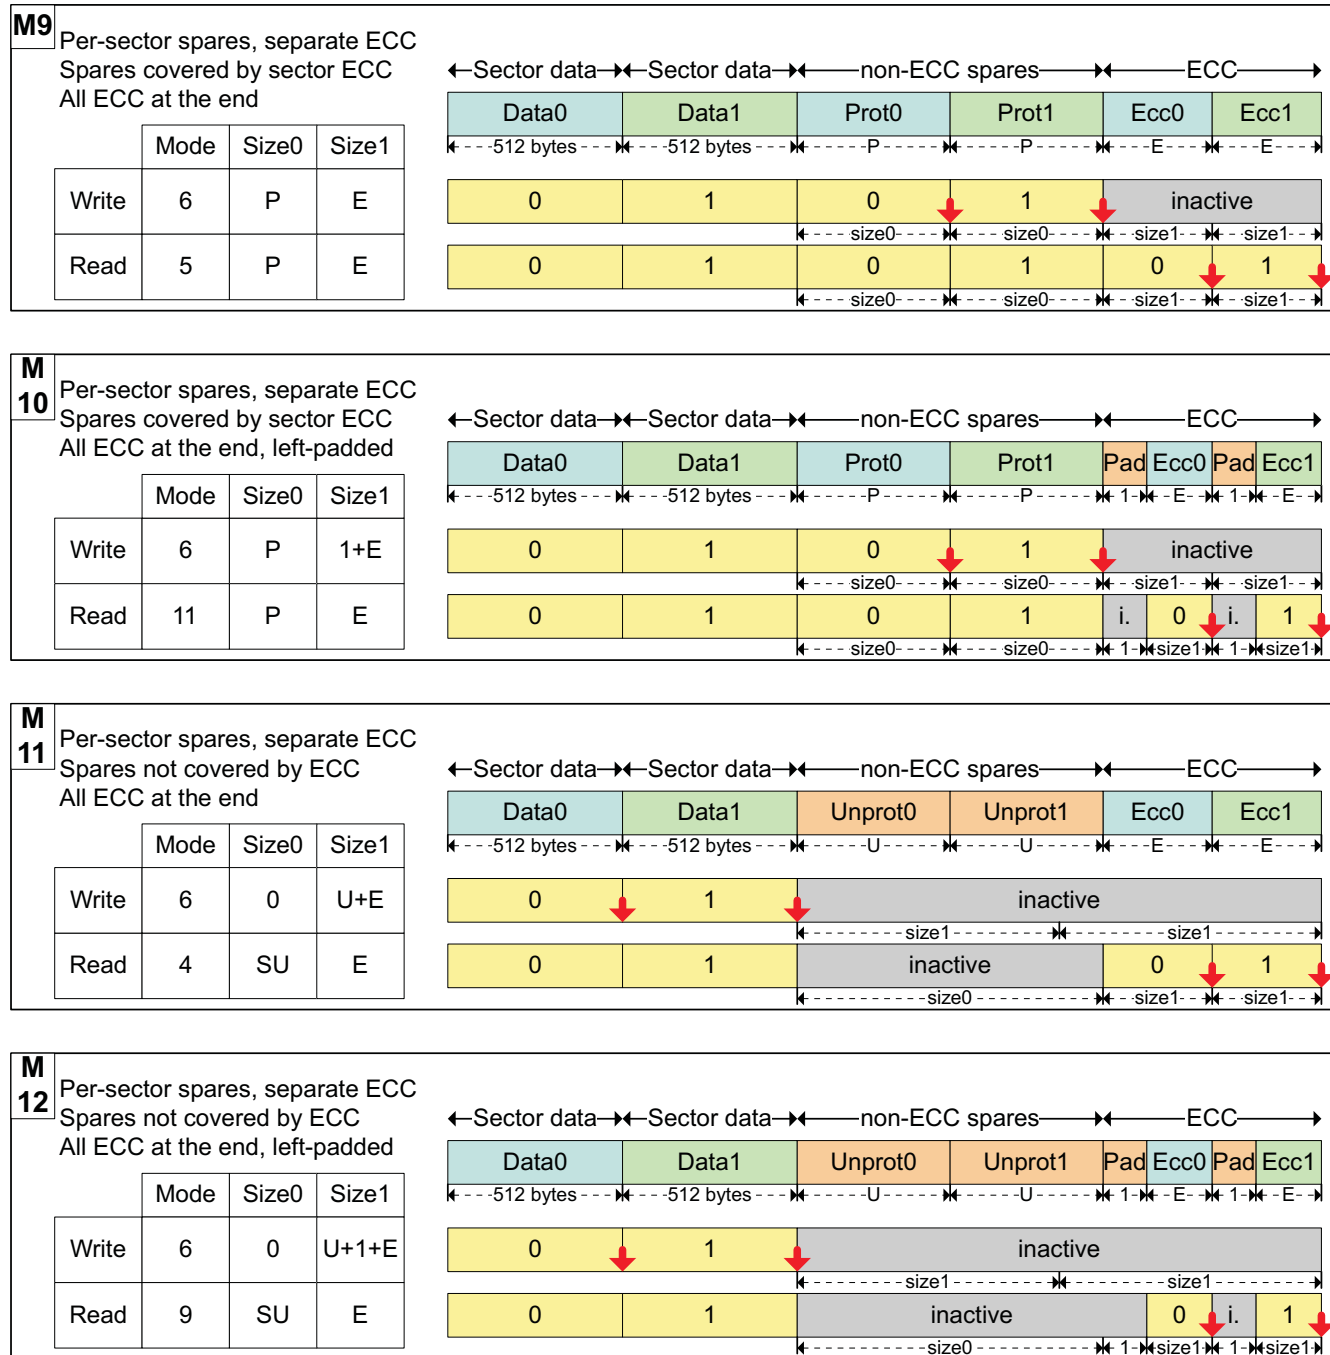

gpmc-034

11.1.5.14.3.2.3.3 Per-Sector Spare Mapping, with ECC Separated at the End of the Page

In these schemes, each 512-byte sector of the main area is associated with 2 sections of the spare area.

- ECC section, all aligned at the end of the page
- other data section, aligned before the ECCs, each of which may or may not be protected by its sectors ECC

Figure 11-35. NAND Page Mapping and ECC: Per-Sector Schemes, with Separate ECC

gpmc_035

11.1.5.14.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the MCU system frequency; such NAND read or write accesses issued by the processor will impact the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine uses an embedded 64 bytes (32 Word16) FIFO to prefetch data

from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled either by the MCU through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or the sDMA through DMA request synchronization, with a programmable request byte size in both prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. In consequence, it is limited to NAND data-stream access. The engine relies on the MCU NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, the engine data reads and writes sequencing is solely based on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the GPMC.GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the GPMC.GPMC_PREFETCH_CONFIG1[19:16] PFPWWEIGHTEDPRIO field.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access). The engine does not include an address generator, and the request is limited to chip-select target identification. The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

Note: The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

11.1.5.14.4.1 General Basic Programming Model

The engine can be configured only if the GPMC.GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is de-asserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the GPMC.GPMC_PREFETCH_CONFIG1[26:24] ENGINECSSELECTOR field.

In both prefetch and write-posting modes, the engine respectively uses byte or Word16 access requests for an 8- or 16-bit wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT fields must be programmed accordingly as a number of bytes or a number of Word16.

When the GPMC.GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE bit is set, the FIFO entry on the L3 interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through the GPMC.GPMC_NAND_COMMAND_i, GPMC.GPMC_NAND_ADDRESS_i, and GPMC.GPMC_NAND_DATA_i registers (where i = 0 to 7).

The FIFO entry on the L3 interconnect port can be accessed with Byte, Word16, or Word32 access size, according to little-endian format, even though the FIFO input is 32-bit wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC.GPMC_PREFETCH_STATUS[30:24] FIFOPINTER field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots which can be written in write-posting mode. The GPMC.GPMC_PREFETCH_STATUS[13:0] COUNTVALUE field monitors the number of remaining bytes to be read or written by the engine according to the TRANSFERCOUNT value. The FIFOPINTER and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPINTER equals 0, that is, the FIFO is empty, a host read access receives the byte last read from the FIFO as its response. In case of Word32 or Word16 read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPINTER equals 0, that is, the FIFO is full, a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

11.1.5.14.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC.GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is cleared.

The MCU NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC.GPMC_PREFETCH_CONTROL[0] STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (configured, reset, and enabled) before the prefetch engine is started, so that the ECC is correctly computed on all data read by the prefetch engine.

When the GPMC.GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it only sets the STARTENGINE bit when the NAND device is in a ready state, meaning data is valid for prefetching.

When the GPMC.GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active to inactive wait signal transition is detected. The transition detector must be cleared before any transition detection; see Section 11.1.5.14.2.2. The GPMC.GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR field selects which gpmc_wait pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit field before NAND address phase completion when in synchronized mode. The prefetch engine will start when an active to inactive wait signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to ensure that the FIFO is always filled with as much data as acceptable, until the programmed GPMC.GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT field is completed.

Table 11-15. Prefetch Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Prefetch engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 7	Selects the chip-select associated with a NAND device where the prefetch engine is active.
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request

Table 11-15. Prefetch Mode Configuration (continued)

Bit Field	Register	Value	Comments
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2 [13:0]		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1 [3]	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1 [17:16]	0 to 3	(If SynchroMode = 1) Selects wait pin edge detector
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1 [27]	0/1	See Section 11.1.5.14.4.6 .
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1 [30:28]		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1 [7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL [0]	1	Starts the prefetch engine

11.1.5.14.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by the MPU or by an sDMA channel.

In MPU draining mode, the FIFO status can be monitored through the [GPMC.GPMC_PREFETCH_STATUS](#)[30:24] FIFOPINTER field or through the [GPMC.GPMC_PREFETCH_STATUS](#)[16] FIFOTHRESHOLDSTATUS bit. The FIFOPINTER indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the [GPMC.GPMC_IRQENABLE](#)[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the [GPMC.GPMC_IRQSTATUS](#)[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must read all the available bytes, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the [GPMC.GPMC_PREFETCH_STATUS](#)[13:0] COUNTVALUE field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the [GPMC.GPMC_IRQENABLE](#)[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the [GPMC.GPMC_IRQSTATUS](#)[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

Note: The COUNTVALUE value is only valid when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the [GPMC.GPMC_PREFETCH_CONFIG1](#)[2] DMAMODE bit must be set so that

the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel owning this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

11.1.5.14.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC.GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is set.

The MCU NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC.GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MCU NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are properly calculated on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC.GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC.GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT accesses have been completed.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MCU NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must only be issued when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

Table 11-16. Write-Posting Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Write-posting engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 7	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	1	Selects write-posting mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request

Table 11-16. Write-Posting Mode Configuration (continued)

Bit Field	Register	Value	Comments
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2 [13:0]		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1 [3]	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1 [27]	0/1	See Section 11.1.5.14.4.6 .
CYCLOOPTIMIZATION	GPMC_PREFETCH_CONFIG1 [30:28]		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1 [7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL [0]	1	Starts the prefetch engine

11.1.5.14.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by the MPU or by an sDMA channel.

In MPU filling mode, the FIFO status can be monitored through the [FIFOPOINTER](#) or through the [GPMC.GPMC_PREFETCH_STATUS](#)[16] [FIFOTHRESHOLDSTATUS](#) bit. [FIFOPOINTER](#) indicates the current number of available free byte places in the FIFO, and the [FIFOTHRESHOLDSTATUS](#) bit, when set, indicates that at least [FIFOTHRESHOLD](#) free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the [GPMC.GPMC_IRQENABLE](#)[0] [FIFOEVENTENABLE](#) bit is set. When the interrupt is fired, the [GPMC.GPMC_IRQSTATUS](#)[0] [FIFOEVENTSTATUS](#) bit is set. To clear the interrupt, the MPU must write enough bytes to fill the FIFO, or enough bytes to get below the programmed threshold, and the [FIFOEVENTSTATUS](#) bit must be cleared to get further interrupt events. The [FIFOEVENTSTATUS](#) bit must always be cleared prior to asserting the [FIFOEVENTENABLE](#) bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the [STARTENGINE](#) bit.

The posting completion can be monitored through the [GPMC.GPMC_PREFETCH_STATUS](#)[13:0] [COUNTVALUE](#) field. [COUNTVALUE](#) indicates the current number of remaining data to be written based on the [TRANSFERCOUNT](#) value. An interrupt is issued by the GPMC when the write-posting process completes (that is, [COUNTVALUE](#) equal to 0) if the [GPMC.GPMC_IRQENABLE](#)[1] [TERMINALCOUNTEVENTENABLE](#) bit is set. When the interrupt is fired, the [GPMC.GPMC_IRQSTATUS](#)[1] [TERMINALCOUNTSTATUS](#) bit is set. To clear the interrupt, the MPU must clear the [TERMINALCOUNTSTATUS](#) bit. The [TERMINALCOUNTSTATUS](#) bit must always be cleared prior to asserting the [TERMINALCOUNTEVENTENABLE](#) bit to clear any out-of-date logged interrupt event.

Note: The [COUNTVALUE](#) value is only valid if the write-posting engine is active and started, and an interrupt is only issued when [COUNTVALUE](#) reaches 0, that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the [DMAMode](#) bit field in the [GPMC.GPMC_PREFETCH_CONFIG1](#)[2] [DMAMODE](#) bit must be set so that the GPMC issues a DMA hardware request when at least [FIFOTHRESHOLD](#) bytes-free places are available in the FIFO. The DMA channel owning this DMA request must be programmed so that a number of bytes equal to the value programmed in the [FIFOTHRESHOLD](#) bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request has been completed.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch ([STARTENGINE](#) set to 1). The associated DMA channel must always be enabled by the MPU after setting the [STARTENGINE](#) bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, the DMA or the MPU fill the FIFO with no consideration to the associated byte enables. Any byte stored in the FIFO is written into the memory device.

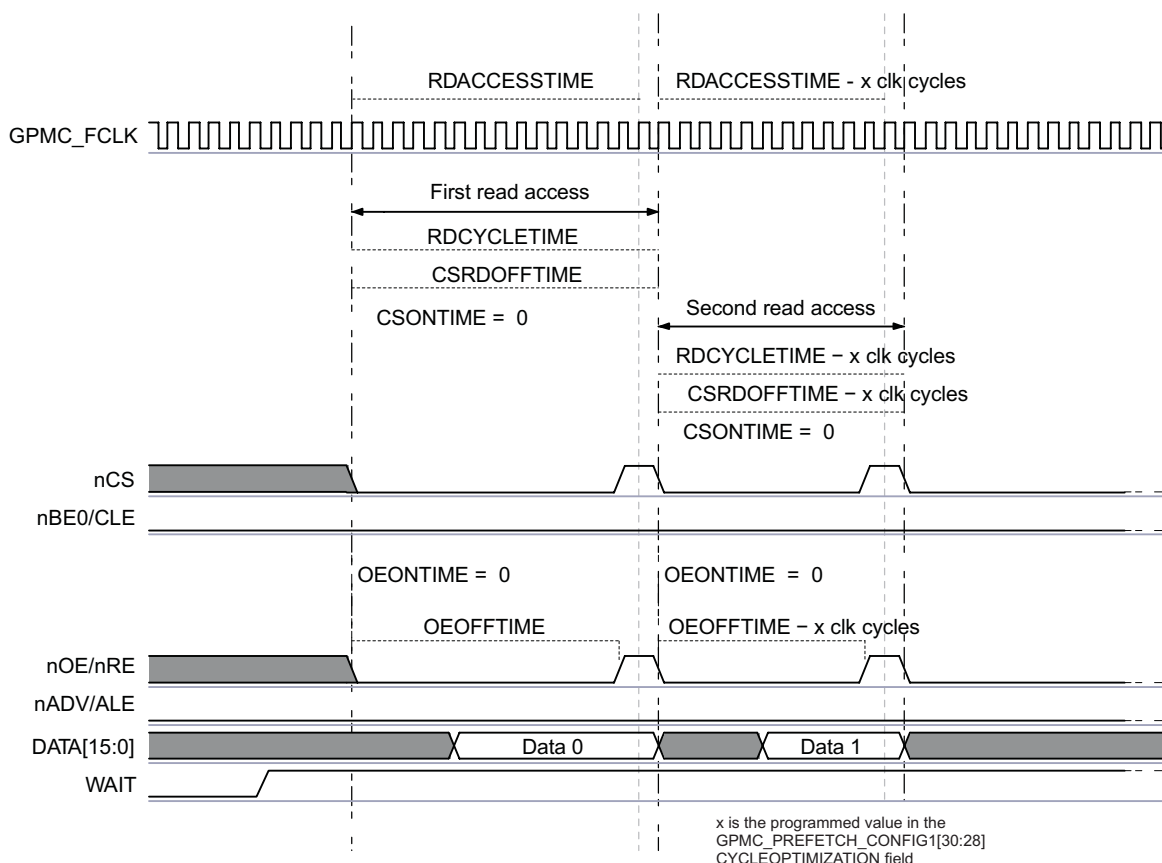

11.1.5.14.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated nCS signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates the CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMECSSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and MPU accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC.GPMC_NAND_DATA_i location, $i = 0$ to 7) are never optimized.

The GPMC.GPMC_PREFETCH_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC.GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION field defines the number of GPMC_FCLK cycles to be suppressed from the RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSOFFTIME, ADVOFFTIME, OEOFFTIME, and WEOFFTIME timing parameters.

Figure 11-36 highlights that, in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMECSSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION field.

Figure 11-36. NAND Read Cycle Optimization Timing Description

gpmc-036

11.1.5.14.4.7 Interleaved Accesses between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected to.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC.[GPMC_PREFETCH_CONFIG1](#)[23] PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC.[GPMC_PREFETCH_CONFIG1](#)[19:16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 0x2. Considering the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

11.1.6 GPMC Use Cases and Tips

11.1.6.1 How to Set GPMC Timing Parameters for Typical Accesses

11.1.6.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8-bit or 16-bit-width memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples show how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Manufacturer: NOR Flash
- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104 MHz clock frequency
- Read access time: 80 ns

11.1.6.1.2 Typical GPMC Setup

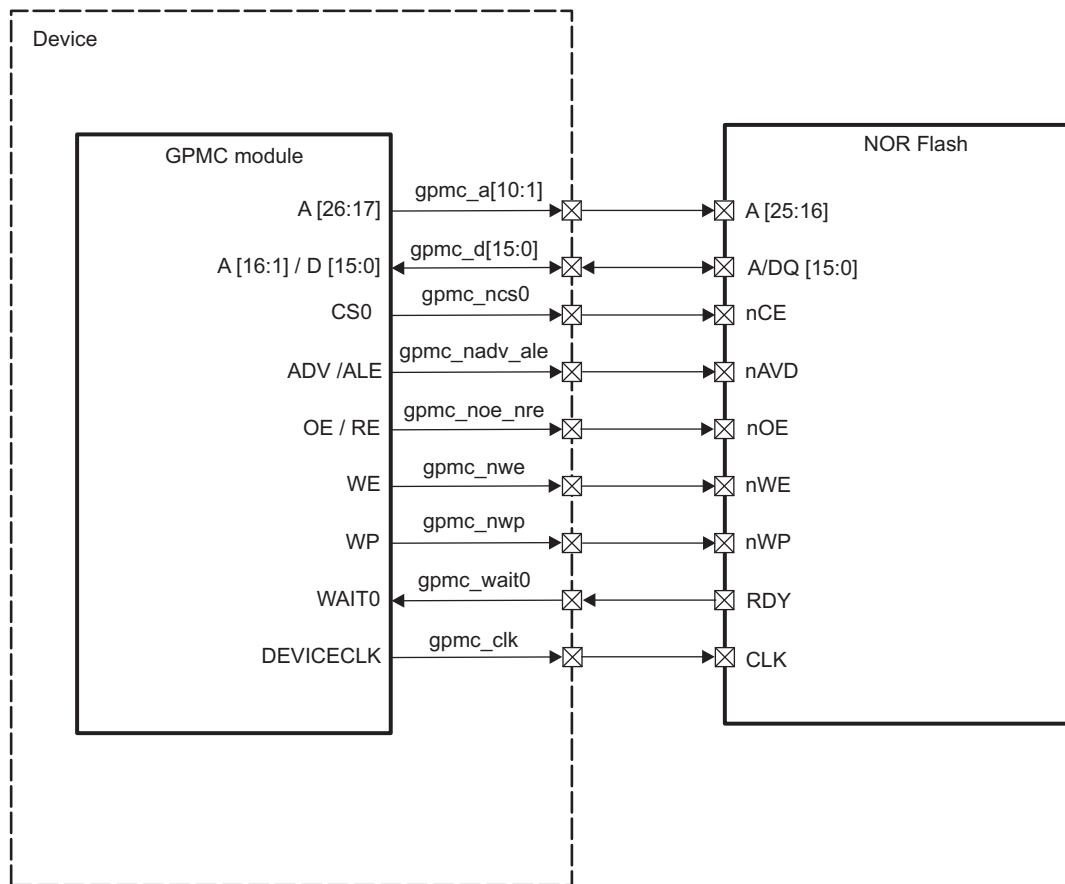

Table 11-17 lists some of the I/Os of the GPMC module.

Table 11-17. GPMC Signals

Signal Name	I/O	Description
GPMC_FCLK	Internal	Functional and interface clock. Acts as the time reference.
gpmc_clk	I/O	External clock provided to the external device for synchronous operations
gpmc_a[10: 1]	O	Address
gpmc_d[15: 0]	I/O	Data-multiplexed with addresses A[16:1] on memory side
gpmc_ncs	O	Chip-select
gpmc_nadv_ale	O	Address valid enable
gpmc_noe_nre	O	Output enable (read access only)
gpmc_nwe	O	Write enable (write access only)
gpmc_wait[3:0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

Figure 11-37 shows the typical connection between the GPMC module and the attached NOR Flash memory.

Figure 11-37. GPMC Connection to External NOR Flash Memory

gpmc_037

The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

11.1.6.1.2.1 GPMC Configuration for Synchronous Burst Read Access

The clock runs at 104 MHz ($f = 104 \text{ MHz}$; $T = 9,615 \text{ ns}$).

Table 11-18 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 11-19 shows how to calculate timings for the GPMC using the memory parameters.

Figure 11-38 shows the synchronous burst read access.

Table 11-18. Useful Timing Parameters on the Memory Side

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	nCS setup time to clock	0
tACS	Address setup time to clock	3
tIACC	Synchronous access time	80

Table 11-18. Useful Timing Parameters on the Memory Side (continued)

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tBACC	Burst access time valid clock to output delay	5,2
tCEZ	Chip-select to High-Z	7
tOEZ	Output enable to High-Z	7
tAVC	nADV setup time	6
tAVD	nAVD pulse	6
tACH	Address hold time from clock	3

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read Access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One burst of data is processed in one clock cycle ($T = 9,615$ ns). The read access time between 2 bursts of data is tBACC = 5,2 ns. Therefore, data setup time is a clock period - tBACC = 4,415 ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: nCS/nOE hold time (nCS and nOE must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read Access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

Table 11-19. Calculating GPMC Timing Parameters

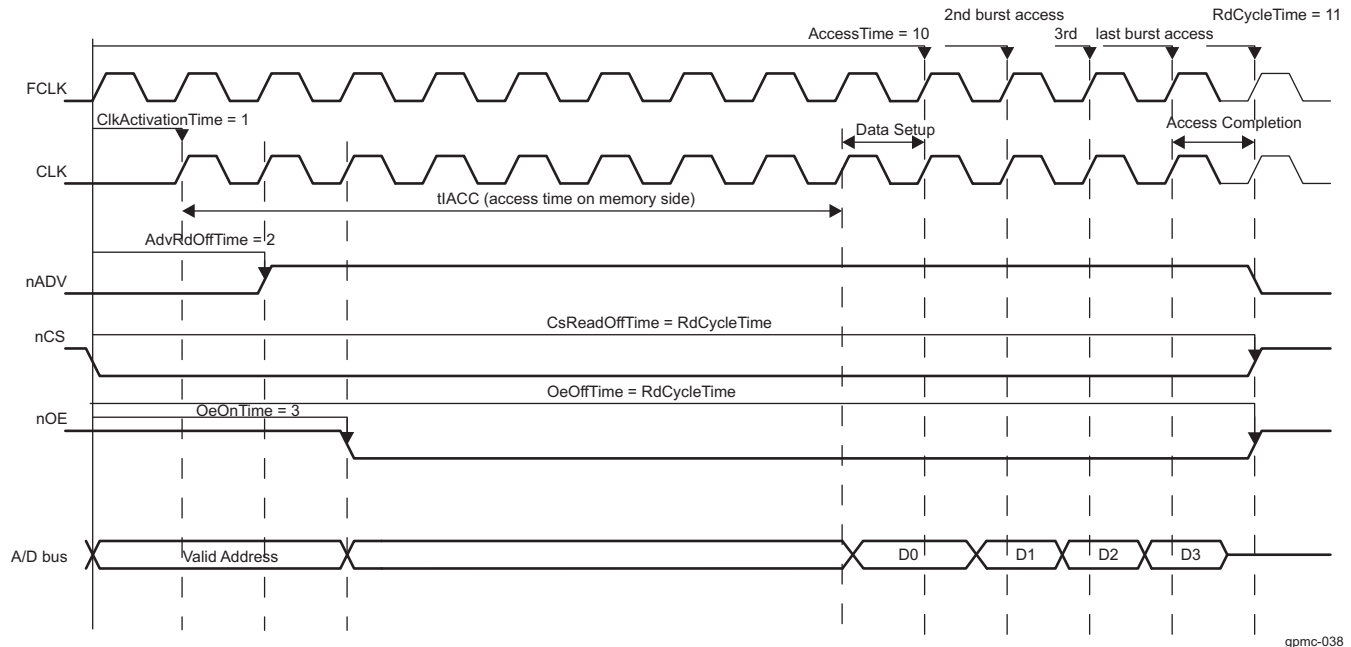

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime	min (tCES, tACS)	3	1	CLKACTIVATIONTIME = 0x1
RdAccessTime	roundmax (ClkActivationTime + tIACC + DataSetupTime)	94,03: (9,615 + 80 + 4,415)	10 : roundmax (94,03 / 9,615)	ACCESSTIME = 0x0A
PageBurstAccessTime	roundmax (tBACC)	roundmax (5,2)	1	PAGEBURSTACCESSTIME = 0x1
RdCycleTime	AccessTime + max (tCEZ, tOEZ)	101, 03: (94, 03 + 7)	11	RDCYCLETIME = 0x0B
CsOnTime	tCES	0	0	CSONTIME = 0x0
CsReadOffTime	RdCycleTime	-	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAVC ⁽¹⁾	0	0	ADVONTIME = 0x0
AdvRdOffTime	tAVD + tAVC ⁽²⁾	12	2	ADVRDOFFTIME = 0x02
OeOnTime ⁽³⁾	(ClkActivationTime + tACH) < OeOnTime < (ClkActivationTime + tIACC)	-	3 for instance.	OEONTIME = 0x3
OeOffTime	RdCycleTime	-	11	OEOFFTIME = 0x0B

⁽¹⁾ The external clock provided to the NOR flash is not yet available.

⁽²⁾ AdvRdOffTime - AdvOnTime = tAVD; thus, AdvRdOffTime = tAVD + AdvOnTime = tAVD + tAVC.

⁽³⁾ OeOnTime must guarantee that addresses are available. It must not exceed the availability of the first burst of data.

Figure 11-38. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)

gpmc-038

11.1.6.1.2.2 GPMC Configuration for Asynchronous Read Access

The clock runs at 104 MHz ($f = 104 \text{ MHz}$; $T = 9,615 \text{ ns}$).

Table 11-20 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 11-21 shows how to calculate timings for the GPMC using the memory parameters.

Figure 11-39 shows the asynchronous read access.

Table 11-20. AC Characteristics for Asynchronous Read Access

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from nCS low	80
tAAVDS	Address setup time to rising edge of nADV	3
tAVDP	nADV low time	6
tCAS	nCS setup time to nADV	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Z	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

$$\text{RdCycleTime} = \text{RdAccessTime} + \text{AccessCompletion} = \text{RdAccessTime} + 1 \text{ clock cycle} + \text{tOEZ}$$

- First, on the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 11-20: the number of clock cycles between the address capture (nADV rising edge) and the data valid on the output bus.
The GPMC side requires some hold to allow the data to be captured correctly and the access to be finished.
- To read the data correctly, the GPMC must capture it with enough data setup time; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
- There must also be a data hold time for correctly reading the data (checking that there is no nOE/nCS deassertion while reading the data). This data hold time is 1 clock cycle (AccessTime + 1).

- To complete the access, nOE/nCS signals are driven to High-Z. AccessTime + 1 + tOEZ is the read cycle time.
- Addresses can now be relatched and a new read cycle begun.

Table 11-21. GPMC Timing Parameters for Asynchronous Read Access

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime		n/a (asynchronous mode)		
AccessTime	round max (tCE)	80	9	ACCESSTIME = 0x09
PageBurstAccess Time	n/a (single access)			
RdCycleTime	AccessTime + 1cycle + tOEZ	96, 615	11	RDCYCLETIME = 0x0B
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsReadOffTime	AccessTime + 1 cycle	89, 615	10	CSRDOFFTIME = 0x0A
AdvOnTime	tAAVDS	3	1	ADVONTIME = 0x1
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVROFFTIME = 0x01
OeOnTime	OeOnTime >= AdvRdOffTime (multiplexed mode)	-	3 for instance	OEONTIME = 0x3
OeOffTime	AccessTime + 1cycle	89, 615	10	OEOFFTIME = 0x0A

Figure 11-39. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)

gpmc-039

11.1.6.1.2.3 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9, 615 ns).

Table 11-23 shows how to calculate timings for the GPMC using the memory parameters.

Table 11-22 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 11-40 shows the synchronous burst write access.

Table 11-22. AC Characteristics for Asynchronous Single Write (Memory Side)

AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60

Table 11-22. AC Characteristics for Asynchronous Single Write (Memory Side) (continued)

AC Characteristics on the Memory Side	Description	Duration (ns)
tAVDP	nADV low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20
tCS	nCS setup time to nWE	3
tCAS	nCS setup time to nADV	0
tAVSC	nADV setup time	3

For asynchronous single write access, write cycle time is $WrCycleTime = WeOffTime + AccessCompletion$ = $WeOffTime + 1$. For the AccessCompletion: 1 cycle is required for data hold time (nCS deassertion).

Table 11-23. GPMC Timing parameters for Asynchronous Single Write

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Registers Configuration
ClkActivationTime		n/a (asynchronous mode)		
AccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime		n/a (single access)		
WrCycleTime	WeOffTime + AccessCompletion	57, 615	6	WRCYCLETIME = 0x06
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsWrOffTime	WeOffTime + 1	57, 615	6	CSWROFFTIME = 0x06
AdvOnTime	tAVSC	3	1	ADVONTIME = 0x1
AdvWrOffTime	tAVSC + tAVDP	9	1	ADVWROFFTIME = 0x01
WeOnTime	tCS	3	1	WEONTIME = 0x1
WeOffTime	tCS + tWP + tWPH	48	5	WEOFFTIME = 0x05

Figure 11-40. Asynchronous Single Write Access (Timing Parameters in Clock Cycles)

gpmc-040

11.1.6.2 How to Choose a Suitable Memory to use with the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

11.1.6.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or device, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit width asynchronous or synchronous memory or device (8-bit: non burst device only)
- 16-bit address and data multiplexed NOR flash devices (pSRAM, OneNAND™, ...)
- 8- and 16-bit NAND flash device

Note: Non-multiplexed NOR flash devices are supported by the GPMC but their usage is highly limited. As only ten address pins are available on the GPMC interface, the maximum device size supported is 2KB.

11.1.6.2.1.1 Memory Pin Multiplexing

This section highlights the interfacing differences of the GPMC supported memories.

Table 11-24. Supported Memories Interfaces

Function	16-bit Address/Data muxed pSRAM or NOR Flash ⁽¹⁾	OneNAND	16-bit NAND	8-bit NAND
gpmc_a10	A26			
gpmc_a9	A25

gpmc_nwp	nWP (Write Protect)		nWP (Write Protect)	
gpmc_wait0	WAIT0		R/nB0 (Ready/Busy)	
gpmc_wait1	WAIT1		R/nB1	
gpmc_wait2	WAIT2		R/nB2	
gpmc_wait3	WAIT3		R/nB3	

11.1.6.2.1.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device, i.e. read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Thanks to its high density NAND is best suited to devices requiring high capacity data storage, such as pictures, music, or data files. NAND non-volatility, makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 11-25 summarizes the NAND interface signals level applied to external device or memories.

Table 11-25. NAND Interface Bus Operations Summary

Bus operation	CLE	ALE	nCE	nWE ⁽¹⁾	nRE ⁽¹⁾	nWP
Read (cmd input)	H	L	L	RE	H	x
Read (add input)	L	H	L	RE	H	x
Write (cmd input)	H	L	L	RE	H	H
Write (add input)	L	H	L	RE	H	H
Data input	L	L	L	RE	H	H
Data output	L	L	L	H	FE	x
Busy (during read)	x	x	H ⁽²⁾	H ⁽²⁾	H ⁽²⁾	x
Busy (during program)	x	x	x	x	x	H
Busy (during erase)	x	x	x	x	x	H
Write protect	x	x	x	x	x	L
Stand-by	x	x	H	x	x	H/L ⁽³⁾

⁽¹⁾ RE stands for rising edge, FE stands for falling edge

⁽²⁾ Can be either nCE high, or WE and nRE high.

⁽³⁾ nWP should be biased to CMOS high or CMOS low for standby

11.1.6.2.1.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND which is a sequential access device, NOR is directly addressable, i.e. is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities it has slow write and erase functions compared to NAND architecture.

Table 11-26 summarizes the NOR interface signals level applied to external device or memories.

Table 11-26. NOR Interface Bus Operations Summary

Bus operation	CLK	nADV	nCS	nOE	nWE	WAIT	DQ[15:0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

11.1.6.2.1.4 Other Technologies

Other supported device type interact with the GPMC through the NOR interface protocol.

OneNAND™ is a high density and low-power memory device. OneNAND™ is based on single- or multi-level-cell NAND core with SRAM and logic, and interfaces as a synchronous NOR Flash, plus has synchronous write capability. It reads faster than conventional NAND and write faster than conventional NOR flash. Hence, it is appropriate for both mass storage and code storage.

pSRAM stands for pseudo-static random access memory. pSRAM is a low-power memory device for mobile applications. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR Flash, plus has synchronous write capability.

11.1.6.2.2 GPMC Features and Settings

This section lists GPMC features and settings:

- Supported device type: up to eight NAND or NOR protocol external memories or devices
- Operating Voltage: 1.8V;
- Maximum operating frequency provided externally: up to 100MHz (single device) with an L3-clock of 100MHz. Up to 83MHz (L3-clock divided by two) with an L3-clock of 166MHz. See the device-specific Data Manual for precise information.
- Maximum GPMC addressing capability: 1 GByte divided into eight chip-selects
- Maximum supported memory size: 256 MBytes (must be a power-of-2)
- Minimum supported memory size: 16 MBytes (must be a power-of-2). Aliasing occurs when addressing smaller memories.
- Data path to external memory or device: 8- and 16-bit wide
- Burst and page access: burst of 4-8-16 Word16
- Supports bus keeping
- Supports bus turn around

11.1.7 GPMC Registers

This section provides information about the GPMC instance in this product. [Table 11-28](#) provides a summary of the GPMC registers. The remaining parts of this section describe the registers within the module instance.

Table 11-27. Instance Summary

Module Name	Base Address	Size
GPMC	0x6E00 0000	16 Mbytes

11.1.7.1 GPMC Register Mapping Summary

11.1.7.2 GPMC Register Descriptions

Note: All GPMC registers are aligned to 32-bit address boundaries. All register file accesses, except to [GPMC_NAND_DATA_i](#) register, are little endian. If the [GPMC_NAND_DATA_i](#) register location is accessed, the endianness is access-dependent.

Description	The GPMC_ERR_TYPE register stores the type of error when an error occurs																																	
Type	RW																																	
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
RESERVED																ILLEGALMCMD						RESERVED			ERRORNOTSUPPADD		ERRORNOTSUPPMCMD		ERRORTIMEOUT		RESERVED		ERRORVALID	
Bits	Field Name		Description																Type		Reset													
31:11	RESERVED		Write 0s for future compatibility. Read returns 0s.																RW		0x000000													
10:8	ILLEGALMCMD		System Command of the transaction that caused the error																R		0x0													
7:5	RESERVED		Write 0s for future compatibility. Read returns 0s.																RW		0x0													
4	ERRORNOTSUPPADD		Not supported Address error 0x0: No error occurs 0x1: The error is due to a non supported Address																R		0x0													
3	ERRORNOTSUPPMCMD		Not supported Command error 0x0: No error occurs 0x1: The error is due to a non supported Command																R		0x0													
2	ERRORTIMEOUT		Time-out error 0x0: No error occurs 0x1: The error is due to a time out																R		0x0													
1	RESERVED		Write 0s for future compatibility. Read returns 0.																RW		0x0													
0	ERRORVALID		Error validity status - Must be explicitly cleared with a write 1 transaction 0x0: All error fields no longer valid 0x1: Error detected and logged in the other error fields																RW		0x0

11.1.7.2.8 GPMC_CONFIG

Table 11-43. GPMC_CONFIG

Address Offset	0x0000 0050		
Physical Address	0x6E00 0050	Instance	GPMC
Description	The configuration register allows global configuration of the GPMC		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																WAIT3PINPOLARITY				WAIT2PINPOLARITY				WAIT1PINPOLARITY				WAIT0PINPOLARITY			
																RESERVED				WRITEPROTECT				RESERVED				LIMITEDADDRESS			
																												NANDFORCEPOSTEDWRITE			

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00000
11	WAIT3PINPOLARITY	Selects the polarity of input pin WAIT3 0x0: WAIT3 active low 0x1: WAIT3 active high	RW	0x1
10	WAIT2PINPOLARITY	Selects the polarity of input pin WAIT2 0x0: WAIT2 active low 0x1: WAIT2 active high	RW	0x0
9	WAIT1PINPOLARITY	Selects the polarity of input pin WAIT1 0x0: WAIT1 active low 0x1: WAIT1 active high	RW	0x1
8	WAIT0PINPOLARITY	Selects the polarity of input pin WAIT0 0x0: WAIT0 active low 0x1: WAIT0 active high	RW	0x0
7:5	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
4	WRITEPROTECT	Controls the WP output pin level 0x0: WP output pin is low 0x1: WP output pin is high	RW	0x0
3:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
1	LIMITEDADDRESS	Limited Address device support 0x0: No effect 0x1: A26-A11 are not modified during an external memory access.	RW	0x0

Bits	Field Name	Description	Type	Reset
0	NANDFORCEPOSTEDWRITE	Enables the Force Posted Write feature to NAND Cmd/Add/Data location 0x0: Disables Force Posted Write 0x1: Enables Force Posted Write	RW	0x0

Bits	Field Name	Description	Type	Reset
31	WRAPBURST	Enables the wrapping burst capability. Must be set if the attached device is configured in wrapping burst 0x0: Synchronous wrapping burst not supported 0x1: Synchronous wrapping burst supported	RW	0x0
30	READMULTIPLE	Selects the read single or multiple access 0x0: Single access 0x1: Multiple access (burst if synchronous, page if asynchronous)	RW	0x0
29	READTYPE	Selects the read mode operation 0x0: Read Asynchronous 0x1: Read Synchronous	RW	0x0

Bits	Field Name	Description	Type	Reset
28	WRITEMULTIPLE	Selects the write single or multiple access 0x0: Single access 0x1: Multiple access (burst if synchronous, considered as single if asynchronous)	RW	0x0
27	WRITETYPE	Selects the write mode operation 0x0: Write Asynchronous 0x1: Write Synchronous	RW	0x0
26:25	CLKACTIVATIONTIME	Output GPMC_CLK activation time 0x0: First rising edge of GPMC_CLK at start access time 0x1: First rising edge of GPMC_CLK one GPMC_FCLK cycle after start access time 0x2: First rising edge of GPMC_CLK two GPMC_FCLK cycles after start access time 0x3: Reserved	RW	0x0
24:23	ATTACHEDDEVICEPAGE LENGTH	Specifies the attached device page (burst) length 0x0: 4 Words 0x1: 8 Words 0x2: 16 Words 0x3: Reserved (1 Word = Interface size)	RW	0x0
22	WAITREADMONITORING	Selects the Wait monitoring configuration for Read accesses (Reset value is BOOTWAITEN input pin sampled at IC reset) 0x0: Wait pin is not monitored for read accesses 0x1: Wait pin is monitored for read accesses	RW	0x-
21	WAITWRITEMONITORING	Selects the Wait monitoring configuration for Write accesses 0x0: Wait pin is not monitored for write accesses 0x1: Wait pin is monitored for write accesses	RW	0x0
20	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
19:18	WAITMONITORINGTIME	Selects input pin Wait monitoring time 0x0: Wait pin is monitored with valid data 0x1: Wait pin is monitored one GPMC_CLK cycle before valid data 0x2: Wait pin is monitored two GPMC_CLK cycle before valid data 0x3: Reserved	RW	0x0
17:16	WAITPINSELECT	Selects the input WAIT pin for this chip-select (Reset value is BOOTWAITSELECT input pin sampled at IC reset for CS0 and 0 for CS1-7) 0x0: Wait input pin is WAIT0 0x1: Wait input pin is WAIT1 0x2: Wait input pin is WAIT2 0x3: Wait input pin is WAIT3	RW	0x-
15:14	RESERVED	Write 0s for future compatibility. Reads returns 0	RW	0x0
13:12	DEVICESTYPE	Selects the device size attached (Reset value is BOOTDEVICESTYPE input pin sampled at IC reset for CS0 and 0x1 for CS1 to CS7) 0x0: 8 bit 0x1: 16 bit 0x2: Reserved 0x3: Reserved	RW	0x-

Bits	Field Name	Description	Type	Reset
11:10	DEVICETYPE	Selects the attached device type 0x0: NOR Flash like, asynchronous and synchronous devices 0x1: Reserved 0x2: NAND Flash like devices, stream mode 0x3: Reserved	RW	0x0
9	MUXADDDATA	Enables the Address and data multiplexed protocol (Reset value is CS0MUXDEVICE input pin sampled at IC reset for CS0 and 0 for CS1-7) 0x0: Non Multiplexed attached device 0x1: Address and data multiplexed attached device	RW	0x-
8:5	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
4	TIMEPARAGRANULARITY	Signals timing latencies scalar factor (Rd/WrCycleTime, Rd/WrAccessTime, PageBurstAccessTime, CSOnTime, CSRd/WrOffTime, ADVOnTime, ADVRd/WrOffTime, OEOnTime, OEOffTime, WEOOnTime, WEOffTime, Cycle2CycleDelay, BusTurnAround, TimeOutStartValue) 0x0: x1 latencies 0x1: x2 latencies	RW	0x0
3:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
1:0	GPMCFCLKDIVIDER	Divides the GPMC_FCLK clock 0x0: GPMC_CLK frequency = GPMC_FCLK frequency 0x1: GPMC_CLK frequency = GPMC_FCLK frequency / 2 0x2: GPMC_CLK frequency = GPMC_FCLK frequency / 3 0x3: GPMC_CLK frequency = GPMC_FCLK frequency / 4	RW	0x0

11.2 SDRAM Controller (SDRC) Subsystem

This section describes the SDRAM controller (SDRC) subsystem of the OMAP35x Applications Processor.

11.2.1 SDRC Subsystem Overview

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

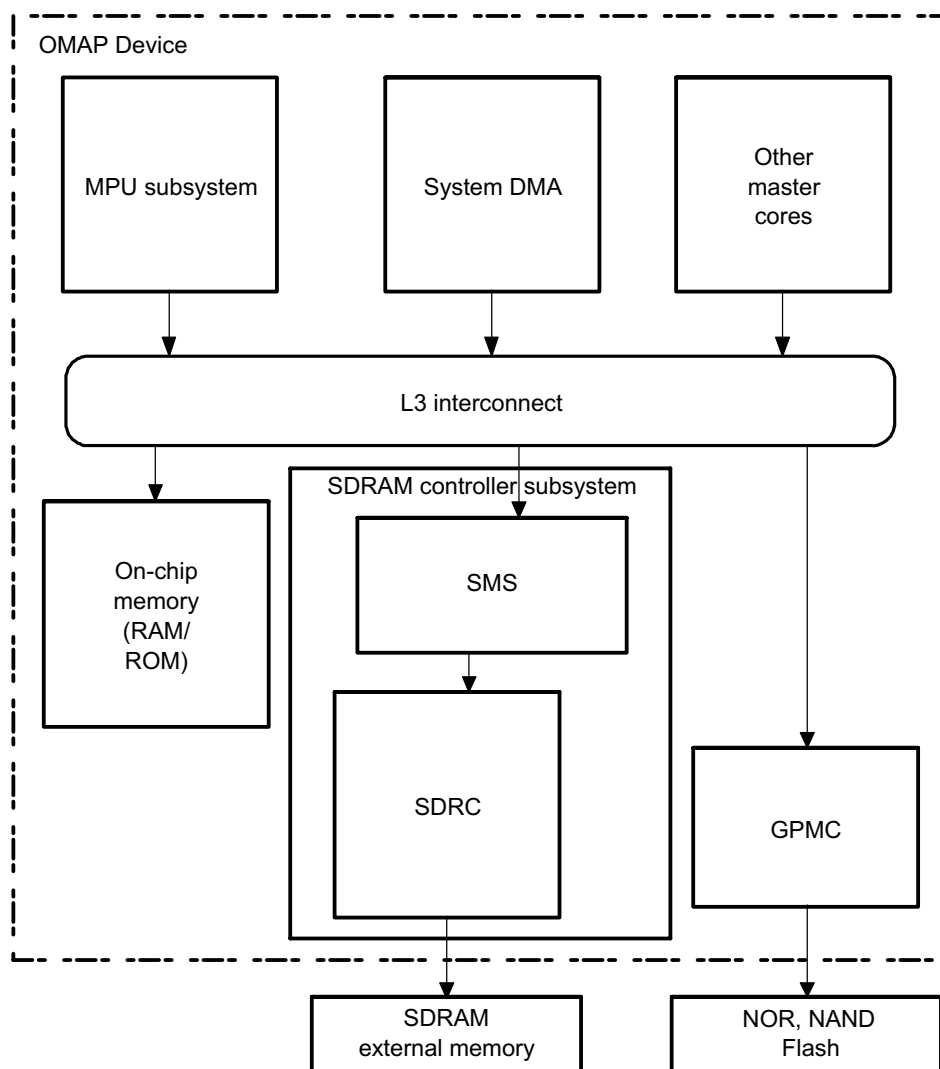

The SDRC subsystem module provides connectivity between the OMAP Applications Processor and external discrete or POP-ed low-power double-data-rate SDRAM (LPDDR).

The SDRC subsystem provides a high-performance interface to a variety of fast memory devices. It comprises two submodules:

- The SDRAM Memory Scheduler (SMS), consisting of scheduler, security firewall, and virtual rotated frame-buffer (VRFB) modules.
- The SDRC.

[Figure 11-41](#) shows the SDRC subsystem environment.

Note: For DDR connectivity, refer to the device specific data manual.

Figure 11-41. SDRC Subsystem Environment

sdrc-001

11.2.1.1 Features

The main features of the SDRC subsystem module are:

- Security firewall
 - Eight regions can be defined.
 - Independently programmable read/write access control
 - Independently programmable security control
- VRFB module
 - Minimizes SDRAM page-miss penalty when accessing graphics buffer in nonnatural raster-scan order
 - Supports rotations of 0, 90, 180, and 270 degrees
 - Transparent to software applications
 - 12 concurrent rotation contexts
- Memory-access scheduler
 - Optimizes latency and bandwidth usage between initiators
 - Supports secure transactions controlled by security firewall

- Per-system initiator group quality-of-service (QoS) control
- $8 \times 8 \times 64$ request queue FIFO for optimal scheduling
- Programmable arbitration scheme
- Focus on real-time memory processes (LCD display, camera interface)
- Focus on MPU/DSP memory latency
- Fair arbitration between other system initiators (DMAs, video subsystem, SGX accelerator)
- Exclusive read-write transaction support
- Region-based security firewall in accordance with OMAP Applications Processor security management
- SDRAM Controller
 - Support for two independent CSs, with their corresponding register sets, and independent page tracking
 - Supports the following memory type:
 - Low-Power Double Data Rate SDRAM (LPDDR)
 - Memory device capacity:
 - 16 Mbits, 32 Mbits, 64 Mbits, 128 Mbits, 256 Mbits, 512 Mbits, 1 Gbit, and 2 Gbits device support
 - Memory device organization
 - 2-bank support for 16 Mbits and 32 Mbits
 - 4-bank support for 64 Mbits to 2 Gbits
 - Flexible row/column address multiplexing schemes
 - Bank linear addressing
 - 16- or 32-bit data path to external SDRAM memory
 - 1 Gbyte maximum addressing capability
 - Device driver strength feature for mobile DDR supported
 - New flexible address-muxing scheme lets users choose different bank mapping allocations by configuring the bank and column address decoding ordering.
 - Fully pipelined operation for optimal memory bandwidth usage
 - Burst support
 - Memory burst support
 - System burst for mobile DDR SDRAM: system burst translated into memory burst size of 4
 - Read interrupt by read, write interrupt by write
 - CAS latency support 1, 2, 3, 4, 5
 - Fully programmable ac timing parameters (on a per-parameter basis). Parameters are set according to the memory interface clock frequency with respect to the attached memory device timing specifications.
 - Fine tuning of the controlled delay elements when operating with DDR memory
 - Dynamic endianness support
 - 9×64 bit lookahead FIFO in the SDRAM controller with a maximum of four transaction entries
 - Low-power management support
 - Dynamic power-saving features (internal clock gating)
 - Static power-saving features
 - Support for all standard low-power memory features
 - Support for enhanced low-power features (mobile devices)
 - Very low-power controlled-delay technology for optimal performance with DDR memory
 - Can operate with mobile DDR memory at very low clock rates
 - Autorefresh and self-refresh management

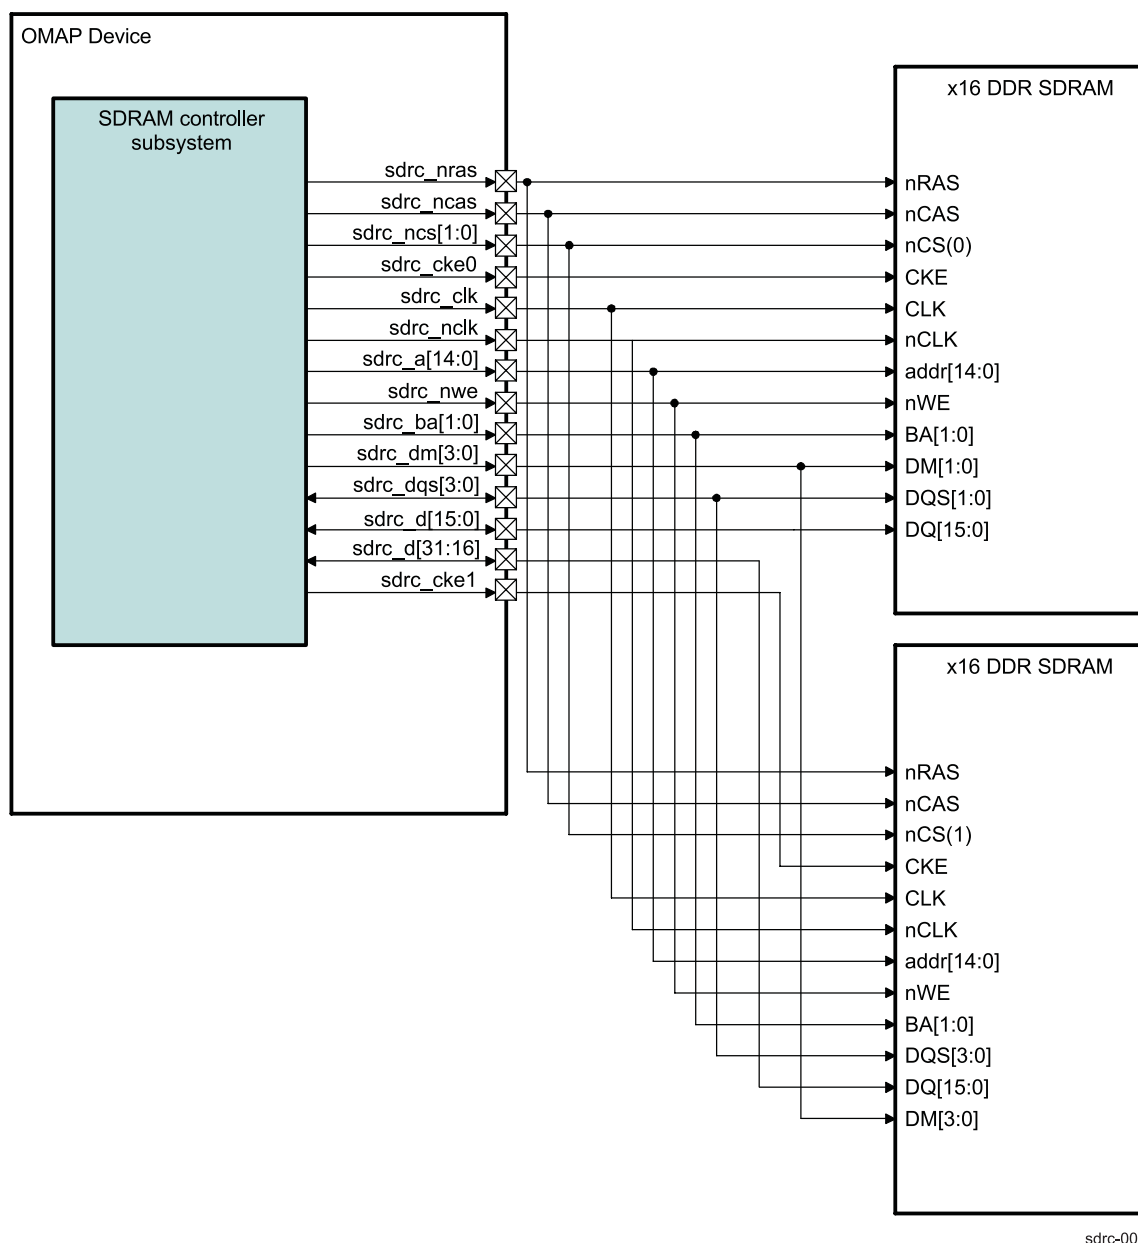

Note: The OMAP Applications Processor does not support regular DDR devices due to electrical incompatibility.

11.2.2 SDRC Subsystem Environment

11.2.2.1 SDRC Subsystem Description

Figure 11-42 shows the SDRC subsystem interfacing with one 16- and one 32-bit DDR memories.

Figure 11-42. SDRC Subsystem Connections to DDR SDRAM

Note: For DDR connectivity, refer to the device specific data manual.

Table 11-93 lists SDRC subsystem I/O pins.

Table 11-93. SDRC Subsystem I/O Description

Pin	Type	Description
sdrc_d[31:0]	I/O	32-bit wide data bus
sdrc_ba[1:0]	O	Bank address 1-0
sdrc_a[14:0]	O	Address bus
sdrc_ncs[1:0]	O	Chip-select 1-0 (active low)
sdrc_clk	O	Clock
sdrc_nclk	O	Clock invert
sdrc_cke0	O	Clock enable (CS0)
sdrc_cke1	O	Clock enable (CS1)
sdrc_nras	O	Row address strobe (active low)
sdrc_ncas	O	Column address strobe (active low)
sdrc_nwe	O	Write enable (active low)
sdrc_dm[3:0]	O	Data mask
sdrc_dqs[3:0]	I/O	Data output strobe

11.2.2.2 External Interface Configuration

11.2.2.2.1 CS0, CS1 Memory Spaces

The SDRC can be connected independently to two external SDRAM memories.

Note: For DDR connectivity, refer to the device specific data manual.

SDRAM memory is supported in sizes of 16 Mbits, 32 Mbits, 64 Mbits, 128 Mbits, 256 Mbits, 512 Mbits, 1 Gbit, and 2 Gbits. See [Section 11.2.4.4.1](#) for more information on CS memory spaces.

Note: The OMAP Applications Processor does not support regular DDR devices (see [Section 11.2.5.3.5.1, Chip-Select Configuration](#)).

11.2.2.2.2 AC Timing Control

The SDRC permits the configuration of many of the ac timing parameters controlling the SDRAM transaction timing.

It is required to adapt the transaction timing parameters to any memory device attached to the SDRC.

Note: See the OMAP device-specific data manual for optimum results.

A totally independent, complete set of parameters exists for each CS. The ac parameters and their quantification are summarized in [Section 11.2.5.3.1, Chip-Select Configuration](#).

11.2.2.2.3 Address Multiplexing

A flexible address scheme has been added to support any new type of address scheme and SDRAM density. This new address-muxing scheme lets users choose a different bank mapping allocation by configuring the order of the bank and row address decoding (column address always remains the same). The SDRC.SDRC_MCFG_p[7:6] BANKALLOCATION field defines the order of the bank and row decoding of the incoming system address. The BANKALLOCATION field can be set on a CS basis. For more details about the flexible address scheme, see [Section 11.2.4.4.3, Address Multiplexing](#).

The programming model is compatible with the legacy fixed address scheme and with the new flexible address scheme. This section describes the fixed address multiplexing configurations for both SDRAM components.

The legacy fixed address scheme is selected when the SDRC.SDRC_MCFCG_p[19] ADDRMUXLEGACY bit is set to 0 (where p = 0 or 1 for SDRC CS0 or CS1). The fixed address multiplexing configurations are described in this section, for both SDRAM components. An address multiplexing scheme is chosen by programming the SDRC.SDRC_MCFCG_p[24:20] ADDRMUX field of the SDRC_MEMCFG registers on a per chip select basis (p = 0 or 1 for CS0 or CS1). [Table 11-94](#) and [Table 11-95](#) show all pre-defined address multiplexing schemes for SDRAM memory components.

Table 11-94. SDRC Address Multiplexing Scheme Selection vs SDRAM Configurations (x16 Memory Interface)

								1	64M x 32
BA1, BA0	2	A0-A9	10	A0-A14	15	MUX29	4096	1	128M x 32
BA1, BA0	2	A0-A9; A11	11	A0-A12	13	MUX15	2048	4	64M x 8
								2	64M x 16
								1	64M x 32

Table 11-94 is valid per CS (in the table, the total size in Mbits corresponds to a single CS). Both chips must use the same address scheme, but can use different address multiplexing configurations.

Figure 11-43 through Figure 11-45 show all the SDRAM MUX schemes, including the mapping of the 32-bit system address of the column and row addresses of the memory device.

Note: The bank-select bit (BA1) does not exist for 2-bank devices.

11.2.3 SDRC Subsystem Integration

Figure 11-46 shows how the SMS and SDRC modules are integrated into the OMAP Applications Processor and how they interact with the PRCM module.

Figure 11-46. SDRC Integration to the OMAP Applications Processor

11.2.3.1 Clocking, Reset, and Power Management Scheme

11.2.3.1.1 Clocking

11.2.3.1.1.1 SMS

The SMS is a single clock domain module. The same clock is used for the interconnect system interface, the SDRC interface, and all internal operations.

SMS_CLK comes internally from the PRCM module and runs at the L3 interconnect frequency. It is also used as a functional clock for the SMS module.

The source of the SMS_CLK is the PRCM CORE_L3_ICLK output: CORE_L3_ICLK belongs to the L3 interconnect clock domain.

11.2.3.1.1.2 SDRC

The SDRC is a single-clock domain module. The same clock is used for both the interconnect and the memory interface. The SDRC_CLK clock comes from the PRCM and runs at the L3 interconnect frequency. SDRC_CLK is also used as a functional clock for the SDRC.

The SDRC_CLK clock source is the PRCM CORE_L3_ICLK output: CORE_L3_ICLK belongs to the L3 interconnect clock domain.

An SDRC_CLKX2 clock is provided by the PRCM at a double frequency of the SDRC_CLK clock. This clock can be used in the LPDDR write path, depending on the configuration.

As a power-saving feature, when the SDRC no longer requires the clock domain, the software can disable it at the PRCM level by setting the EN_SDRC bit in the PRCM.CM_ICKLEN1_CORE[1] register.

Note: The domain clock is shut down only if all other modules that receive the clock are capable and ready to accept this idle request and have IdleAck asserted.

For details, see the *Power, Reset, and Clock Management* chapter.

11.2.3.1.2 Hardware Reset

Global reset of the SDRC is done by activating the CORE_RST signal in the CORE_RST domain (see the *Power, Reset, and Clock Management* chapter).

There is one global reset signal, SDRC_GLOBALRESET, which is qualified by the signal SDRC_POWERON. This qualification differentiates whether the signal is a cold reset or a warm reset.

- On a cold reset (that is, the power-on reset, when SDRC_POWERON = 0 and SDRC_GLOBALRESET is applied), all registers and state-machines within the SDRC are asynchronously reset.
- On a warm reset (that is, any other system reset condition under control of the chip top-level power manager, SDRC_POWERON = 1 when SDRC_GLOBALRESET is applied), the SDRC registers and the FSM are not reset, but the external SDRAM memory can be optionally placed in self-refresh mode, depending on the configuration of the SDRC.SDRC_POWER_REG[7] SRFONRESET bit.

11.2.3.1.3 Software Reset

The SMS and SDRC modules can be reset under software control through the SMS.SMS_SYSCONFIG[1] SOFTRESET and SDRC.SDRC_SYSCONFIG[1] SOFTRESET bits, respectively.

A software reset has the same action as a hardware cold reset, that is, the FSM and all registers are reset immediately and unconditionally.

11.2.3.1.4 Power Management

The SDRC power is supplied by the CORE power domain. For details, see the *Power, Reset, and Clock Management* chapter.

The dynamic voltage and frequency scaling (DVFS) technic is described in the following section while other power-saving features and different idle modes are described in [Section 11.2.4.4, SDRC](#).

11.2.3.1.4.1 Dynamic Voltage and Frequency Scaling

If the input clock SDRC_CLK from the PRCM module is changed during operations, the DLL may enter an undefined state and memory accesses may be corrupted. For this reason, it is necessary to manually assert the SDRC_IDLEREQ signal before any clock frequency change. This manual access is done through a register in the chip clock controller. The SDRC then finishes processing all open transactions. If this option is activated in the [SDRC_POWER_REG\[6\]](#) SRFRONIDLEREQ bit, it puts the memory into self-refresh. When done, it unlocks the DLL and puts it into a power-down state, through the [SDRC.SDRC_DLLA_CTRL\[6:5\]](#) DLLMODEONIDLEREQ field. The SDRC then asserts the SDRC_SIDLEACK signal and the input clock frequency can be changed or stopped, depending on the scenario. After the input clock is stable again, SDRC_IDLEREQ is de-asserted. The DLL then relocks and the SDRC can be accessed normally. Putting the DLL in idle mode during the clock frequency change is required because it cannot automatically relock. It might get into a non-functional state and a new manual DLL configuration phase would then be required, with the risk of corrupting accesses in the mean time.

11.2.4 SDRC Subsystem Functional Description

The SMS optimizes the SDRAM memory usage to provide:

- The QoS level required by each of the initiators in the system
- A security firewall that controls access protection to the memory
- A VRFB module (also called the 2D rotation engine) that minimizes the SDRAM page-miss penalty when accessing rotated (that is, nonsequentially addressed) lines in a graphic frame buffer

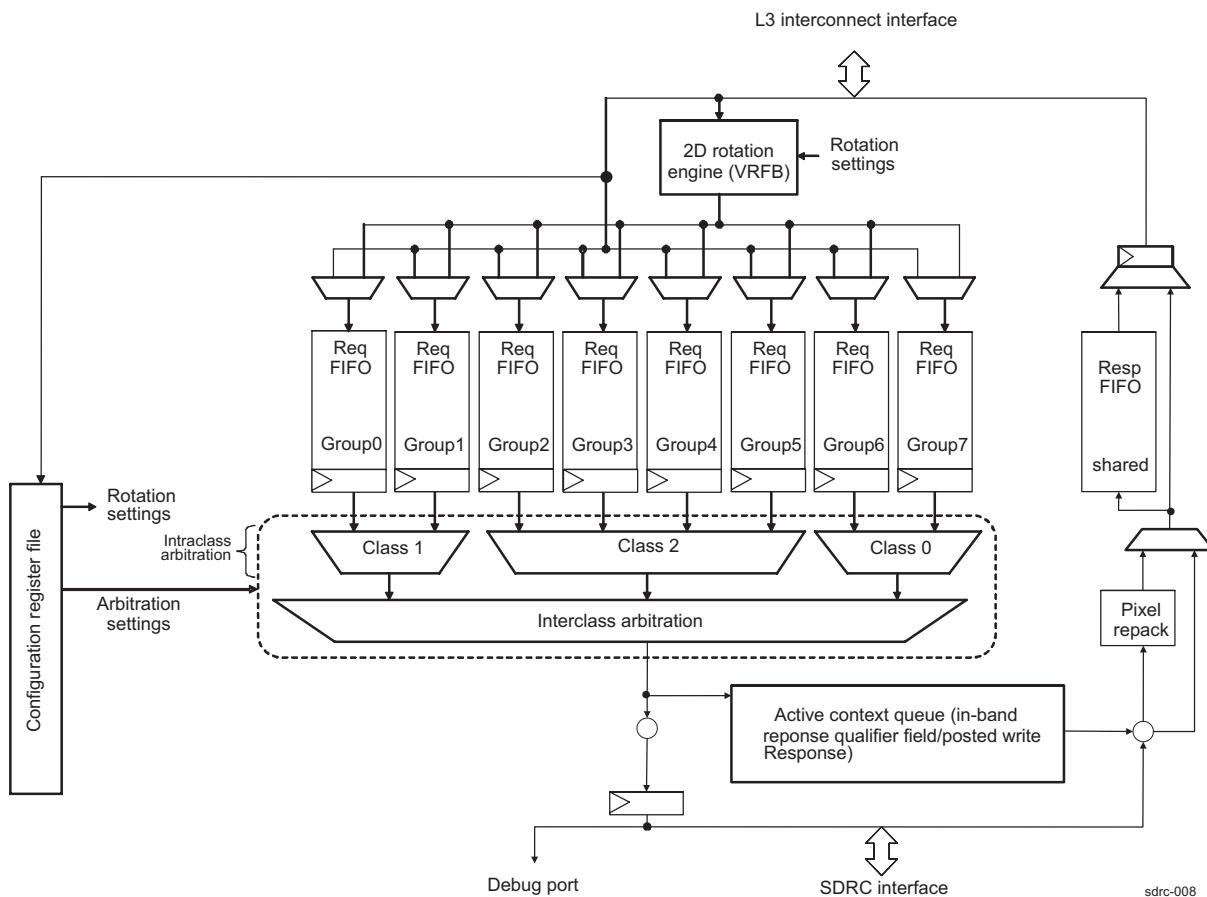

11.2.4.1 SDRAM Memory Scheduler

The SMS module is split into the following subsystems:

- L3 interconnect slave port
- VRFB: rotation engine (RE)
- Configuration register file
- Security check unit
- Request buffers
- Arbitration logic
- SDRC interface: master port
- Debug port
- Response buffer

Figure 11-47 shows the top-level diagram of the SMS.

Figure 11-47. SMS Top-Level Diagram

sdrc-008

11.2.4.1.1 Memory Access Scheduling

Note: For a description of the SMS mode of operation and arbitration policy, see [Section 11.2.6, SDRC Use Cases and Tips](#).

The SMS includes a set of FIFOs to queue the requests received from the system interconnect or processed by the RE. The FIFO entry contains a complete interconnect request, plus internal qualifiers added by the RE which are required to correctly process the requests modified (or generated) by the RE.

The SMS also includes a response FIFO, which is shared by all response threads. This FIFO provides full support for the response flow-control interconnect extension (handshake protocol).

When a memory transaction request arrives in the memory-access scheduler after being processed by the VRFB module, the request is sent to one of eight FIFO queues. Security firewall comes after the FIFOs.

The allocation to a particular queue is fixed and depends on the source of the request. To prioritize concurrent transactions and optimize memory usage, each FIFO queue (and hence the memory-access request source) is categorized into one of these three arbitration classes:

- **Class 0 (highest priority):** For bandwidth-sensitive devices with severe real-time constraints. The system fails when the bandwidth requirement is not met. LCD or video display cores, camera capture cores belong to this category.
- **Class 1:** For latency-sensitive devices where system performance degrades severely when the average memory-access latency increases. These initiators also generally have some significant bandwidth requirements. All CPU cores are class 1 initiators.
- **Class 2:** For all other devices, possibly with high-bandwidth requirements but without being too latency-sensitive. Associated initiators may also have significant requirements in terms of bandwidth, but if the bandwidth budget requirement cannot be serviced, the system performance degrades, but remains functional (the system does not fail). General-purpose system DMA, multimedia accelerators (graphics, imaging, video) belong to this category.

The arbitration between Class 1 and Class 2 is programmable.

[Table 11-96](#) shows the mapping of FIFO queues and memory-access request sources to arbitration classes.

Table 11-96. Arbitration Class Allocation

Class	FIFO Queue	Source Device
0	6	D2D
	7	Display and Camera subsystems
1	0	MPU subsystem (instruction and data access)
	1	IVA2 subsystem (instruction, data access, and MMU)
2	2	IVA2 subsystem DMA (read and write), sDMA WR
	3	SGX
	4	USB (HS + FS), DAP
	5	sDMA (read)

A 2-level arbitration scheme determines the FIFO queue from which the next memory transaction is granted.

Note: In the register description, a group represents a FIFO queue of requests from the initiator.

11.2.4.1.2 Arbitration Policy

A 2-level arbitration scheme is implemented to grant access to the SDRC. The arbitration uses fully combinatorial logic, and the granted request is clocked before being issued on the interface master port of the SDRC.

- Intra-class arbitration: A first level of arbitration is done in parallel within each class between the different thread groups (request FIFOs).
- Interclass arbitration: A second level of arbitration is done among the three winners of the in-class arbitration.

11.2.4.1.2.1 Arbitration Policy within a Burst and at a Burst Boundary

Arbitration is performed on the transaction boundary. The transaction can be either a single transaction or a burst transaction.

- Within a burst, if the thread cannot provide the subsequent request of the burst, a mechanism provides a wait for one idle cycle before moving the arbitration grant to the next thread. If only one idle cycle appears on one thread, an arbitration grant must not move (the next request served must be from the same thread). One idle cycle is then inserted in the SDRC request path.
- If the thread still cannot provide the request in the next cycle, the slot can be awarded to another initiator to avoid locking the SDRAM resource, if a thread cannot supply a subsequent request within the burst. In this case, there must not be a second idle cycle insertion in the SDRC request path. A burst with fewer than two idle cycles cannot be interrupted by a higher priority request.
- On burst boundary, the arbitration does not wait one idle cycle before moving the arbitration grant. As soon as the thread cannot request one transaction at a burst boundary, the arbitration grant can move to the next thread.

This is also valid within the ExtendedGrant and NOFServices windows; as soon as the thread cannot request a transaction, the arbitration grant can move to the next thread. For more information, see the following descriptions of the ExtendedGrant and NOFServices features.

11.2.4.1.2.2 Burst-Complete Feature (BURST-COMPLETE Field in SMS_CLASS_ARBITER0, SMS_CLASS_ARBITER1, SMS_CLASS_ARBITER2)

A burst request can be submitted to the arbitration either as soon as the first request of the burst is received by the SMS, or when at least one complete burst is buffered into the FIFO. The behavior is programmable on a per-group basis using the BURST-COMPLETE field of the [SMS_CLASS_ARBITER0](#), [SMS_CLASS_ARBITER1](#), and [SMS_CLASS_ARBITER2](#) registers. A per-FIFO counter tracks the number of complete bursts in a FIFO.

11.2.4.1.2.3 ExtendedGrant Feature (EXTENDEDGRANT Field in SMS_CLASS_ARBITER0, SMS_CLASS_ARBITER1, SMS_CLASS_ARBITER2)

EXTENDEDGRANT is a programmable control field that allows a group to be granted for N consecutive transactions (single or burst), assuming the group is still requesting service (FIFO is not empty). EXTENDEDGRANT is applicable on a single/burst boundary. This multiple-service grant is intended to take advantage of the high probability of two consecutive transactions within a group accessing consecutive memory addresses (that is, in the same SDRAM page). This mechanism does not apply to consecutive transactions that have been split by the RE. The maximum number of consecutive grants is given in the EXTENDEDGRANT field of the [SMS_CLASS_ARBITER0](#), [SMS_CLASS_ARBITER1](#), and [SMS_CLASS_ARBITER2](#) registers. The allowed range is 1 to 3.

The ExtendedGrant logic is in the internal class arbitration but must be propagated to the interclass arbitration. The flag qualifying a second-service request is provided to the interclass arbiter so the extended grant scheme can be applied at the second level of arbitration.

- Class 0 requests can still override the ExtendedGrant scheme of class 1/class 2. Within an ExtendedGrant window, hand-over to another class/thread (granting another thread) can occur as soon as one idle cycle appears in the thread at burst or single boundary.
- The PWM counter of the interclass arbitration obeys the ExtendedGrant completion before handing priority to the other class.
- When a split transaction from the RE is interleaved within an ExtendedGrant window, completion of the ExtendedGrant window starts with the last ExtendedGrant counter value (not the initial value), because there are two independent counters for ExtendedGrant and NOFServices. The ExtendedGrant counter is reloaded to its programmed value when it reaches 0.

11.2.4.1.2.4 NOFServices Feature (SMS.SMS_CLASS_ROTATIONm[4:0] NOFSERVICES Field)

NOFSERVICES is a programmable control field that allows consecutive transactions (single or burst) coming from the VRFB (with an RE_split qualifier) to be granted consecutively, assuming the group is still requesting service (FIFO is not empty). NOFServices is applicable to the RE single/burst boundary. The maximum number of consecutive grants is given by the NOFSERVICES field of the SMS.SMS_CLASS_ROTATIONm registers. The allowable range is 1 to 31.

The NOFServices logic is in the internal class arbitration, but must be propagated to the interclass arbitration. The flag qualifying a second-service request is provided to the interclass arbiter so the extended grant scheme can be applied at the second level of arbitration.

- Class 0 requests can still override the NOFServices scheme of class 1/class 2. Within a NOFService window, hand-over to another class/thread (granting another thread) can occur as soon as one idle cycle appears in the thread at burst or single boundary. A burst with fewer than two idle cycles cannot be interrupted by a class 0 request.
- The PWM counter of the interclass arbitration obeys the NOFServices completion before handing priority to the other class.
- When a split transaction from the RE is interleaved within an ExtendedGrant window, completion of the NOFservices window starts with the last NOFServices counter value (not the initial value), because there are two independent counters for ExtendedGrant and NOFServices.

If a transaction split by the VRFB follows a nonsplit transaction currently being executed on the SDRC side, an arbitration slot occurs on the nonsplit transaction boundary, regardless of the status of the ExtendedGrant counter. This is because the chances of a nonsplit transaction and a split transaction accessing the same SDRAM page are low. Similar behavior would be observed for a split transaction followed by a nonsplit transaction. The NOFServices counter is reloaded with its programmed value when it reaches 0.

11.2.4.1.3 Internal Class Arbitration

Class 0, class 1, and class 2 internal arbitrations are performed according to the following rules:

- Within a class, a standard least-recently-used (LRU) policy is applied. The LRU thread, if not empty, is granted when an arbitration decision occurs. LRU is applied taking into account the ExtendedGrant/NOFServices counter status. Grant is given to another nonempty LRU thread only if the current thread is serviced for ExtendedGrant/NOFServices times.
- On top of the LRU policy, a high-priority group can be defined through the SMS.SMS_CLASS_ARBITER0[7:6] HIGHPRIOVECTOR field. The high-priority group is unique and programmable. If a high-priority thread in a class, which was previously empty, starts requesting service, the current thread that has been given grant is completely serviced as per ExtendedGrant/NOFServices strategy and then the grant is given to the high-priority thread.

11.2.4.1.3.1 Interclass Arbitration

The interclass arbitration is managed using a time-varying policy driven by the following rules:

- The interclass arbitration is a PWM-like (Pulse Width Modulation) logic that defines two request-based windows:
 - Class 1 has higher priority than class 2 during M requests of class 1, where M is defined by the CLASS1PRIO parameter.
 - Class 2 has higher priority than class 1 during the next N requests of class 2, where N is defined by the CLASS2PRIO parameter. For more information on priority between classes, see [Section 11.2.6.2.2.3](#).
- The PWM counter is decremented each time the class is processing a single 64-bit request in its high-priority window.
- A class 0 request always has the highest priority. The PWM counter is frozen while class 0 requests are being serviced.
- A class 1 transaction can be serviced during the class 2 high-priority window if class 2 is not requesting service (conversely, a class 2 transaction can be serviced during the class 1 high-priority window if class 1 is not requesting service). The PWM counter is frozen when the grant is given to the thread that is not in its high-priority window.

- NOFServices/ExtendedGrant have higher priority than the PWM counter.
- The PWM counter is reloaded with M and N when it reaches 1 and an arbitration decision must be made.
- The priority order is as follows:
 - Current burst service lock (assuming subsequent burst requests available when required)
 - Class 0
 - ExtendedGrant and NOFServices atomicity (assuming subsequent burst requests available when required)
 - Class 1 if PWM priority is to class 1; class 2 if PWM priority is to class 2
 - Class 2 if PWM priority is to class 1; class 1 if PWM priority is to class 2

11.2.4.1.4 Security Firewall

Access permissions can be defined in the target memory address space on a per-initiator basis. Initiators are differentiated using the interconnect ConnID extension.

Permissions are allocated to the various initiators on a per-region basis. The memory regions are programmable using a start address and an end address that are defined with 64 Kbytes granularity. Up to seven distinct regions can be defined; the software must ensure that they do not overlap.

The remaining memory space (total memory space minus the protected areas) is defined as region 0. This region has security attributes programmable in the same manner as the other regions.

Depending on whether the access is a read or a write, and depending on the in-band request qualifiers, a region may be given specific access permissions. When an access is received by the SMS, the access checked against the access attributes.

- The read permission is initiator-based and is controlled using the SMS.SMS_RG_RDPERMi register.
- The write permission is initiator-based and is controlled using the SMS.SMS_RG_WRPERMi register.
- The REQINFO bits taken into account are the incoming MReqInfo attributes: Security, debug, privilege, and attribute, along with the host parameter decoded in the SMS module (see the SMS.SMS_RG_ATTi[31:0] REQINFO field). For the SMS firewall, the host parameter is set for the MPU initiator and the sDMA initiator. The decoding of the host parameter, based on the MPU ConnID and sDMAConnID generic parameters (defined at design time), is done inside the SMS module.
- Whether the access is accepted (there is one valid bit for each ReqInfo pattern) can be specified for each ReqInfo pattern. ReqInfo permission is controlled using the region attributes register SMS.SMS_RG_ATTi[31:0] REQINFO field.

Table 11-97 lists the security ReqInfo parameters ordering.

Table 11-97. Security ReqInfo Parameters Ordering

Host	Privilege	Security	Debug	Type	Req Info	SMS.SMS_RG_ATTi[31:0] REQINFO Field

⁽¹⁾ Access to the region is not allowed

Table 11-97. Security ReqInfo Parameters Ordering (continued)

Host	Privilege	Security	Debug	Type	Req Info	SMS.SMS_RG_ATTi[31:0] REQINFO Field
0: Nonhost 1: Host	0: User 1: Supervisor	0: Public 1: Secure	0: Functional 1: Debug	0: Data Transfer 1: Opcode Fetch		
1	1	1	1	1	31	0b1000...000000

When all [SMS_RG_ATTi\[31:0\]](#) REQINFO bits are set to 0 the access to the region is not allowed.

Set the REQINFO[0] bit to 1 when NonHost-User-Public-Functional-Data accesses are permitted in this region.

Set the REQINFO[1] bit to 1 when NonHost-User-Public-Debug-Data accesses are permitted in this region.

Set the REQINFO[31] bit to 1 when Host-Supervisor-Secure-Debug-Opcode accesses are permitted in this region.

Any bit of the [SMS_RG_ATTi\[31:0\]](#) REQINFO field corresponds to a particular combination of the five attribute bits. When all [SMS_RG_ATTi\[31:0\]](#) REQINFO bits are set to 1 the region is full-access allowed.

The security unit performs the following checks to authorize or reject an access to the external memory:

- Compute the Region ID based on the transaction address.
- Generate a violation if overlapping of security regions is detected.
- From the Region ID, get the attributes for the region that has been hit.
- Check the transaction REQINFO attributes with respect to the region attributes (security, debug, privilege, type, and host).
- Reject the transaction if the attributes are not compatible.
- From the Region ID and the transaction qualifiers (MCmd, ConnID), check the initiator permissions for performing the access (read, write).
- Reject the transaction if there is no permission.

The protection regions are organized in security priority levels (from Level 0 to Level 2) to prevent problems with overlapping region and corner cases associated with them; the lowest level has the lowest priority (see [Figure 11-48](#)).

Figure 11-48. Security Region Organization

sdrc-009

Region 0 (default region containing the whole memory space): Level 0

Region 1 (allows dynamic reprogramming of regions): Level 2

Regions 2–7 (protection regions): Level 1

Region 1 has the highest priority to perform dynamic masking of other already-programmed regions when they are reprogrammed.

Overlapping regions of the same priority level is forbidden and results in a security violation when an access to the concerned region occurs. This security violation is reported in the error-log register. Priority-level handling is done in the hardware; it does not involve any specific software development.

All transactions are checked, including those the RE has processed.

When detecting a security violation on an incoming request, the SMS respects the response ordering within the faulty thread.

A violation flag is raised internally and the MThreadID field is logged. Generation of the interconnect error response is then local to the SMS; the response buffer must be used to manage the potential response collision with regular SDRC responses.

To program a rotation context, set the security level per context through the SMS. [SMS_SECURITY_CONTROL](#) ROTCTXTiLOCK bits ($i = [0:11]$). That is, on context i : are all transactions allowed or is access restricted to secure transactions only?

11.2.4.1.5 Rotation Engine

Applications must often perform image rotation between the orientation of images stored in external memory and the orientation with which they must be displayed. The device offers a hardware mechanism that allows rotation tasks to be implemented efficiently, transparent to software applications, thereby keeping the MPU and DSP CPUs free for other tasks. For a description of the RE mechanism, see [Section 11.2.6, SDRC Use Cases and Tips](#).

The SMS includes address processing support for rotated displays (90, 180, and 270 degrees). This function is realized by the VRFB submodule, also called the rotation engine (RE) in this document.

The primary goal of the VRFB is to eliminate the SDRAM page-miss penalty when reading graphics data in nonnatural raster scan order (that is, top to bottom, bottom to top, right to left).

The 2D-rotation module (the VRFB) is included as a black box that intercepts incoming requests when addressed to the virtual frame buffer. If the address of the request targets the VRFB address space, the request is sent to the RE. It processes the address and reinserts the modified request in the SMS request path. The SMS translates the virtual address into physical SDRAM addresses and reinserts a request or multiple requests in the SMS request path to the SDRC.

Note: The use of the word *virtual* does not refer to the usual CPU-related MMU concept; the word is used in a more general context of the address remapping feature, which decouples the system from the actual storage physical organization of the graphics data in the external memory.

The VRFB can be abstracted as a 3-port module:

- Interconnect input port
- Interconnect output port
- Configuration port; all programmable control registers are part of the SMS register file, which is described in [Section 11.2.4.1.5.3, VRFB Configuration Port](#).

11.2.4.1.5.1 VRFB Input Port

The VRFB receives a 29-bit address, and two decoding signals, from the SMS module. The 29-bit address is decoded to determine the context and the rotation view of the request.

The VRFB address space is a 768 Mbytes address space split into two non-contiguous virtual address spaces:

- Address space 0: 256 MB in quarter Q1 (start address: 0x7000 0000, end address: 0x7FFF FFFF)
- Address space 1: 512 MB in quarter Q3 (start address: 0xE000 0000, end address: 0xFFFF FFFF)

It can manage up to 12 concurrent rotation contexts. [Table 11-98](#) details the address space of each context.

Table 11-98. VRFB Contexts Virtual Address Spaces vs Rotation Angle

Context Number	0°	90°	180°	270°
0	0x7000 0000	0x7100 0000	0x7200 0000	0x7300 0000
1	0x7400 0000	0x7500 0000	0x7600 0000	0x7700 0000
2	0x7800 0000	0x7900 0000	0x7A00 0000	0x7B00 0000
3	0x7C00 0000	0x7D00 0000	0x7E00 0000	0x7F00 0000
4	0xE000 0000	0xE100 0000	0xE200 0000	0xE300 0000
5	0xE400 0000	0xE500 0000	0xE600 0000	0xE700 0000
6	0xE800 0000	0xE900 0000	0xEA00 0000	0xEB00 0000
7	0xEC00 0000	0xED00 0000	0xEE00 0000	0xEF00 0000

10	0xF800 0000	0xF900 0000	0xFA00 0000	0xFB00 0000

Table 11-98. VRFB Contexts Virtual Address Spaces vs Rotation Angle (continued)

Context Number	0°	90°	180°	270°
11	0xFC00 0000	0xFD00 0000	0xFE00 0000	0xFF00 0000

11.2.4.1.5.2 VRFB Output Port

The VRFB output port can be a delayed copy of the input port, with the address field transformed. Depending on the rotated view that is active, an incoming transaction can also be split into several internal transactions.

The pipeline delay between the input and the output ports is three clock periods.

11.2.4.1.5.3 VRFB Configuration Port

The configuration port allows 12 concurrent rotation settings.

The VRFB address space is a 768 Mbytes (256 + 512) address space split into two noncontiguous spaces. It can manage up to 12 concurrent rotation settings.

The VRFB configuration port includes all the settings required to control the 12 rotation contexts. This is an input-only port. All settings are provided from the SMS control register file.

For each of the 12 contexts, the buffer physical base address, image height and width, and pixel size can be configured through the following registers (where n is the context number, from 0 to 11):

- SMS.SMS_ROT_PHYSICAL_BAn[30:0] PHYSICALBA field
- SMS.SMS_ROT_SIZEEn[26:16] IMAGEHEIGHT and SMS.SMS_ROT_SIZEEn[10:0] IMAGEWIDTH fields
- SMS.SMS_ROT_CONTROLn[1:0] PS field

The memory arrangement for the pixels of a frame buffer accessed through the RE is tile-based. A tile is a rectangular array of pixels. The tile size should match the page size of the SDRAM component attached to the controller for optimal performance.

The tile size is defined using the SMS.SMS_ROT_CONTROLn[10:8] page height (PH) and [6:4] page width (PW) fields.

The image height and image width (SMS.SMS_ROT_SIZEEn[26:16] IMAGEHEIGHT and [10:0] IMAGEWIDTH fields, expressed in bytes) must be multiples of the tile height and width, respectively. Some padding is required if the image size does not fit this requirement.

For a configuration example, see [Section 11.2.5.1.2, VRFB Context Configuration](#).

11.2.4.1.6 Register Security

For the following register groups, use the SMS.SMS_SECURITY_CONTROL register to independently restrict permission to write to the SMS registers to secure accesses:

- VRFB context configuration registers (independently for each context)
- Memory-access scheduler arbitration registers
- Firewall registers, soft reset bit, error registers, and the security control register itself

Writing restrictions to the security firewall memory region registers (including SMS.SMS_SECURITY_CONTROL) depend on the control module configuration.

If an illegal access is attempted (for example, a nonsecure write access to a register configured as secure), a security violation is indicated to the security module. The address where the security violation occurs and the type of violation can be read from the SMS.SMS_ERR_ADDR and SMS.SMS_ERR_TYPE registers.

To determine if a HS version of your device is available and for more information on HS devices, please refer to your device-specific data manual.

11.2.4.1.7 Security Violation Reporting

The SMS firewall can detect security violations and report them to the overall system by using the following qualifiers:

- The in-band error response to a non-authorized access
 - The out-of-band error signal generation using two out-of-band error signals
- Based on the fact that there is no way to prevent the debugger from generating firewall violations during debug, and that users cannot stop checking for functional violations, two out-of-band security violation signals are set when:

- A functional violation is detected
- A debug violation is detected

These signals are asserted on each error detection from a read, write, or posted write faulty access: they are deasserted when the software clears the error bit in the [SMS_ERR_TYPE](#) register.

11.2.4.2 Module Power Saving

Power-saving is managed through the SMS.[SMS_SYSCONFIG](#) register.

The [SMS_SYSCONFIG](#)[4:3] SIDLEMODE field defines the power management strategy (Force Idle mode, No Idle mode, or Smart Idle mode). See [Section 11.2.4.3](#) for more details on the system power management.

By default, the internal interface clock gating strategy is enabled as the [SMS_SYSCONFIG](#)[0] AUTOIDLE bit is set to 0x1 after reset. When all FIFO queues are empty and no ongoing transactions remain, the L3 interconnect clock is disabled inside the SMS thus reducing power consumption. The L3 interconnect clock can be disabled after a programmable delay defined in the [SMS_POW_CTRL](#)[7:0] IDLEDELAY bit field.

When there is new activity on the interconnect interface, the interconnect clock is restarted without any latency penalty. It is recommended to enable this mode to reduce power consumption.

There is an internal interface clock gating strategy within the SDRC controller. This power-saving feature is always active.

11.2.4.3 System Power Management

The SMS can be configured through the SMS.[SMS_SYSCONFIG](#) register to be in one of these idle modes:

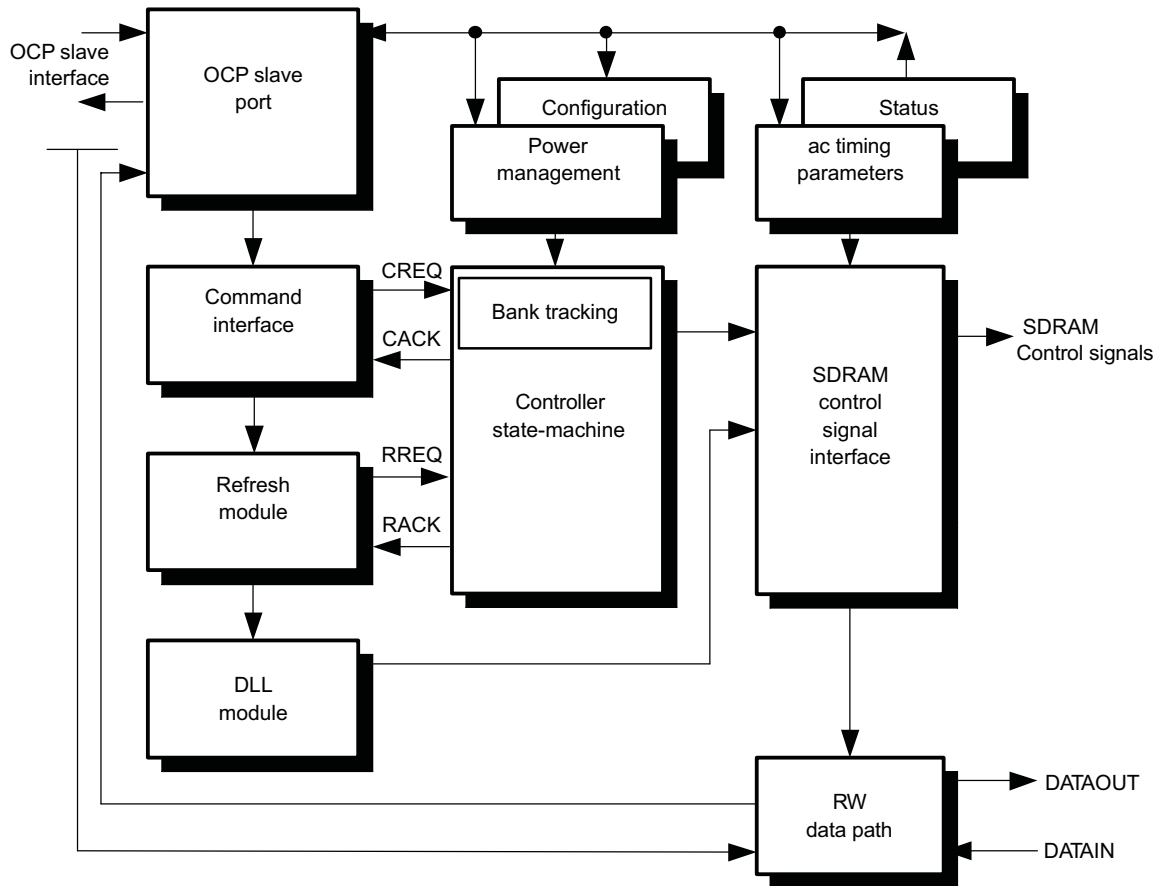

- No-idle mode (the SMS.[SMS_SYSCONFIG](#)[4:3] SIDLEMODE field is set to 0x1): The module never goes into idle state.
- Force-idle mode (the SMS.[SMS_SYSCONFIG](#)[4:3] SIDLEMODE field is set to 0x0): The module goes into idle state immediately after receiving the request from the PRCM.
- Smart-idle mode (the SMS.[SMS_SYSCONFIG](#)[4:3] SIDLEMODE field is set to 0x2): SidleAck is asserted once the module has confirmed there are no more outstanding transactions with the SDRC.

11.2.4.4 SDRC

The SDRC provides two configurable memory areas. Each supports low-power DDR SDRAM from 16 Mbits to 2 Gbits, depending on the memory organization.

Flexible row/column addressing schemes are possible with 2-bank support for 16 Mbits and 32 Mbits memories, and 4-bank support for 64 Mbits, 128 Mbits, 256 Mbits, 512 Mbits, 1 Gbit, and 2 Gbits memories.

[Figure 11-49](#) shows the architecture of the SDRC.

Figure 11-49. SDRC Architecture

sdrc-010

11.2.4.4.1 CS0-CS1 Memory Spaces

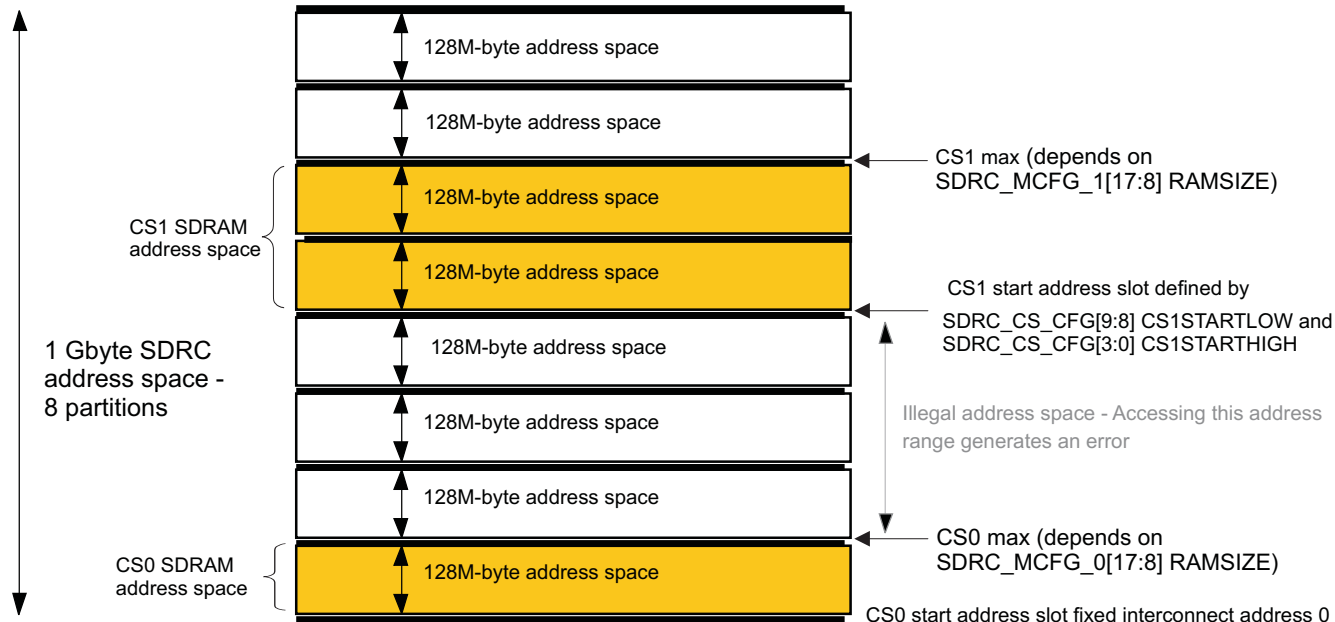

11.2.4.4.1.1 Chip-Select 0 Start Address

- CS0 always starts at address 0 with respect to the local interconnect address.
- The valid CS0 range is 0 - CS0max, where CS0max is defined in the SDRC.SDRC_MCFG_p[17:8] RAMSIZE field where p=0 (for CS0), and by the number of banks.

11.2.4.4.1.2 Chip-Select 1 Start Address

- CS1 start address is programmable.
- The default base address for CS1 after reset is defined in the register description.
- The SDRC 1 Gbyte / 8 Gbits address space is segmented so that 7 possible CS1 start address locations (8 in total minus 1 reserved for CS0) are defined by the SDRC.SDRC_CS_CFG[3:0] CS1STARTRHIGH field as shown in Figure 11-50.
- Each 128M-byte address space is also segmented into 32M-byte address spaces defined by the SDRC.SDRC_CS_CFG[9:8] CS1STARTLOW field so that 64 possible CS1 start address locations are defined by the SDRC.SDRC_CS_CFG[3:0] CS1STARTRHIGH and SDRC.SDRC_CS_CFG[9:8] CS1STARTLOW fields.
- The valid CS1 range is:
CS1 start address slot - CS1max, where CS1max is defined by SDRC.SDRC_MCFG_p[17:8] RAMSIZE where p=1 (for CS1) and SDRC.SDRC_CS_CFG registers.

Figure 11-50. CS0/CS1 Chip-Select Start Address Slots

sdrc-011

11.2.4.4.1.3 SDRAM Memory Combinations on CS1 and CS0

The SDRAM data bus width on each CS is determined by the SDRC.[SDRC_SHARING](#)[11:9] CS0MUXCFG and SDRC.[SDRC_SHARING](#)[14:12] CS1MUXCFG fields of the memory-sharing registers.

Note: For DDR connectivity, refer to the device specific data manual.

11.2.4.4.2 Bank Tracking

The main state-machine controls all the accesses to external memories.

The SDRC contains hardware for tracking open pages. Up to four open pages are tracked per CS, for a maximum of eight open pages tracked.

To efficiently pipeline accesses, the SDRC includes a request look-ahead FIFO that analyzes interconnect requests with respect to the status of the target banks. A bank status can be any of the following:

- Bank open on another row
- Bank closed
- Bank open on the same row

The SDRC state-machine generates the appropriate sequence of memory commands. All precharge and active commands are hidden as much as possible, to optimize the memory bandwidth usage.

The look-ahead FIFO depth is 9×64 -bit requests, with a limit of four different transactions. As soon as the look-ahead FIFO stores four complete transactions or when it is full, the SCmdAccept is deasserted and any incoming request is blocked.

Requests sent to the SDRC are treated in order. The four transactions limit in the SDRC look-ahead FIFO ensures that high-priority requests performance is not hampered by a succession of SDRAM page close/page open cycles due to previous lower priority requests already accepted by the SDRC. With this limit, requests not accepted by the SDRC will have to go through the SMS arbitration at a later time. If a high-priority request has arrived in the SMS in the mean time, it will be passed to the SDRC before any lower-priority request, as defined in the regular SMS arbitration scheme.

11.2.4.4.3 Address Multiplexing

A flexible address scheme allows for the support of any new type of SDRAM address multiplexing and density.

The programming model has changed but is still compatible with the legacy fixed address scheme. Both chips, hence both CS must use the same address scheme (fixed or flexible), but can use different address multiplexing configurations.

A dedicated bit controls the address scheme used: the legacy fixed address scheme or the new flexible address scheme:

- The legacy fixed address scheme is selected when the SDRC.[SDRC_MCFG_p](#)[19] ADDRMUXLEGACY bit is set to 0 (where p = 0 or 1 for SDRC CS0 or CS1).
- A new flexible address-muxing scheme configuration is selected with the SDRC.[SDRC_MCFG_p](#)[19] ADDRMUXLEGACY bit set to 1 (where p = 0 or 1 for SDRC CS0 or CS1).

To use this new flexible address scheme, configure the row address width and the column address with the SDRC.[SDRC_MCFG_p](#)[26:24] RASWIDTH and SDRC.[SDRC_MCFG_p](#)[22:20] CASWIDTH fields.

For more information about fixed address multiplexing configurations for SDRAM components, see [Section 11.2.2.2.3, Address Multiplexing](#).

11.2.4.4.4 Bank Allocation Setting

11.2.4.4.4.1 System Address Decoding

The SDRC has a 64-bit slave interface connected to the L3 main system interconnect. The regular allocation is to see the system address bus as the concatenation bank-row-column. The SDRC controller translates the interconnect request (read or write to memory for instance) into a series of commands and bank, row, column signals. The commands are sent to the external SDRAM through the `sdrc_ncs`, `sdrc_nras`, `sdrc_ncas` and `sdrc_nwe` signals. The bank, row and column addresses are sent through `sdrc_a` and `sdrc_ba` with the associated command. Those words can be defined as follow:

- Bank: the address of one of the four (or two) banks
- Row: the address of a page
- Column: the address of a word in a page

The bank signals are used to select which of the bank is accessed when transferring data from or to the SDRAM. In the first cycle, the SDRAM memory latches the row address (`nRAS` low): the adequate bank and row are activated. Next cycle, the SDRAM memory latches the column address (`nCAS` low): the adequate column is activated. The address is hence decoded: memory cells are sensed by sense amplifier and data is read from or written to output buffers.

[Section 11.2.4.4.4.2](#) shows a block diagram of a 512 Mbits SDRAM memory (8M x 16 x 4 banks). The data bus `DQ[15:0]` has a 16-bit width. Rows are addressed through `A0-A12` (8192 rows) and columns through `A0-A9` (1024 columns).

sdrc-042

11.2.4.4.3 SDRC Controller Commands

Before any read or write command can be issued to a bank in the external memory, a row in that bank must be opened. This is accomplished by the active command, by which both the bank and the row are selected. More than one bank (up to 4 according to the memory used) can be active at any time. Once a row is opened, a read or write command can be issued to that row. The row remains active until a precharge or read/write to another row in the same bank or refresh to the bank.

Autorefresh command is used during normal operation mode. This command is non-persistent, i.e. it must be issued each time a refresh is required. The device requires a refresh of all rows in a periodic interval. This command takes some time (according to the memory used) and during this phase no read or write command can be processed. A precharge-all (i.e. precharge command impacting all banks) is issued before any autorefresh sequence.

An active command to a row of a bank for which another row is already active can only be issued after the previous row has been closed. The precharge command is used to deactivate the open row in a particular bank. The bank is available for a subsequent row access some time after the row precharge command is issued. A minimum time is needed to close and to open a new row.

A subsequent active command to another bank can be issued while the first bank is being accessed without closing the row in the first bank. This results in a reduction of row access time in the same bank. In this case, it is not necessary to deactivate (with a precharge command) the row in the other banks. Up to 4 banks, depending on the memory used, can be activated at the same time. In each bank, one row can be selected at a time.

11.2.4.4.4 The BANKALLOCATION Parameter

In order to optimized SDRAM memory accesses in a throughput point of view, the SDRC controller supports various bank-row-column allocation. The bank-row-column allocation choice depends on many parameters such as the number of initiators in the use case, the memory usage (accesses bandwidth, frequency) and so on.

The SDRC controller support the regular allocation where the system address bus is seen as the concatenation bank-row-column but it also supports two other types of allocation. The SDRC_MCFCG_p[7:6] BANKALLOCATION field (where p = 0 or 1 for CS0 or CS1) selects the type of allocation. This feature modifies the bank, row, and column address decoding order:

- BANKALLOCATION = 0x0: Bank-row-column
- BANKALLOCATION = 0x1: Bank1-row-bank0-column
- BANKALLOCATION = 0x2: Row-bank-column

Only the flexible address-muxing scheme allow choosing different bank mapping allocations throughout the BANKALLOCATION parameter, i.e. the legacy address-muxing scheme does not.

The flexible address-muxing scheme (SDRC_MCFCG_p[19] ADDRMUXLEGACY = 0x1) allows choosing different bank mapping allocations. The SDRC.SDRC_MCFCG_p[7:6] BANKALLOCATION field (p = 0 or 1 for CS0 or CS1) defines the ordering of the bank, column and row decoding of the incoming system address. The BANKALLOCATION field can be set on a CS basis.

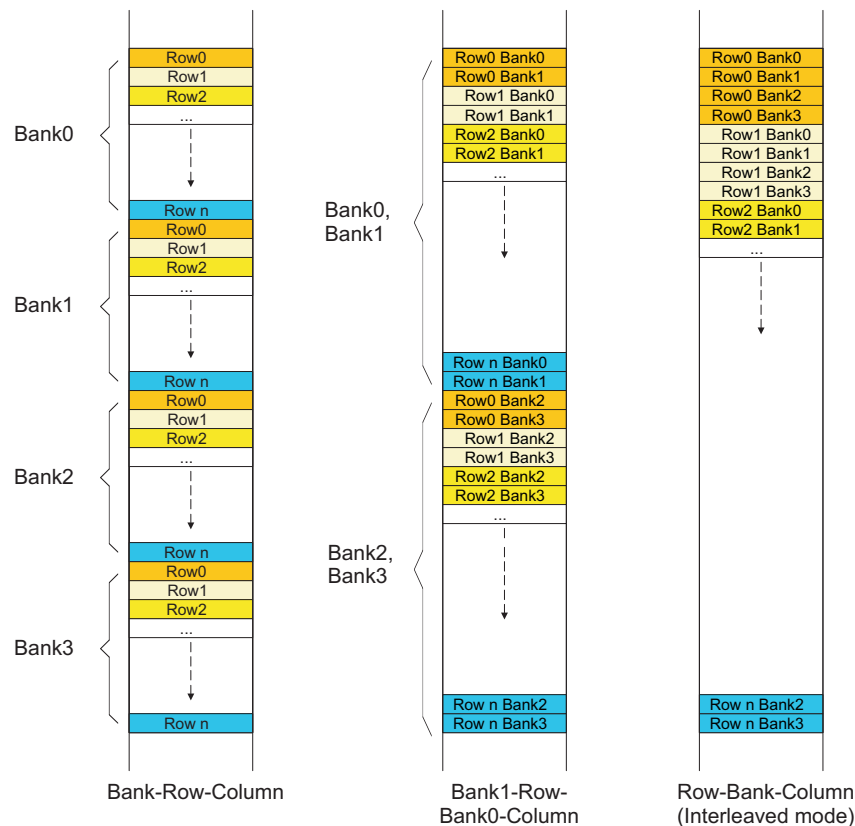

In usual allocation the system address bus is seen as a concatenation of bank-row-column. For instance, let's consider the SDRAM used in [Section 11.2.6.3, Typical SDRC connection to an External SDRAM Device](#) section: a 512 Mbits SDRAM (8M x 16 x 4 banks). The system address received from the interconnect into the SDRC is composed of:

- 2 system address bits used as the bank address (going to SDRC controller sdrc_ba[1:0] pins)
- 13 system address bits used as the row address (going to SDRC controller sdrc_a[12:0] pins)
- 10 system address bits used as the column address (going to SDRC controller sdrc_a[12:0] pins)

Setting the BANKALLOCATION field to 0x1 or 0x2 changes the order of the system address decoding, as shown in [Section 11.2.4.4.5](#).

[Section 11.2.4.4.6](#) compares Bank-row-column and Row-bank-column memory accesses.

sdrc_044

The latency to charge another row in the same bank (i.e. to close the opened page and to open another one) is bigger than the latency involved with an access to a given row in another bank. By moving bank select signals ahead of column and after row addresses, bank interleaving is guaranteed to happen more often. More frequent use of the interleaved mode means less overall SDRAM access time and, thus, yields to better overall performance.

In some use case, several initiators access to the same bank (bank0 for instance) in external SDRAM memory at a time. With this kind of scenario, a lot of penalties are added because of rows opening and closing. The BANKALLOCATION setting improves the latency for reading and writing operations, by optimizing memory accesses through the reduction of deactivate sequence usage, hence by reducing time penalties.

The bank1-row-bank0-column allocation is a good compromise between the legacy bank allocation (bank-row-column) and the full interleaving bank allocation (row-bank-column). In some use case, it might be necessary to keep only half of the memory refreshed (on bank0 and bank1 for instance) while the two other banks are unused. In full interleaving bank allocation the memory must be refreshed through the self-refresh mode, while with bank1-row-bank0-column the memory can be refreshed either through self-refresh mode or through partial array self-refresh mode.

In the next paragraph, an exemple of latence is given based on the Mobile DDR SDRAM 512-Mbit SDRAM memory data sheet. [Table 11-99](#) gives the duration for some AC timing parameters. The frequency used in the exemple is 133 MHz, that is $tCK = 7.5$ ns. The CAS latency = 3.

Table 11-99. Mobile DDR SDRAM AC Timings Parameters

AC Timing Parameter	Description	Duration (ns)
tRFC	Autorefresh cycle time	80 (min)
tRP	Row precharge time	22.5 (or 3 tCK)
tRC	Row cycle time	67.5 (or 9 tCK)
tRAS	Row active time	45 (or 6 tCK)
tRCD	nRAS to nCAS delay time	22.5 (or 3 tCK)
tRRD	Row active to row active delay time	15 (or 2 tCK)

The latency to access another row in the same bank depends on tRP and tRAS timings because a precharge command followed by an active command must be issued. Hence, 6 tCK are needed to close the current row and to open another one.

When accessing another bank, the latency to access another row depends on tRAS timing only because the closing of the current row is not mandatory. In other words only an active command must be issued. Hence, 3 tCK are needed to open another row in a different bank.

Single initiator use case:

When the initiator wants to access a page in a bank for the first time, it only opens this page. It takes 3 tCK. When the initiator is done with this page, it closes this page and opens another one. It takes 6 tCK.

Two initiators use case:

When one initiator wants to access a page in the same bank, it must necessarily close the current page and open the page he wants to access. It takes 6 tCK.

When one initiator wants to access a page this time in another bank, there could be less page opening and closing. For instance if the initiator wants to open a page in another bank where no page is opened it takes only 3 tCK rather than 6 tCK if it was another page in the same bank.

11.2.4.4.5 Data Multiplexing During Write Operations

11.2.4.4.5.1 External Bus Combinations

The SDRC pin allocation scenarios are provided in [Table 11-100](#). These scenarios are defined on a per-CS basis for maximum flexibility. The pin allocation configurations allow implementation of combinations of the 16-/32-bit external interfaces listed in this table. The data multiplexer receives a 64-bit word from the SDRAM command queue and partitions the data into a series of 16-bit or 32-bit accesses. The data multiplexer also steers the data to the appropriate data lane. The data partitioning and data steering are determined by the SDRC.[SDRC_SHARING](#)[11:9] CS0MUXCFG and SDRC.[SDRC_SHARING](#)[14:12] CS1MUXCFG fields.

Table 11-100. SDRC Data Lane Configurations

Device pins	sdrc_d[31:24]	sdrc_d[23:16]	sdrc_d[15:8]	sdrc_d[7:0]	
	DataLane[31:16]		DataLane[15:0]		
	DQS3	DQS2	DQS1	DQS0	
	DQM3	DQM2	DQM1	DQM0	SDRC. SDRC_SHARING [14:9] CSnMUXCFG field
	D[31:0]				0x0, 0x1
	D[15:0]				0x2, 0x7
			D[15:0]		0x3
					0x4, 0x5, 0x6: Reserved

11.2.4.4.5.2 Endianness-Aware Unpacking

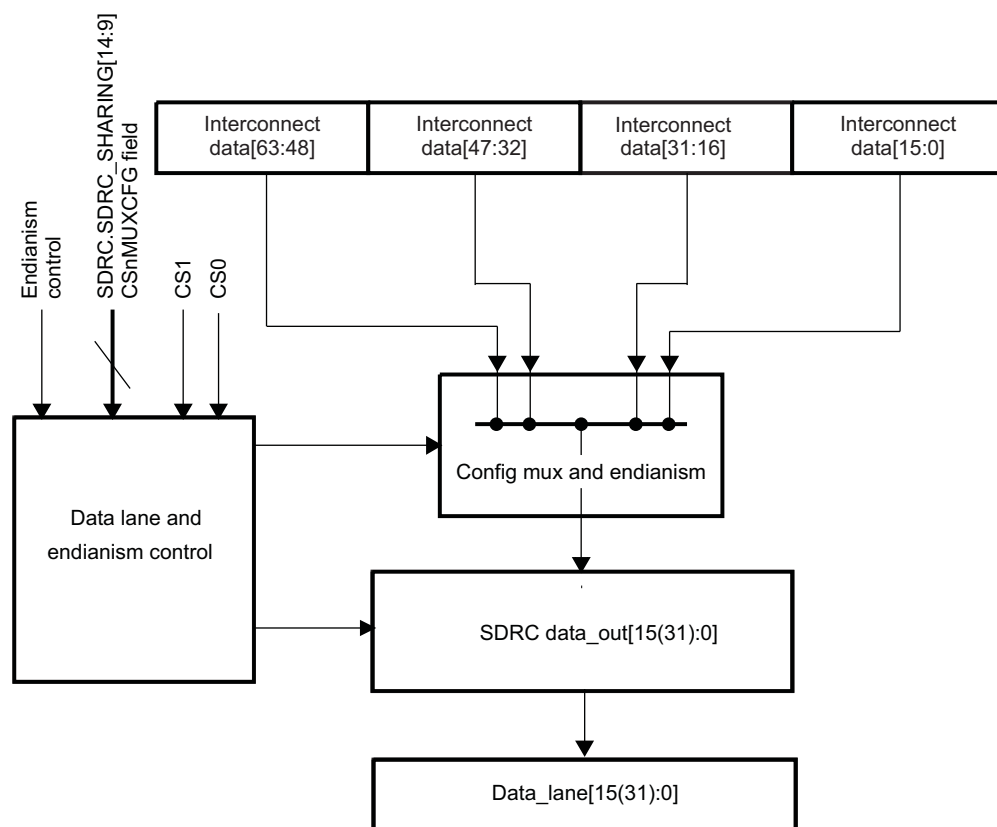

Data transactions can be either big or little endian; the transaction endianness is determined by an in-band interconnect qualifier. Muxing 64-bit data to 16-/32-bit data is performed according to this qualifier.

For a 64-bit interconnect little-endian write transaction on a 16-/32-bit memory, Data[15(31):0] is written at the lowest memory address, and Data[63:48(32)] is written at the highest memory address.

For a 64-bit interconnect big-endian write transaction on a 16-/32-bit memory, Data[15(31):0] is written at the highest memory address, and Data[63:48(32)] is written at the lowest memory address.

Figure 11-51 shows the data multiplexing scheme.

Figure 11-51. Data Multiplexing Scheme

sdrc-012

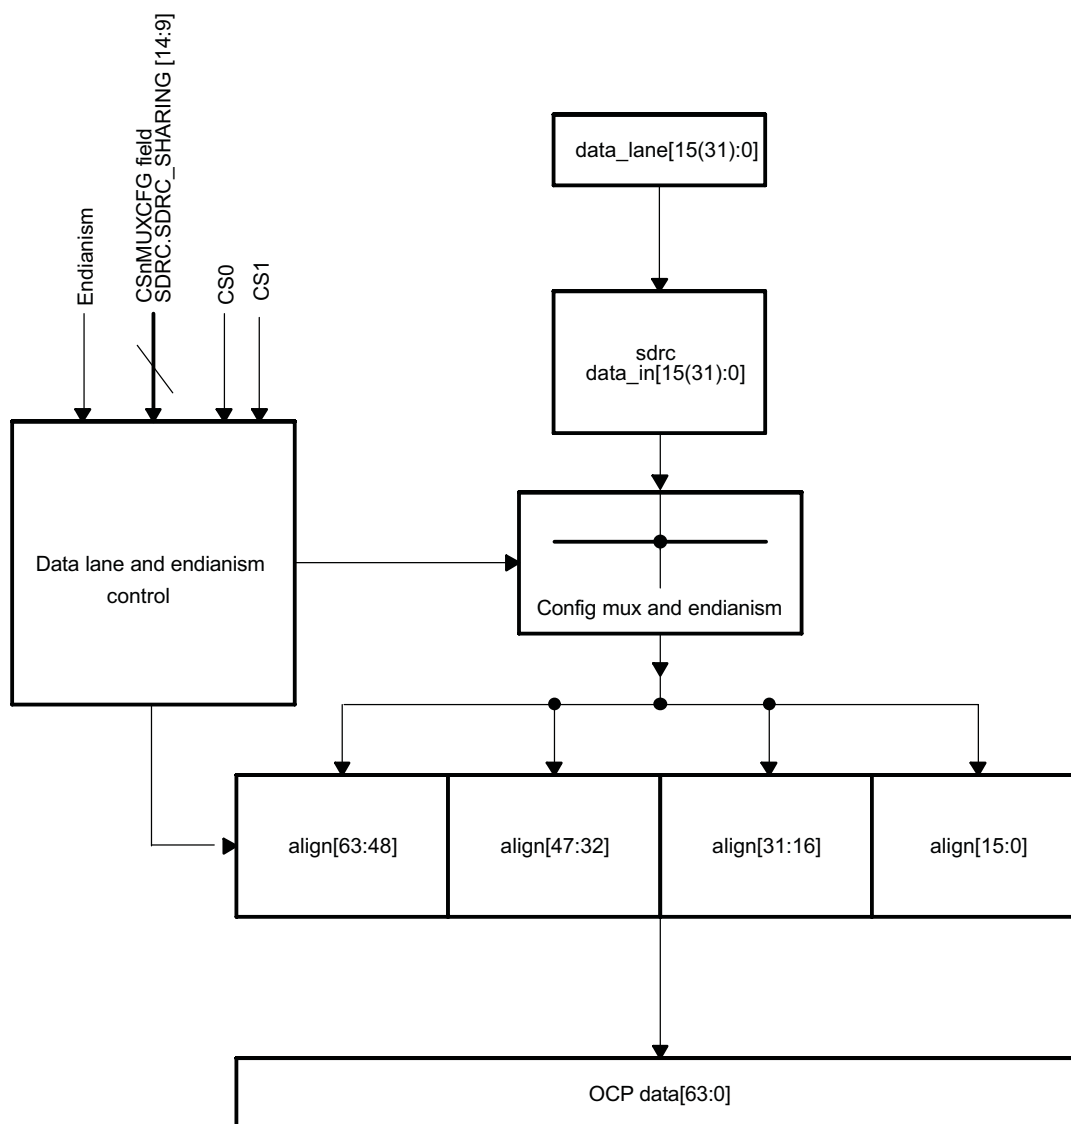

11.2.4.4.6 Data Demultiplexing During Read Operations

11.2.4.4.6.1 External Bus Combinations

The SDRC pin allocation scenarios are shown in Table 11-100. These scenarios are defined on a per-CS basis for maximum flexibility. The pin allocation configurations allow implementation of combinations of 16-/32-bit external interfaces. The data demultiplexer receives 16-/32-bit data from the relevant SDRC data lane, and then performs a data packing function. The packing function formats the data into 64-, 32-, 16-, or 8-bit format. The data demultiplexer also steers the data from the appropriate data lane. The data partitioning and data steering are determined by the SDRC.SDRG_SHARING[11:9] CSOMUXCFG and SDRC.SDRG_SHARING[14:12] CS1MUXCFG fields.

Figure 11-52 shows the data demultiplexing scheme.

Figure 11-52. Data Demultiplexing Scheme

sdrc-013

11.2.4.4.6.2 Endianness-Aware Packing

Data transactions can be either big or little endian; their endianness is determined by an in-band interconnect qualifier. Demuxing 16-/32-bit memory data to 64-bit interconnect data is performed according to this qualifier.

For a 64-bit interconnect little-endian read transaction on a 16-/32-bit memory, Data[15(31):0] is read from the lowest memory address, and Data[63:48(32)] is read from the highest memory address.

For a 64-bit interconnect big-endian read transaction on a 16-/32-bit memory, Data[15(31):0] is read from the highest memory address, and Data[63:48(32)] is read from the lowest memory address.

To preserve data integrity in all situations, that is, regardless of the effective scalar size of the transferred data (byte, Word16, Word32, or DWord64), the endianness specified during the read operation must match that specified during the write operation. If there is no match, the packing and unpacking operations are not consistent. There is no attempt to perform endianness conversion in the SDRC; only endian-aware width conversion is performed.

11.2.4.4.7 Refresh Management

Refresh management can be divided as follows:

- Self-refresh management
- Autorefresh management (programmable refresh period)

11.2.4.4.7.1 Self-Refresh Management

Self-refresh is entered to place an attached SDRAM into an autonomous refresh mode, typically when the OMAP Applications Processor enters an idle mode and switches the SDRAM clock off.

In self-refresh, the SDRAM supplies the row address generation required to refresh and retain data in the absence of external clocking.

Self-refresh can be entered using any of the following methods:

- Manually, under software control per CS
- Upon a reset event: automatically on a warm reset event (if the SDRC is programmed to enter self-refresh on warm reset)
- Upon a hardware request: automatically on an idle request sent by the system power manager (if the SDRC is programmed to enter self-refresh on idle request)
- Automatically after a (programmable) period of inactivity on the interconnect interface (if enabled by setting the SDRC.SDRC_POWER_REG[5:4] CLKCTRL field to 0x2)

Self-refresh can be exited as follows:

- Manual software command (exit from self-refresh mode; see [Section 11.2.5.3.4, DLL/CDL Configuration](#))
- Automatically after receiving a read or write transaction to access memory

11.2.4.4.7.2 Autorefresh Management

When autorefresh is enabled, a programmable hardware counter within the SDRC generates a periodic event that triggers either a single refresh or a burst of consecutive refresh commands. This is the standard refresh mode used when the system is active, while the running applications regularly access the SDRAM.

An autorefresh command can also be applied using the SDRC.SDRC_MANUAL_p register (see [Section 11.2.5.3.4, DLL/CDL Configuration](#)). This method can be used to generate a device-specific initialization sequence after power up or after the memory device exits from a low-power mode (self-refresh or deep-power-down).

The autorefresh request period is a user-controlled parameter programmed to meet the specification of the memory devices. Each time an autorefresh request is issued, the SDRC can service the autorefresh using any of the following commands:

- Single autorefresh command
- Burst of four autorefresh commands
- Burst of eight autorefresh commands

When a burst of four or eight is selected, the programmed period value is automatically scaled in hardware by 4 or 8. Consequently, the value to be programmed does not depend on the selected burst length.

11.2.4.4.8 System Power Management

Unlike the SMS, the SDRC can be configured only in smart-idle mode by setting the SDRC.SDRC_SYSCONFIG[4:3] IDLEMODE field to 0x2. Once all asserted output interrupts are acknowledged, the SDRC goes into idle state after it receives the request from the PRCM module.

The SDRC acknowledge is conditioned by the internal activity of the SDRC.

- Note:** As soon as the SDRC goes out of idle state, stalled accesses can be accepted and processed:
- In DDR fixed delay mode, the accesses will be processed (unstalled) after expiration of `MODEFIXEDEDELAYINITLAT`.

11.2.4.4.9 Power-Saving Features

In the SDRC there are three ways to save power and they can be applied simultaneously:

- Page opening/closure policy
- Dynamic low-power mode
- Static low-power mode

11.2.4.4.9.1 Page Opening/Closure Policy

The OMAP Applications Processor supports only one page policy. The SDRC.[SDRC_POWER_REG](#)[0] `PAGEPOLICY` bit must be set to 1.

The SDRC tracks open pages, if any, and determines whether the current access is to an open or a closed page. If the accessed page is open, the SDRC executes the access immediately. The SDRC performs the following procedure:

1. If the current page is already open on this bank the SDRC automatically issues a *precharge* command to close that bank.
2. Opens the accessed page by issuing an *active* command to that bank
3. Executes the access by issuing a *read* or *write* command

Up to four pages can be open simultaneously with a limit of one page per bank. The pages remain open until one of the following occurs:

- New read or write request to another page in the same bank
- Autorefresh request (a *precharge all* command is issued first)
- Self-refresh entry request (a *precharge all* command is issued first)
- Manual *precharge all* command

11.2.4.4.9.2 Dynamic Low-Power Operating Modes

The dynamic low-power operating modes of the SDRC are designed to:

- Control the external SDRAM clock(s)
- Control the internal clock gating of the SDRC when the interconnect interface is idle
- Control the self-refresh functionality

The external SDRAM is controlled through the SDRC.[SDRC_POWER_REG](#)[3] `EXTCLKDIS` and SDRC.[SDRC_POWER_REG](#)[2] `PWDENA` bits. The `EXTCLKDIS` bit is used to disable the external clock when no access is ongoing on the memory interface, whereas the `PWDENA` bit is used to activate the power-down mode of the target memory by pulling the relevant CKE low each time the memory interface is idle.

When the `PWDENA` bit is enabled but the `EXTCLKDIS` bit is not enabled, the SDRC still provides a free-running clock to the external memories: clock gating is done internal to the memory component for power savings.

`EXTCLKDIS` should only be modified when no access is in progress on the SDRAM interface. Software control is required to make sure the interface is idle.

CKE is dynamically controlled based on the current memory command. There is a zero-latency penalty when this mode is enabled.

The SDRC has three modes of automatic internal clock-gating behavior when the interconnect interface is idle, that is. there are no outstanding active transactions in progress. These modes are controlled through the SDRC.[SDRC_POWER_REG](#)[5:4] `CLKCTRL` and SDRC.[SDRC_POWER_REG](#)[23:8] `AUTOCOUNT` fields.

- Mode 0: The autoclock gating feature is disabled. No internal clock gating is performed in the SDRC in response to the detection of an idle state on the interconnect interface.
- Mode 1: A 16-bit counter starts decrementing when an interconnect idle condition is detected. The counter start value is loaded from the AUTOCOUNT 16-bit field. When this counter times out, internal clock gating within the SDRC is enabled.
- If an interconnect active command is received before the counter times out, or if an internal autorefresh request is issued, the procedure is aborted, the counter stops decrementing, and the request is serviced immediately.
- Mode 2: This mode is similar to mode 1, but before the internal clock gating, the SDRC places the SDRAM into self-refresh mode and turns off the external SDRAM clock. This is the lowest power mode.

To achieve maximum power savings, TI recommends the use of the PWDENA-, EXTCLKDIS-, and CLKCTRL-related features.

Table 11-101 explains the different power-saving configurations that can be programmed with the SDRC.SDRC_POWER_REG[3] EXTCLKDIS, SDRC.SDRC_POWER_REG[2] PWDENA, and SDRC.SDRC_POWER_REG[5:4] CLKCTRL bits.

Table 11-101. Dynamic Power Saving Configurations

CLKCTRL	EXTCLKDIS	PWDENA	CKE	External SDRC CLK ⁽¹⁾	SDRAM State	Latency When Exiting Power Mode
0	0	0	Always high	Always on	Keep previous state	
0	0	1	Low when no access	Always on	Power-down	Zero-latency penalty
0	1	0	Always high	Off when no access	Keep previous state	
0	1	1	Low when no access	Off when no access	Power-down	One cycle penalty
1	0	0	Always high	Always on	Keep previous state	
1	0	1	Low when no access	Always on	Power-down	Zero-latency penalty
1	1	0	Always high	Off when no access	Keep previous state	
1	1	1	Low when no access	Off when no access	Power-down	One cycle penalty
2	0	0	Low when no access	Off when no access after AUTOCOUNT expiration	Enter self-refresh after AUTOCOUNT expiration	
2	0	1	Low when no access	Off when no access after AUTOCOUNT expiration	Enter self-refresh after AUTOCOUNT expiration	
2	1	0	Low when no access	Off when no access	Enter self-refresh after AUTOCOUNT expiration	
2	1	1	Low when no access	Off when no access	Enter self-refresh after AUTOCOUNT expiration	

⁽¹⁾ EXTCLK can be set to 1 all the time for power optimization purposes, except when manual commands are sent. In this case, users must set EXTCLKDIS to 0 to ensure that a clock signal is provided to the memory device.

Note: When connected to a DDR memory, the SDRC never gates the clock provided to the DLL components, so that the DLL remains locked during these idle modes. This avoids the maximum of 500 clock cycles latency required for relocking the DLL when the DLL clock is switched off.

All settings for the power-saving features are common to the two CSs. When two CSs are used, however, only the accessed CS exits self-refresh or deep-power-down mode.

If the SDRC.SDRC_POWER_REG[6] SRFONIDLEREQ bit is enabled, the SDRC enters self-refresh

mode on a hardware idle request from the PRCM. The memory clock is automatically switched off, after which the SDRC sends an acknowledge back to the PRCM. In this situation, the power manager can switch the SDRC clock off. Therefore, if the SDRC is connected to a DDR memory, and if the DLL is enabled and in TrackingDelay mode, the SDRC waits for the lock status bit of the DLL to be asserted before accessing the memory when the system exits the idle state. The WAKEUPPROC bit of the [SDRC_POWER_REG](#) register enables the SDRC to automatically wait for 500 cycles (DLL relocking maximum time) before accessing the memory instead of using the LOCK signal. These 500 wait cycles are obeyed only when the DLL is set in TrackingDelay mode. For DLL ModeFixedDelay mode, the access is processed immediately. This mechanism is independent of the CLKCTRL field.

Note: DLL Behavior Upon a Warm Reset Assertion:

Upon a warm reset event, the DLL is disabled and is no longer locked ([SDRC_DLLA_CTRL](#)[3] ENADLL and [SDRC_DLLA_STATUS](#)[2] LOCKSTATUS bits are reset). The input clock runs at low frequency. To prevent the DLL from remaining unlocked, the software must re-enable the DLL by setting the ENADLL bit to 1. Then, after a maximum of 500 cycles latency required to relock it, the DLL is locked (LOCKSTATUS bit = 1). Thus, the DLL is locked on the stable input clock and, therefore, ready to process incoming requests so that the SDRC can again access the memory.

11.2.4.4.9.3 Static Low-Power Operating Modes

The software-driven controls for low-power operation modes include:

- Possibility to put the memory in self-refresh using the manual command register ([SDRC.SDRC_MANUAL_p](#) (where p = 0 or 1 for SDRC CS0 or CS1). Each CS can be controlled independently. If both CSs are in self-refresh, the external SDRAM clock can be switched off by setting the [SDRC.SDRC_POWER_REG](#)[3] EXTCLKDIS control bit to 1. Self-refresh can be exited automatically if an access is initiated onto the CS. Only DPD must be exited manually.
- Possibility to put the memory in deep-power-down mode, if supported by the SDRAM, using the manual command register. Each CS can be controlled independently. The external SDRAM clock can be switched off if both CSs are either in self-refresh or deep-power-down mode by setting the [SDRC.SDRC_POWER_REG](#)[3] EXTCLKDIS control bit to 1. Another manual command must be used for the memory to exit deep-power-down mode. After a memory exits from that mode all data are lost, and a full initialization sequence must be sent to the device, before it can be used.

11.2.4.4.10 SDRC Power-Down Mode

In some applications, the SDRC power domain can be powered down while the external memory is in self-refresh mode.

When the SDRC is powered off, an isolation stage prevents an unwanted exit from self-refresh when the context is restored. SDRC outputs that control the SDRAM are set to maintain self-refresh or deep-power-down (CKE low).

When a reset occurs, the default reset state of the SDRC is power-down enable (PDE).

When exiting the off mode:

- Power is restored to the SDRC.
- The software reconfigures all registers. If the NOMEMORYMRS bit is set, the MR and EMR registers can be set through the [SDRC.SDRC_MR_p](#) and [SDRC.SDRC_EMR2_p](#) registers (see [Section 11.2.4.5, Mode Registers](#)).
- Exit from self-refresh mode is achieved through the [SDRC.SDRC_MANUAL_p](#) CMDCODE field. Because exit from the self-refresh field is unconditional (that is, the current state of the SDRC state-machine is not considered), ensure that autorefresh is disabled.

Once the context is successfully restored, the software can reinitialize the SDRAM or return the SDRAM to self-refresh. When the device successfully exits self-refresh, autorefresh must be re-enabled.

11.2.4.4.11 Controlled Delay Line

The DLL/CDL module (Smartreflex-compatible) is a hard macro composed by one master delay-locked loop (DLL) and five slave controlled delay lines (CDL). It is used to generate precise delays suitable for DDR read and write operations. DLL delays are tracked at high frequency on process dispersion, and voltage and temperature variations (PVT) .

A CDL is a component with a clock input signal, a clock output signal, and a delay value input. The output signal is the input signal delayed according to the delay value.

The DLL output is a command that controls the CDLs (plus the controlled voltage) and assures an output signal with 90-degree delay with respect to its input signal. The DLL contains five CDL blocks.

11.2.4.4.11.1 Purpose of the DLL/CDL Module

In DDR applications, the DLL and CDL combination helps provide a data strobe (DQS) with a delay suitable to the main read and write RAM operations that exceed 83 MHz. The DLL functions within a locking range of 75 to 166 Mhz. Below 75 MHz, the DLL must be used in unlocked mode. For lower clock frequencies, set the DLL to bypass mode.

DLL/CDL is used to delay the incoming DQS in case of DDR read, or delay the output DQ (data lines) in case of DDR write (and, hence, to increase the ac timing margin).

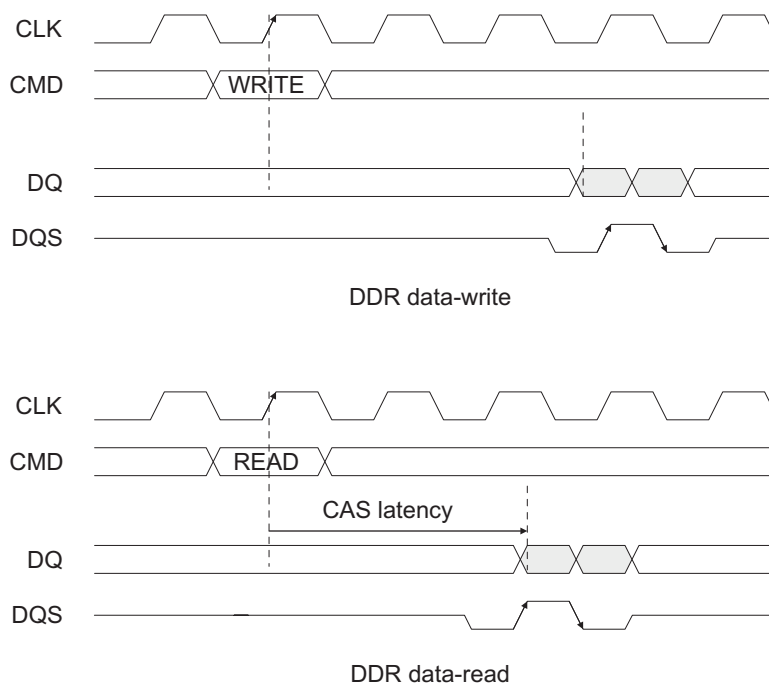

DQS is propagated with the data (thus reducing the impact of the propagation delay) and is used by the receiver to sample the data.

The DLL/CDL combination minimizes the negative effects caused by skews and jitters of clock signals. The delay introduced by the CDL base unit depends on PVT conditions. Moreover, the CDL timing delay is not a linear function of the DLL counter offset. By means of the DLL feedback loop, the delay value is updated in real time and is adjusted according to voltage and temperature variations.

DDR interfaces transmit data on both edges of the DQS bidirectional data strobe. Address and control signals transmit at half the data frequency (that is, at the DDR clock frequency) and latch only on the rising edge of the transmit clock.

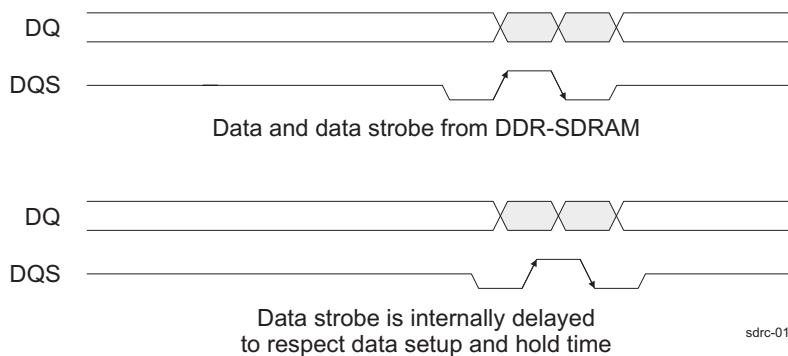

The bidirectional data strobe (DQS) is transmitted externally, along with data, for use in data capture at the receiver. `sdrc_dqs[3:0]` is an SDRC I/O that connects the SDRC with DDR SDRAM DQS pins. See [Figure 11-42](#) for an overview of DDR SDRAM connection with the SDRC controller. DQS is transmitted by the DDR SDRAM during reads and by the SDRC during writes. DQS is edge-aligned with data for reads and center-aligned with data for writes, as shown in [Figure 11-53](#). Another DDR write path can be selected with the `WRITEDDRCLKX2DIS` bit of the `SDRC_DLLA_CTRL` register. This path uses a double frequency input clock coming from the PRCM to achieve proper generation of MDDR write data bytes, center-aligned with the corresponding DQS lines. It is recommended to set the `WRITEDDRCLKX2DIS` bit to 0 to use this path.

[Figure 11-53](#) shows the generic DDR data-write and data-read waveforms.

Figure 11-53. Generic DDR Data-Write and Data-Read Waveforms

sdrc-014

Figure 11-54 shows the DDR SDRAM data and data strobe DQS signals exiting synchronously and in phase during a data read. DQS signals are used to sample incoming data internally and, hence, must be delayed to create data-setup and data-hold time at the synchronization flip-flop inputs, as shown in the bottom waveforms of Figure 11-54. This is the goal of the DLL/CDL module.

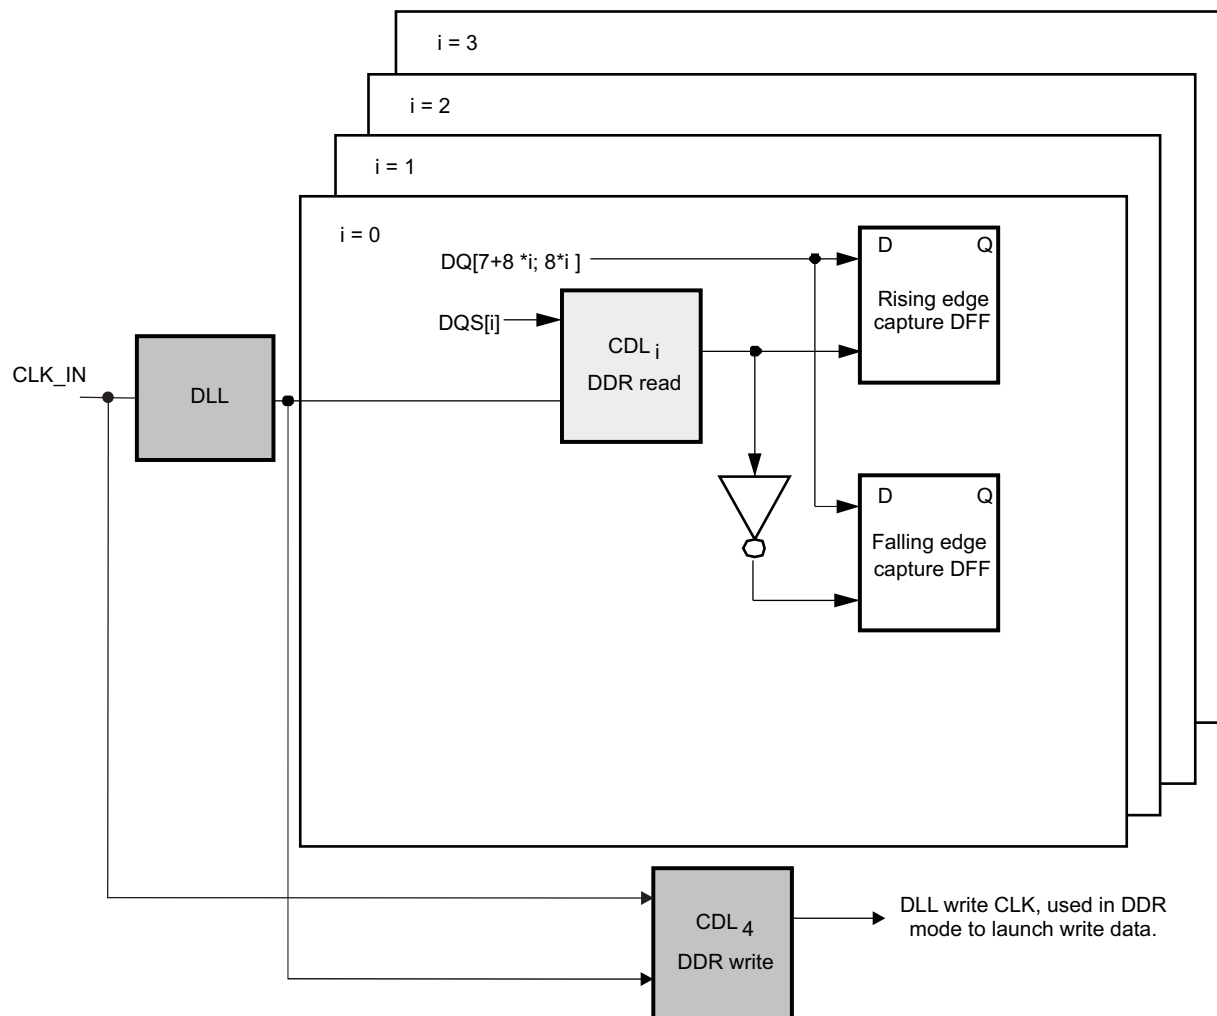

Figure 11-54. Required Synchronization DFF Input Signals

sdrc-015

11.2.4.4.11.2 DLL/CDL Module Architecture

Figure 11-55 shows how the DLL/CDL interacts with the synchronization flip-flops. See Table 11-100 for more information on device pins and SDRC data-lane configurations regarding DQS.

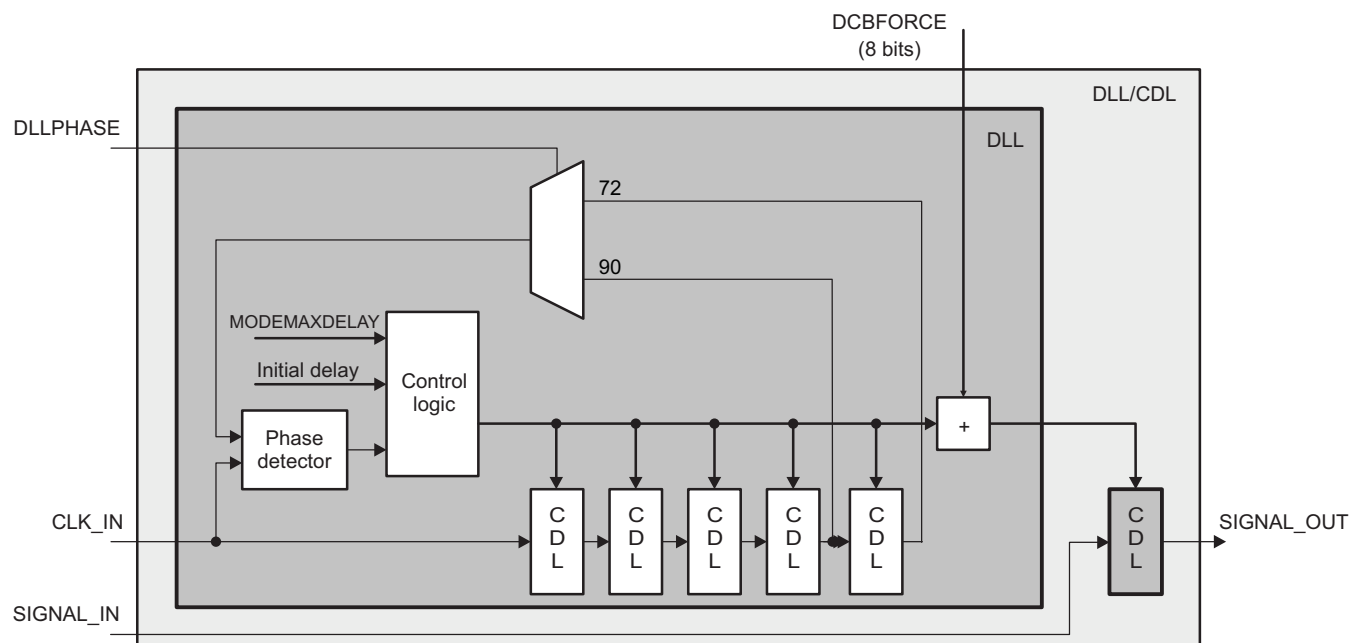

Figure 11-55. DLL/CDL Architecture

sdrc-016

Figure 11-56 shows a simplified block diagram of the DLL/CDL module.

Figure 11-56. Simplified DLL/CDL Block Diagram

sdrc-017

The DLL circuit contains five delay elements in series. Hence, the DLL output code and regulator output voltage determine a delay equivalent to one fifth of the reference input period in a stand-alone DLL/CDL (those CDLs are delay elements integrated into the DLL and are not shown in Figure 11-55). In other words, DLL/CDL delay is equivalent to either 72 or 90 degrees, i.e. respectively to a quarter or a fifth of a DDR clock period. It is recommended for read accesses to use 72 degrees (SDRC_DLLA_CTRL[1] DLLPHASE = 0x0) and for write accesses 90 degrees without DLL/DCDL (SDRC_DLLA_CTRL[1] DLLPHASE = 0x1 and SDRC_DLLA_CTRL[3] ENADLL = 0x0).

11.2.4.5 Mode Registers

11.2.4.5.1 Mode Register (MR)

It is a 12-bit register and controls the following parameters:

- Write burst mode (SDRC.SDRC_MR_p[9] WBST bit (where p = 0 or 1 for SDRC CS0 or CS1)
- CAS latency (SDRC.SDRC_MR_p[6:4] CASL field)
- Serial/interleaved mode (SDRC.SDRC_MR_p[3] SIL bit)
- Burst length (SDRC.SDRC_MR_p[2:0] BL field)

MR is accessible through SDRC.SDRC_MR_p (where p = 0 or 1 for SDRC CS0 or CS1). Writing to SDRC.SDRC_MR_p initiates an implicit load mode register command qualified by BA1, BA0 = 0, 0.

11.2.4.5.2 Extended Mode Register 2 (EMR2)

It is a 12-bit register and controls the following parameters:

- Temperature-compensated self-refresh (SDRC.SDRC_EMR2_p[4:3] TCSR field)
- Partial array self-refresh (SDRC.SDRC_EMR2_p[2:0] PASR field)

EMR2 is accessible through SDRC.SDRC_EMR2_p (where p stands for CS0 or CS1). Writing to SDRC.SDRC_EMR2_p initiates an implicit load mode register command qualified by BA1, BA0 = 1, 0.

Note: PASR Setting Before Entering Self-Refresh Mode:

PASR (Partial Array Self-Refresh) allows memory accesses to all banks when the attached memory is not in self-refresh. The software must ensure that after a self-refresh mode with PASR field enabled on banks, only accesses to the refreshed parts of the memory are performed. Failure to do so may result in fetching corrupted data.

11.2.5 SDRC Subsystem Basic Programming Model

This section contains programming guides on setting up the SMS and SDRC registers according to the required application.

11.2.5.1 SMS Basic Programming Model

11.2.5.1.1 SMS Firewall Usage

Use the SMS.[SMS_SECURITY_CONTROL](#) register to allow access to the registers.

Because region 0 always has level 0 priority, it can be masked by any protected region.

To configure a region:

1. Set the SMS.[SMS_RG_ATTi](#) register (where i is the region index from 0 to 7).
2. Set the SMS.[SMS_RG_RDPERMi](#) register.
3. Set the SMS.[SMS_RG_WRPERMi](#) register.
4. Set the SMS.[SMS_RG_STARTj](#) register (except for region 0. j is the region index from 1 to 7).
5. Set the SMS.[SMS_RG_ENDj](#) register (except for region 0. j is the region index from 1 to 7).

Region 0 is always active. There are no start and an end address for region 0. As soon as the SMS.[SMS_RG_STARTj](#)[30:16] STARTADDRESS and SMS.[SMS_RG_ENDj](#)[30:16] ENDADDRESS registers (where j = 1 to 7) are programmed, the firewall is activated. To prevent unexpected violations, ensure that the protection regions do not overlap.

Region 1 ensures the proper dynamic programming of protection for regions 2 through 7. For example, the protected region A is set and currently accessed, but it must be enlarged. To avoid deactivating region A and exposing its content to unwanted leakage, region 1 can be used to mask this whole area during reprogramming. When region A is correctly reprogrammed, region 1 can be deactivated.

If the secure system wants to restrict use of the firewall to secure mode, the security control register allows setting of a bit that locks the access to all registers to secure supervisor only.

On general-purpose (GP) devices, when all the required regions are programmed, the locking mechanism allows freezing the configuration, thus ensuring no further reprogramming.

To program the SMS firewall region in secure and supervisor privilege only, the [SMS_SECURITY_CONTROL](#) register allows any transaction or only secure and supervisor privilege accesses to:

- Rotation context registers (only secure privilege required)
- Arbitration control registers (only secure privilege required)
- Region 1 security firewall registers
- Error log registers (only secure privilege required)
- Security control register configuration lock bit
- Firewall lock bit
- Soft-reset lock bit (only secure privilege required)

If these fields are programmed to 0x1 (meaning that secure and supervisor privilege transaction is required), then nonsecure and supervisor privilege accesses to corresponding registers do not modify the register values and generate an ERRORSECREG error in the [SMS_ERR_TYPE](#) register.

11.2.5.1.2 VRFB Context Configuration

Using the RE requires several initialization programming steps. After an RE context is set up, an application can use it transparently, as if addressing a frame buffer object with a standard raster-based memory arrangement.

1. Define the page configuration. This operation usually depends only on the external memory device. The same page settings are then applied to any newly created rotated frame buffer.

Consider an SDRAM device with 1024-byte pages. The page can be defined as a 16×64 array. The page is not necessarily a square (32×32 is also a suitable value). It is recommended that the longest side corresponds to the access direction requiring the maximum bandwidth.

In terms of register settings, in any context that uses that page size:

Page (page) width = 2^{pw} bytes (that is, $pw = 6$)

Page (page) height = 2^{ph} rows (that is, $ph = 4$)

2. The application must allocate the appropriate amount of memory in the SDRAM address space, as required by the size of the frame buffer object.

Example: Create a 400×300 frame buffer, 16 bits per pixel

- Pixel size = 2^{ps} bytes (that is $ps = 1$)
- Number of pages per line: $400 \times 2/64 = 12.5$, rounded up to 13
- Number of pages per column: $300/16 = 18.75$, rounded up to 19

In terms of register settings, the image size parameters correspond to the enlarged image, and are programmed to:

- Image width = w pixels (that is, $w = 13 \times 64 / 2 = 416$)
- Image height = h pixels (that is, $h = 19 \times 16 = 304$)

Note: In this example, the values obtained are not integer values, but are rounded up to the closest integer value. This results in a loss of physical memory, generally negligible compared to the total size of the image.

In terms of memory allocation (in the physical memory), this corresponds to a $416 \times 304 \times 2 = 252,928$ -byte buffer.

The physical base address of this buffer must be aligned on a page boundary (in that example, a 1024-byte boundary; that is, the 10 LSBs of the base address must be all zeros). This buffer must be allocated as a contiguous memory segment.

All these parameters, once determined, must be loaded in the registers of the chosen context (there are 12 VRFB contexts with 12 independent sets of registers).

Example, context 1:

- Configure the physical base address of the frame buffer. Example: 512 Mbytes, start of CS0, SMS.SMS_ROT_PHYSICAL_BAn[30:0] PHYSICALBA = 0x20000000 (where $n = 1$)
 - Configure the image height and width:
Image width (416): SMS.SMS_ROT_SIZE_n[10:0] IMAGEWIDTH = 0x1A0 (where $n = 1$)
Image height (304): SMS.SMS_ROT_SIZE_n[26:16] IMAGEHEIGHT = 0x130
 - Configure the control parameters:
Pixel size (example: 2 bytes, 2^1 bytes): SMS.SMS_ROT_CONTROL_n[1:0] PS = 0x1 (where $n = 1$)
Page (page) size (example: 1024 bytes = 64 bytes \times 16 bytes)
Page height (example: 16 rows, 2^4 rows): SMS.SMS_ROT_CONTROL_n[10:8] PH = 0x4
Page width (example: 64 bytes, 2^6 bytes): SMS.SMS_ROT_CONTROL_n[6:4] PW = 0x6
3. The frame buffer just created is now ready for use by the different system initiators (MPU, sDMA, LCD controller, etc.).

From the perspective of these modules, the frame buffer object can be accessed at the following VRFB address-space memory locations:

- Context 1 0-degree view: 0x7400 0000
- Context 1 90-degree view: 0x7500 0000
- Context 1 180-degree view: 0x7600 0000
- Context 1 270-degree view: 0x7700 0000

The start address of the view corresponds to the logical origin of the image ($x = 0$, $y = 0$). The image pitch parameter, commonly defined as the distance between two vertically adjacent pixels, is fixed to 2048 pixels.

Example of usage by the application:

In a system using an 400×300 LCD panel that has a native landscape orientation, the natural scan order is as shown in [Figure 11-57](#).

Figure 11-57. Natural Scan Order

sdrc-018

The display buffer is the one created in the example sequence.

When the application is running and uses the portrait orientation for the display (typically, a PDA-type application):

- The LCD controller accesses the frame buffer using the 0-degree view.
- The processor and other initiators, such as 2D DMA or 3D accelerators, use the 90-degree view.

When the application is running and uses the landscape orientation for the display (typically, a video recorder/player or gaming application):

- The LCD controller still accesses the frame buffer using the 0-degree view.
- The processor and other initiators, such as 2D DMA or 3D accelerators, also use the 0-degree view. See [Section 11.2.6.1.1](#).

11.2.5.1.3 Memory-Access Scheduler Configuration

The memory-access scheduler is configured as follows:

- Register security settings
 - SMS.[SMS_SECURITY_CONTROL](#) register
 - Arbitration control registers security level (SMS.[SMS_SECURITY_CONTROL](#)[5] ARBITRATIONREGSLOCK bit)
- For each of the three classes, the arbitration parameters are:
 - SMS.[SMS_CLASS_ARBITER0](#) through SMS.[SMS_CLASS_ARBITER2](#)
 - One high-priority FIFO queue in the class (HIGHPRIOVECTOR field)
 - Number of consecutive transactions to perform (EXTENDEDGRANT field)
 - Burst transaction submitted for arbitration immediately or after the burst has been buffered (BURST-COMPLETE field)

11.2.5.1.4 Error Logging

All data transfers in the SMS are full handshake. The SMS uses this capability to signal the system when a transaction error is detected.

The SMS captures the address of the faulty access in the SMS.[SMS_ERR_ADDR](#) register. The error type is logged in the SMS.[SMS_ERR_TYPE](#) register. Once a faulty access is logged and the SMS.[SMS_ERR_TYPE](#)[0] ERRORVALID bit is set, the next faulty accesses cannot be logged before clearing the ERRORVALID bit.

In the case of an interconnect transaction, an error response is generated if any of the following occur:

- An incoming request arrives after an idle request from the PRCM.
- An illegal command is received.

- A protection region overlap is detected.
- A nonsecure or non-supervisor write access to the security control register is detected.
- Protection errors.

It is assumed that the system interconnect on which the SMS is plugged is responsible for signaling the error event to the host MPU based on the interconnect response. The MPU error handler can then consult the error logging registers.

The security control register allows locking the SMS.SMS_ERR_ADDR and SMS.SMS_ERR_TYPE registers to secure- and supervisor-only accesses. This configuration is highly recommended for high-security devices. For GP devices, ErrorLog can remain public.

11.2.5.2 SDRC Configuration

11.2.5.2.1 Reset Behavior

The reset behavior of the SDRC can be classified into three subgroups:

- Asynchronous cold-reset (power-on reset) behavior
- Asynchronous warm reset behavior
- Synchronous soft-reset behavior

When the system-wide power-on reset is applied through cold reset, all flops are reseted to their default values, and all state-machines are returned to their idle states.

The programming model for data recovery following a warm reset is as follows:

- Program the SDRC.SDRC_POWER_REG register to enable the SDRC.SDRC_POWER_REG[7] SRFONRESET bit.

A warm reset condition is then issued.

- The SDRC enters self-refresh mode since the SRFONRESET bit is set.
- The SDRC does not execute global SDRC reset since the reset is not qualified as cold.
- The SDRC state-machine maintains the external memory device in self-refresh.

The first SDRC access to the configuration register must then be:

1. Check the SDRC configuration.
2. Exit self-refresh mode using the manual command register.

A software-controlled reset is also available by using the SDRC.SDRC_SYSCONFIG[1] SOFTRESET bit (set this bit to 1 to activate the reset). The completion of the reset can be determined by reading the SDRC.SDRC_SYSSTATUS[0] RESETDONE bit.

When the SDRC is reseted due to the presence of either a soft or cold reset, all SDRC flops are reset.

Note: SDRC Requirement at First Power-Up to have sdrc_cke Pin High.

To be compliant with JEDEC standard, sdrc_cke pins values are forced to 1 during the initial memory power-up phase: software must ensure that sdrc_cke pin is released after the initialization phase; it happens only at first power-up (on a cold reset). Thus, at the end of the initial SDRC power-up sequence and before programing the PWDENA field, software must ensure that sdrc_cke pin is driven by SDRC module. Then, value of the PWDENA field can be modified. Refer to [Section 11.2.5.4.1](#) for more details on sdrc_cke driving.

11.2.5.3 SDRC Setup

A number of device parameters must be set before executing the initialization sequence.

11.2.5.3.1 Chip-Select Configuration

Chip-select CS0 always starts at 0x8000 0000 (with respect to the 32-bit interconnect address). There is no restriction on the presence of any SDRAM on either CS0 or CS1.

The total address space of the SDRC is 1 Gbyte / 8 Gbits. The total address space is divided into 8×128 Mbytes partitions as shown in Figure 11-50. Each partition is a possible start address for CS1, except for the partition occupied by CS0.

The start address for CS1 is defined by the SDRC.SDRC_CS_CFG[9:8] CS1STARTLOW and SDRC.SDRC_CS_CFG[3:0] CS1STARTHIGH fields.

Space 0, selected by the SDRC using the CS0 (nCS0) output pin, is always at offset 0 from the SDRAM memory space base address. The size of this area is programmable through the SDRC.SDRC_MCFG_p[17:8] RAMSIZE field, where $p = 0$. Space 1, selected by the SDRC using the CS1 (nCS1) output pin, is at an offset from the SDRAM memory space base address; this offset is programmable in 128 Mbytes increments. The size of this area is programmable through the SDRC.SDRC_MCFG_p[17:8] RAMSIZE field, where $p = 1$. The type of device for each area is programmable through the SDRC.SDRC_MCFG_p register (where $p = 0$ or 1 for SDRC CS0 or CS1).

Note: Ensure that space 0 and space 1 do not overlap each other or extend farther than the maximum 1 Gbyte SDRC memory space as explained in Global Memory Space Mapping section of the *Memory Mapping* chapter.

11.2.5.3.2 Memory Configuration

The memory configuration is defined on a per-CS basis through the SDRC.SDRC_MCFG_p register (where $p = 0$ or 1 for SDRC CS0 or CS1).

Table 11-102 lists the memory configuration.

Table 11-102. Memory Configuration

Bit Field	Comments
ADDRMUXLEGACY	Address multiplexing scheme
RAMSIZE	Defines the physical RAM address space in terms of 2 Mbytes chunks
B32NOT16	External device data bus width.
DEEPPD	Set this bit if the memory supports deep-power-down mode. (This bit is only a flag for software. It does not affect any SDRC function.)
DDRTYPE	Mobile DDR
RAMTYPE	SDRAM type

Note: Exported Register Reset Values and Lock Bit

The SDRC.SDRC_MCFG_p and SDRC.SDRC_SHARING reset values are exported in the control module. At reset, these registers take the value previously stored in the control module. A new bit is added to each register to provide the capability to lock these three registers into read-only accesses:

- SDRC.SDRC_MCFG_p[30] LOCKSTATUS bit ($p = 0$ or 1 for CS0 or CS1)
- SDRC.SDRC_SHARING[30] LOCK bit

The reset value of each lock bit is also imported from the control module.

11.2.5.3.3 SDRAM AC Timing Parameters

The AC parameters described in Table 11-103 can be independently programmed (standard JEDEC LPDDR1 terminology is used here) in clock cycles for each of the two memory areas through registers SDRC.SDRC_ACTIM_CTRLA_p and SDRC.SDRC_ACTIM_CTRLB_p ($p = 0$ or 1, depending on the CS area).

Table 11-103. Programmable AC Parameters

SDRC AC Parameter	Description	Range (Clock Ticks)
tRFC	AUTO REFRESH to ACTIVE / AUTO REFRESH command period (autoReFresh Cycle time)	0 - 31
tRC	ACTIVE to ACTIVE command period (Row Cycle time)	0 - 31
tRAS	ACTIVE to PRECHARGE command period	0 - 15
tRP	PRECHARGE command period (Row Precharge time)	0 - 7
tRCD	ACTIVE to READ or WRITE delay (Row-to-Column Delay time)	0 - 7
tRRD	ACTIVE bank A to ACTIVE bank B delay	0 - 7
tWR	WRITE Recovery time (also known as tDPL)	0 - 7
tDAL	Auto precharge write recovery + precharge time	0 - 31
tWTR	Internal Write to Read command delay (also known as tCDLR)	0 - 7
tCKE	CKE min pulse width (high and low pulse width)	0 - 7
tXP	Exit Power-Down to next valid command delay	0 - 7
tXSR	Self-Refresh exit to next valid command delay	0 - 255

Example of configuration:

If there is a minimum tRC requirement of 88 ns at 100 MHz, $88/10 = 9$ (8.8 is rounded up).

Therefore, nine clock cycles must be set.

The SDRC AC parameters described in [Table 11-104](#) are hard-coded.

Table 11-104. Nonprogrammable AC Parameters

SDRC AC Parameter	Description	Range (Clock Ticks)	Comment
tMRD	MODE REGISTER SET command period	3	
tDQSS	Write command to first DQS latching transition	1 (0.75 - 1.25 CK)	
tRPRE	Read preamble	1 (0.9 - 1.1 CK)	DQS is held low for read when driving on the same cycle as the read command is stopped.

Note: The SDRC uses tXSR only when exiting self-refresh mode, regardless of the first command issued. The SDRC systematically inserts an autorefresh command before it serves the first request.

11.2.5.3.4 DLL/CDL Configuration

The DLL unit is configured by writing to the SDRC.SDRC_DLLA_CTRL register. This register contains the following fields:

- FIXEDDELAY
- MODEFIXEDDELAYINITLAT
- WRITEDDRCLKX2DIS
- DLLMODEONIDLEREQ
- DLLIDLE
- ENADLL
- LOCKDLL
- DLLPHASE

To support low-frequency DDR access, set the DLL in Fixed Delay mode by setting the `SDRC_DLLA_CTRL` [2] `LOCKDLL` bit to 0x1. In this mode, the `SDRC_DLLA_CTRL` [31:24] `FIXEDELAY` field allows the programming of the CDL delay. This provides the correct fixed DCB code based on the input frequency. Only the voltage precharge part of the DLL is still used to control the CDL instances in this mode, but the control loop is broken and the voltage control is inactive.

When fixed delay mode is enabled, a counter (programmable through the `SDRC_DLLA_CTRL` [23:16] `MODEFIXEDELAYINITLAT` field) based on the input frequency allows the SDRC to stall all incoming requests. Once this counter expires, the SDRC starts accessing the memory. The DLL characterization has showed that this feature is not useful and that this value shall be set to 0x0, leading actually a null delay.

`WRITEDDRCLKX2DIS` controls which clock is used for the write data path. The `WRITEDDRCLKX2DIS` bit ensures the proper MDDR write data bytes by using a double frequency input clock coming from the PRCM module.

The DLL can be put in idle mode using the `SDRC_DLLA_CTRL`[4] `DLLIDLE` bit. When in idle mode, the DLL lock is lost. The precharge voltage is kept stable to enable faster relock when going back to a functional state. If set, this bit overrides the `ENADLL` bit. Thus, avoid completely powering down the DLL by keeping the precharge voltage and cutting off the analog loop. Exiting from this idle mode saves some clock cycles compared to exiting from power-down mode. Refer to the note (DLL behavior upon a warm reset assertion) in [Section 11.2.4.4.9.2, Dynamic Low-Power Operating Modes](#). Furthermore, the `SDRC_DLLA_CTRL`[6:5] `DLLMODEONIDLEREQ` field defines the modes (Power-Down / `DLLIDLE` / No action) of the DLL that are automatically entered upon an `Idle_req` assertion. The DLL mode (TrackedDelay or ModeFixedDelay mode) is updated only when `Idle_req/Idle_ack` handshake protocol occurs, warm reset occurs, `PWRDN` is enabled, or `DLLIDLE` mode enabled.

Power-Down mode is asserted upon warm reset assertion. If power-down and `DLLIDLE` are asserted simultaneously, power-down overwrites `DLLIDLE` mode inside the `DLLCDL` cell.

To modify the SDRC input clock when the DLL is locked and active, the DLL must first enter either its idle mode or its power-down mode. The SDRC input frequency can be changed by using any of the following scenarios:

- Internal signals handshaking protocol with PRCM module
- Warm reset event
- `DLLIDLE` mode
- Power-Down mode

The `ENADLL` bit controls the `PWRDN` mode of the DLL module.

The `LOCKDLL` bit sets the DLL in TrackedDelay (lock) or ModeFixedDelay (unlock) mode. ModeFixedDelay mode is supported up to 83MHz.

The `DLLPHASE` control bit is used to set up the nominal delay tracked by the DLL. It is recommended for read accesses to use 72 degrees and for write accesses 90 degrees without DLL/DCDL. See [Section 11.2.4.4.11](#) for more information on the CDL/DLL module.

11.2.5.3.5 Mode Register Programming and Modes of Operation

The SDRC contains a group of registers known as the Memory Mode Registers. These registers define the operational modes of the target SDRAM.

- MR: Mode Register used to define operational parameters.
- EMR1: Extended Mode used to define operational parameters exclusive to DDR SDRAM (irrelevant to the SDRC since regular DDRs are not supported).
- EMR2: Extended Mode used to define operational parameters exclusive to mobile SDRAM.

11.2.5.3.5.1 Mode Register (MR)

The 12-bit `SDRC_MR_p` register (p = 0 or 1 for CS0 or CS1) controls the following parameters:

- Write burst mode
- CAS latency
- Serial/interleaved mode

- Burst length

When programming the SDRC.[SDRC_MR_p](#) bit fields (where p = 0 or 1 for SDRC CS0 or CS1), consider the following:

- CAS latencies of 1, 2, 3, 4, and 5 are supported (CASL).
- Only serial mode (not interleaved mode) is supported (SIL = 0x0).
- A burst length of 4 is supported for DDR SDRAM (BL = 0x4).
- Burst lengths of 1 (BL = 0x0), 8 (BL = 0x3), and full page (BL = 0x7) are not supported.

Writing to SDRC.[SDRC_MR_p](#) initiates an implicit Load Mode register command qualified by BA1, BA0 = 0,0 except if the NOMEMORYMRS bit is set.

11.2.5.3.5.2 Extended Mode Register 2 (EMR2)

The SDRC.[SDRC_EMR2_p](#) register (p = 0 or 1 for CS0 or CS1) is specific to mobile SDRAM devices. It is a 12-bit register that controls the following standard parameters:

- Partial Array Self-Refresh (PASR)
- Temperature Compensated Self-Refresh (TCSR)
- Driver Strength (DS)

The SDRC.[SDRC_EMR2_p](#)[2:0] PASR field programs the partial array self-refresh feature. The SDRC.[SDRC_EMR2_p](#)[4:3] TCSR field programs the temperature compensated self-refresh feature.

Writing to SDRC.[SDRC_EMR2_p](#) initiates an implicit load mode register command qualified by BA1, BA0 = 1,0 except if [SDRC_SYSCONFIG](#)[8] NOMEMORYMRS is set.

11.2.5.3.6 Autorefresh Management

The SDRAM refresh configuration register group controls refresh management in normal operation. This group contains two SDRC.[SDRC_RFR_CTRL_p](#) registers that are defined on a per-CS basis and contain the following bit fields:

- SDRC.[SDRC_RFR_CTRL_p](#)[1:0] ARE (where 'p' stands for SDRC CS values 0 and 1)
- SDRC.[SDRC_RFR_CTRL_p](#)[23:8] ARCV (where 'p' stands for SDRC CS values 0 and 1)

These bit fields can enable and disable autorefresh. Autorefresh bursts of 1, 4, and 8 are programmed using these fields. The autorefresh burst starts when the 16-bit autorefresh counter decrements to 0. The ARCV field loads the autorefresh counter with a 16-bit autorefresh value. The ARCV value is calculated using the following formula:

$$\text{Refresh value} = (\text{refresh interval} / \text{clock period} / \text{number of rows}) - \text{margin}$$

Note: Memory refresh interval in time unit. Margin is 50 (cycles).

The margin considers the possibility of an ongoing access when the counter expires, thus delaying the effective refresh sequence.

The value to be programmed is independent of the burst-refresh configuration: if a burst-refresh is configured, the value is automatically scaled in hardware to the burst-refresh size.

Autorefresh is enabled by programming the SDRC.[SDRC_MANUAL_p](#)[3:0] CMDCODE field to 0x2 (where p = 0 or 1 for SDRC CS0 or CS1).

11.2.5.3.7 Page Closure Strategy

The page closure strategy is defined on a per-bank basis by setting the SDRC.[SDRC_POWER_REG](#)[0] [PAGEPOLICY](#) bit. SDRC defines one type of page closure strategy:

1. High power/high bandwidth: Bandwidth consumption is critical.

The SDRC tracks open pages. The SDRC determines whether the current access is an open page or a closed page. The SDRC does the following:

1. If the current page is already open on this bank the SDRC automatically issues a *precharge* command to close that bank.
2. Opens the accessed page
3. Executes the access

In the worst case, four pages (one page per bank) may be opened simultaneously.

The PAGEPOLICY bit must be set to 1 to enable this mode.

11.2.5.4 Manual Software Commands

The manual commands register `SDRC.SDRC_MANUAL_p` (where $p = 0$ or 1 for SDRC CS0 or CS1) is used to implement software-driven commands:

- NOP command
- Precharge All command
- Autorefresh command
- Enter deep-power-down command
- Exit deep-power-down command
- Enter self-refresh command
- Exit self-refresh command
- Set CKE high command
- Set CKE low command

These commands are described in the following section:

- NOP (CMDCODE: 0x0)

When the `SDRC.SDRC_MANUAL_p[3:0]` CMDCODE field is programmed with 0x0, the SDRC issues a NOP/inhibit command. The following table lists the status of the SDRC memory port signals.

NOP does not initiate any new operation, but it is needed to complete operations that require more than a single clock cycle-like autorefresh.

Inhibit is also a NOP. `nCS` high disables the command decoder so that `nRAS`, `nCAS`, `nWE`, and all the address inputs are ignored.

Command	nCS	nRAS	nCAS	nWE
Inhibit	H	X	X	X
NOP	0	H	H	H

- Precharge all (CMDCODE: 0x1)

When the `SDRC.SDRC_MANUAL_p[3:0]` CMDCODE field is programmed with 0x1, the SDRC issues a precharge all command. The following table lists the status of the SDRC memory port signals.

During the command, address A10 remains high, and bank information (BA0 and BA1) is don't care.

All banks can be precharged at the same time by using the precharge all command.

At the end of `tRP`, after performing precharge on all of the banks, they enter the idle state.

Command	A10	nCS	nRAS	nCAS	nWE
Precharge all	H	L	L	H	L

- Autorefresh (CMDCODE: 0x2)

When the `SDRC.SDRC_MANUAL_p[3:0]` CMDCODE field is programmed with 0x2, the SDRC issues an autorefresh command. The following table lists the status of the SDRC memory port signals.

In addition to the signal status mentioned below, the CKE signal is at logic high for autorefresh.

The autorefresh command can only be asserted when all banks are in idle state and the device is not in power-down mode (CKE is high in the previous cycle).

The autorefresh command must be followed by NOPs until the autorefresh operation completes.

All banks are in the idle state at the end of the autorefresh operation.

Command	nCS	nRAS	nCAS	nWE
Autorefresh	L	L	L	H

- Enter deep-power-down (CMDCODE: 0x3)

When the SDRC.SDRC_MANUAL_p[3:0] CMDCODE field is programmed with 0x3, the SDRC executes an enter DPDM command. This command is used for low-power devices (that is, MDDR devices that support deep-power-down mode). The following table shows the status of the SDRC memory port signals.

The device enters deep-power-down mode by having nCS and nWE held at logic low with nRAS and nCAS high at the rising edge of the clock, while CKE is low.

Command	nCS	nRAS	nCAS	nWE	CKE
Enter DPDM	L	H	H	L	L

- Exit deep-power-down command (CMDCODE: 0x4)

When the SDRC.SDRC_MANUAL_p[3:0] CMDCODE field is programmed with 0x4, the SDRC executes an exit deep-power-down command. The device exits deep-power-down mode when the inhibit command is sampled with CKE held at logic high.

- Enter self-refresh (CMDCODE: 0x5)

When the SDRC.SDRC_MANUAL_p[3:0] CMDCODE field is programmed with 0x5, the SDRC puts the memory into self-refresh. The signal status is the same as defined in autorefresh, and CKE is held at logic low during the self-refresh entry command.

The self-refresh mode is entered from the all-banks-idle state by asserting nCS, nRAS, nCAS, and CKE low, and nWE high.

Once the self-refresh mode is entered, only the CKE state being low matters; all other inputs, including the clock, are ignored and remain in self-refresh mode.

- Exit self-refresh (CMDCODE: 0x6)

When the SDRC.SDRC_MANUAL_p[3:0] CMDCODE field is programmed with 0x6, the SDRC executes the self-refresh exit command and, after meeting the tXSR timing parameter, executes one autorefresh command to adhere to the memory protocol. It is an exit self-refresh command when CKE is detected high with a NOP command.

Self-refresh is exited by restarting the external clock and then asserting CKE high. This must be followed by NOPs for a minimum time of tXSR before the SDRAM reaches idle state to begin normal operation.

- Set the CKE signal high (CMDCODE: 0x7)

When the SDRC.SDRC_MANUAL_p[3:0] CMDCODE field is programmed with 0x7, CKE is set to high. An example of where this command is used is during DDR memory initialization.

- Set the CKE signal low (CMDCODE: 0x8)

When the SDRC.SDRC_MANUAL_p[3:0] CMDCODE field is programmed with 0x8, CKE is set to low. An example of where this command can be used is to put memory in power-down mode.

11.2.5.4.1 DDR Initialization Sequence

The initialization sequence is executed after the following occur:

1. Power is applied.
2. The clock is stable.
3. The power-on reset sequence is executed.

The initialization sequence is executed by programming the following manual command registers, in the SDRC.SDRC_MANUAL_p[3:0] CMDCODE bit field, on a per-CS basis:

1. Set CMDCODE to 0x0 (NOP command), for a minimum delay of 200 μ s. Another way to stabilize the connected device internal circuits is to deactivate the corresponding CS for the same amount of time.

CAUTION

It is the programmer's responsibility to ensure that the next command (precharge all command) is sent after a minimum delay of 200 μ s. Other timings to respect, such as tRP timing between precharge all command and autorefresh command are automatically handled by the SDRC controller depending on the timing values programmed in the adequate registers.

2. Set CMDCODE to 0x1 (precharge all command) to precharge all banks.
3. Set CMDCODE to 0x2 (autorefresh command). The autorefresh command is automatically generated after a time of tRP, hence [SDRC_ACTIM_CTRLA_p\[17:15\]](#) TRP (where p = 0 or 1, for CS0 or CS1) must be programmed as stated in the external memory datasheet.
4. A second autorefresh command must be programmed. Set CMDCODE to 0x2 another time.
5. Then configure the mode register [SDRC_MR_p](#) (p = 0 or 1) with BA0 and BA1 set to 0.

Because the mode register powers up in an unknown state, it must be loaded before applying any operational command.

When MR is reprogrammed, a suitable time must elapse before an active command is issued. The hardware ensures this by fixing tMRD to two clock cycles. The SDRC can handle CKE as force on CKE is released through the control module.

After VDD initialization `sdrc_cke0` and `sdrc_cke1` signals are forced outside the SDRC subsystem by the control module. When the external SDRAM device is correctly initialized the control module must release the force on these `sdrc_cke` signals by clearing the corresponding MUXMODE bit fields in `CONTROL.CONTROL_PADCONF_SAD2D_SBUSFLAG[18:16]` and `CONTROL.CONTROL_PADCONF_SDRC_CKE1[2:0]` bit fields for `sdrc_cke0` and `sdrc_cke1` respectively. See [Section 11.2.5.2.1](#) for more information on reset behavior.

11.2.5.4.2 Read/Write Access

The commands required for a normal read/write access are automatically generated as a function of the following:

- The read/write command
- The address bus. A10 defines precharge all
- The relevant [SDRC_MR_p](#) / [SDRC_EM2_p](#) registers

11.2.5.4.3 Memory Power Management

11.2.5.4.3.1 Clock Enable Management

The SDRC supports two autonomous clock enable pins CKE0 and CKE1. Each CS (CS0 or CS1) has its own CKE signal. Power management of the CS0 memory is controlled by CKE0. Power management of the CS1 memory is controlled by CKE1. This allows the SDRAM memories associated with CS0 or CS1 to be independently placed in power-down, deep-power-down (DPD) or self-refresh (SR) mode. This is achieved using the manual control register `SDRC.SDRC_MANUAL_p[3:0]` CMDCODE field which is defined on a per chip select basis. Entry and exit of these low-power modes is achieved using the relevant CMDCODE.

Once the memory associated with a CS has been powered down in deep-power-down mode it cannot be powered up by dynamic power management features. It can only exit the low-power state through the programming of the relevant CMDCODE. The SDRC can automatically exit other low-power modes.

11.2.5.4.3.2 Clock-Controlled Memory Power Management

The SDRC power-management register (SDRC.[SDRC_POWER_REG](#)) contains the EXTCLKDIS field, which controls suspension of the external clock on a per-CS basis. Writing 1 to this field in the relevant register freezes the clock with a latency dependent on the SDRC.[SDRC_POWER_REG](#) register programming. Subsequently, writing 0 to this field in the relevant register enables the clock with a latency dependent on the SDRC.[SDRC_POWER_REG](#) register programming.

11.2.5.4.3.3 Manual Power-Down Mode Power Management

For a DDR, the sequence is as follows:

DDR Mechanism/Power-Down Mode Entry

1. Ensure that no access is currently pending or active.
2. To reduce power consumption (not mandatory): disable DLL by setting the ENADLL field of the relevant SDRC.[SDRC_DLLA_CTRL](#) register to 0x0.
3. Program the CMDCODE field of the relevant manual command register to 0001.
This ensures that all banks are idle by executing a precharge all command.
4. Program the CMDCODE field of the relevant manual command register to 0000.
This executes a NOP command.
5. Program the CMDCODE field of the relevant manual command register to 1000.
This sets the relevant CKE low.
6. Maintain the clock at a stable value.

DDR Mechanism/Power-Down Mode Exit

1. Provide clock.
2. Program the CMDCODE field of the relevant manual command register to 0111.
This sets the relevant CKE high.
3. Program the CMDCODE field of the relevant manual command register to 0000.
This executes a NOP command.
4. Program the CMDCODE field of the relevant manual command register to 0001.
This ensures that all banks are idle by executing a precharge all command.
5. Enable DLL by setting the ENADLL field of the relevant SDRC.[SDRC_DLLA_CTRL](#) register to 0x1.

The amount of time the SDRC spends in power-down mode must not exceed the refresh period; otherwise, data becomes corrupted.

11.2.5.4.3.4 Deep-Power-Down Mode Power Management

When in deep-power-down mode the power distribution to the entire memory array is cut. The programming model for deep-power-down mode is as follows:

Deep-Power-Down Mode Entry

- Precharge all banks (CMDCODE: 0x1). This ensures that all banks are idle.
- Enter deep-power-down mode (CMDCODE: 0x3).

Deep-Power-Down Mode Exit

- Exit deep-power-down mode (CMDCODE: 0x4).

The MR and EMR values are retained upon exiting deep-power-down mode.

Note: Because power-pown entry/exit sequences depend on memory devices, see the memory specification for the complete sequence.

11.2.5.4.3.5 Manual Self-Refresh Mode Power Management

The programming model for entering and exiting self-refresh mode is as follows:

Self-Refresh Entry

- Precharge all banks (CMDCODE: 0x1).
- NOP (CMDCODE: 0x0)
- Enter self-refresh mode (CMDCODE: 0x5).

There is no need for the software to disable the autorefresh in the SDRC.[SDRC_RFR_CTRL_p](#) register before entering self-refresh. The autorefresh counter is reseted in hardware so that an autorefresh cycle is automatically generated immediately after a self-refresh exit, and before any other command.

Self-Refresh Exit

- Exit self-refresh mode (CMDCODE: 0x6).
- If needed, reconfigure SDRC registers as required.
- Enable autorefresh by programming:
 - The relevant SDRC.[SDRC_RFR_CTRL_p](#)[23:8] ARCV field
 - The relevant SDRC.[SDRC_RFR_CTRL_p](#)[1:0] ARE field to the desired refresh burst

11.2.5.5 Error Management

All data transfers in the SDRC operate a system of full handshaking. A valid read or write request that is presented to the SDRC by the L3 interconnect sequencer results in the SDRC acknowledging the transfer by raising the SCmdAccept flag. Failure to do this within a defined temporal window constitutes an error. Errors can arise from the following sources:

- Any transaction while the memory is in deep-power-down mode
- An illegal initiator access. The address of the last illegal access is captured in the SDRC.[SDRC_ERR_ADDR](#) register

If an error occurs, the software error handler performs the following actions:

- Interrogates the ERRORVALID field of the SDRC.[SDRC_ERR_TYPE](#) register to verify the presence of an error
- Interrogates the ERRORDPD field of the SDRC.[SDRC_ERR_TYPE](#) register to determine whether a transaction error resulting from the device being in deep-power-down mode is present
- Interrogates the ERRORCONNID field of the SDRC.[SDRC_ERR_TYPE](#) register to determine whether a transaction error resulting from an illegal access by an interconnect initiator is present
- Interrogates the ERRORADD field of the SDRC.[SDRC_ERR_TYPE](#) register to determine whether a transaction error resulting from an illegal address is present:
 - Interconnect access to an address outside the memory space (0x0)
 - Interconnect access to an address outside the register space (0x1)
- Writes 0 to the ERRORVALID field of the SDRC.[SDRC_ERR_TYPE](#) register to clear the active error status
- Executes error recovery from software

11.2.6 SDRC Use Cases and Tips

11.2.6.1 How to Program the VRFB

11.2.6.1.1 VRFB Rotation Mechanism

An inherent limitation of SDRAM technology is high-memory latency caused by page-miss penalties incurred when downloading to a memory cache. For example, switching from one page to another in external memory can cause a page-miss, indicating that the page accessed for the current pixel is different from that for the previous pixel.

A DMA engine is used to rotate pictures in external DRAM, but this rotation method increases the number of page misses.

The efficient way to rotate image data in external SDRAM is to use the VRFB module, which is an RE embedded in the SMS of the OMAP Applications Processor, as shown in [Figure 11-58](#). It is configured in the SMS registers.

Accessing images stored in external SDRAM in a non-natural order requires an address transaction: the virtual address of an image is translated into a physical address in the corresponding buffer. Address translation causes an image to be rotated in 0-, 90-, 180-, or 270-degree views. With multiple views of the image, the RE can change addresses and issue multiple requests to the SDRC so that a maximum of consecutive accesses is performed, thus decreasing the number of page-miss penalties. The RE cannot reorder requests to the SDRAM.

A VRFB context defines the configuration used to access a picture in external SDRAM. For each VRFB context, a set of registers in the SMS describes:

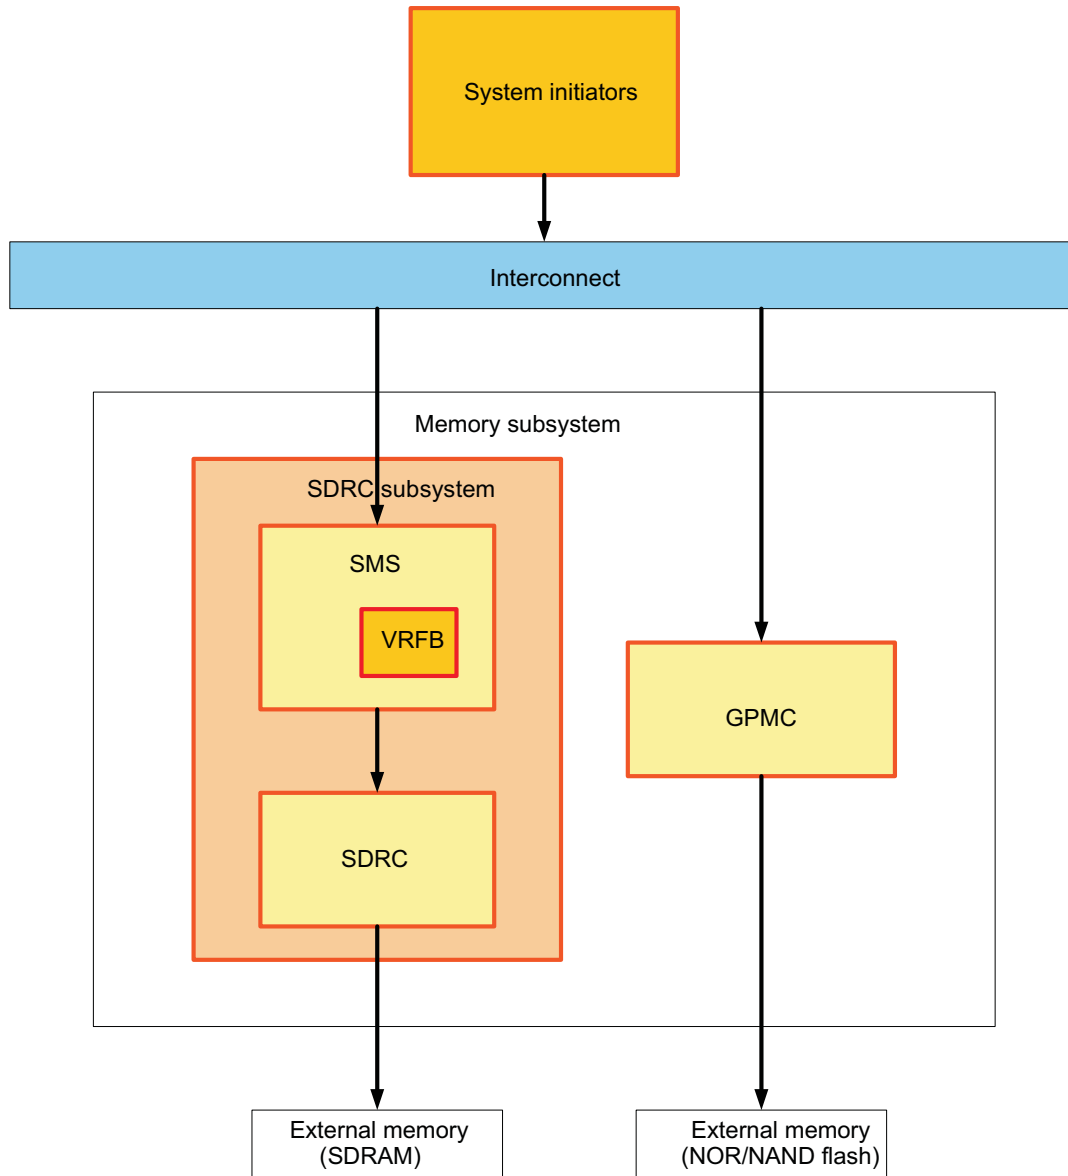

- The size of the page (height and width)
- The picture parameters before rotation (width, height, and pixel format)
- The rotation angle (0-, 90-, 180-, or 270-degree)
- The physical base address in external memory

Any initiator in the OMAP Applications Processor can access up to 12 images simultaneously, each image having an independent context. These 12 contexts is considered virtually addressed image buffers. Each context is assigned to a physical image buffer.

The virtual address space of each context is subdivided into four separate address regions pointing to the same physical image buffer but corresponding to the four possible rotations: 0/90/180/270.

After the VRFB context is configured, all data accesses to an address space are automatically translated when accessing SDRAM through the RE.

Figure 11-58. SDRC Subsystem Overview

sdrc-019

11.2.6.1.2 Setting a VRFB Context

Note: YUV Format

The YUV standard shows a color space with three elements:

- Y for luminance
- U for chrominance
- V for chrominance

As shown in [Figure 11-59](#), pixel format (not pixel size) used in the YUV standard is spread onto a 32-bit data structure:

- This 32-bit data structure represents a packet of two pixels: P0 and P1.
- Each element (Y0, Y1, U, and V) is coded in 8 bits.
- P0 = Y0; U, V, and P1 = Y1, U, V.

There are 24 bits of information per pixel (Y, U, and V); however, because the chrominance elements U and V are common to both P0 and P1 pixels, only 16 bits are used to store a pixel in YUV format. The YUV standard uses a 32-bit data structure to represent 2 pixels; the pixel format uses 32 bits (4 bytes).

Thus, when defining YUV image parameters, the image width must be set to one-half the number of pixels per row and the pixel format must be set to 4 bytes, because the YUV pixel data is spread onto a 32-bit word representing 2 pixels.

[Figure 11-59](#) shows the pixel representation of the YUV format.

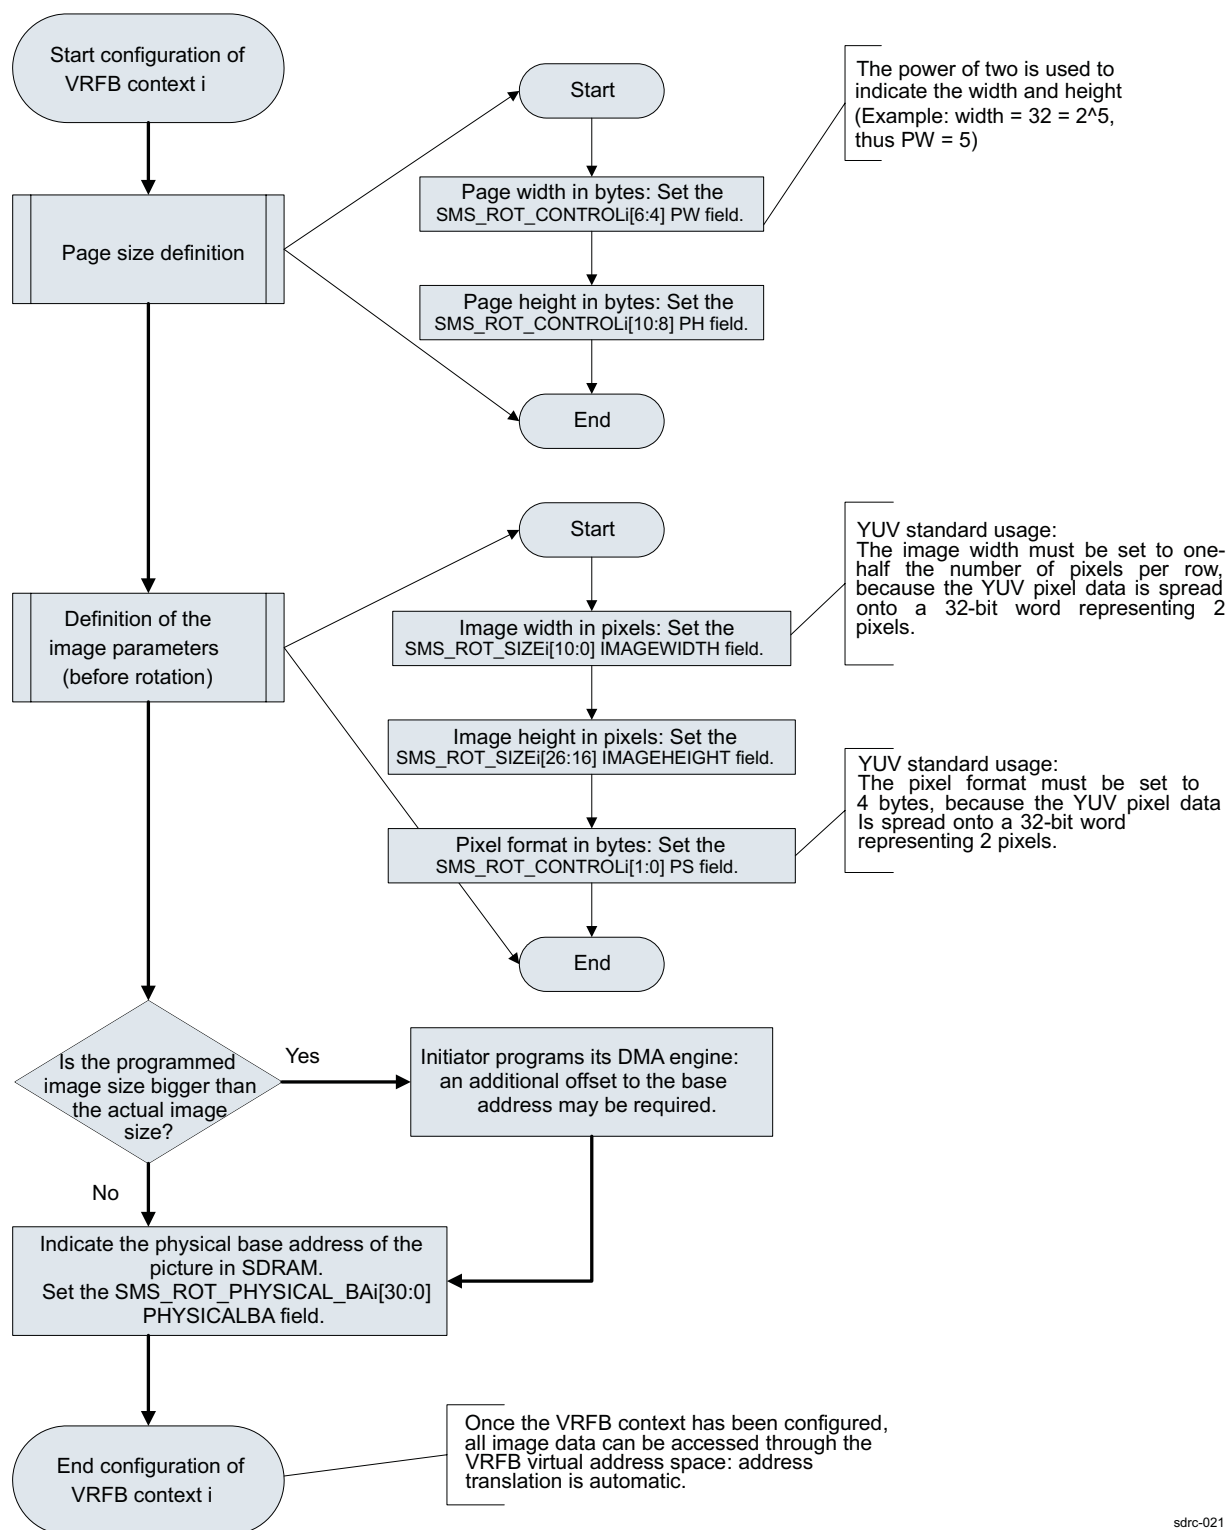

Figure 11-59. YUV Format: Pixel Representation

sdrc-020

Figure 11-60 shows a generic way to configure a VRFB context to perform a rotation view on pixel data in external DRAM.

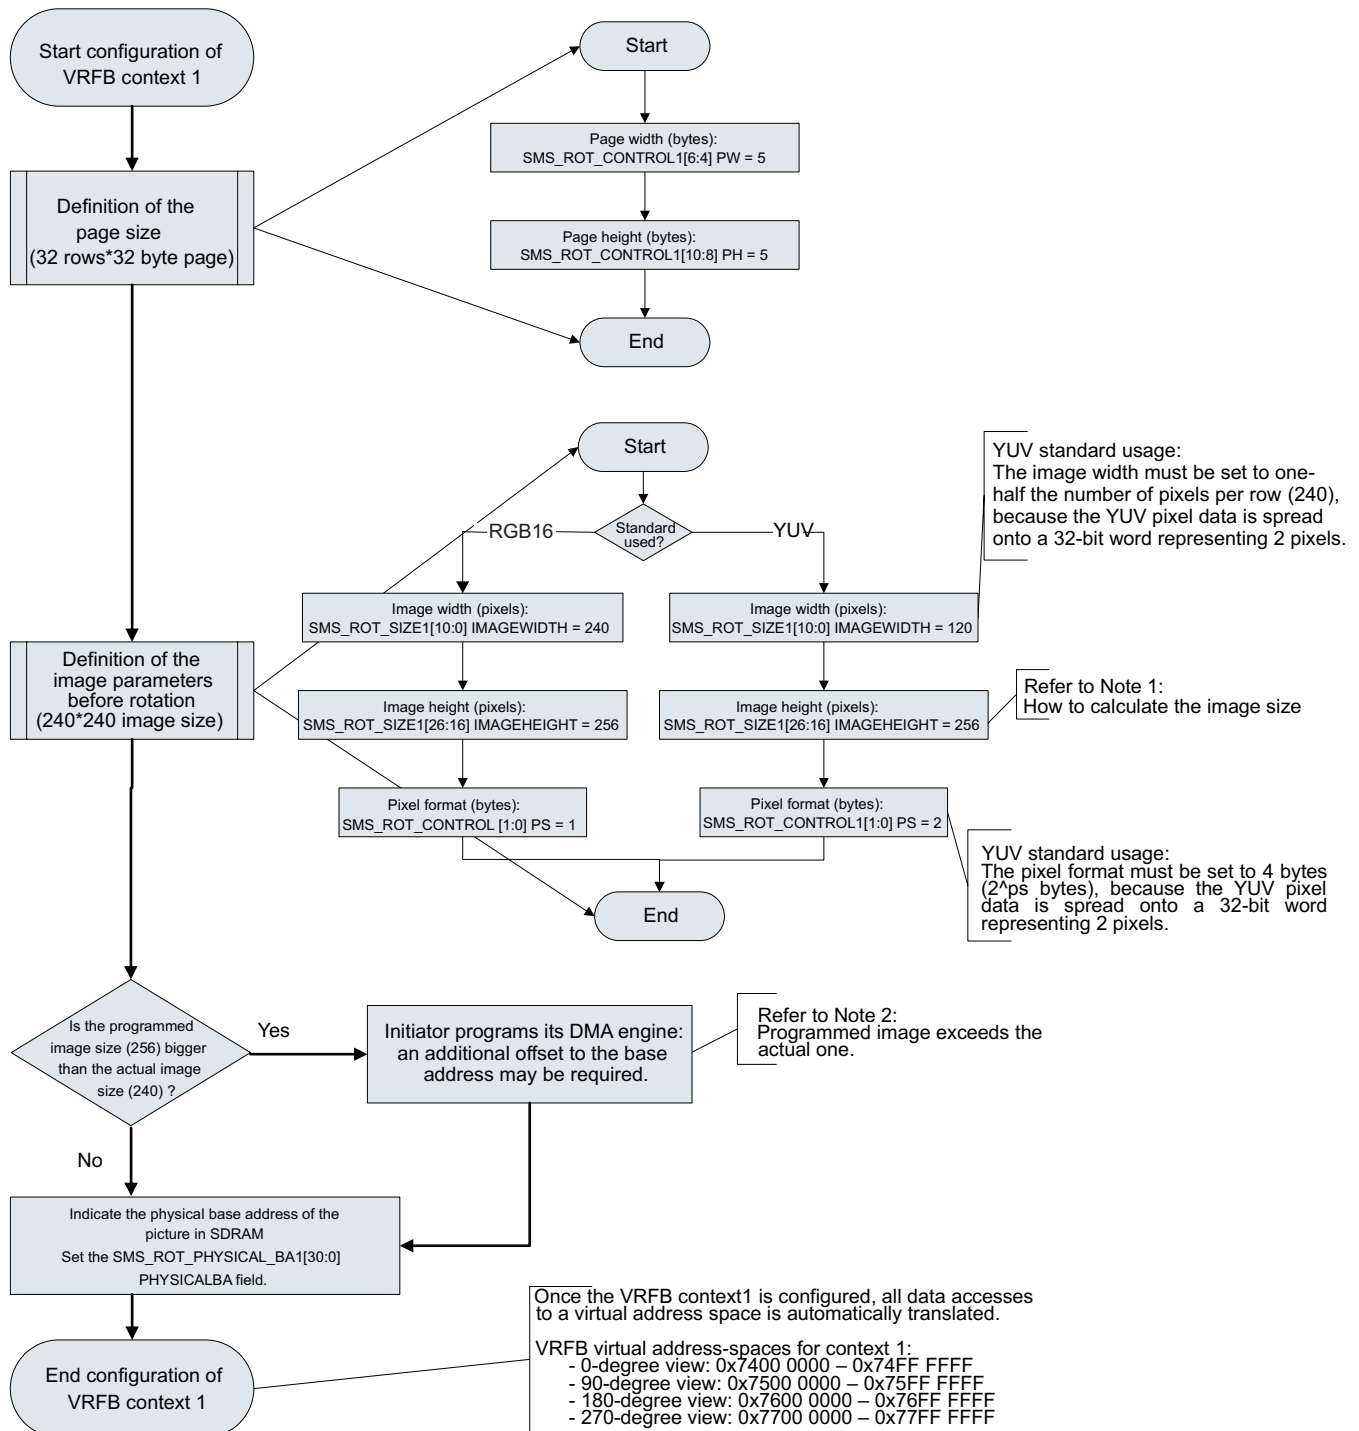

Figure 11-60. VRFB Context Configuration

sdrc-021

Figure 11-61 is an example of VRFB context configuration using both RGB and YUV image formats. This example represents the configuration of a 1024-byte page size (32 × 32 byte page) and a 240 × 240 image size using VRFB context 1.

Figure 11-61. Example of VRFB Context 1 Configuration

sdrc-022

Table 11-105 lists guidelines for calculating image size.

Table 11-105. Calculating Image Size⁽¹⁾⁽²⁾

Steps		RGB16 Format (16-bit Pixel Format)		YUV Format (32-bit Pixel Format)	
		IMAGEWIDTH	IMAGEHEIGHT	IMAGEWIDTH	IMAGEHEIGHT
1	Calculate the required number of pages per line and per column.	240 pixels/32 bytes × 2 bytes per pixel = 15 pages per line	240/32 rows = 7.5, rounded to 8 pages per column	120 pixels/32 bytes × 4 bytes per pixel format = 15	240/32 rows = 7.5, rounded to 8
2	Using the number of pages calculated in Step 1, calculate the image size in pixels.	15 × 32 bytes/2 bytes per pixel = 240	8 × 32 rows = 256	15 × 32 bytes/4 bytes per pixel format = 120	256

⁽¹⁾ Working on a page basis, the image size must be a multiple of the page size.

⁽²⁾ Depending on the page dimensions and the image size, the programmed image size (256) is larger than the actual image size (240).

To use VRFB rotation, each initiator must configure its DMA engine correctly; an additional offset to the base address may be required. For details, see the *Display Subsystem* chapter.

11.2.6.1.3 Applicative Use Case and Tips

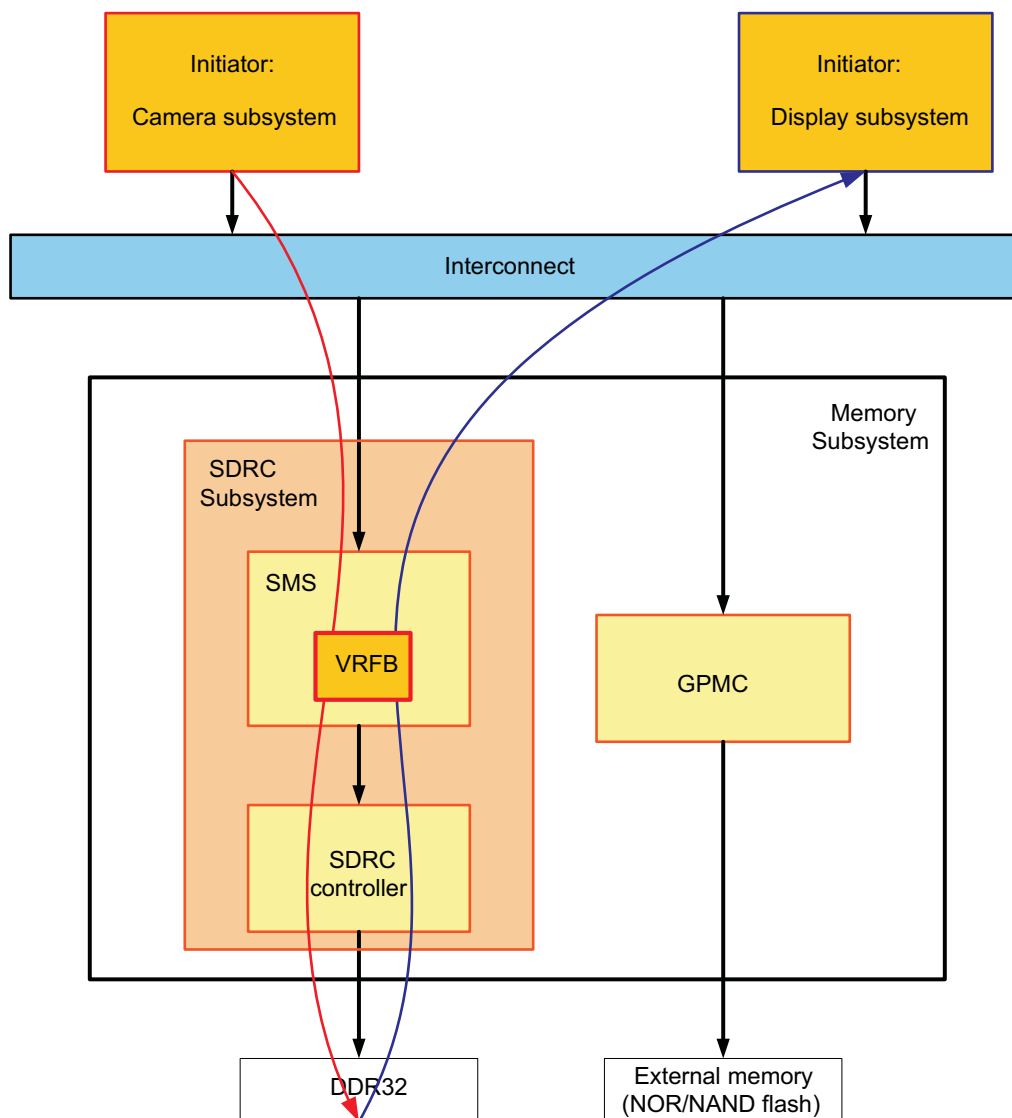

Use Case Scenario: Display a Rotated QVGA Image

Figure 11-62 this use case. The camera captures an image with a particular rotation and stores the pixel data in external memory. Displaying the image on the LCD requires different orientation.

The following components interact while displaying the rotated image:

- SDRC subsystem
- Camera subsystem
- Display subsystem
- External DDR
- VRFB

Figure 11-62. Display a Rotated QVGA Image

sdrc-023

The following conditions exist for this application:

- QVGA image size is 320×240 (width \times height).
- Pixel format is YUV4:2:2 (YUV2) in little endian.
- The rotation view is 90 degrees.
- The VRFB context is VRFB context 1.
- The camera module writes QVGA images to external DRAM at 15 fps.
- The display subsystem reads QVGA images from external DDR32 at 60 fps and displays them on the LCD screen.
- Read and write initiators use burst mode:
 - The camera uses 8×64 -bit burst size.
 - The display uses 8×32 -bit burst size.
 - Double-indexing mode is selected.
- The physical address of the buffer in external memory is 0x8030 0000.
- The memory allocation for the buffer is $320 \times 240 \times 16$ -bit (or $160 \times 240 \times 32$ -bit).
- The camera subsystem uses its dedicated DMA channel 0.

- The display subsystem uses its video channel 1.

Configuring the VRFB through the SMS Registers

The size of the page supported by the DDR32 memory is 1K byte, which is arranged as 32 × 32 bytes page (width × height).

Configuring the page size:

- [SMS_ROT_CONTROLn](#)[6:4] PW = 5 (where n = 1)
- [SMS_ROT_CONTROLn](#)[10:8] PH = 5

Configuring the image parameters:

- [SMS_ROT_SIZE](#)n[10:0] IMAGEWIDTH = 160 (where n = 1)
- [SMS_ROT_SIZE](#)n[26:16] IMAGEHEIGHT = 256
- [SMS_ROT_CONTROLn](#)[1:0] PS = 2

Physical base address and rotation angle:

- [SMS_ROT_PHYSICAL_BA](#)n[30:0] PHYSICALBA = 0x8030 0000 (where n = 1).

The image data is accessed at the following virtual address range for 90-degree rotation: 0x7500 0000 – 0x75FF FFFF.

CAUTION

Image rotation using the YUV2 image format causes the stream to become untidy. The display must be specifically configured to read and reorganize the stream to conform to the YUV2 standard.

Tips for Configuring Successful Rotation

The following guidelines ensure optimal image rotation:

- **Page arrangement:**
Usually, the recommendation is to have a *square* page. If this is not possible, the longest page side should correspond to the access direction that requires the maximum bandwidth; set the longest page side to optimize the page break.
Using a 1024-byte page size, a 32 × 32-byte page arrangement is used as an example. With a 2K-byte page organized as a 32 × 64 byte page, depending on the read or write operation, set the longest page size to optimize the page break. If 0 is written and the 270-degree view is read, page height is greater than page width (PH > PW). Set PH to 64 bytes (PH = 6).
- **Virtual address memory arrangement:**
When accessing image data through virtual addresses, the maximum line size supported by the VRFB is 2,048 pixels.
In the memory buffer, the distance between two vertically adjacent pixels is fixed at 2,048 multiplied by the pixel format in bytes. This means that when reading or writing image data through virtual addresses, there must be an offset of: (2048 – IMAGEWIDTH) × PS bytes at the end of every line.
- **Base address alignment:**
For optimization, the base address is aligned on the page size. For instance, a 1K-byte page size organized as a 32 × 32-byte page is aligned on 0x400 (to be adjusted on the base address).
- **To improve performance on 90° rotation consider two things:**
 - Because a read access can appear more critical than a write access, a posted write may be appropriate.
 - When performing burst accesses with 90° or 270° rotation views, the burst is split on the memory side, adding latency.
For a burst access with 90° rotation, split the data of the burst on the write side (not the read side):
 - Write in 270° and read in 0°.

11.2.6.2 SMS Mode of Operation

11.2.6.2.1 The SDRAM Memory Scheduler and Arbitration Policy

The SDRAM memory scheduler improves access to external memory by:

- Optimizing SDRAM bandwidth
- Prioritizing requests to external memory

This mechanism relies on a complex arbitration policy that employs specific terminology:

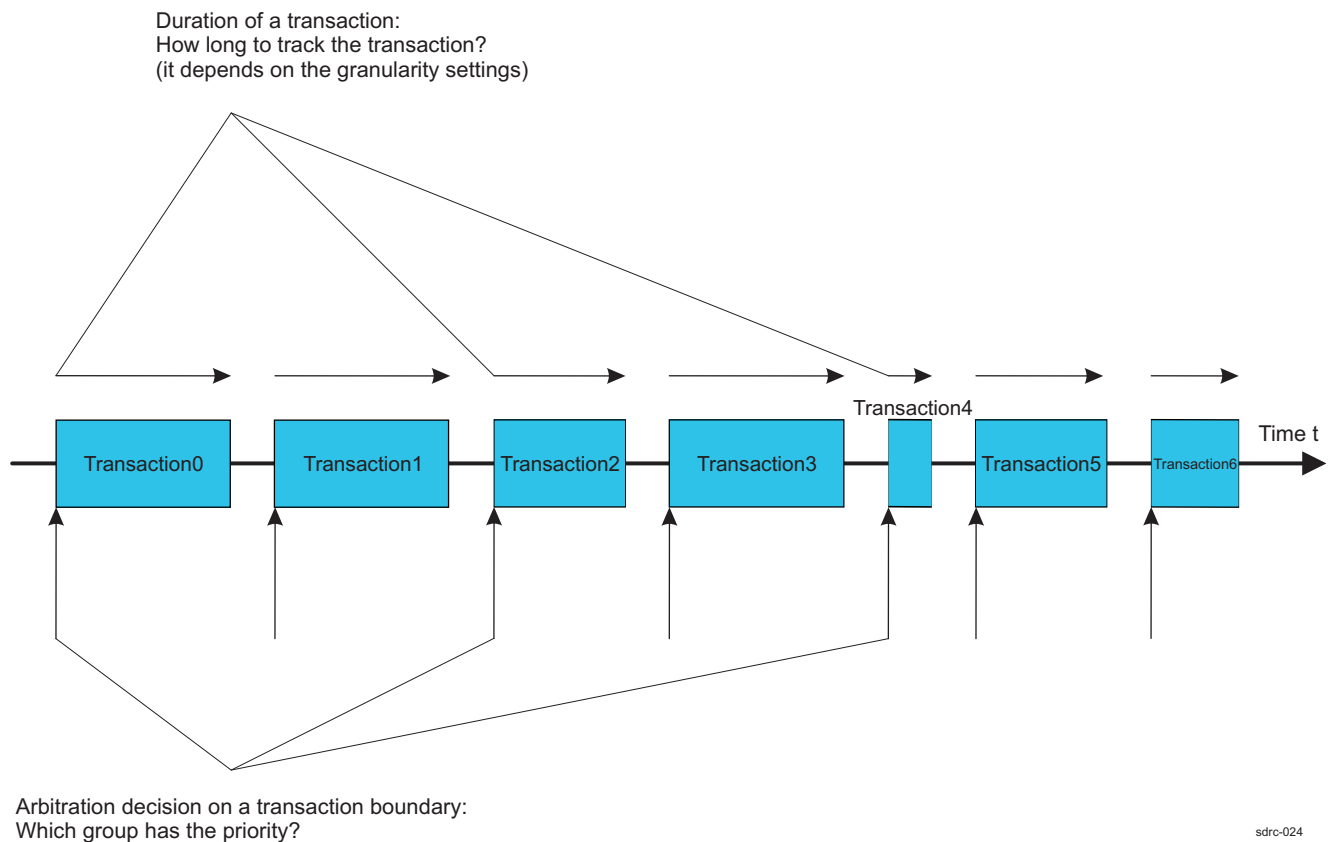

- Group: a FIFO queue of requests from initiators
- Class: A collection of groups
- Transaction: A full burst request
- Arbitration grant: Authorization of a service requested by an initiator

The arbitration policy operates on two interdependent mechanisms:

- The arbitration decision, which establishes priority for processing requests. The question: Which request is processed next? occurs on a transaction boundary.
- Arbitration granularity, which determines the length of an arbitration grant. The question: How long to keep the grant? defines the boundary of the arbitration decision point in time.

Figure 11-63, shows the link between these two concepts. On a transaction boundary, the questions: What request is serviced next, and for how long? merge the two mechanisms. The mechanisms for specifying the granularity of requests also influence the boundary of a transaction.

Figure 11-63. Arbitration Granularity Versus Arbitration Decision

11.2.6.2.2 The Arbitration Decision

The SMS module controls arbitration. Requests from initiators for access to the external SDRAM are collected into several independent FIFO queues, and each queue is assigned to a class. Priority is then assigned to groups and classes; this defines the next request to be serviced.

11.2.6.2.2.1 Burst-Complete Mechanism

The burst-complete mechanism applies granularity to the arbitration scheme. Access cannot be granted to a group within a class until a complete burst has been stored in the FIFO.

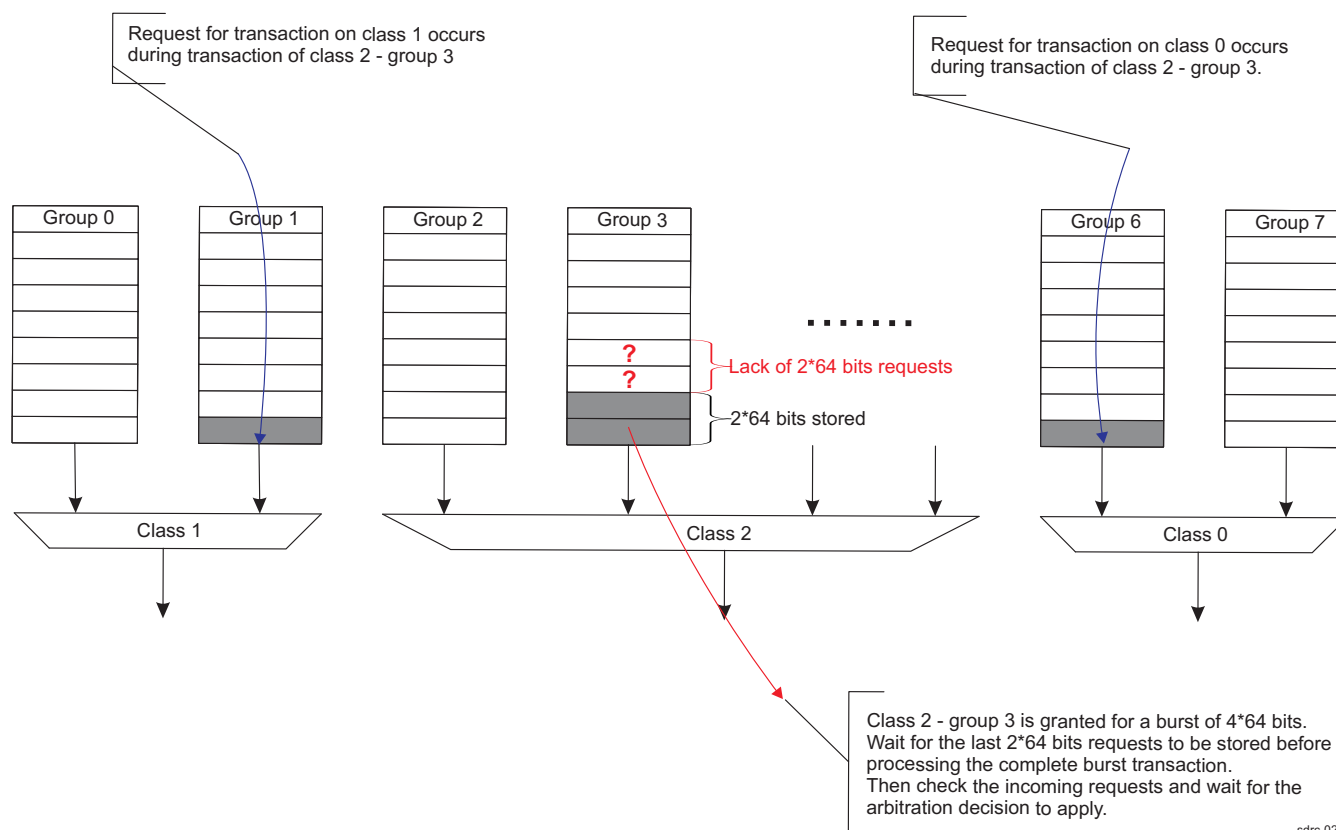

Example:

There is no ongoing transaction on Class 0. The initiator requests a 4×64 -bit burst on Group 3 of Class 2 (SMS_CLASS_ARBITER2[27] BURST-COMPLETE = 0x1). Only 2×64 -bit requests are stored in the FIFO.

The mode of operation is:

- Wait for the last 2×64 -bit request to be stored in the FIFO.
- Arbitration is requested once all requests of a burst have been received.
- After the 4×64 -bit burst is complete, the transaction occurs.
- The arbitration choice mechanism resumes:
 - Were there any incoming requests during the last transaction?
 - What is the next request to be serviced/granted?

Figure 11-64. BURST-COMPLETE on Class 2-Group 3

11.2.6.2.2.2 Priority Between Groups

The SMS.SMS_CLASS_ARBITERi[7:6] HIGHPRIOVECTOR field defines the priority between groups in a class.

11.2.6.2.2.3 Priority Between Classes

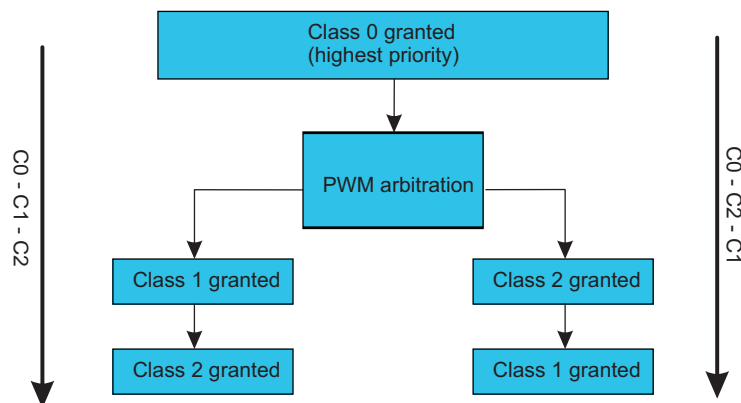

Class 0 always has the highest priority. Then you program a weight within the arbitration of Class 1 and Class 2:

- The SMS.SMS_INTERCLASS_ARBITER[23:16] CLASS1PRIO field specifies the number (M) of transactions dedicated to Class 1.
- The SMS.SMS_INTERCLASS_ARBITER[7:0] CLASS2PRIO field specifies the number (N) of transactions dedicated to Class 2.

M and N parameters are used to set a PWM arbitration. For instance, two schemes appear: at time t, Class 1 is serviced for M cycles, directly followed by service to Class 2 for N cycles. On the opposite, if Class 2 is serviced first for N cycles, then Class 1 is granted for M cycles. Arbitration is given more importance; Class 1/2 is favored over Class 2/1. As shown in Figure 11-65, two arbitration schemes can appear:

- Class 0 is serviced first, followed by Class 1, then Class 2 (C0 - C1 - C2).
- Class 0 is serviced first, followed by Class 2, then Class 1 (C0 - C2 - C1).

Figure 11-65. Priority Between Classes

SMS_INTERCLASS_ARBITER[7:0] CLASS1PRIO field:
defines the number M of transactions dedicated to class 1.

SMS_INTERCLASS_ARBITER[23:16] CLASS2PRIO field:
defines the number N of transactions dedicated to class 2.

sdrc-026

11.2.6.2.3 Arbitration Granularity

Arbitration is the mechanism that give more or less importance to incoming requests depending on the initiator origin. Granularity influences the boundary of a transaction because it imposes the following questions:

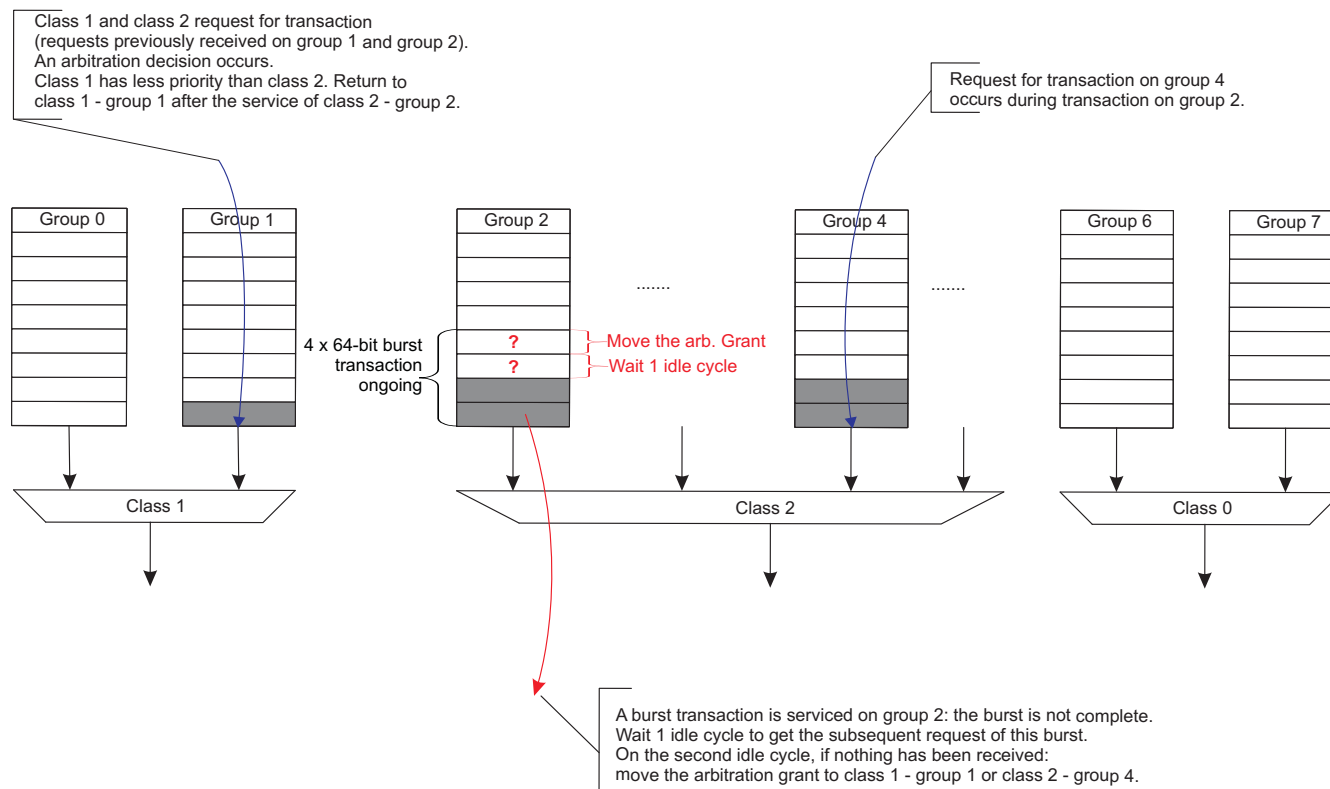

- How many requests to service?
- How long to track the current transaction?
- When to make the next arbitration decision, or when does the next transaction boundary occur?

11.2.6.2.3.1 Idle Cycle

The idle gives more granularity to the arbitration; it lets the arbiter wait one idle cycle before moving the arbitration grant to another thread.

Within a burst (see Figure 11-66 for an example):

1. A thread requests a burst transaction. According to the thread ID, the last request was serviced on Class 2 – Group 2.
2. The thread cannot provide the subsequent request of the burst. The module waits for one idle cycle without moving the arbitration grant, to receive the subsequent request (from the same thread).
3. On the second idle cycle, if the subsequent request has not been received, the arbitration grant is moved so that a request from another thread is serviced.

Figure 11-66. Idle Cycle Mechanism within a Burst

sdrc-027

Two bursts must be serviced at the burst boundary. One idle cycle after servicing these two bursts, the arbitration grant is moved.

11.2.6.2.3.2 Extended-Grant Mechanism

The extended-grant mechanism gives additional granularity to the arbitration. An extended grant defines the number of consecutive transactions (from 1 to 3) a group is granted.

Example:

Requests were already available on Class 1-Group 0 and Class 2-Group 3.

An arbitration decision occurs: grant access to Class 1-Group 0.

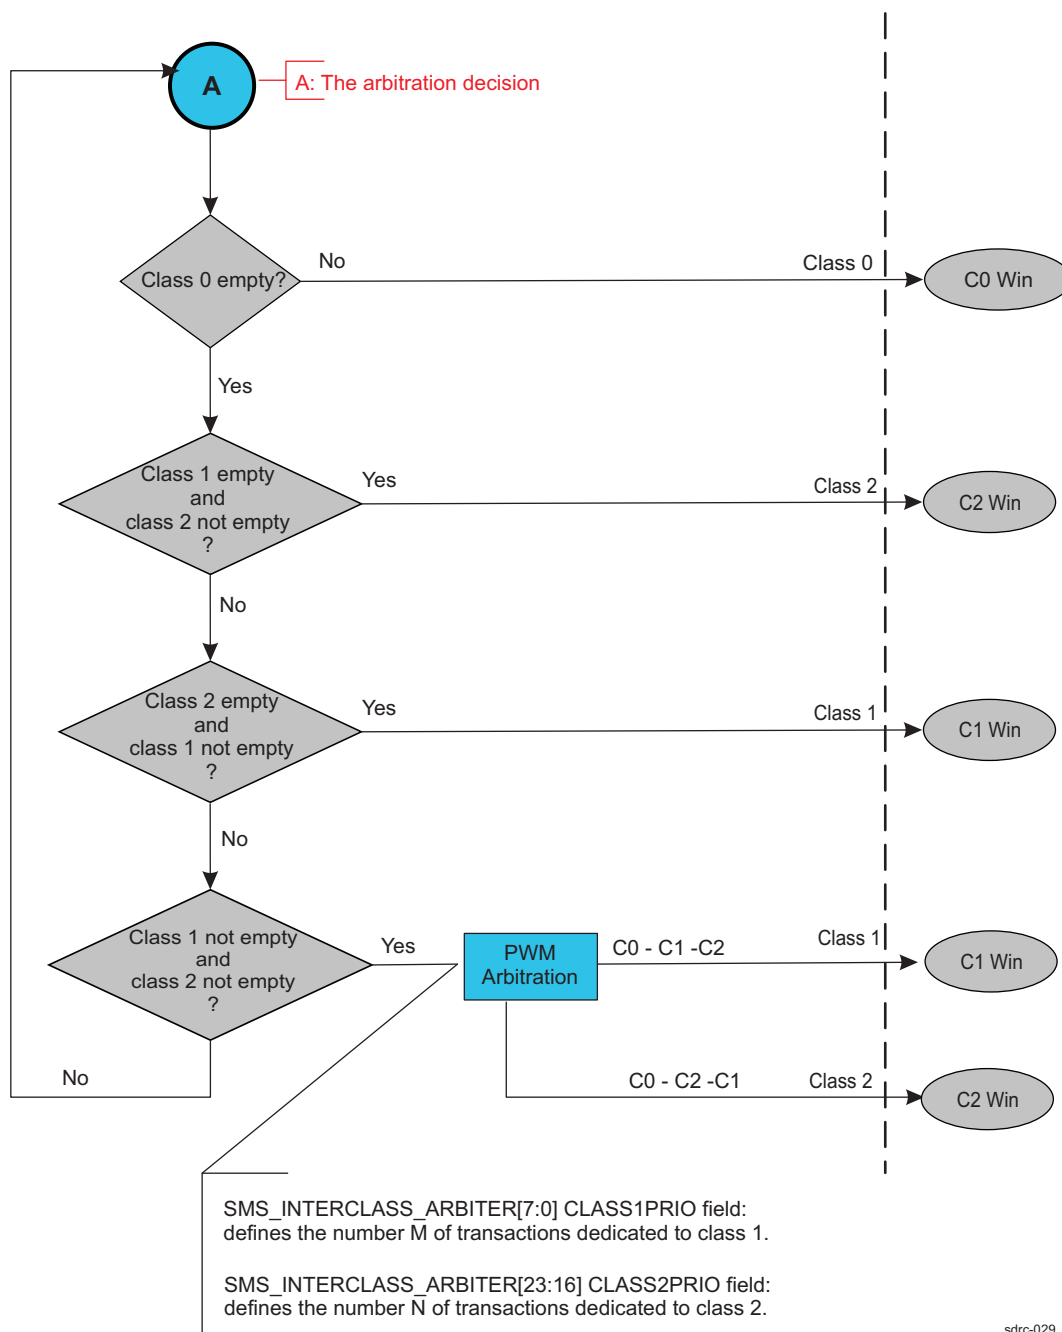

A request is now being serviced on Class 1-Group 0 with `SMS_CLASS_ARBITER1[9:8]`

`EXTENDEDGRANT = 0x3` (three consecutive transactions are granted to Group 0). The mode of operation is:

- Process the request for three cycles.
- If another request comes from another class (even Class 0) during the processing, it is ignored; the arbiter does not treat incoming requests.
- After three consecutive transactions, return to the arbitration decision:
 - Were there any incoming requests during the last transaction?
 - What is the next request to be serviced?

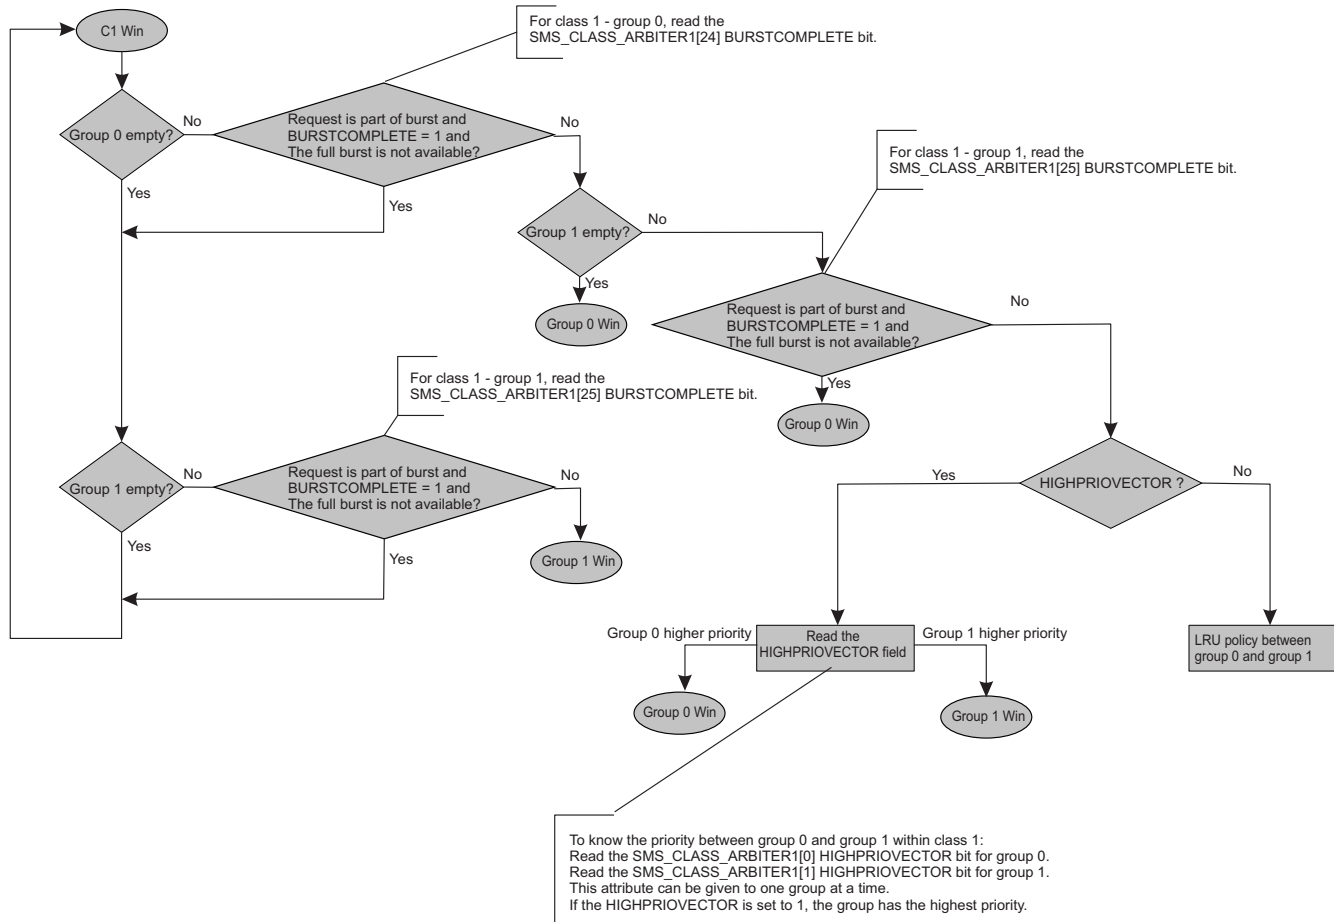

Figure 11-67 shows this mechanism on Class 1 - Group 0:

11.2.6.3 Typical SDRC Connection to an External SDRAM Device

The SDRAM controller (SDRC) transfers data to and from standard SDRAM based on user request. It interfaces between an external SDRAM memory subsystem and the SDRAM Memory Scheduler that optimizes memory access for each application.

This section shows a typical connection between the SDRC module and an external SDRAM. The use case explains important parameters and their required configurations.

11.2.6.3.1 External Memory Attached to the SDRC Module

The SDRC module supports the following external memory types:

- Low-power DDR SDRAM device

This section describes how to calculate the SDRC timing parameters and provides a typical setup of those parameters according to the access performed.

A 512 Mb mobile DDR SDRAM memory with the following characteristics has been chosen:

- Type: Mobile DDR SDRAM
- Size: 512 Mbits ($8M \times 16 \times 4$ banks)
- Data bus: 16-bit width
- Speed: 133-MHz clock frequency, 7.5-ns clock period

11.2.6.3.2 DDR-SDRAM Memory General Facts

This section details the interconnection of the Mobile DDR SDRAM with the SDRC interface; it then gives a basic SDRAM workflow and introduces the difference between the autorefresh and self-refresh concepts.

11.2.6.3.2.1 Mobile DDR Interconnection with SDRC

Figure 11-72 shows a simplified interconnection diagram of the mobile DDR SDRAM with the SDRC interface.

Figure 11-72. Mobile DDR SDRAM to SDRC Interface

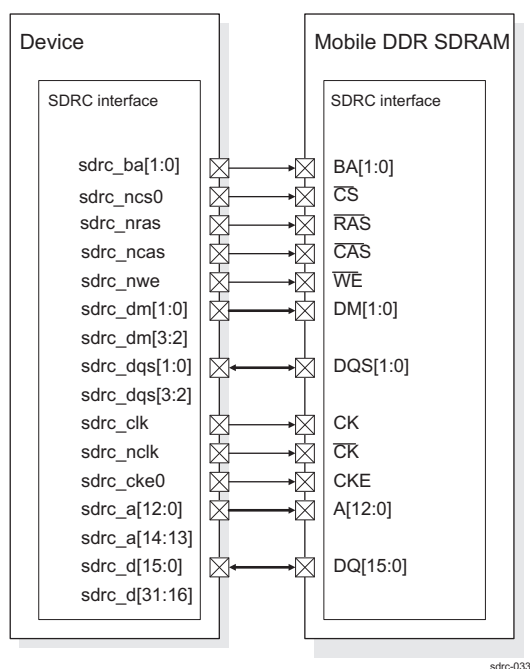

Table 11-106 recalls SDRC module's I/Os from a SDRC point of view.

Table 11-106. SDRC Signals Description

Signal Name	I/O ⁽¹⁾	Description
sdrc_clk, sdrc_nclk	O	Address and control input signal sample clock
sdrc_cke0	O	Clock-enable signal
sdrc_ncas, sdrc_nras, sdrc_nwe	O	Column address strobe, row address strobe, and write enable. Defines the command being entered
sdrc_ba0, sdrc_ba1	O	Bank address outputs
sdrc_dm[3:0]	O	Data mask. sdrc_dm[0] corresponds to the data on sdrc_d[7:0]; sdrc_dm[1] corresponds to the data on sdrc_d[15:8]. sdrc_dm[3:2] unconnected.
sdrc_ncs0	O	Chip-select for external SDRAM selection (only one enabled here)
sdrc_a[12:0]	O	Address bus sdrc_a[14:13] unconnected.
sdrc_d[15:0]	I/O	Data bus sdrc_d[31:16] unconnected.
sdrc_dqs0, sdrc_dqs1	I/O	DDR data strobe. Output with read data, input with write data sdrc_dqs[3:2] unconnected.

(1) I = Input; O = Output

11.2.6.3.2.2 SDRAM Operating Flow

This section illustrates the basic DDR-SDRAM workflow. For more information on SDRAM operation, refer to the *Low Power Double Data Rate (LPDDR) SDRAM* specification (JEDEC committee JC42.3) or to the Mobile DDR SDRAM documentation.

Figure 11-73 shows a simplified operating diagram of the power up sequence required to correctly power up an SDRAM.

Figure 11-74 shows a simplified diagram of the normal operating sequence.

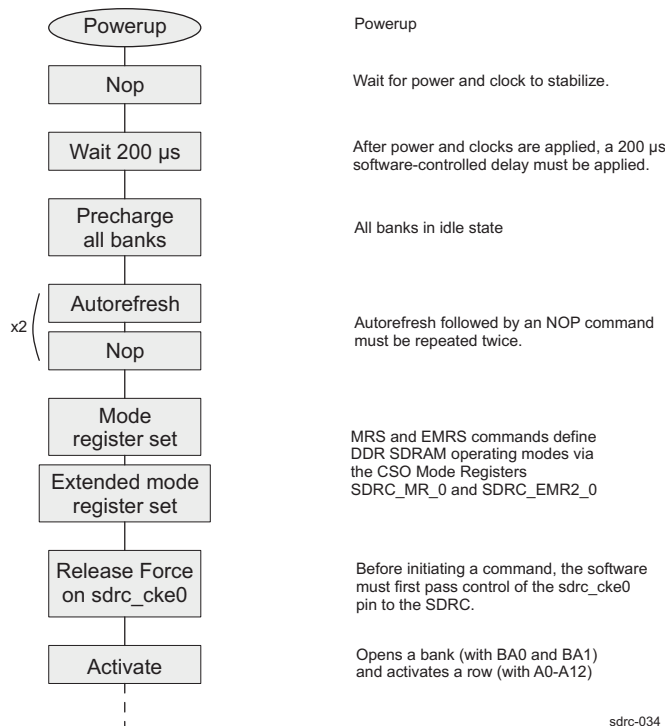

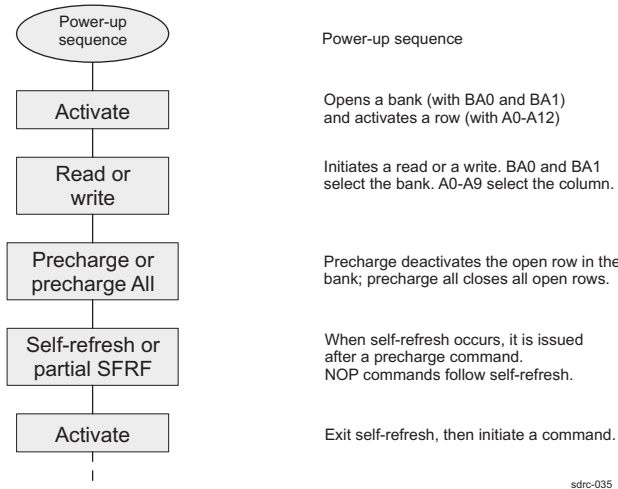

Figure 11-73. SDRAM Powerup Sequence

Figure 11-74. Normal Operating Sequence

11.2.6.3.2.3 Autorefresh vs Self-Refresh

What are the differences between an autorefresh and a self-refresh?

DDR SDRAM devices require a refresh of all rows in 64 ms intervals as specified in the JEDEC LPDDR SDRAM standard. The autorefresh period may depend on the technology. Each refresh is generated either by an autorefresh command from the SDRC in normal mode, or by an internal counter in the SDRAM in self-refresh mode.

The autorefresh command must be generated each time a refresh is required. The average refresh interval period (tREFI), also called autorefresh duty cycle, is given by the division of 64 ms into the number of rows (8192 for the selected mobile DDR SDRAM). An internal refresh controller in the SDRAM takes care of the refreshing process and control, and the autorefresh command must be issued regularly by the SDRAM controller.

The self-refresh command is used when the system is powered down and enables data retention even if the clock is stopped.

For more information on refresh modes, see [Section 11.2.4.4.7, Refresh Management](#).

11.2.6.3.3 SDRC Typical Setup

When a given external memory device has been selected, the SDRC must be configured according to the memory parameters.

11.2.6.3.3.1 Memory Type General Configuration

Table 11-107 summarizes the mobile DDR SDRAM address configuration.

Table 11-107. Mobile DDR SDRAM Address Configuration

Item	Description
RAM size	512 Mbits
Number of banks	4
Bank address pins	BA0, BA1
Row addresses	A0-A12
Column addresses	A0-A9
tREFI (μs)	7.8

The following parameters must be configured in register `SDRC.MCFG_p`, where $p = 0$ (configuration register for the SDRAM connected to the `sdrc_ncs0`) as follow:

- `SDRC_MCFG_p[19]` ADDRMUXLEGACY = 0x1 selects the flexible address mux scheme.
- `SDRC_MCFG_p[1:0]` RAMTYPE = 0x1 selects DDR-SDRAM.
- `SDRC_MCFG_p[2]` DDRTYPE = 0x0 is the default setting that sets the DDR memory type as mobile DDR.
- `SDRC_MCFG_p[17:8]` RAMSIZE = 0x020 is the RAM address space size expressed in 2-Mbyte chunks. In this example, the DDR SDRAM size is 512 Mbits or 64 Mbytes. These are 32 2-Mbyte chunks, that is, 20 2-Mbyte chunks expressed in hexadecimal format.
- `SDRC_MCFG_p[4]` B32NOT16 = 0x0. The external SDRAM bus width is 16-bit.
- `SDRC_MCFG_p[26:24]` RASWIDTH = 0x2 because RAS width is 13 bits.
- `SDRC_MCFG_p[22:20]` CASWIDTH = 0x5 because CAS width is 10 bits.
- `SDRC_MCFG_p[3]` DEEPPD = 0x1. The memory device supports deep-power-down mode.
- Other bit fields as LOCKSTATUS and BANKALLOCATION may be set up as required.

11.2.6.3.3.2 Mode Register Configuration

The SDRAM mode of operation is defined through the mode register as follow ($p = 0$ for CS0):

- `SDRC_MR_p[6:4]` CASL = 0x3. The CAS latency, or read period, is 3 clock cycles long.
- `SDRC_MR_p[2:0]` BL = 0x2. The memory burst length must be set at 4 for DDR SDRAM.
- `SDRC_MR_p[3]` SIL = 0x0. The serial mode is always used.
- `SDRC_MR_p[9]` WBST = 0x0. Write burst equals read burst.

To configure the DLL/CDL module as second clock write path, set up the `SDRC_DLLA_CTRL` register as follows:

- `SDRC_DLLA_CTRL[7]` WRITEDDRCLKX2DIS = 0x1 so that the DLL/CDL write path can be used as mobile DDR write path.
- `SDRC_DLLA_CTRL[3]` ENADLL = 0x1 enables the DLL.
- `SDRC_DLLA_CTRL[2]` LOCKDLL must be set to 0 for high-speed operations.
- `SDRC_DLLA_CTRL[1]` DLLPHASE. 0x0 for read accesses or 0x1 for write accesses. This respectively corresponds to a CDL delay of a quarter of a clock period or a fifth of a clock period.

The recommended configuration is to use the data path using double frequency logic rather than the DLL/CDL write path. This is obtained by setting WRITEDDRCLKX2DIS to 0x0.

11.2.6.3.3.3 SDRAM Programmable AC Timing Parameters Configuration

Some parameters are hard-coded in the SDRC. Apart from those parameters, users can program a list of programmable AC timings via the [SDRC_ACTIM_CTRLA_p](#) and [SDRC_ACTIM_CTRLB_p](#) registers, where $p = 0$ or 1 , depending on the SDRAM chip (in the section $p = 0$, since only one chip is connected to the SDRC interface). The setup values are expressed in clock cycles.

[Table 11-108](#) summarizes the most important AC timing parameters to be configured. $F = 133$ MHz and $t_{CK} = 7.5$ ns for the clock signal.

Table 11-108. Mobile DDR SDRAM AC Timings Parameters

AC Timing Parameter	Description	Duration (ns)
t_{RC}	Row cycle time	67.5 (or 9 t_{CK})
t_{RAS}	Row active time	45 (or 6 t_{CK})
t_{RP}	Row precharge time	22.5 (or 3 t_{CK})
t_{RCD}	nRAS to nCAS delay time	22.5 (or 3 t_{CK})
t_{RFC}	Autorefresh cycle time	80 (min)
t_{RRD}	Row active to row active delay time	15 (or 2 t_{CK})
t_{DPL}	Data-in to precharge command time or tWR (write recovery time)	15 (or 2 t_{CK})
t_{WTR}	Write-to-read time (also called tCDLR). Last data in to read command	1 t_{CK}
t_{CKE}	CKE minimum pulse width time (high and low pulse width)	2 t_{CK}
t_{DAL}	Last data in to active delay time	2 $t_{CK} + t_{RP}$
t_{XSR}	Exit self-refresh to active command time	120
t_{XP}	Exit power-down to active command time	25

Before calculating the timing parameters on the SDRC side, let's define some terms used to describe the timing between the controller and the memory device:

- nRAS to nCAS delay time is the row-activating phase, or minimum time between an ACTIVE and a READ or WRITE command.
- CAS latency is the time between a READ or a WRITE command and the data driven on DQ lines. With $CL = 3$, the first data element is valid at $(2 \times t_{CK} + t_{AC})$ after the clock at which the READ command is registered. With $CL = 2$, the first data element is valid at $(t_{CK} + t_{AC})$ after the clock at which the READ command is registered. t_{AC} is the DQ output window relative to the clock, and is the long term component of DQ skew.
- Row active time is the minimum bank activate to PRECHARGE time. A PRECHARGE cannot start until t_{RAS} has elapsed.
- Row precharge time: Following the PRECHARGE command, a subsequent command to the same bank cannot be issued until t_{RP} is met. After t_{RP} , an ACTIVE command to the same bank can be initiated.
- Row cycle time is the minimum time between the activation of a first row and the activation of another row in the same bank. It is also called ACTIVE to ACTIVE command period.
- Last data in to active delay time is the minimum time between the last data in and the next ACTIVE command.
- Autorefresh cycle time: Refreshing starts with an AUTO REFRESH command and ends when t_{RFC} is met.

[Figure 11-75](#) shows a simplified timing diagram of a burst read of SDRAM.

Figure 11-75. SDRAM Burst-Read Timing Diagram

The [SDRC_ACTIM_CTRLA_p](#) register (p = 0) must be programmed with the AC timing parameters listed in [Table 11-109](#). Values are expressed in number of tCK periods.

Table 11-109. Calculation of the SDRC.SDRC_ACTIM_CTRLA_p Timing Parameters

DDR-SDRAM Parameter Name	Number of Clock Cycles (F = 133 MHz, tCK = 7.5 ns)	SDRC_ACTIM_CTRLA_p Bit Field Value
tRC	9	TRC = 0x09
tRAS	6	TRAS = 0x6
tRP	3	TRP = 0x3
tRCD	3	TRCD = 0x3
tRFC	80 / 7.5 (minimum)	TRFC = 0x0B
tRRD	2	TRRD = 0x2
tDPL	2	TDPL = 0x2
tDAL	2x1 + 4 (in clock cycles)	TDAL = 0x6

The [SDRC_ACTIM_CTRLB_p](#) (p = 0) register must be programmed with the AC Timing Parameters listed in [Table 11-110](#). Values are expressed in number of tCK.

Table 11-110. Calculation of the SDRC.SDRC_ACTIM_CTRLB_p (p = 0) Timing Parameters

DDR-SDRAM Parameter Name	Number of Clock Cycles (F = 133 MHz, tCK = 7.5 ns)	SDRC_ACTIM_CTRLB_p Bit Field Value (p=0)
tCDLR	1	TWTR [17:16] = 0x1
tCKE	2	TCKE [14:12] = 0x2
tXP	25 ns ⁽¹⁾	TXP [10:8] = 0x4
tXSR	120 / 7.5	TXSR [7:0] = 0x10

⁽¹⁾ JEDEC LPDDR SDRAM standard states 25 ns with a minimum of 1 clock period.

11.2.6.3.4 Autorefresh Management Configuration

In normal operation mode, the autorefresh is managed by the SDRAM refresh configuration register [SDRC_RFR_CTRL_p](#) (where $p = 0$). The autorefresh counter is uploaded with the result of $(t_{REFI} / t_{CK}) - 50$.

50 (cycles) is a margin in case a command is already in progress on the SDRAM interface, thus requiring delay before initiating the autorefresh command. See [Section 11.2.5.3.6, Autorefresh Management](#), for more details.

[Table 11-111](#) details the required configuration.

Table 11-111. Calculation of the SDRC.SDRC_RFR_CTRL_p ($p = 0$) Timing Parameter

DDR-SDRAM Parameter Name	Contents Formula	SDRC_RFR_CTRL_p Bit Field Value ($p=0$)
Autorefresh counter value	$(7.8 \mu s / 7.5 ns) - 50$	ARCV [23:8] = 0x03DE
Autorefresh enable	Load Autorefresh counter with 8 for maximum Autorefresh burst length	ARE [1:0] = 0x3

11.2.6.4 Camcorder Use Case: How to Configure the VRFB

11.2.6.4.1 Overview

This section discusses the configuration of the VRFB for rotating the video from the camera subsystem. The VRFB receives a video from the camera subsystem as a sequence of images. These images are then saved into SDRAM through the SDRC. [Figure 11-76](#) is an overview of the VRFB in the camcorder use case.

Figure 11-76. SDRC Camcorder Use Case Overview

After the VRFB configuration, the rotation process is transparent to the MPU operations. Four buffers are required in SDRAM to ensure stabilization, a smooth encoding process, and a tearing-free preview on the LCD display. Each of the four buffers uses a concurrent context. For each context, the following parameters must be configured:

- Page and pixel size
- Picture parameter (image height and width)
- Buffer physical base address

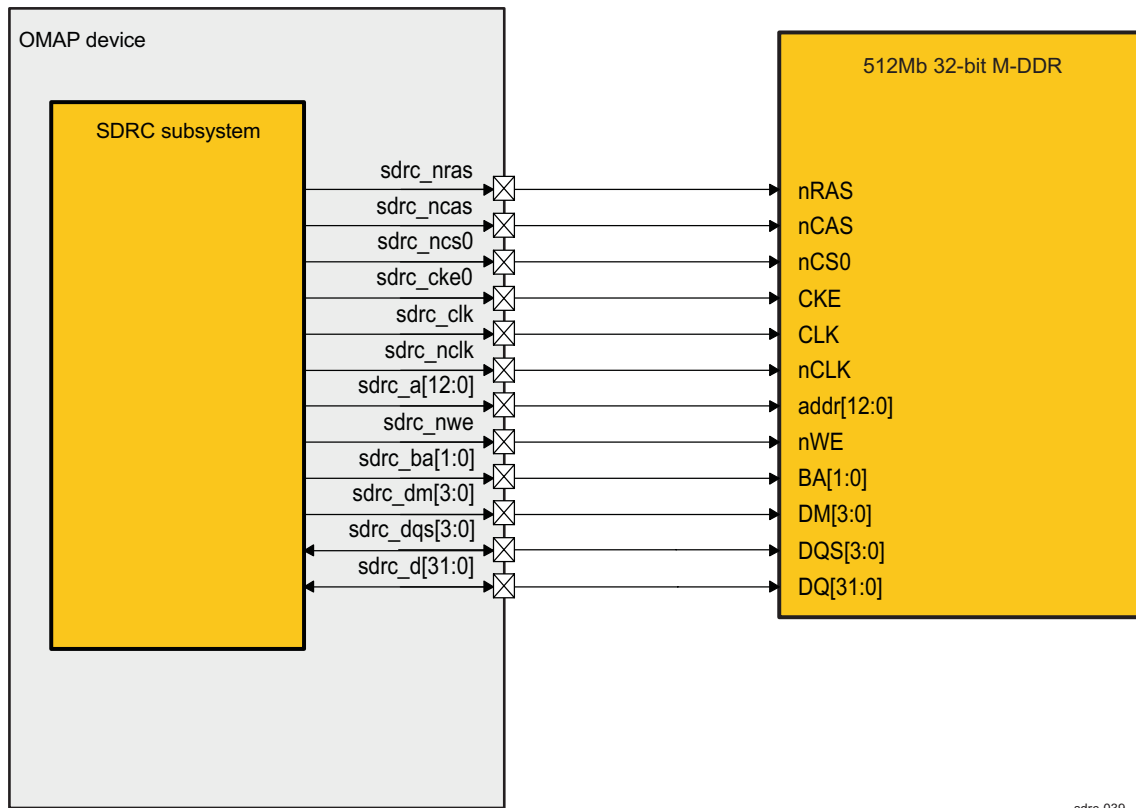

11.2.6.4.2 Environment

In this use case, the SDRC controller is connected to an external 512Mb 32-bit Mobile DDR SDRAM 166-MHz device (16M × 32).

The SDRC_CLK clock source fed to the SDRAM is the PRCM CORE_L3_ICLK output.

The SDRAM device is connected to the SDRC subsystem (see [Figure 11-77](#)). For more information on the SDRC environment, see [Section 11.2.2, SDRC Subsystem Environment](#).

Figure 11-77. SDRC Camcorder Use Case Environment

11.2.6.4.3 Data Path

In this use case, the VRFB manages the rotation of the video stream, which is a sequence of images in YUV 4:2:2 format received from the camera subsystem.

- Write actual image received from the camera subsystem into SDRAM through the VRFB in the first view (0°).
- Display the image in SDRAM on the external display through the display subsystem in any of the four available VRFB views (0°, 90°, 180°, or 270°).

See [Figure 11-62](#) for the VRFB data path of this use case.

The row increment in the SDRAM is programmed in the display subsystem registers and depends on the VRFB rotation angle.

11.2.6.4.4 Programming Flow

A main function automatically configures the VRFB contexts. This function is called four times to configure each of the four contexts. For each context, a set of parameters is given to the function:

- The actual image width and height (from the camera subsystem)
- The physical address (of the given context)
- The rotation of the context

The main function initializes the VRFB in three steps:

1. Virtual frame buffer configuration. This is done with a page size calculation function, as described in [Section 11.2.6.4.4.1](#).
2. Image size configuration. This is done with a picture size calculation function, as described in [Section 11.2.6.4.4.2](#).
3. Physical base address configuration, as described in [Section 11.2.6.4.4.3](#).

11.2.6.4.4.1 Page Size Calculation Function

The page size is configured through three parameters: page width (PW), page height (PH), and pixel size (PS). The three page size parameters are configured into the `SMS_ROT_CONTROLn` registers, where n is the context number ($n = 0$ to 3):

- Page width: `SMS_ROT_CONTROLn[6:4]` PW. The PW parameter defines the page width according to the value of 2^{PW} bytes.
- Page height: `SMS_ROT_CONTROLn[10:8]` PH. The PH parameter defines the page height according to the value of 2^{PH} lines.
- Pixel format: `SMS_ROT_CONTROLn[1:0]` PS. The PS parameter defines the pixel size according to the value of 2^{PS} bytes. In this use case, the pixel size is a constant linked to the YUV 4:2:2 format. For more details about YUV 4:2:2 format, see [Section 11.2.6.1.2, Setting a VRFB Context](#).

The recommendation is to have a squared page arrangement. The page can be defined as a 32-byte \times 32-byte array (1024-byte page) or 16-byte \times 16-byte array (256-byte page). This arrangement is pixel-based, which means the pixel size must be part of the calculation. Other settings are possible, but from a performance point of view it is recommended to have the page size consistent with the SDRAM page (that is, 2K bytes for the Mobile DDR SDRAM).

In this use case, however, the page size calculation function defines the page width and the page height. The pixel size is not part of the calculation. Hence, instead of having a 64 \times 32 page (because a pixel takes 2 bytes) the function calculates a 32 \times 32 page. This gives a page size of 1K-byte, and memory area usage is optimized.

First, the function checks whether the width of the image received from the camera is a multiple of 32 bytes. If the width is not a multiple of 32 bytes, the function checks whether the image is a multiple of 16 bytes. If the image from the camera is neither a multiple of 32 bytes nor 16 bytes, the function sets the page width to 32 bytes as the default. In this use case, the image received from the camera has a width of 736 pixels.

1. Check that 736 is a multiple of 32: $736 / 32 = 23$. It is. As a consequence, the page width is 32 (bytes).
2. Configure a page width of 32 with the 2^{PW} bytes formula: `SMS_ROT_CONTROLn[6:4]` PW = 0x5.
Then, the function checks whether the height of the image received from the camera is a multiple of 32 (rows). If the height is not a multiple of 32 (rows), the function checks whether the image is a multiple of 16 rows. If the image from the camera is neither a multiple of 32 rows nor 16 rows, the function sets the page height to 32 rows as the default. In this use case, the image received from the camera has a height of 560 lines.
3. Check that 560 is a multiple of 32: $560 / 32 = 17.5$. It is not.
4. Check that 560 is a multiple of 16: $560 / 16 = 35$. It is. As a consequence, the page height is 16 (lines).
5. Configure a page height of 16 with the 2^{PH} lines formula: `SMS_ROT_CONTROLn[10:8]` PH= 0x4.
The pixel format of this use case is YUV 4:2:2. Two pixels are stored on 4 bytes.
6. Configure a pixel size of four bytes with the 2^{PS} bytes formula: `SMS_ROT_CONTROLn[1:0]` PS = 0x2.

11.2.6.4.4.2 Picture Size Calculation Function

The picture size is configured through two parameters: image width (IMAGEWIDTH) and image height (IMAGEHEIGHT). Two sizes must be distinguished:

- Actual image width and actual image height. This is the size of the image received by the camera subsystem.
- Programmed image width and programmed image height. This is the size of the image programmed in the VRFB.

Figure 11-78 shows the actual image width (IW) and image height (IH) versus the programmed image width ($IW + \Delta IW$) and programmed image height ($IH + \Delta IH$).

Figure 11-78. VRFB Actual Image Size vs Programmed Image Size

sdr-040

The programmed image size parameters are configured into the [SMS_ROT_SIZE_n](#) registers, where n is the context number (n = 0 to 3):

- Image width: [SMS_ROT_SIZE_n\[10:0\]](#) IMAGEWIDTH. This parameter is expressed in the number of pixels.
- Image height: [SMS_ROT_SIZE_n\[26:16\]](#) IMAGEHEIGHT. This parameter is expressed in the number of pixels.

The picture size calculation function determines the required number of pages per line and per column using the page size calculated previously. That is a page width of 8 pixels (32 bytes and 4-byte pixel) and a page height of 16 pixels.

1. Determine the required number of pages per line with the formula:

$$\left[\left(\frac{\text{actual_image_width}}{2} \right) \text{ pixels} / \text{page_width bytes} \right] \times \text{pixel_size bytes/pixel}$$

This gives a required number of pages per line of $[(736 / 2) / 32] \times 4 = 46$.
 If the number of pages per line is not an integer, it must be rounded up; for instance, if the result was 46.25 the number of pages required per line would be 47. Figure 11-78 shows this point.
2. Determine the required number of pages per column with the formula:

$$\text{actual_image_height pixels} / \text{page_height lines}$$

This gives a required number of pages per column of $(560) / 16 = 35$.
 If the number of pages per column is not an integer, it must be rounded up.

Finally, calculate the programmed image size in pixels using the number of pages calculated above:

1. Calculate the programmed image width with the formula:

$$(\text{rounded_up_number_of_pages_per_line} \times \text{page_width bytes}) / \text{pixel_size bytes/pixel}$$

This gives a programmed image width of $(46 \times 32) / 4 = 368$.

The function sets `SMS_ROT_SIZEn`[10:0] IMAGEWIDTH = 0x170.

2. Calculate the programmed image height with the formula:
(rounded_up_number_of_pages_per_column × page_height_lines)
This gives a programmed image height of (35 × 16) = 560.
The function sets `SMS_ROT_SIZEn`[26:16] IMAGEHEIGHT = 0x230.

Because the actual image is a multiple of the page size (both width and height, as explained in [Section 11.2.6.4.4.1](#)), the actual image size and the programmed size are the same. In other words, ΔIW and ΔIH are null in this use case.

11.2.6.4.4.3 Physical Base Address Configuration

The physical base address is the address of the picture in the external SDRAM. In this use case, the address space of CS0 is 512 Mbits, ranging from 0x8000 0000 to 0x83FF FFFF because the Mobile DDR SDRAM is a 512 Mbits memory device.

The physical address of the picture is a parameter entered by the user. It is directly written into the `SMS_ROT_PHYSICAL_BAn`[30:0] PHYSICALBA bit field (where n = 0 to 11, for the 12 contexts).

11.2.6.4.4.4 VRFB Use Case Summarizing Register Values

[Table 11-112](#) summarizes all the VRFB registers to be configured with the required values.

Table 11-112. VRFB Use Case Summarizing Register Print

Register Name	Context Number n	Physical Address	Value	Value Description
<code>SMS_ROT_CONTROL_n</code>	0	0x6C00 0180	0x0000 0452	The page size is 8-pixel wide and 16-pixel high. This is a width of 32 bytes and a height of 16 lines. The pixel format is YUV 4:2:2 (2 pixels take 4 bytes).
	1	0x6C00 0190		
	2	0x6C00 01A0		
	3	0x6C00 01B0		
<code>SMS_ROT_SIZE_n</code>	0	0x6C00 0184	0x0230 0170	Actual image size is 736 × 560. This gives 368 × 560 with the YUV 4:2:2 pixel format
	1	0x6C00 0194		
	2	0x6C00 01A4		
	3	0x6C00 01B4		
<code>SMS_ROT_PHYSICAL_BA_n</code>	0	0x6C00 0188	0x8090 0000	Example of physical base address
	1	0x6C00 0198	0x8100 0000	
	2	0x6C00 01A8	0x8190 0000	
	3	0x6C00 01B8	0x8200 0000	

11.2.6.5 Understanding SDRAM Subsystem Address Spaces

11.2.6.5.1 Physical vs Virtual Address Spaces

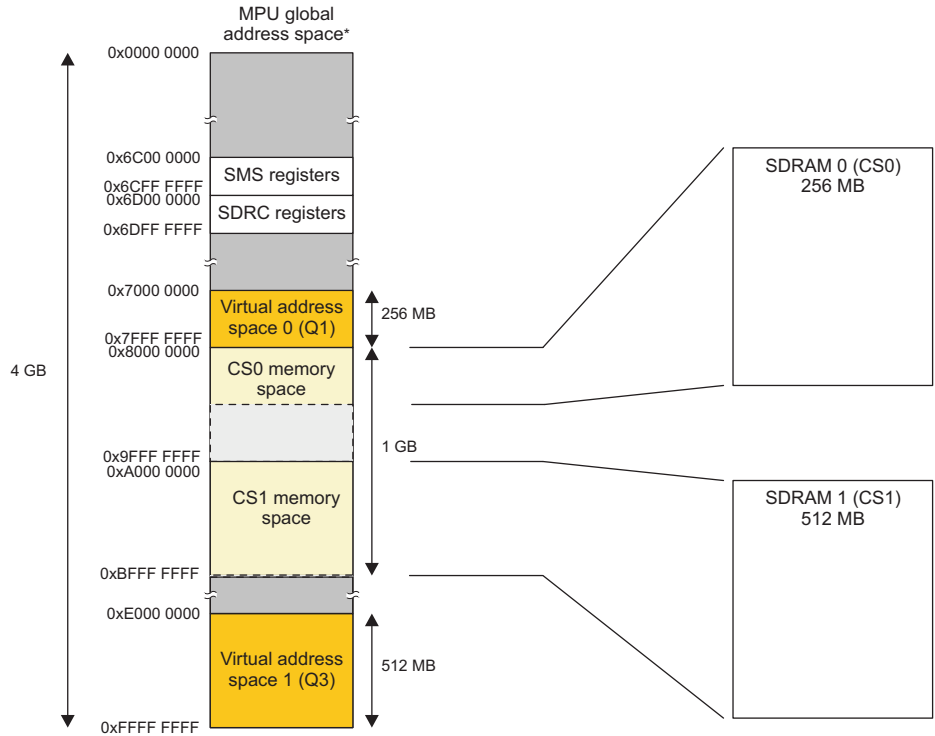

One thing that the SMS does is to translate virtual addresses into physical SDRAM addresses in case of rotation only, i.e. when accessing virtual address space 0 (quarter 1) and virtual address space 1 (quarter 3) as depicted in [Figure 11-79](#). The SMS then reinserts a request, or multiple requests depending on the SMS parameters, in the SMS request path to the SDRC controller (through the VRFB or not).

The SDRAM subsystem global memory space mapping reaches 1.768 GBytes:

- 1 GByte of CS memory space (CS0 and CS1 memory spaces): the SDRC controller automatically accesses the two external memory devices through direct accesses (addresses are simply translated).

- 768 MBytes of virtual address space (address space 0 and address space 1): the SDRC controller automatically accesses the two external memory devices through re-organized access (requests are modified accordingly to the context number and rotation angle before address translation). See section [Section 11.2.6.5.1.2](#) for more information on VRFB contexts and rotation angles.

Figure 11-79. SDRC Address Space in MPU Global Address Space

* Internal physical address, from a SW point of view

sdrc-037

Configuration registers space is detailed in the following table:

Table 11-113. SDRC and SMS Configuration Registers Space

Module	Start Address	End Address	Total Space
SMS	0x6C00 0000	0x6CFF FFFF	16MB
SDRC	0x6D00 0000	0x6DFF FFFF	16MB

11.2.6.5.1.1 Physical Address Space

The physical address space of the SDRC is 1 GByte (maximum addressing capability).

The SDRC has a memory device capacity of 16 Mbits to 2 Gbits. 16 Mbits / 2 MBytes is the smallest granularity of supported memory device.

11.2.6.5.1.2 Virtual Address Space

The SDRC-SMS virtual memory space is a memory space used to access a subset of the SDRC memory space through the rotation engine (Virtual Rotation Frame Buffer). The virtual address space size is 768 MBytes split into two parts: the first 256-MByte part is in the second quarter (Q1) of the memory; the second 512-MByte part is in the fourth quarter (Q3) of the memory. See chapter 2, *Memory Mapping*, for more information on global memory mapping.

The VRFB is a rotation engine that:

- supports rotations of 0, 90, 180, and 270 degrees
- can handle up to 12 concurrent rotation contexts

The VRFB has therefore 48 different contexts in the virtual address space. [Table 11-114](#) gives the VRFB address-space memory locations at which the frame buffer object can be accessed. The table summarizes the virtual addresses of all 48 available image buffer from a global memory space (top level) point of view.

Table 11-114. VRFB Contexts vs Rotation Angle

Context Number	0°	90°	180°	270°
0	0x7000 0000	0x7100 0000	0x7200 0000	0x7300 0000
1	0x7400 0000	0x7500 0000	0x7600 0000	0x7700 0000
2	0x7800 0000	0x7900 0000	0x7A00 0000	0x7B00 0000
3	0x7C00 0000	0x7D00 0000	0x7E00 0000	0x7F00 0000
4	0xE000 0000	0xE100 0000	0xE200 0000	0xE300 0000
5	0xE400 0000	0xE500 0000	0xE600 0000	0xE700 0000
6	0xE800 0000	0xE900 0000	0xEA00 0000	0xEB00 0000
7	0xEC00 0000	0xED00 0000	0xEE00 0000	0xEF00 0000
8	0xF000 0000	0xF100 0000	0xF200 0000	0xF300 0000
9	0xF400 0000	0xF500 0000	0xF600 0000	0xF700 0000
10	0xF800 0000	0xF900 0000	0xFA00 0000	0xFB00 0000
11	0xFC00 0000	0xFD00 0000	0xFE00 0000	0xFF00 0000

The physical address of a page is calculated with the formula:

Physical address = Physical base address + Base address of page

where *Physical base address* is defined through the SMS_ROT_PHYSICAL_BAn[30:0] PHYSICALBA field (buffer physical base address on which the rotation occurs), and *Base address of page* is the address obtain in function of the context number and rotation angle as given in [Table 11-114](#).

11.2.6.5.2 CS Memory Spaces

Two SDRC chip-selects (sdrncs0 and sdrncs1) are available to access two external SDRAM memories.

11.2.6.5.2.1 SDRAM Capacity Calculation

This section aims to explain how to calculate an SDRAM device capacity.

From the following SDRAM characteristics:

- 4 banks (BA0-BA1)
- Row addresses: A0-A12
- Column addresses: A0-A9
- 16-bit data bus to external memory

First calculate the number of addressable locations:

- Number of address lines: 13 (A0-A12)
- Number of banks address lines: 2 (BA0-BA1)
- Maximum number of rows = 13 (number of address lines used for row decoding)
- Maximum number of columns = 10 (number of address lines used for column decoding)

Total locations in a bank = $(2^{13}) \times (2^{10})$

Then calculate the total locations in the device:

Total locations in the device = (Number of banks) \times (Total locations in a bank) = $(2^2) \times (2^{13} \times 2^{10}) = 2^{25}$

Finally calculate the SDRAM device capacity:

Total device capacity = (Total locations in the device) \times (Device organization) = $(2^{25}) \times (16) = 2^{29}$ bits

Hence, the device has a maximal capacity of 512 Mbits (or 64 MBytes).

In the same way, the SDRC maximal capacity can be calculated as follow:

- Number of address lines: 15 (A0-A14)
- Maximum number of rows = 15 (limited by the number of address lines, hence do not program SDRC_MCFG_p[26:24] RASWIDTH above 15)
- Maximum number of columns = 12 (limited by SDRC_MCFG_p[22:20] CASWIDTH)
- Data bus width to external device: 32-bit

SDRC total capacity = $(2^{15} \times 2^{12}) \times 32 = 4$ Gbits (or 512 MBytes)

Hence, the SDRC has a maximum addressing capability of 8 Gbits / 1 GByte (as seen in [Section 11.2.6.5.1.1](#)) and can manage SDRAM devices with capacity of up to 4 Gbits / 512 MBytes (see caution below).

CAUTION

As the SDRC controller is aligned on the JEDEC LPDDR1 SDRAM standard, it is guaranteed that SDRAM with up to 1 Gbits capacity are supported. At the time of writing 2 Gbits and 4 Gbits Low Power DDR SDRAM are not yet in production and depending on their design (i.e. number of banks, page size, and other characteristics) these SDRAM might or might not be supported by the SDRC controller.

11.2.6.5.2.2 CS Size

Each chip-select has its programmable size. The CS size is expressed in SDRC_MCFG_p[17:8] RAMSIZE (p = 0 or 1 for CS0 or CS1) as a number of 2-MBytes chunks.

For instance, when connecting a 256 Mbits SDRAM memory (see mux scheme MUX7 in table 1-2) to the SDRC controller, RAMSIZE must be set with the value 0x010 (32 MBytes = 2-MB \times 16).

11.2.6.5.2.3 CS Start and End Addresses

See figure [Figure 11-80](#), *CS0/CS1 Chip-Select Start Address Slots* for a graphical representation of CS starts addresses and CS size.

CS0 start address is fixed at :

- 0x0000 0000 from a SDRC point of view
- 0x8000 0000 from a global memory space point of view.

Hence, when connecting a 256 Mbits / 32 MBytes SDRAM memory (16M \times 8 such as in MUX6, [Table 11-94](#)), CS0 end address is 0x0200 0000 (SDRC point of view).

CS1 start address is programmable and its default value is :

- 0x2000 0000 from a SDRC address point of view
- 0xA000 0000 from a global memory space point of view.

The SDRC 1 Gbyte address space is segmented into eight 128 MBytes address spaces, which are themselves segmented into four 32 Mbytes address spaces, so that 32 possible CS1 start address locations are defined as depicted in [Figure 11-80](#). Note that the first 32 MBytes address space of the first 128 MBytes address space is reserved to CS0 (address 0x0000 0000). Any other address can be used as CS1 start address. To define a CS1 start address, set SDRC_CS_CFG[9:8] CS1STARTLOW and SDRC_CS_CFG[3:0] CS1STARTRHIGH fields as follow:

- SDRC_CS_CFG[3:0] CS1STARTRHIGH corresponds to one of the eight 128 MBytes address spaces (total address space of SDRC is 1 GByte): 0x0000 for the first partition up to 0x0111 for the eighth partition. Note that SDRC_CS_CFG[3] must always be set at 0.
- SDRC_CS_CFG[9:8] CS1STARTLOW corresponds, for a given 128 MBytes address space, to one of the four 32 MBytes address spaces: 0x00 for the first up to 0x11 for the fourth.

Hence, to have a start address of 0x2000 0000 (SDRC point of view) when connecting a 2048 Mbits SDRAM memory (64M × 32 such as in MUX25, [Table 11-95](#)), SDRC_CS_CFG[9:8] CS1STARTLOW must be set to 0x00 (first 32 MBytes address space as depicted in [Figure 11-80](#)) and SDRC_CS_CFG[3:0] CS1STARHIGH must be set to 0x0100 (fourth 128 MBytes address space). Note that the start address must be aligned on the memory size.

The CS1 end address (0x3000 0000) can be deduced from the CS1 size, that is from the RAMSIZE parameter, which take the value 0x80 when connecting a 2048 Mbits SDRAM memory.

Description	This register configures the virtual rotated frame buffer module for context #n.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																PH		RESERVED	PW		RESERVED	PS									

Bits	Field Name	Description	Type	Reset
31:11	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x000000
10:8	PH	Exponent based 2 value, 2 ^{ph} indicates the page height in bytes for context #n.	RW	0x0
7	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
6:4	PW	Exponent based 2 value, 2 ^{pw} indicates the page width in bytes for context #n.	RW	0x0
3:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
1:0	PS	Exponent based 2 value, 2 ^{ps} indicates the pixel size in bytes for context #n. A value of 3 is invalid.	RW	0x0

11.2.8.2.7 SDRC_DLLA_CTRL

Table 11-169. SDRC_DLLA_CTRL

Address Offset	0x0000 0060	Instance	SDRC
Physical Address	0x6D00 0060		
Description	This register controls the SDRC DLL A resource used for fine timing tuning on a double-data-rate interface.		
Type	RW		
31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16	15 14 13 12 11 10 9 8	7 6 5 4 3 2 1 0
FIXEDELAY	MODEFIXEDELAYINITLAT	RESERVED	WRITEDDRCLKX2DIS DLLMODEONIDLEREQ DLLIDLE ENADLL LOCKDLL DLLPHASE RESERVED

Bits	Field Name	Description	Type	Reset
31:24	FIXEDELAY	Phase offset value in ModeFixedDelay mode. Maximum frequency supported in this mode is 83 MHz. FIXEDELAY steps are defined after DLL cell characterization.	RW	0x00
23:16	MODEFIXEDELAYINITLAT	Initial latency before first request to be processed in ModeFixedDelay mode ⁽¹⁾ 0x0: no initial latency before first access 0x1: 2 clock cycles before first access 0x2: 4 clock cycles before first access 0x3: 6 clock cycles before first access 0x4 : 8 clock cycles before first access ... 0xFF: 510 clock cycles before first access	RW	0x00
15:8	RESERVED	Write 0s for future compatibility. Reads return 0s.	RW	0x00
7	WRITEDDRCLKX2DIS	Disable MDDR write path using the double frequency input clock. 0x0: MDDR write path using the double frequency clock logic 0x1: MDDR write path using the DLL/CDL write path logic	RW	0x0
6:5	DLLMODEONIDLEREQ	Selects the DLL mode upon hardware idle request 0x0: DLL in Power-down mode upon hardware idle request 0x1: DLL in DLL idle mode upon hardware idle request 0x2: No action upon hardware idle request. Input clock frequency must not be changed. 0x3: Reserved for future use (no action upon hardware idle request).	RW	0x0
4	DLLIDLE	Enables the CQ0040v1 DLL Idle mode 0x0: DLL Idle mode disabled 0x1: DLL Idle mode enabled	RW	0x0
3	ENADLL	Enables DLL 0x0: DLL disabled 0x1: DLL enabled	RW	0x0

⁽¹⁾ The DLL characterization shows that this feature is not useful and that this value shall be left at 0x0.

Bits	Field Name	Description	Type	Reset
2	LOCKDLL	<p>Selects the DLL functionality between the TrackingDelay mode (previously called lock mode) or the ModeFixedDelay mode (previously called unlock mode). The DLL mode is updated in the DLL cell after:</p> <ul style="list-style-type: none"> - DLLIDLE mode - DLL power-down mode <p>0x0: LOCKDLL at 0 puts the DLL in TrackingDelay mode (tracking counter started).</p> <p>0x1: LOCKDLL at 1 puts the DLL in ModeFixedDelay mode. The fixed delay defined in FIXEDDELAY bit field is used to delay DQS lines for read accesses.</p>	RW	0x0
1	DLLPHASE	<p>Nominal digitally controlled delay when DLL is enabled</p> <p>Recommendation is read 72 degrees and write 90 degrees without DLL/DCDL (i.e. using WRITEDDRCLKX2DIS).</p> <p>0x0: 72 degrees (20% of the clock period)</p> <p>0x1: 90 degrees (25% of the clock cycle)</p>	RW	0x0
0	RESERVED	Write 0s for future compatibility. Reads return zero.	RW	0x0

11.2.8.2.9 SDRC_POWER_REG

Table 11-173. SDRC_POWER_REG

Address Offset	0x0000 0070	Instance	SDRC
Physical Address	0x6D00 0070		
Description	The SDRC power management register defines the global power management policy (shared by CS0/CS1).		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED				WAKEUPPROC	RESERVED	AUTOCOUNT										SRFRONRESET	SRFRONIDLEREQ	CLKCTRL	EXTCLKDIS	PWDENA	RESERVED	PAGEPOLICY									

Bits	Field Name	Description	Type	Reset
31:27	RESERVED	Write 0s for future compatibility. Reads return 0s.	RW	0x00
26	WAKEUPPROC	Select if after a SDRC wake-up in DDR mode (in DLL TrackingDelay mode), the first request is stalled during 500 cycles latency or until the lock signal from the DLL/CDL analog cell is asserted. 0x0: SDRC allows DDR access after 500 L3 clock cycles 0x1: SDRC allows DDR access as soon as DLL LOCKSTATUS bit is 1	RW	0x0
25:24	RESERVED	Write 0s for future compatibility. Reads return 0s.	RW	0x0
23:8	AUTOCOUNT	16-bit programmable count value used for delayed automatic clock gating and self-refresh entry, assuming CLKCTRL field is not 0	RW	0x0000
7	SRFRONRESET	Enter self refresh when a warm reset is applied: 0x0: Feature disabled 0x1: Feature enabled	RW	0x1
6	SRFRONIDLEREQ	Enter self refresh when on hardware idle request: 0x0: Feature disabled 0x1: Feature enabled	RW	0x0
5:4	CLKCTRL	Clock control feature defines clock gating and self refresh: 0x0: No auto clk feature turned on 0x1: Enable internal clock gating on timeout of Auto_cnt 0x2: Enable self-refresh on timeout of Auto_cnt 0x3: Reserved	RW	0x0
3	EXTCLKDIS	Disable the clock provided to the external memories: 0x0: Enable clock 0x1: Disable clock- Logical 0 is applied.	RW	0x0
2	PWDENA	Activate the power-down mode of the target memory through CKE pin. 0x0: Power-down mode feature disabled 0x1: Power-down mode feature enabled	RW	0x1

Bits	Field Name	Description	Type	Reset
1	RESERVED	Write 0 for future compatibility. Read returns 0.	RW	0x0
0	PAGEPOLICY	Page/segment closure policy with respect to power versus bandwidth trade-off - Must be set to 1 0x0: Reserved - must not be used 0x1: High-power/high bandwidth mode (HPHB)	RW	0x1

11.3 On-Chip Memory (OCM) Subsystem

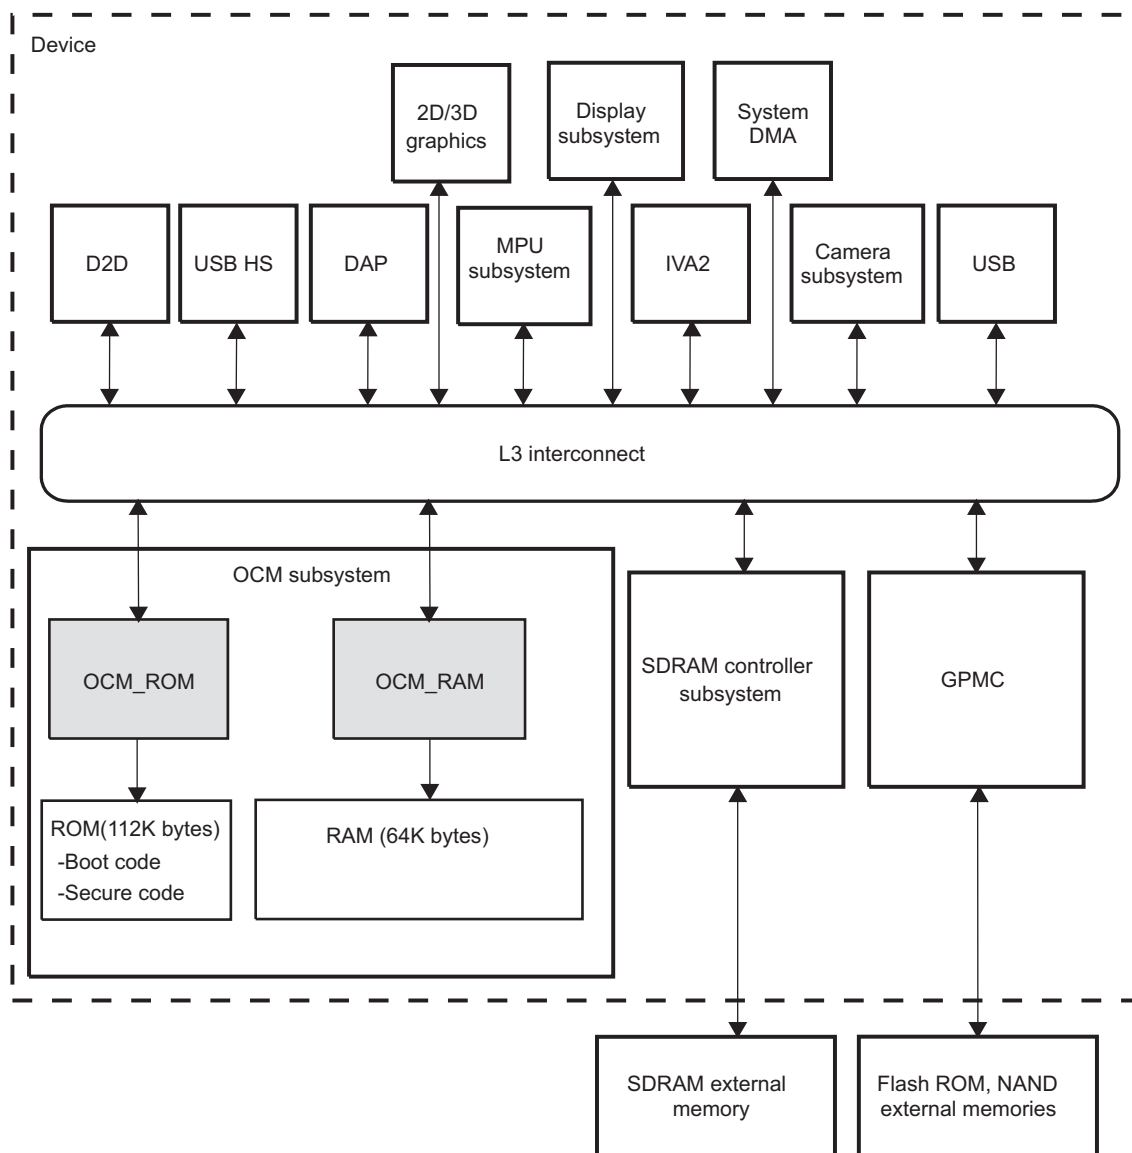

11.3.1 OCM Subsystem Overview

The on-chip memory subsystem consists of two separate on-chip memory controllers, one connected to an on-chip ROM (OCM_ROM) and the other connected to an on-chip RAM (OCM_RAM). Each memory controller has its own dedicated interface to the L3 interconnect.

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

Figure 11-81 is an overview of the OCM subsystem.

Figure 11-81. OCM Subsystem Overview

ocm-001

Multiple L3 initiators (such as remote devices) have access to the RAM through 2D/3D graphics, the MPU subsystem, sDMA, the camera subsystem, the display subsystem, IVA2, and USB.

ROM is used for direct boot code, boot from external NAND flash, and secure code.

11.3.2 OCM Subsystem Integration

11.3.2.1 Description

The OCM_ROM and OCM_RAM allow transactions between the system initiators and the multiple memories, through the L3 interconnect.

Figure 11-82 shows the integration of the OCM subsystem to the OMAP processor.

Figure 11-82. OCM Subsystem Integration to the Device

ocm-002

11.3.2.2 Clocking, Reset, and Power-Management Scheme

11.3.2.2.1 Clocking

The on-chip boot ROM and RAM are clocked only when they are accessed.

The interface clock OCM_CLK comes from the PRCM module and runs at the L3 interconnect frequency. The OCM_CLK source is PRCM CORE_L3_ICLK output. This clock is also used as the functional clock for the OCM module.

For the OCM subsystem, no register enables the gating of OCM_CLK.

However, OCM does support the handshaking protocol with the PRCM module. It is not programmable by software. The following signals support the handshaking protocol for ROM and RAM devices:

- OCMROM_IDLREQ/OCMROM_SIDLEACK (for ROM devices)
- OCMRAM_IDLREQ/OCMRAM_SIDLEACK (for RAM devices)

OCM_CLK is gated if all modules (including the OCM) belonging to the L3 CLK domain send a SldleAck back to the PRCM module after reception of the MIdleReq request.

For details, see the *Power, Reset, and Clock Management* chapter.

When the memory is not accessed by the system, the module performs automatic clock gating. Because the clock to the memory is dynamically gated, there is no extra latency when the clock must be switched on after an idle state.

11.3.2.2.2 Hardware Reset

Global reset of the module is performed by activation of the CORE_RST in the core reset domain (see the *Power, Reset, and Clock Management* chapter).

11.3.2.2.3 Power Domain

OCM power is supplied by the CORE power domain (see the *Power, Reset, and Clock Management* chapter).

11.3.3 OCM Subsystem Functional Description

11.3.3.1 OCM_ROM

The embedded ROM is used primarily for booting, flashing, and context restoring.

The device-embedded ROM (total 32K bytes) has the following characteristics:

- The ROM contains the boot area.
- The OCM_ROM supports single and burst access transactions.
- The OCM_ROM operates at full interconnect clock frequency.
- The COM_ROM needs three cycles for initial access and one cycle per subsequent access.

The memory space of the embedded ROM starts at 0x4001 4000 and ends at 0x4001 BFFF.

11.3.3.2 OCM_RAM

By default, only 2K bytes are nonsecure after reset; however, the configuration can then be changed to adapt to booting/flashing, normal boot, or to any application requirement.

The device-embedded RAM has the following characteristics:

- Operates at full L3 interconnect clock frequency
- Fully pipelined, one 32-bit access per cycle
- Restricted access support, based on:
 - A region-based partitioning (see the L3 firewall description)
 - The module owner of the access, with respect to its read and write permission to that region
 - The transaction attributes of the access, with respect to the region permission properties:
 - Secure/nonsecure
 - User/supervisor
 - Code/data access

The OCM_RAM can be partitioned using the L3 firewall (see the *Interconnect* chapter) and used as:

- Public RAM for normal RAM, or
- Secure RAM:
 - For secure data and instructions
 - For secure Level 2 data and instruction cache:
 - Secure stack
 - Secure global data
 - Secure heap
 - Secure decrypted applications
 - Crypto keys

The OCM_RAM can be partitioned using the L3 firewall and used as:

- Public RAM for a video frame buffer
- Secure RAM for a secure video frame buffer
- Secure RAM for computing heavy DRM applications such as real-time video decryption
- Secure RAM for any application

The RAM memory space starts at 0x4020 0000 and ends at 0x4020 FFFF.

11.4 Revision History

Table 11-189 lists the changes made since the previous version of this document.

Camera Interface Subsystem (ISP)

This chapter describes the camera interface subsystem (ISP) in the OMAP35x Applications Processor.

Note: This chapter describes the camera interface subsystem of the OMAP35x Applications Processor only. The camera subsystem for lower-tier devices will be described in a future version of the TRM.

12.1 Camera ISP Overview

The camera ISP is a key component for imaging and video applications such as video preview, video record, and still-image capture with or without digital zooming.

The camera ISP provides the system interface and the processing capability to connect RAW image-sensor modules to the OMAP35x Applications Processor.

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

Figure 12-1 shows the camera ISP.

Figure 12-1. Camera ISP Highlight

camisp-001

12.1.1 Camera ISP Features

The camera ISP can support the following features:

- **Image sensor:**
 - Interface with various image sensors:
 - R, G, B primary colors

- Ye, Cy, Mg, G complementary colors
- Support for electronic rolling shutter (ERS) and global-release reset shutters
- **Parallel interface:** The parallel interface supports two modes:
 - **SYNC mode:** In this mode, the image-sensor module provides horizontal and vertical synchronization signals to the parallel interface, along with the pixel clock. This mode works with 8-, 10-, 11-, and 12-bit data (above 10-bit RAW data, the processing pipe cannot be used; data must be transferred to memory). SYNC mode supports progressive and interlaced image-sensor modules.
 - **ITU mode:** In this mode, the image-sensor module provides an ITU-R BT 656-compatible data stream. The horizontal and vertical synchronization signals are not provided to the interface. Instead, the data stream embeds start-of-active (SAV) and end-of-active video (EAV) synchronization code. This mode works in 8- and 10-bit configurations. It supports only progressive image-sensor modules.

Note:

- Up to 8-bit data at 130 MHz can be transferred to memory.
 - Up to 10-bit data at 75 MHz can be processed by the image pipeline or transferred to memory.
 - Up to 12-bit data at 75 MHz can be transferred to memory as is, or after processing inside the CCDC. It can also be internally converted to 10-bit data for full processing.
-
- **Video processing:** The video-processing hardware removes the need for expensive camera modules to perform processing functions. The hardware pipeline contains two parts: front end and back end:
 - **CCDC:** Performs signal-processing operations on RAW image input data. The output data can go directly to memory for software processing, or to IPIPE for further processing. Signal-processing operations include:
 - Optical clamping
 - Optical black clamp
 - Black-level compensation
 - Look-up table (LUT) based faulty pixel correction
 - 2D lens-shading compensation
 - Data formatter
 - Output formatter
 - **IPIPE:** Performs signal-processing operations on RAW image input data. Outputs YCbCr 4:2:2 data.
 - **Preview module:** Signal-processing operations include:
 - A-law decompression: transforms non-linear 8-bit data to 10-bit linear data. The CCDC module can perform A-law compression
 - Noise reduction and faulty pixel correction
 - Dark frame capture and subtraction
 - Horizontal median filter
 - Programmable filter: 3x3 kernel of the same color
 - Couplet faulty pixel correction
 - Digital gain
 - White balance
 - Programmable color filter array (CFA) interpolation: 5x5 kernel
 - Black adjustment
 - Programmable color correction (RGB to RGB)
 - Programmable gamma correction: 1024 entries for each color
 - Programmable color conversion (RGB to YCbCr 4:4:4)
 - Color subsampling (YCbCr 4:4:4 to YCbCr 4:2:2)
 - Luminance enhancement (non-linear), chrominance suppression and offset
- The preview module can also work from memory to memory.

- **Resizer module:** Performs on-the-fly upsampling (up to x4) and downsampling (down to x0.25) of YCbCr 4:2:2 data by applying high-quality horizontal and vertical filters. The horizontal and vertical resizer ratios are independent. Applicable ratios are 256/N, with N ranging from 64 to 1024. This feature enables digital zooming (upsampling) and video preview (downsampling).
The resizer module can also work from memory to memory. Higher or lower ratios can be obtained by combining on-the-fly resizing followed by memory-to-memory resizing.
- **Statistic collection modules (SCM):** The host CPU uses statistics to adjust various parameters for processing image data.
 - **3A metrics:** Collects on-the-fly RAW image data metrics, which are required to perform the control loops for auto white balance (AWB), auto exposure (AE), and autofocus (AF). The MPU subsystem typically uses data metrics to adjust various parameters for processing image data.
 - **Histogram:** Performs on-the-fly pixel binning of RAW image, based on color value ranges and regions. Supports up to 4 regions and up to 256 bins per color. The MPU subsystem typically uses the histogram with 3A metrics to adjust various parameters for processing image data.
The histogram module can also work from memory to memory.
- **Central-resource shared buffer logic (SBL):** Buffers and schedules memory accesses requested by camera ISP modules
- **Circular buffer:** Prevents storage of full image frames in memory when data must be postprocessed and/or preprocessed by software
- **Memory management unit (MMU):** Manages virtual-to-physical address translation for external addresses and solves the memory-fragmentation issue. Enables the camera driver to dynamically allocate and deallocate memory; the MMU handles memory fragmentation.
- **Clock generator:** Generates two independent clocks that can be used by two external image sensors
- **Secure mode:** Used to store sensitive captured images
- **Timing control:**
 - Generation of two clocks that can be used by the external image sensors
 - Generation of signals for strobe flash, mechanical shutter, and global reset. Support for red-eye removal.
- **Open core protocol (OCP) compliant:**
 - One 64-bit master interface connected to L3
 - One 32-bit slave interface connected to L4

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

12.2 Camera ISP Environment

12.2.1 Camera ISP Functions

Table 12-1 describes the camera ISP functions and the corresponding application fields.

Table 12-1. Camera ISP Functions

Function	Description
Parallel interface in generic configuration (SYNC mode)	The camera ISP supports up to 12 bits (Most image-processing pipeline operations support only up to 10 bits; when it is more than 10 bits, some limited capabilities apply to CCDC only). The camera ISP can interface with RAW interlaced or progressive image sensors using RGB or complementary color mosaic filters.
Parallel interface in ITU-R BT.656 configuration (ITU mode)	The camera ISP can extract the synchronization signal start of active video and end of active video from the ITU-R BT.656 bit stream. 8-bit and 10-bit modes are supported.

12.2.2 Camera ISP Signal Descriptions

Table 12-2. I/O Description

Signal Name	I/O ⁽¹⁾	Description	Parallel SYNC Mode	Parallel ITU Mode
cam_hs	I/O	Line trigger input/output signal	+	
cam_vs	I/O	Frame trigger input/output signal	+	
cam_fld	I/O	Field identification input/output signal	+	
cam_pclk	I	Parallel interface pixel clock	+	+
cam_d[11:0]	I	Parallel mode: input data bits 0 to 11	+	+ [9:0] when bridge is not used; [7:0] when bridge is used
cam_wen	I	External write-enable signal	+	
cam_strobe	O	Flash strobe control signal	+	+
cam_shutter	O	Mechanical shutter control signal	+	+
cam_global_reset	I/O	Global reset release shutter signal	+	+
cam_xclka	O	External clock for the image-sensor module	+	+
cam_xclkb	O	External clock for the image-sensor module		

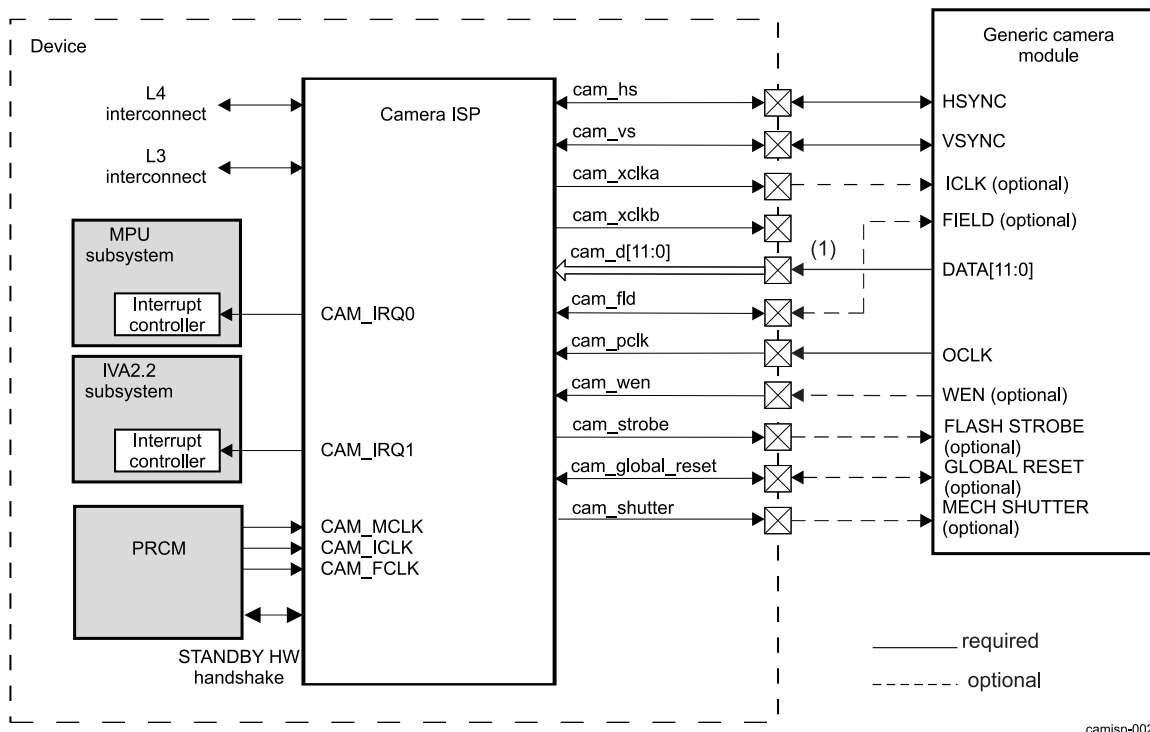

(1) I = Input, O = Output, PWR = Power

12.2.3 Camera ISP Modes

- Parallel interface in generic configuration

Figure 12-2 shows a block diagram of the parallel interface in generic configuration.

Figure 12-2. Parallel Interface in Generic Configuration

(1) These signals are muxed. They are controlled by registers CONTROL_PADCONF_CAM_FLD and CONTROL_PADCONF_CAM_D.

CAUTION

The parallel interface in generic configuration mode works with 8-, 10-, 11-, and 12-bit sensors. 8 to 12 bits refers to data-lane count, not pixel coding. For example, when a video decoder is used, it sends 16 bits per pixel. The data is transmitted through 8 data lanes at x2 pixel clock. The bridge can be used to reassemble the 16-bit pixels.

Note: For information about using the data-lane shifter for different configurations, see [Table 12-14](#).

- Parallel interface in ITU-R BT.656 configuration

Figure 12-3 shows a block diagram of the parallel interface in ITU-R BT.656 configuration.

Figure 12-3. Parallel Interface in ITU-R BT.656 Configuration

camisp-003

Note: For information about using the data-lane shifter for different configurations, see [Table 12-14](#).

12.2.4 Camera ISP Protocols and Data Formats

12.2.4.1 Parallel Generic Configuration Protocol and Data Format (8, 10, 11, 12 Bits)

The SYNC mode implements a generic parallel interface with the image sensor. The SYNC mode supports 8 to 14-bit-wide data signals.

In this configuration, no assumptions are made on the data format of pixels, but the dynamic range is limited to 8-, 10-, 12- or 14-bit (data can be pure luminance for black and white sensor, RGB444, Bayer RGB, etc.). The pixel data is presented on `cam_d`, where one pixel is sampled for every `cam_pclk` rising edge (or falling edge, depending on the configuration of `cam_pclk` polarity). For more information, see [Section 12.4](#).

Additional pixel times between rows represent blanking periods. Active pixels are identified by a combination of two additional timing signals: horizontal synchronization (`cam_hs`) and vertical synchronization (`cam_vs`). During the image-sensor readout, these signals define when a row of valid data begins and ends, and when a frame starts and ends.

Note: For correct operation, the clock `cam_pclk` must run during blanking periods (`cam_hs` and `cam_vs` inactive). `cam_pclk` must start before sending `cam_d` and start `cam_vs` and `cam_hs`.

[Figure 12-4](#) and [Figure 12-5](#) show the frame and data timing, respectively, based on synchronization signals in the parallel No BT configuration.

Figure 12-4. Synchronization Signals and Frame Timing in SYNC mode

Figure 12-5. Synchronization Signals and Data Timing in SYNC mode

Note: The pixel clock can be gated to qualify valid pixels. It can also be gated during blanking periods to reduce power consumption. However, at least 4 clock pulses are required before sending active image data and synchronization information. 8 clock pulses are required after the end of active video. Extra-clock pulses are allowed but not required during the line blanking periods.

Figure 12-6 shows the timing diagram of the SYNC move clock gating.

Figure 12-6. SYNC Mode Clock Gating

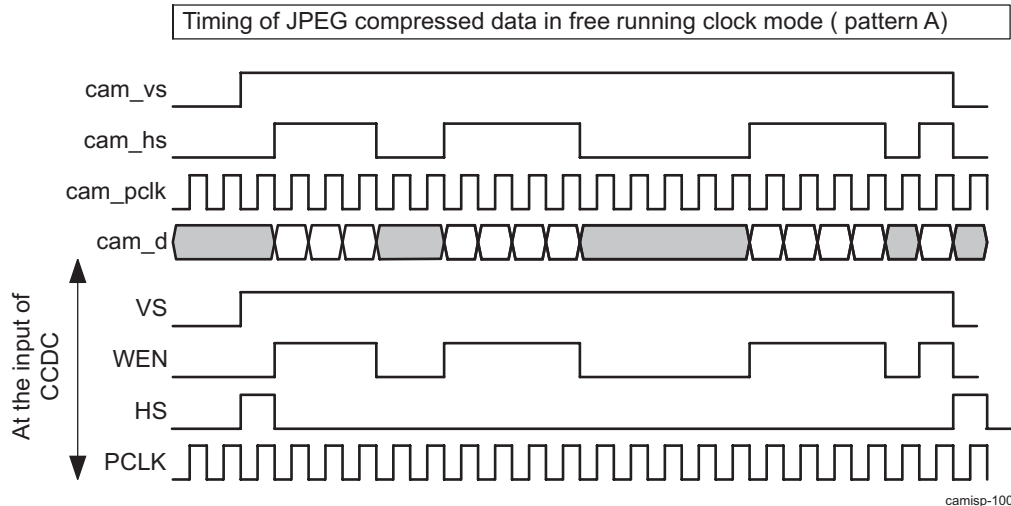

12.2.4.2 Parallel Generic Configuration: JPEG Sensor Connection on the Parallel Interface

Some camera modules integrate an image-signal processor (ISP) and a JPEG encoder. The CCDC can interface with these camera modules and transfer the received JPEG stream to memory.

Only pattern A mode is supported. To use this mode, set the [ISP_CTRL](#) [30] JPEG_FLUSH bit.

Figure 12-7 shows timing diagrams for an A pattern.

Figure 12-7. JPEG Stream Timing Diagrams

CAUTION

The bridge cannot be used for JPEG sensor connections.

12.2.4.3 ITU-R BT.656 Protocol and Data Format (8, 10 Bits)

CAUTION

The ITU-R BT.656 mode cannot be used when the bridge is enabled.

The camera ISP interface supports data in ITU-R BT.656 format.

The ITU-R BT.656 standard specifies a method of transferring YUV422 data over an 8- or 10-bit video interface.

Figure 12-8 shows the data timing diagram with embedded synchronization signal.

Figure 12-8. Data Timing With Embedded Synchronization Signals (8-Bit Case)

In BT.656, the data words (8- or 10-bit) in which the eight most-significant bits (MSBs) are all set to 1, or all set to 0 are reserved. Only 254 of the possible 256 8-bit word values, and 1016 of the possible 1024 10-bit word values represent signal values.

The data is multiplexed in the following order: Cb0 Y0 Cr0 Y1 Cb2 Y2 Cr2 Y3, etc., where the byte sequence Cb2n Y2n Cr2n refers to interleaved luminance and chroma samples and the following byte Y2n + 1 corresponds to the next luminance sample.

The BT.656 protocol uses unique timing reference signals embedded in the video stream. The synchronization signals cam_hs and cam_vs are not needed. This reduces the number of wires required for a BT.656 video interface.

There are two timing reference codes: The start of active video (SAV) reference code precedes each video data block, and the end of active video (EAV) follows each video block. Each timing reference signal consists of a 4-byte sequence in the following hexadecimal format: **FF 00 00 XY**. The first 3 bytes are a fixed preamble (See the ITU-R BT.656 specification). The fourth byte (XY) contains information defining field identification (F), blanking (V), and SAV/EAV information (H), and 4 parity bits calculated as a function of F, V, and H (see the ITU-R BT.656 specification).

Table 12-3 lists the video timing reference codes for SAV and EAV.

Table 12-3. Video Timing Reference Codes for SAV and EAV

Data Bit Number	First Word (FF)	Second Word (00)	Third Word (00)	Fourth Word (XY)
9 (MSB)	1	0	0	1
8	1	0	0	F
7	1	0	0	V
6	1	0	0	H
5	1	0	0	P3
4	1	0	0	P2
3	1	0	0	P1
2	1	0	0	P0
1	1	0	0	0
0	1	0	0	0

Table 12-4 contains a description of the F, V, and H signals.

Table 12-4. F, V, H Signal Descriptions

Signal	Value	Command
F	0	Field 1
	1	Field 2
V	0	0
	1	Vertical blank
H	0	SAV
	1	EAV

The resulting Hamming distance between any two code words is four, allowing two error detections and one error correction. To enable or disable the error-correcting capability, configure the [CCDC_REC656IF](#) [1] ECCFVH bit.

Note: The 2-bit errors are detected, but not flagged or corrected. Errors of more than 2 bits are not corrected or flagged.

Table 12-5 lists the F, V, and H protection (error-correction) bits.

Table 12-5. F, V, H Protection (Error-Correction) Bits

F	V	H	P3	P2	P1	P0
0	0	0	0	0	0	0
0	0	1	1	1	0	1
0	1	0	1	0	1	1
0	1	1	0	1	1	0
1	0	0	0	1	1	1
1	0	1	1	0	1	0
1	1	0	1	1	0	0

Table 12-5. F, V, H Protection (Error-Correction) Bits (continued)

F	V	H	P3	P2	P1	P0
1	1	1	0	0	0	1

When operating in CCIR-656 mode, data is stored in SDRAM according to the format shown in [Table 12-6](#) when [CCDC_SYN_MODE](#) [11] PACK8 is enabled.

Table 12-6. BT.656 Mode Data Format in SDRAM

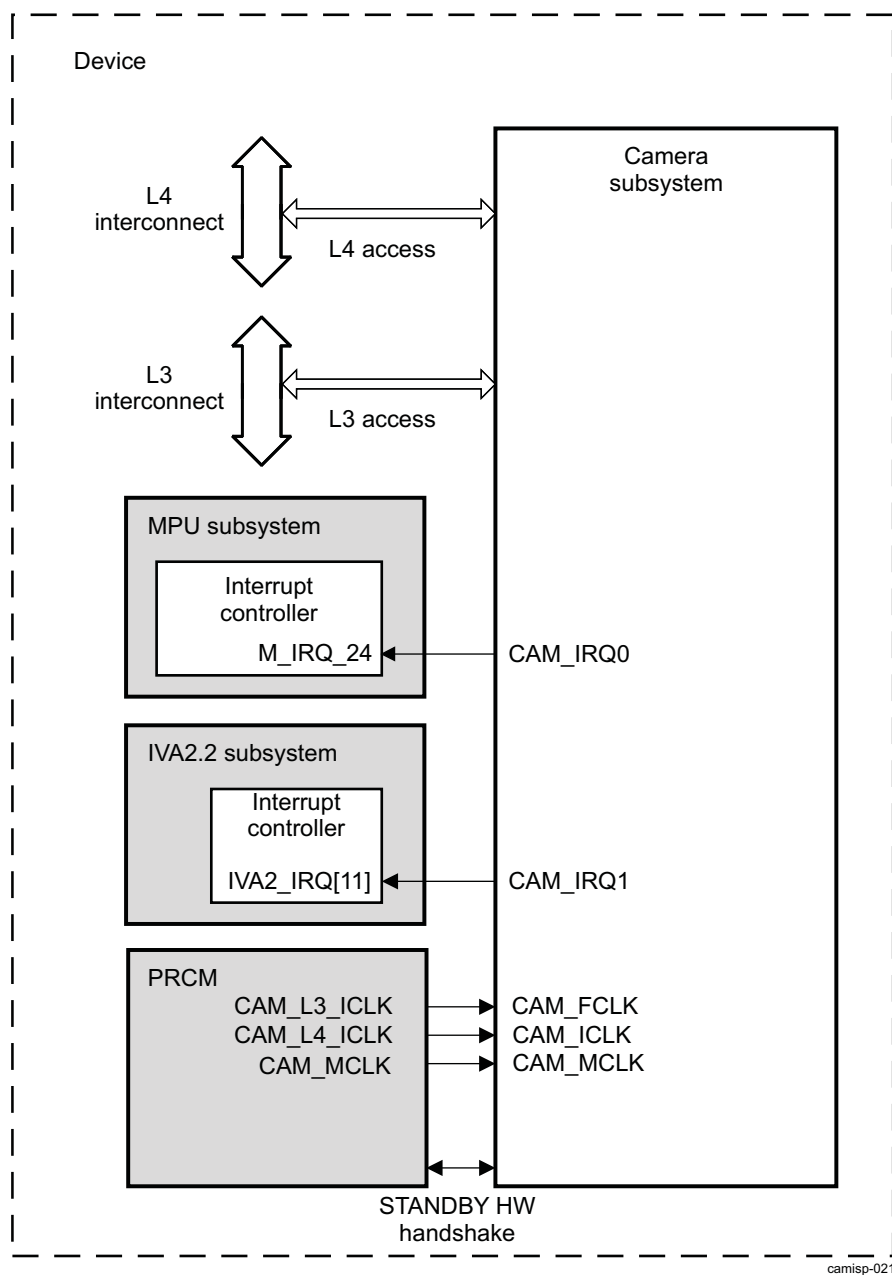

8 bit x 4	Pixel3 (Y1/Cr0)	Pixel2 (Cr0/Y1)	Pixel1 (Y0/Cb0)	Pixel0 (Cb0/Y0)
	Bit 31			Bit 0

Note: It is important to note that the CCDC outputs the XY code in the SAV and EAV into memory. To eliminate this, users must set the SPH register field to +1. In addition, the NPH register field must be set to accurately represent the number of active pixels.

12.3 Camera ISP Integration

Figure 12-9 shows the camera ISP integration.

Figure 12-9. Camera ISP Integration

camisp-021

12.3.1 Clocking, Reset, and Power-Management Scheme

12.3.1.1 Clocks

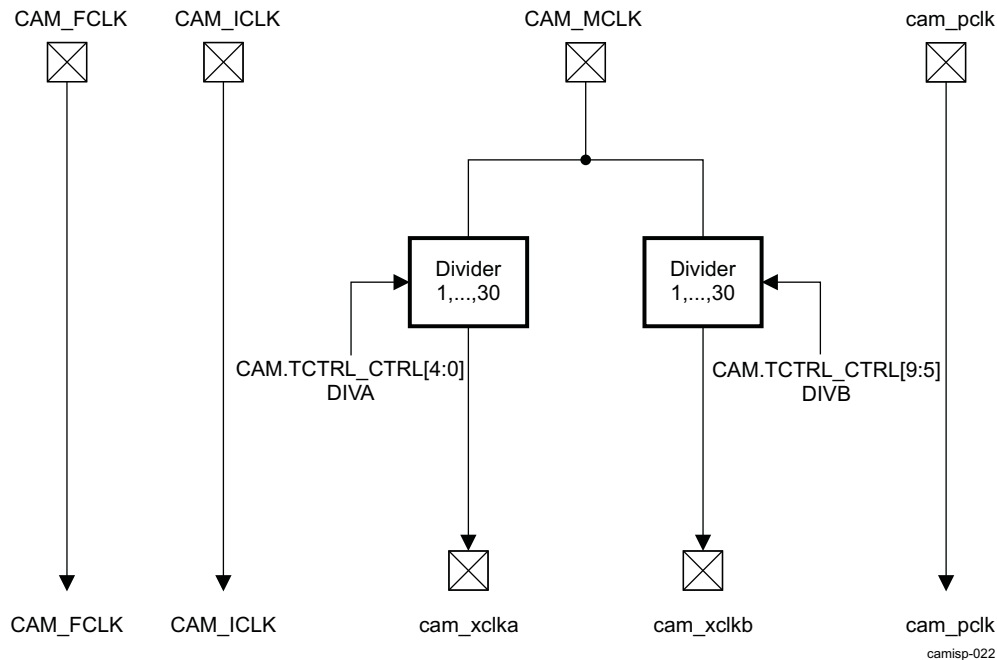

There are four clock domains in the camera ISP:

- Functional clock domain
- Interface clock domain
- Serial sensor clock domain
- Parallel sensor clock domain

12.3.1.1.1 Clock Tree

Figure 12-10 shows the clock tree for the camera ISP module.

Figure 12-10. Clock Tree

12.3.1.1.2 Clock Descriptions

Table 12-7 describes the camera ISP clocks.

Table 12-7. Clock Descriptions

Signal Name	I/O	Description
CAM_FCLK	Input	Functional clock (L3 interconnect clock domain) → Functional clock domain
CAM_ICLK	Input	Interface clock (L4 interconnect clock domain) → Interface clock domain
CAM_MCLK	Input	Internal clock from PRCM at 216 MHz. The CAM_MCLK is only used by the clock generator to generate cam_xclka and cam_xclkb
cam_xclka	Output	External clock for the image-sensor module. → For serial or parallel sensor
cam_xclkb	Output	External clock for the image-sensor module. → For serial or parallel sensor
cam_pclk	Input	Parallel mode: pixel clock for parallel input data. The data on the parallel interface are presented on cam_d, one pixel for every cam_pclk rising or falling edge. → Parallel sensor clock domain

12.3.1.1.3 Clock Configuration

- CAM_FCLK control and settings

The CAM_FCLK clock runs at the device L3 clock frequency.

The CAM_FCLK source is the PRCM CAM_L3_ICLK output.

When the camera ISP no longer needs CAM_FCLK, the software can disable it at PRCM level by setting the PRCM.CM_ICLK_CAM [0] EN_CAM bit to 0x0. Note that the clock is not effectively shut down until the camera ISP module has reached the IDLE state (that is, it does not generate anymore traffic on the device interconnect and is internally idled). For information, note that an automatic HW handshake protocol takes place between the camera ISP and the PRCM to prevent CAM_FCLK from being cut while the module is processing or transferring data.

An autoidle mode can be activated for this clock (PRCM.CM_AUTOIDLE_CAM [0] AUTO_CAM bit set to 1). This allows global management of the CAM_FCLK clock along with the CAM power domain at PRCM level. For more information, see the *Power, Reset, and Clock Management* chapter.

- CAM_ICLK control and settings

CAM_ICLK is the interface clock. It runs at device L4 interconnect clock speed and triggers access to the camera ISP L4 interface. Its source is the PRCM CAM_L4_ICLK output.

When the camera ISP no longer needs CAM_ICLK, the software can disable it at PRCM level by setting to 0x0 the PRCM.CM_ICLK_CAM [0] EN_CAM bit. Note that the clock is not effectively shut down until the camera ISP module has reached the IDLE state (that is, it does not generate anymore traffic on the device interconnect and is internally idled). As information, note an automatic HW handshake protocol takes place between the camera ISP and the PRCM to prevent CAM_ICLK from being cut while the module is processing or transferring data.

An autoidle mode can be activated for this clock (PRCM.CM_AUTOIDLE_CAM [0] AUTO_CAM bit set to 1). This allows global management of the CAM_ICLK clock along with the CAM power domain at PRCM level. For more information, see the *Power, Reset, and Clock Management* chapter.

- CAM_MCLK control and settings

The source for CAM_MCLK is the PRCM CAM_MCLK output. It is generated through a peripheral DPLL and its frequency can be adjusted using the PRCM.CM_CLKSEL_CAM CLKSEL_CAM bit field. When the module no longer needs it, it can be disabled at PRCM level by setting the PRCM.CM_FCLKEN_CAM EN_CAM bit to 0x0. Note that the PRCM register bit setting has a direct effect on the clock; in other terms, there is no HW handshake protocol to ensure whether the clock can be cut regarding the camera ISP activity: as soon as the bit is set to 0x0, CAM_MCLK is shut down.

- cam_xclka and cam_xclkb control and settings
cam_xclka and cam_xclkb are generated inside the camera ISP module from CAM_MCLK clock input. [Table 12-8](#) and [Table 12-9](#) give the settings of the related bit fields.

Table 12-8. cam_xclka Configuration

ref_clk	CAM.TCTRL_CTRL[4:0] DIVA field	cam_xclka
CAM_MCLK	0x0	Stable low level. Divider disabled.
	0x1	Stable high level. Divider disabled.
	0x2	CAM_MCLK/2

	0x1F	CAM_MCLK

Table 12-9. cam_xclkb Configuration

ref_clk	CAM.TCTRL_CTRL[9:5] DIVB field	cam_xclkb
CAM_MCLK	0x0	Stable low level. Divider disabled.
	0x1	Stable high level. Divider disabled.
	0x2	CAM_MCLK/2

	0x1F	CAM_MCLK

12.3.1.2 Power Management

Power consumption can be reduced at two different levels:

- A local power-management optimization

- A system power management

12.3.1.2.1 Local Power Management

To optimize power consumption, a local autoidle feature is implemented on the CAM_ICLK interface clock at camera ISP module level. By enabling this autoidle feature, CAM_ICLK is automatically gated at the module boundary as soon as it is not required and restarted without any latency when needed again. This allows power saving when the module is not involved in any transfer from/to the device interconnect. This autoidle feature is enabled by setting:

- [ISP_SYSCONFIG](#) [0] AUTO_IDLE bit to 1
- MMU_SYSCONFIG [0] AUTOIDLE bit to 1
- [ISP_CTRL](#) [21] SBL_AUTOIDLE bit to 1

The decision to gate the interconnect clock is based on interface activity, regardless of hardware handshake protocols.

After a reset, this mode is disabled, by default.

Note: It is recommended that this mode be enabled to reduce power consumption.

12.3.1.2.2 System Power Management

As part of the system power management scheme, the camera ISP module interacts with the PRCM through an automatic standby hardware protocol that allows dynamic power savings at CAMERA power domain level.

Being an initiator on the L3 interconnect, the camera ISP module alerts the PRCM as soon as it is ready to switch to a lower power state. Prior to any power state change to the CAMERA power domain, the PRCM first shuts off the camera clocks, depending on the camera ISP behavior and the clock settings at PRCM level. Namely, as soon as the camera ISP is ready to go to STANDBY, it asserts an automatic HW STANDBY request to the PRCM, which shuts down the clocks if they have been previously disabled by software and then potentially change the CAMERA power domain state. Refer to the *Power, Reset, and Clock Management* chapter for further details.

When it goes to standby, the camera ISP module alerts the PRCM differently, depending on the [ISP_SYSCONFIG](#) [13:12] MIDDLE_MODE bit field settings. The entry conditions for the camera ISP to go into standby mode are:

- The module has finished any current transaction and does not generate any more traffic on the interconnect.
- The module is idle (on-going transactions are finished).

The MIDDLE_MODE bit field allows the following settings for the camera ISP module:

- Force standby

The camera ISP is set to force standby when MIDDLE_MODE is set to 0x0. In this mode, the camera ISP module asserts its HW standby request to the PRCM as soon as it is disabled. Namely, the camera ISP is disabled when the following bit fields are set to 0x0:

- [ISP_CTRL](#) [13] RSZ_CLK_EN
- [ISP_CTRL](#) [12] PRV_CLK_EN
- [ISP_CTRL](#) [11] HIST_CLK_EN
- [ISP_CTRL](#) [10] H3A_CLK_EN
- [ISP_CTRL](#) [8] CCDC_CLK_EN

- No standby

The camera ISP is set to no standby when MIDDLE_MODE is set to 0x1. In this mode, the camera ISP module never asserts its standby request to the PRCM. Note that this also prevents the CAMERA power domain from going to a lower power state. Refer to the *Power, Reset, and Clock Management* chapter for further details.

- Smart standby

The camera ISP module is set to smart standby when `MIDDLE_MODE` is set to 0x2. In this mode, the camera ISP module asserts its HW standby request to the PRCM according with its internal activity (namely, when there is no more activity on the camera ISP master interface, that is, when there is no more data in the central resource buffer).

Note that a standby request asserted to the PRCM does not necessarily lead to `CAM_FCLK` and `CAM_ICLK` being cut. Indeed, the PRCM must also be set correctly for that purpose.

The clocks are cut, allowing a CAMERA power state change if:

- `PRCM.CM_ICLKEN_CAM[0] EN_CAM = 0` and `PRCM.CM_FCLKEN_CAM[0] EN_CAM = 0`
- `PRCM.CM_FCLKEN_CAM[0] EN_CAM = 0`, (`PRCM.CM_ICLKEN_CAM[0] EN_CAM = 1`, `PRCM.CM_AUTOIDLE_CAM[0] = 1`, and a domain transition is required at PRCM level).

Refer to the *Power, Reset, and Clock Management* chapter for further details.

12.3.1.3 Power Domain

The camera ISP belongs to the CAMERA power domain. For more information about the CAMERA power domain, see the *Power, Reset, and Clock Management* chapter.

12.3.1.4 Resets

12.3.1.4.1 Hardware Reset

Global reset of the camera ISP module is accomplished by activation of the `CAM_RST` signal in the CAMERA domain (for more information, see the *Power, Reset, and Clock Management* chapter).

12.3.1.4.2 Software Reset

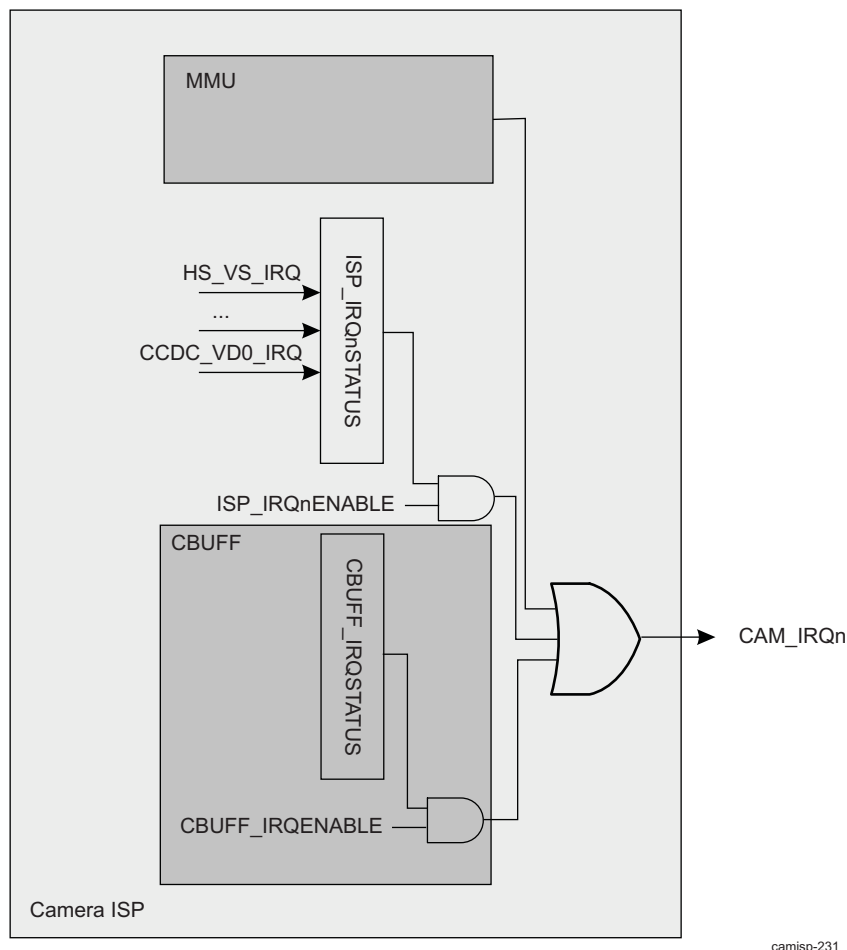

A global software reset can be accomplished by setting the camera ISP `ISP_SYSCONFIG [1] SOFT_RESET` bit to 1. Setting this bit enables active software reset functionality equivalent to hardware reset for the entire module.

12.3.2 Hardware Requests

12.3.2.1 Interrupt Requests

Figure 12-11 shows the interrupt generation tree of the camera subsystem.

Figure 12-11. Interrupt Generation Tree

The camera ISP can generate two interrupts:

- CAM_IRQ0 is an interrupt to the MPU subsystem interrupt controller. It is mapped on M_IRQ_24.
- CAM_IRQ1 is an interrupt to the IVA2.2 subsystem interrupt controller. It is mapped on IVA2_IRQ[11].

Table 12-10 summarizes events that cause interrupts.

Table 12-10. Camera ISP Interrupts

Event	Mask	Description
ISP_IRQ0STATUS [31] HS_VS_IRQ	ISP_IRQ0ENABLE [31] HS_VS_IRQ	HS or VS synchronization event: triggered if a rising or falling edge is detected on the HS or VS signal. The rising or falling edge and the HS or VS signal selection are chosen with the ISP_CTRL [15:14] SYNC_DETECT bit field.
ISP_IRQ0STATUS [30] SEC_ERR_IRQ	ISP_IRQ0ENABLE [30] SEC_ERR_IRQ	Security error event: triggered when a privilege violation error occurs.
ISP_IRQ0STATUS [29] OCP_ERR_IRQ	ISP_IRQ0ENABLE [29] OCP_ERR_IRQ	ISP OCP error: triggered when an OCP error occurs: SResp = ERR. The cause may be a security violation.
ISP_IRQ0STATUS [28] MMU_ERR_IRQ	ISP_IRQ0ENABLE [28] MMU_ERR_IRQ	MMU error

Table 12-10. Camera ISP Interrupts (continued)

Event	Mask	Description
ISP_IRQ0STATUS [25] OVF_IRQ	ISP_IRQ0ENABLE [25] OVF_IRQ	Central-resource SBL overflow: triggered when one of the buffers in the central-resource SBL overflows.
ISP_IRQ0STATUS [24] RSZ_DONE_IRQ	ISP_IRQ0ENABLE [24] RSZ_DONE_IRQ	RESIZER module - resizer processing-done event: Triggered at the end of the frame when processing is complete for the current frame. It applies to one-shot and continuous modes.
ISP_IRQ0STATUS [21] CBUFF_IRQ	ISP_IRQ0ENABLE [24] CBUFF_IRQ	CBUFF module event. See CBUFF_IRQSTATUS to know which interrupt it is.
ISP_IRQ0STATUS [20] PRV_DONE_IRQ	ISP_IRQ0ENABLE [20] PRV_DONE_IRQ	PREVIEW module - processing-done event: triggered at the end of the frame when processing is complete for the current frame.
ISP_IRQ0STATUS [19] CCDC_LSC_PREFETCH_ERROR	ISP_IRQ0ENABLE [19] PRV_DONE_IRQ	CCDC module - The prefetch error indicates when the gain table was read too slowly from memory. When this event is pending, the module goes into transparent mode (output = input). Normal operation can be resumed at the start of the next frame after 1) clearing this event 2) disabling the LSC module 3) enabling it
ISP_IRQ0STATUS [18] CCDC_LSC_PREFETCH_COMPLETED	ISP_IRQ0ENABLE [18] CCDC_LSC_PREFETCH_COMPLETED	CCDC module - Indicates the current state of the prefetch buffer. Can be used to start sending the data once the buffer is full to minimize the risk of an underflow. This event is triggered when the buffer contains 3 full paxel rows. It can be used to minimize buffer underflow risks.
ISP_IRQ0STATUS [17] CCDC_LSC_DONE	ISP_IRQ0ENABLE [17] CCDC_LSC_DONE	CCDC module - The event is triggered when the internal state of LSC toggles from BUSY to IDLE. This happens when the LSC module has completed processing the current frame.
ISP_IRQ0STATUS [16] HIST_DONE_IRQ	ISP_IRQ0ENABLE [16] HIST_DONE_IRQ	HIST module - processing-done event: triggered at the end of the frame when processing is complete for the current frame.
ISP_IRQ0STATUS [13] H3A_AWB_DONE_IRQ	ISP_IRQ0ENABLE [13] H3A_AWB_DONE_IRQ	H3A module - auto exposure and auto white balance processing done event: Triggered at the end of the frame when processing is complete for the current frame.
ISP_IRQ0STATUS [12] H3A_AF_DONE_IRQ	ISP_IRQ0ENABLE [12] H3A_AF_DONE_IRQ	H3A module - autofocus processing-done event: triggered at the end of the frame when processing is complete for the current frame.
ISP_IRQ0STATUS [11] CCDC_ERR_IRQ	ISP_IRQ0ENABLE [11] CCDC_ERR_IRQ	CCDC module - Faulty-pixel correction error: Faulty-pixel correction memory underflow. Triggered to signal an error in the faulty-pixel correction logic. The hardware did not have time to read the faulty-pixel LUT from external memory in time.
ISP_IRQ0STATUS [10] CCDC_VD2_IRQ	ISP_IRQ0ENABLE [10] CCDC_VD2_IRQ	CCDC module - Programmable event 2: triggered by the falling edge on the cam_wen signal. This event is not programmable.
ISP_IRQ0STATUS [9] CCDC_VD1_IRQ	ISP_IRQ0ENABLE [9] CCDC_VD1_IRQ	CCDC module - Programmable event 1: triggered after a programmable number of horizontal lines is received after a VS pulse.
ISP_IRQ0STATUS [8] CCDC_VD0_IRQ	ISP_IRQ0ENABLE [8] CCDC_VD0_IRQ	CCDC module - Programmable event 0: triggered after a programmable number of horizontal lines is received after a VS pulse.

Note: n is equal to 0 or 1.

l is equal to 01 or 23.

Table 12-11 summarizes the CBUFF interrupts.

Table 12-11. CBUFF Interrupt Details

Event	Mask	Description
CBUFF_IRQSTATUS [5] IRQ_CBUFF1_OVR	CBUFF_IRQENABLE [5] IRQ_CBUFF1_OVR	Buffer overflow event: The generation of this event depends on the CBUFFx_CTRL.ALLOW_NW_EQ_CR flag and the circular buffer mode (read or write). This event indicates a bandwidth mismatch between data producer and data consumer. When it occurs, CBUFFx does NOT go into error state. However, the data in the physical buffer is very likely to be corrupted.
CBUFF_IRQSTATUS [4] IRQ_CBUFF1_INVALID	CBUFF_IRQENABLE [4] IRQ_CBUFF1_INVALID	Invalid access: <ul style="list-style-type: none"> ISP writes the virtual space of CBUFFx in read mode. ISP reads the virtual space of CBUFFx in write mode. HW writes the virtual space of circular buffer x outside the CW or NW window in write mode. HW reads the virtual space of circular buffer x outside the CW or NW window in read mode. NW full CPU write the DONE bit when physical buffers are not ready for the CPU. This event indicates a wrong configuration of the circular buffer, the camera ISP, or bogus software. When it occurs, CBUFFx goes into an error state. In this state all accesses to the virtual space of CBUFFx are cancelled: they are not forwarded to the physical space. The purpose is to prevent corruption of the physical memory. The error state can be left by disabling the CBUFFx and reenabling it. Before doing so, the SW must ensure that there are no more outstanding requests to the virtual space of CBUFFx.
CBUFF_IRQSTATUS [3] IRQ_CBUFF1_READY	CBUFF_IRQENABLE [3] IRQ_CBUFF1_READY	The CPUW1 physical buffer is ready to be accessed by the CPU.
CBUFF_IRQSTATUS [2] IRQ_CBUFF0_OVR	CBUFF_IRQENABLE [2] IRQ_CBUFF0_OVR	Buffer overflow event. See description of IRQ_CBUFF1_OVR event.
CBUFF_IRQSTATUS [1] IRQ_CBUFF0_INVALID	CBUFF_IRQENABLE [1] IRQ_CBUFF0_INVALID	Invalid access. See description of IRQ_CBUFF1_INVALID event.
CBUFF_IRQSTATUS [0] IRQ_CBUFF0_READY	CBUFF_IRQENABLE [0] IRQ_CBUFF0_READY	The CPUW1 physical buffer is ready to be accessed by the CPU

12.4 Camera ISP Functional Description

12.4.1 Block Diagram

Figure 12-12 is the camera ISP top-level block diagram. The camera ISP supports two simultaneous pixel flows, but only one of them can use the video-processing hardware at a time:

The camera ISP master port is connected to the L3 interconnect, and the slave port is connected to the L4 interconnect (from the camera ISP point of view, commands are output from the camera ISP to the L3 and data are input/output. From the camera ISP point of view, commands are input from the L4 to the camera ISP and data are input/output).

Figure 12-12 shows the camera ISP block diagram.

Figure 12-12. Camera ISP Block Diagram

camisp-025

The camera ISP module comprises several blocks:

- Timing control: Includes a timing generator and a control-signal generator:
 - The timing generator allows the generation of two clocks that can be used by the external image sensors.

- The control-signal generator allows the generation of signals for strobe flash, mechanical shutter, and global reset.
- Bridge-lane shifter:
 - The data-lane shifter gives flexibility to the parallel camera connection and permits dynamic reduction of pixel data.
 - The bridge allows higher transfer rates when data is captured from the parallel interface and sent to memory.
- CCDC: This module provides the camera ISP with a powerful and flexible front end interface. It directly affects the input image data:
 - The CCDC provides an interface to image sensors and digital video sources and processes image data.
- IPIPE: Comprises preview and resizer modules:
 - The preview module is a parameterized hardwired image-processing block whose image-processing functions can be customized for each sensor type to realize good image quality and video frame rates for digital still camera preview displays and video-recording modes.
 - The resizer module provides a means of sizing the input image data to the desired display or video-encoding resolution. Zoom is limited to 4x in both vertical and horizontal directions for each pass. After one (on-the-fly) upscaling pass, the image can be sent to memory and then resent through the resizer.
- Statistics-collection modules (SCM): H3A and histogram modules that provide statistics on the incoming images to help designers of camera systems:
 - The hardware 3A module supports the control loops for AF, AWB, and AE by collecting metrics about RAW image data from the CCDC.
 - The histogram module bins input color pixels, depending on the amplitude, and provide statistics required to implement various 3A (AE/AF/AWB) algorithms and tune the final image/video output. The histogram module can operate on RAW image data from CCDC or memory.
- Central-resource shared buffer logic (CRSBL): Buffers and schedules memory accesses requested by the camera modules
- Circular buffer: Avoids storage of full image frames in the memory when the data must be post and/or preprocessed by software.
- MMU: Performs virtual-to-physical address translation between its interconnect slave and interconnect master access ports

12.4.1.1 Possible Data Paths inside the Camera ISP

Data paths inside the camera ISP hardware depend on the image format sourced by the sensor (RAW RGB, YUV4:2:2, JPEG,...).

Table 12-12 lists the modules used for the different data types. The formats described in the columns are the formats at the inputs of the CCDC (after the bridge-lane shifter). It is the internal parallel format.

Table 12-12. Allowed Data Flows for Hardware at the Input of the CCDC Module

Module	6/7 Bits RAW Format	8/10 Bits RAW Format	11/12/14 Bits RAW Format	YUV4:2:2 Format	Other Formats (JPEG,RGB4:4:4,...)
CCDC	+	+	+	+	+ All formats not treated by hardware
Preview	+	+			
Resizer	+	+		+	
H3A	+ Except AF	+ Except AF for RAW8			
Histogram	+	+			

12.4.1.1.1 RGB RAW Data

Figure 12-13 shows the data path of images in RAW format.

Figure 12-13. Camera ISP/Data Path/RAW RGB Images

RAW data are processed through the CCDC module and are directly pipelined to the preview engine. Another way is to output directly from the CCDC to memory. In the preview block; the format is converted from RAW data to YUV4:2:2 (1). The data can be output to memory (4) or pipelined to the resizer (2). The rescaled YUV4:2:2 image is finally stored in memory (3).

In parallel, processed data in the CCDC are used by the H3A module (A), which writes tables of statistics in memory, and by the HIST module (B). The results of the HIST modules are stored in status registers in the HIST module.

Notes:

- This data path is correct for RAW10 data.
- The data path for RAW8 data is similar to that for RAW10, except that the autofocus module in the H3A does not support RAW8.
- RAW11 data must be sent directly to memory).
- RAW12 data must be sent to memory) or pixel dynamic must be reduced RAW8 or RAW10 by the bridge-lane shifter module, before the CCDC.
- RAW14 data must be sent to memory) or pixel dynamic must be reduced to RAW8 or RAW10 by the bridge-lane shifter module, before the CCDC.

12.4.1.1.2 YUV4:2:2 Data

Figure 12-14 shows the data path of images in YUV4:2:2 format.

Figure 12-14. Camera ISP/Data Path/YUV4:2:2 Images

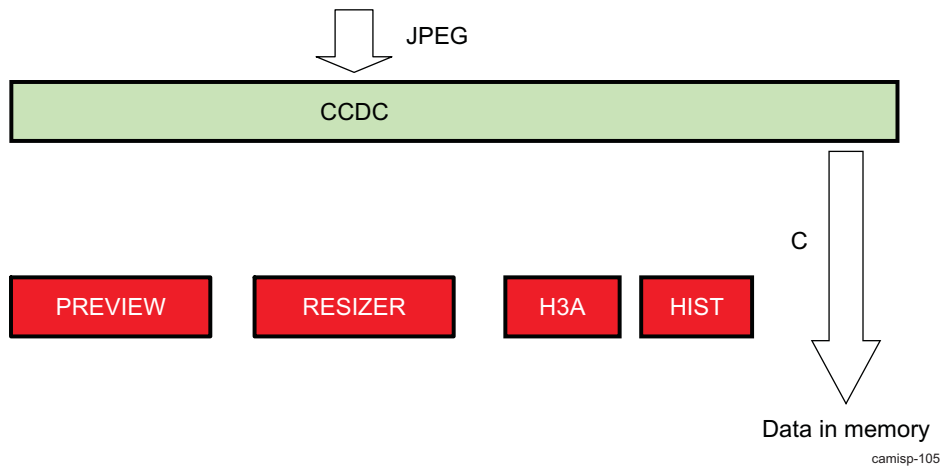

When the sensor-output format is YUV4:2:2, the CCDC block is directly pipelined to the resizer (1) or output directly to the memory (2). The rescaled YUV4:2:2 images are finally stored in memory (2).

The modules in red in Figure 12-14 are not used when the format is YUV4:2:2.

12.4.1.1.3 JPEG Data

Figure 12-15 shows the data path of images in JPEG format.

Figure 12-15. Camera ISP/Data Path/JPEG Images

When the sensor output format is JPEG, the CCDC block is directly output to the memory (2).

The modules in red in Figure 12-15 are not used when the format is JPEG.

12.4.2 Timing Control

12.4.2.1 Timing-Control Features

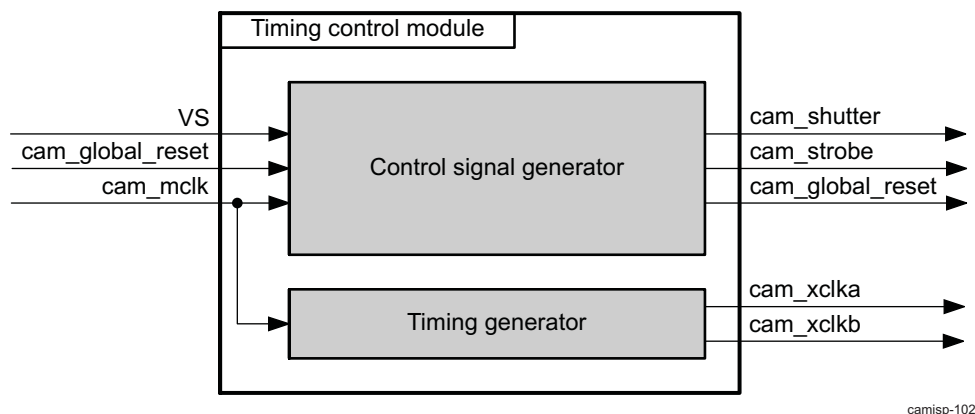

The timing-control module provides two clocks (cam_xclka and cam_xclkb) that can be used by external camera modules. It also generates the control signals (cam_strobe and cam_shutter) for the flash prestrobe, flash strobe, and mechanical shutters.

The timing-control module includes a timing generator and a control-signal generator.

12.4.2.2 Timing Control

Figure 12-16 shows a block diagram of the timing-control module.

Figure 12-16. Timing-Control Module

12.4.2.2.1 Timing Generator

The timing generator generates the cam_xclka and cam_xclkb clocks based on the cam_mclk, which is equal to 216 MHz. The cam_mclk is used only by the clock generator; the cam_xclka and cam_xclkb clocks are not used internally by the camera ISP. The clock divider is programmable.

The possible frequencies of cam_xclka and cam_xclkb and their respective configurations are described in [Section 12.3.1.1.3, Clock Configuration](#).

[Table 12-13](#) summarizes the possible frequencies as a function of the divisor values.

12.4.2.2.2 Control-Signal Generator

The control-signal generator generates the prestrobe, strobe, and shutter signals: cam_strobe and cam_shutter.

The control-signal generator gathers precise timings for the cam_strobe and cam_shutter signals, to assert and deassert the signals at known times. The timing-control-signal generator can be synchronized either on the vertical synchronization signal coming from the PARALLEL interface (cam_vs), or on an externally generated cam_global_reset signal.

A multiplexer controls the PARALLEL interface drives control-signal generation. This multiplexer can also select the externally-generated cam_global_reset signal as the trigger event. The [TCTRL_CTRL \[31\] GRESETDIR](#) register defines the direction of the cam_global_reset signal.

- The external generated cam_global_reset is used as a trigger when [TCTRL_CTRL \[31\] GRESETDIR](#) = 0 and [TCTRL_CTRL\[27:28\] INSEL](#) = 3.
- The internally generated cam_global_reset is used as a trigger when [TCTRL_CTRL \[31\] GRESETDIR](#) = 1 and [TCTRL_CTRL\[27:28\] INSEL](#) = 3.
- If the PARALLEL interface is selected, control-signal generation works for both ITU and SYNC modes and on both output ports: video port and shared-buffer-logic (SBL) port.

The cam_global_reset signal can also be generated internally by the control-signal generator under software control. In this case, the prestrobe and shutter signals are synchronized on the internally generated cam_global_reset signal. The multiplexer controls whether control-signal generation must be triggered by the internal or external cam_global_reset signal.

The prestrobe-, strobe-, and shutter-control signals can be individually enabled at any time. These signals must not be disabled by software.

The clock divider generates the CNTCLK clock based on the cam_mclk clock. The clock divider is programmable. [Table 12-13](#) summarizes the possible frequencies as a function of the divisor values.

Table 12-13. Control-Signal Generator: CNTCLK Frequencies

Divisor Value TCTRL_CTRL [18:10] DIVC	CNTCLK Clock
0 (default)	Clock gated. No clock.
1	216 MHz, free-running.
2	108 MHz
3	72 MHz
4	54 MHz
...	...
510	0.424 MHz
511	0.423 MHz

There are three counters per control signal, for a total of nine counters. Each counter is programmable.

- The frame counter is decreased each time a full new frame is received, based on the EOF events from the CCDC.
 - A new frame is detected in the CCDC module by using the falling edge of the vertical synchronization signal at the input of the CCDC module.

Note: The rising edge of the vertical synchronization signal and the vertical synchronization polarity settings inside the CCDC cannot be used. The modules have no effect on this detection.

- The frame counter determines how many whole frames must be ignored before the delay counter is triggered. The frame counters can be set to 0 to bypass them.
- The delay counter determines the control-signal activation delay. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the control signal is asserted. If the delay counter is set to 0, the control signal is asserted immediately.
- The activation-length counter determines the control-signal assertion length. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the signal is deasserted and the control-signal enable bit is disabled. If the activation length is set to 0, the control signal is not asserted and the control-signal enable bit is disabled.

The polarity of the following signals can be individually selected:

- [TCTRL_CTRL](#) [26] STRBPSTRBPOL for the prestrobe and strobe signals
- [TCTRL_CTRL](#) [24] SHUTPOL for the shutter signal
- [TCTRL_CTRL](#) [30] GRESETPOL for the cam_global_reset signal

The software can trigger the generation of the cam_global_reset signal to the camera module. The signal-activation length is programmable. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the signal is deasserted and the global reset enable bit is disabled ([TCTRL_CTRL](#) [29] GRESETEN bit). If the activation length is set to 0, the control signal is not asserted and the control-signal enable bit is disabled. The polarity of the cam_global_reset signal can be selected ([TCTRL_CTRL](#) [30] GRESETPOL bit).

12.4.3 Bridge-Lane Shifter

The bridge-lane shifter module contains a data-lane shifter and an optional bridge:

- The data-lane shifter routes data sent to physical pins to the proper inputs of the CCDC module. It is controlled by the [ISP_CTRL \[7:6\] SHIFT](#) register. [Table 12-14](#) describes the different configurations.

Table 12-14. Data-Lane Shifter

Sensor	Connected to	Data Lane shifter 0	Data Lane shifter 1	Data Lane shifter 2	Data Lane shifter 3	Note
8 bits	[7:0]	8 bits	6 bits	4 bits	2 bits	
	[9:2]	10 bits	8 bits	6 bits	4 bits	
	[11:4]	12 bits	10 bits	8 bits	6 bits	
10 bits	[9:0]	10 bits	8 bits	6 bits	4 bits	
	[11:2]	12 bits	10 bits	8 bits	6 bits	
12 bits	[11:0]	12 bits	10 bits	8 bits	6 bits	

Blue shading means that the data is too wide for the image pipeline: use IVA2.2.

Green shading means that precision is increased for intermediate results.

Orange shading means that precision is reduced.

Unshaded cells imply normal precision.

- An optional bridge allows the packing of bytes into 16-bit words. When it is used, the maximum data rate allowed is increased. The placement of 8-bit data inside 16-bit words is configurable through the [ISP_CTRL \[3:2\] PAR_BRIDGE](#) register. This mode can be useful to transfer an YCbCr data stream or compressed stream to memory at very high speed:
 - A minimum line-blanking period of 2 pixels must be obeyed when the bridge is enabled.
 - Some CCDC modules cannot work with the bridge. For details, see [Table 12-15](#).

12.4.4 CCDC

12.4.4.1 CCDC Features

The CCDC is responsible for accepting RAW (unprocessed) image/video data from a sensor. It can also accept YUV video data in numerous formats. For RAW inputs, the CCDC output requires additional image processing to transform the input image to a final processed image. This processing can be performed either on-the-fly in the preview engine, or in software on the IVA2.2 subsystem. In parallel, RAW data input to the CCDC can be used for computing statistics (H3A, histogram) to eventually control image/video tuning parameters. The CCDC module supports the following features:

- Image sensors:** Supports most image sensors (resolutions up to 4096 x 4096).
- CCDC interface:** The camera ISP module interface comes either from the external parallel interface. It is a 16-bit interface. To raise this maximum 16-bit interface, the bridge data-lane shifter before the CCDC module allows the packing of 8-bit data into 16 bits (not supported with ITU mode):
 - Data up to 8-bit at 130 MHz can be transferred to memory.
 - Data up to 10-bit at 75 MHz can be processed by the image pipeline or transferred to memory.
 - Data up to 12-bit at 75 MHz can be transferred to memory or internally converted into 10-bit data to be processed by the image pipeline.
 - Supports two synchronization modes:
 - SYNC mode:** In this mode, the cam_hs and cam_vs signals use dedicated wires. Synchronization signals are provided by either the sensor or the camera ISP. This mode works with 8-, 10-, 11-, and 12-bit data. It supports both progressive and interlaced image-sensor modules.
 - ITU mode:** In this mode, the image-sensor module provides an ITU-R BT 656-compatible data stream. Horizontal and vertical synchronization signals are not provided to the interface. Instead, the data stream embeds SAV and EAV synchronization code. This mode works in 8- and 10-bit configurations. It supports only progressive image-sensor modules.

- **RAW data processing:** Output data can go directly to memory for software processing, or to the PREVIEW module for further processing. The operations include:
 - Optical clamp
 - Black-level compensation
 - Faulty-pixel correction
 - 2D map based lens-shading compensation
 - Data formatter
 - Output formatter
- **YUV data processing:** The output data can go directly to memory for software processing or to the resizer module for further processing. The operations include:
 - DC subtract
 - Culling
 - Output formatter
- **Memory ports:** The CCDC module can access memory as a master through the CRSBL, so it does not require the assistance of the system DMA.

12.4.4.2 CCDC Block Diagram

Figure 12-17 shows the top-level block diagram of the CCDC module.

Figure 12-17. CCDC Block Diagram

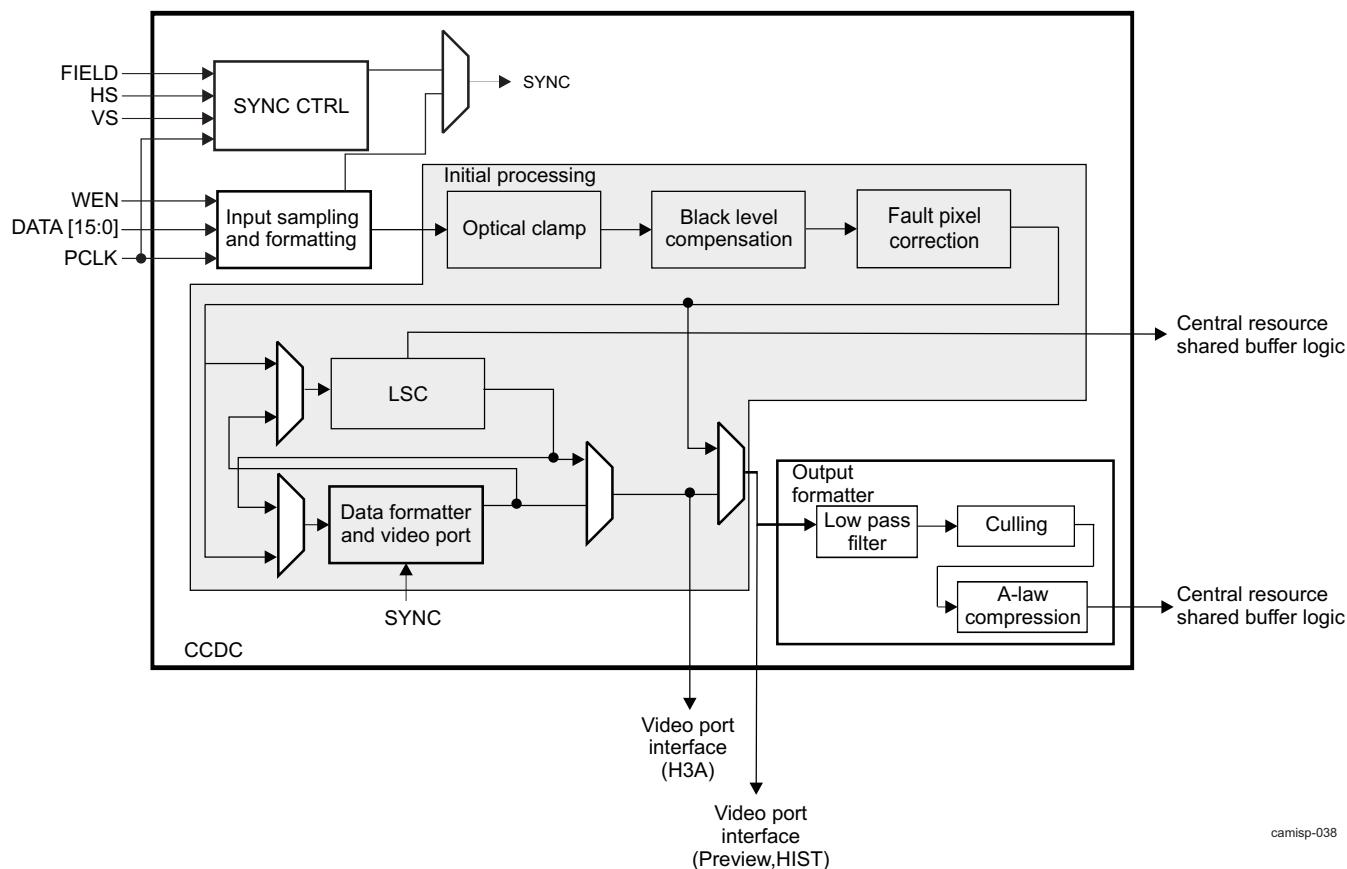

Table 12-15 summarizes allowed data flows through the CCDC.

camisp-038

Table 12-15. Allowed Data Flows Through the CCDC

Module		6/7 Bits RAW Format, SYNC Mode	8/10 Bits RAW Format, SYNC Mode	11/12 Bits RAW Format, SYNC Mode	8/10 Bits YUV4:2:2 Format, BT656 Mode	8/10 Bits YUV4:2:2 Format, SYNC Mode <75 MHz	8/10 Bits YUV4:2:2 Format, SYNC Mode <130 MHz	Other Formats (JPEG...), SYNC Mode
Bridge data-lane shifter	Bridge						+	
CCDC- SYNC CTRL	SYNC CTRL	+	+	+		+	+	+
CCDC-Input sampling and formatting	BT656 decoder				+			
CCDC-Initial processing	DC subtract	+	+	+	+	+	+	
	Optical black clamp	+	+	+				
	Black-level comp	+	+	+				
	Faulty-pixel correction	+	+	+				
CCDC-Data formatter	Data formatter	+	+					
	Shading compensator		+					
	Preview, H3A, HIST data path	+	+					
CCDC- Output formatter	Pixel selection	+	+	+	+	+	+	
	Low-pass filter	+	+	+				
	Culling	+	+	+	+	+	+	
	A-Law	+	+	+				
	Resizer data path				+	+	+	
	Memory data path	+	+	+	+	+	+	+

The data flow through the module differs, depending on whether the input is RAW data or YUV data. It also depends on the application scenario.

For RAW8/10 data ([CCDC_SYN_MODE](#) [13:12] INPMODE = 0 && [CCDC_REC656IF](#) [0] REC656ON = 0), the following functions apply:

- Video-preview and video-capture data flows can pass through the optical-clamp, black-level compensation, faulty-pixel correction, lens-shading compensator, and data-reformatter submodules. Output is transmitted to the HIST H3A modules for further processing.
- JPEG still-image-capture data flow passes through the optical clamp, black-level compensation, faulty-pixel correction, lens-shading compensator, and data-reformatter submodules. Then the data flow is sent to memory through the SBL, Circular buffer, and MMU to be read by the external JPEG CODEC.
- RAW still-image-capture data flow typically passes through the optical clamp, black-level compensation, faulty-pixel correction, lens-shading compensator and output-formatter submodules.

For YUV data ([CCDC_SYN_MODE](#) [13:12] INPMODE = 1 or 2 && [CCDC_REC656IF](#) [0] REC656ON = 1), the following functions apply:

- Data can be written to memory directly through the central-resource SBL module or sent to the resizer module for upscaling or downscaling.

12.4.4.3 CCDC Functional Operations

12.4.4.3.1 SYNC CTRL Module

The SYNC CTRL module receives the pixel-clock signal from the image sensor (PCLK). The module can be slave or master of the horizontal and vertical synchronization signals (HS and VS) and of the field-identification signal (FIELD).

The HS, VS, and FLD signals can be set as inputs or outputs. The polarity of the HS, VS, and FLD signals can be set as positive or negative. If the HS, VS, and FLD signals are output, the signal length can be set.

12.4.4.3.2 Input Sampling and Formatting

CCDC input sampling and formatting are shown in . In this block diagram, the lower data path (A2 output) is the RAW data path; the middle data path (A1 output) is the YUV data path.

- Data is latched by the pixel clock.
- Pixel-clock polarity can be either rising- or falling-edge. This is set through [ISP_CTRL](#) [4] [PAR_CLK_POL](#).
- Data can be interpreted as normal or inverted ([CCDC_SYN_MODE](#)[6] [DATAPOL](#)).
- For RAW data:
 - Data is clipped to the number of LSBs specified in the [CCDC_SYN_MODE](#) [10:8] [DATSIZ](#) field. This also sets the maximum data size allowed in subsequent clipping/limiting operations and is the output data alignment if data is written to memory.
- For YUV data (BT656 or SYNC mode):
 - The MSB of the chroma signal can also be inverted ([CCDC_CFG](#) [13] [MSBINVI](#)). It adds 128 to chrominance signals, to be compatible with several sensors.
- BT656 decoder: Separates data and synchronization signals. This module outputs HS, VS, and FIELD signals.

12.4.4.3.3 CCDC Initial Processing

Optical Clamp

The optical black clamping function provides a means of averaging the optically black pixels and subtracting that value from each input pixel as a first step. The goal is to remove an offset caused by the sensor technology.

The averaging circuit takes an average of masked (black) pixel values from the image sensor, averaging pixels at the start ([CCDC_CLAMP](#) [24:10] [OBST](#)) of each line ([CCDC_CLAMP](#) [30:28] [OBSLEN](#)) and for the number of indicated lines ([CCDC_CLAMP](#) [27:25] [OBSLN](#)), plus an optional gain adjustment ([CCDC_CLAMP](#) [4:0] [OBGAIN](#)), and subtracting this value from the image data at the succeeding line. Users can control the position of the black pixels, the number of pixels (1, 2, 4, 8, or 16) in each line averaged, and the averaged number of lines (1, 2, 4, 8, or 16).

Alternately, users can disable black clamp averaging ([CCDC_CLAMP](#) [31] [CLAMPEN](#)) and select a constant black value for subtraction ([CCDC_DCSUB](#) [13:0] [DCSUB](#)), instead of using the calculated average value.

Note: For YUV data, this operation subtracts a fixed value ([CCDC_DCSUB](#) [13:0] [DCSUB](#)) from the luminance sample. To disable this operation, set the subtraction value to zero.

This function does not clip negative results to 0 for YUV 8 bit input or REC656 input modes ([CCDC_SYN_MODE](#) [13:12] [INPMOD](#) == 2 || [CCDC_REC656IF](#) [0] [REC656ON](#) == 1).

Figure 12-18 shows an optical clamp representation.

Figure 12-18. Optical Clamp Representation

camisp-106

Black-Level Compensation

After the optical clamp, black-level compensation is applied to the data. In this operation, a fixed value, depending on the color (R/Ye, Gr/Cy, Gb/G, and B/Mg), can be subtracted from the data. The offset ([CCDC_BLKCOMP](#) register, fields R_YE, GR_CY, GB_G, B_MG) applied to each data sample is selected according to the pixel position (0/1/2/3) and the color (0/1/2/3) specified for each pixel position ([CCDC_COLPTN](#)). The color pattern definition is flexible to accommodate different sensor types (such as Bayer CFA sampling, Foveon, VGA Movie Mode).

Faulty-Pixel Correction

Faulty-pixel correction in the CCDC module requires the camera driver to have information about the image-sensor faulty-pixel number and positions. This method leads to the best image quality. However, if the position of the faulty pixels is unavailable to the camera driver, it can apply another faulty-pixel correction algorithm in the preview module. This algorithm leads to lower-quality images.

The CCDC module implements an optional ([CCDC_FPC](#) [15] FPCEN) faulty-pixel correction operation using a look-up table stored in external memory, which contains information about the horizontal and vertical positions of the pixels to be corrected, as well as the type of operation to be performed on the pixels. The [CCDC_FPC_ADDR](#) register specifies the starting address in memory for the faulty-pixel correction table.

Note: The memory address must be 64-byte-aligned (6 LSB are ignored).

Note: For YUV data, the faulty-pixel correction operation is not applicable and must be disabled/bypassed ([CCDC_FPC](#) [15] FPCEN).

12.4.4.3.4 Data Formatter, Lens-Shading Compensation, and Video-Port Interface

Note: For YUV data, the data formatter, lens-shading compensation, and video-port interface must be bypassed ([CCDC_FMTCFG](#) [15] VPEN = 0x0 and [CCDC_SYN_MODE](#) [18] VP2SDR = 0x0).

The data-formatter module can be enabled to rearrange data after the faulty-pixel correction operation. It is intended to be used:

- When output data lines from the CCDC include pixels from multiple resolution lines. Internally, these sensors combine pixels from multiple horizontal lines into one output pseudoline.
- To smooth bandwidth. This helps reduce peak bandwidth when image cropping is used with the resizer.

The reformatter module performs the decomposition before the remainder of the normal CCDC processing stages.

The lens-shading compensation (LSC) module can be placed at two different locations:

- Before the data reformatter. It can only be used for Bayer sensors. The H3A video port gets the shading corrected image.
- After the data reformatter. This setup is required for non-Bayer sensors. Histogram and preview modules get the shading corrected image; however, H3A receives a non-corrected image.

Video-port/data-formatter output can also be saved to memory (instead of the RAW data). When [CCDC_SYN_MODE](#) [18] VP2SDR is set to 1, video-port data is sent to the output formatter. In addition, the [CCDC_SYN_MODE](#) [17] WEN bit must be enabled to store the output to memory.

The data-formatter and video-port interfaces are only 10 bits wide; therefore, the input data must be adjusted as it enters these modules. For flexibility, the bits to be retained can be selected by [CCDC_FMTCFG](#) [14:12] VPIN.

The reformatter decomposes each input line into multiple output lines with new, internally generated HS/VS signals. The reformatter sends it to memory or to other camera ISP modules. These new HS/VS signals, rather than the original sensor HS/VS signals, then gate the downstream processing.

Conversion Area Select Parameters

When the data formatter is enabled, HS/VS signals are still generated as output ([CCDC_SYN_MODE](#) [16] VDHDEN = 0x1). The settings for these output signals are in the following fields:

- [CCDC_HD_VD_WID](#)[27:16] HDW
- [CCDC_HD_VD_WID](#)[11:0] VDW
- [CCDC_PIX_LINES](#)[31:16] PPLN
- [CCDC_PIX_LINES](#)[15:0] HLPRF

Note: These four registers are not used when HS/VS signals are input signals ([CCDC_SYN_MODE](#) [16] VDHDEN = 0x0).

Note: The settings reflect those for the sensor readout frame, not the resultant reformatted frame.

Registers [CCDC_FMT_HORZ](#) and [CCDC_FMT_VERT](#) control the interpretation of the input data frame when the data formatter is enabled.

Registers [CCDC_HORZ_INFO](#), [CCDC_VERT_START](#), and [CCDC_VERT_LINES](#) control the interpretation of the input data frame in normal mode (when the data formatter is not enabled).

Figure 12-19 shows the data formatter conversion area selection.

Figure 12-19. Data Formatter Conversion Area Selection

camisp-045

Line Decomposition

When enabled, the reformatter can be configured to operate in line-alternating mode or program mode (CCDC_FMTCFG [1] LNALT).

When line-alternating mode is enabled, the reformatter swaps even and odd lines. Basically, the 0th input line is output as the first line, the first input line is output as the 0th line, and so on. If this option is set, the start and number of lines for the formatter (CCDC_VERT_START and CCDC_VERT_LINES) must be even.

In program mode, or normal reformatter mode, the goal is to convert a single line of movie mode data to 1, 2, 3, or 4 lines of Bayer data. Each incoming line is decomposed according to the data-formatter settings and buffered into an internal line memory. The readout of the resultant multiple reformatted lines occurs as the next input line is being read from the sensor (and reformatted) to ensure that all output lines are fully constructed. The reformatter is subject to the restrictions listed in Table 12-16.

Table 12-16. Reformatter Output Limitations

Number of Output Lines/Input Line	Max Pixels/Output Line
1	4 * 1376
2	2 * 1376
3	1 * 1376
4	1 * 1376

The reformatter derives its flexibility from supporting up to 8 different addresses and a program that can contain up to 16 entries each for the odd and even lines. Each of the 8 addresses supports either autoincrement or autodecrement. This capability is the key for supporting a multitude of readout patterns. The following examples show the programmability of the reformatter. Decomposition is controlled by defining the following parameters:

- [CCDC_FMTCFG \[3:2\] LNUM](#)
Number of lines into which each input line is to be decomposed
- [CCDC_FMTCFG \[11:8\] PLEN_EVEN](#)
Number of program entries on even line
- [CCDC_FMTCFG \[7:4\] PLEN_ODD](#)
Number of program entries on odd line
- [CCDC_FMT_ADDRx \(x=0:7\)](#)
Output line in which the original pixel is to be placed, and initial address on the output line
- [CCDC_PRGEVEN0](#) or [CCDC_PRGEVEN1](#)
Program to be run on the even input lines
- [CCDC_PRGODD0](#) or [CCDC_PRGODD1](#)
Program to be run on the odd input lines

The `CCDC_FMT_ADDRx` registers define 8 address pointers (ADDR0 to ADDR7) that define which output line the input pixel belongs to, and the starting address (position) on that output line. Users can use up to 8 address pointers. The address pointer can be incremented or decremented, depending on the input pixel pattern. The address value computed should always follow the reformatter rules as formerly stated and should never be negative.

Lens-shading compensation

- *Overview*

The purpose of the LSC function is lens-shading correction by multiplying an image with a gain factor 2-D map, pixel by pixel. The image must be in Bayer CFA format having a 2x2 color pattern. The gain factor map is stored in external memory downsampled, and is accessed and upsampled by the LSC module before being applied to the pixel data.

The LSC function is useful for lens-shading compensation and for scene- and image-dependent lighting adjustment. Downsampled gain map reduces memory requirements for storage and bandwidth requirements for access of the gain maps in external memory.

- *Features supported*

- The memory stored gain map is MxN downsampled, M being the horizontal sampling factor, N being the vertical sampling factor, M and N being {4, 8, 16, 32, 64} independently and $N \leq M$
- 8-bit entries in the gain map (in U8Q8, U8Q7, U8Q6, and U8Q5 format with optional base of 1.0)
- Up to 10-bit unsigned image data input/output
- Up to 4096 x 3072 image dimension

- *Functional description*

The lens-shading correction module multiplies an image by a gain map that is stored downsampled in memory. The gain map can be dependent on aperture, lens-shading characteristics, and other photographic settings. It is generally used to correct the dim corner effect, but can also be used to implement adaptive lighting adjustment.

Separate horizontal and vertical sampling factors allow the lens-shading correction to work with the normal 1:1 aspect ratio image pixels, as well as tall-and-skinny pixels typical in the sensor's preview mode image data.

12.4.4.3.5 Output Formatter

The output formatter starts with a framing selection to limit the processing area by setting [CCDC_HORZ_INFO](#), [CCDC_VERT_START](#), and [CCDC_VERT_LINES](#) registers. This framing selection is applied in addition to the framing applied at the beginning and at the end of the data formatter operation if the video-port path to memory is selected ([CCDC_SYN_MODE](#) [18] VP2SDR).

The option to send the CCDC output to the resizer module ([CCDC_SYN_MODE](#) [19] SDR2RSZ) should not be used when in RAW data mode, because the resizer operates only on YUV format data. Use the preview module when resizing is desired in RAW data mode.

Low-pass filter (LPF)

An optional horizontal low-pass antialiasing filter can be applied ([CCDC_SYN_MODE](#) [14] LPF) after reframing. The low-pass filter consists of a simple 3-tap (1/4, 1/2, and 1/4) filter. Two pixels on the left and two pixels on the right of each line are cropped if the filter is enabled. Use of the LPF is intended for bandwidth reduction if culling is enabled.

Note: For YUV data, the LPF must be disabled ([CCDC_SYN_MODE](#) [14] LPF = 0x0).

Culling

An optional culling operation can be enabled ([CCDC_CULLING](#) register). This operation allows selected pixel data to be culled (deleted) from a line ([CCDC_CULLING](#) [31:24] CULHEVN, [CCDC_CULLING](#) [23:16] CULHODD - 8-bit repeating mask, one per field) and selected lines to be culled from a frame ([CCDC_CULLING](#) [7:0] CULV).

Figure 12-20 is an example of how register values apply the decimation pattern to the data. The red pixels are saved to memory and the white pixels are discarded. In this example, [CCDC_CULLING](#) = 0x239A0066:

- [CCDC_CULLING](#) [31:24] CULHEVN = 0x23
- [CCDC_CULLING](#) [23:16] CULHODD = 0x9A
- [CCDC_CULLING](#) [7:0] CULV = 0x66

Note: Culling can be used with YUV data, but care must be taken to preserve the YUV422 output format.

Figure 12-20. CCDC/Culling: Example for Decimation Pattern

	LSB						MSB	
CCDC_CULLING [31:24] CULHEVEN	0	0	1	0	0	0	1	1

CCDC_CULLING[7:0]
CULV

camisp-048

A-Law compression

An optional 10-to-8-bit A-Law compression using a fixed A-Law table can be applied ([CCDC_ALAW](#) [3] CCDTBL) as the final processing stage. Using this causes data width to be reduced to 8 bits and allows packing to 8 bits/pixel when saving to memory. Because data resolution can be greater than 10 bits at this stage, the 10 bits for input to the A-Law operation must be selected ([CCDC_ALAW](#) [2:0] GWDI).

The preview module has an inverse A-Law table (A-Law decompression) option so that this nonlinear operation can be reversed if this saved data is to be read back in for further processing.

Note: A-Law compression should not be used ([CCDC_ALAW](#) [3] CCDTBL = 0) with YUV data.

[Figure 12-21](#) show the A-Law table.

Figure 12-21. A-Law Table

Line-Output Control

Note: Line-output control can be used with YUV data.

The CCDC final stage is line-output control, which controls how the input sensor lines are written to memory. The value of [CCDC_SDR_ADDR](#) [31:0] ADDR defines the starting address where the frame should be written in memory. The value of [CCDC_HSIZE_OFF](#) [15:0] LNOFST defines the distance between two lines for each output line to memory. The starting address and line-offset values should be aligned to 32-byte boundaries; that is, either 16 or 32 pixels, depending on the [CCDC_SYN_MODE](#) [11] PACK8 setting. Register [CCDC_SDOFST](#) can be used to define additional offsets, depending on the field ID and even/odd line numbers. This provides a means to deinterlace an interlaced 2-field input and to invert an input image vertically. See [Table 12-17](#).

Table 12-17. CCDC_SDOFST Description

Register	Description
CCDC_SDOFST [14] FIINV	Invert interpretation of the field ID signal
CCDC_SDOFST [13:12] FOFST	Offset, in lines, of field = 1
CCDC_SDOFST [11:9] LOFST0	Offset, in lines, between even lines on even fields (field 0)
CCDC_SDOFST [8:6] LOFST1	Offset, in lines, between odd lines on even fields (field 0)
CCDC_SDOFST [5:3] LOFST2	Offset, in lines, between even lines on odd fields (field 1)
CCDC_SDOFST [2:0] LOFST3	Offset, in lines, between odd lines on odd fields (field 1)

Line output control: 2D addressing example

The CCDC memory port can be configured to write a subimage into a bigger image buffer. This feature is useful for overlaying a video preview flow with the rest of the display. To use this feature, the [CCDC_SDR_ADDR](#) [31:0] ADDR register points to the first pixel to write and the [CCDC_SDOFST](#) [13:12] FOFST is set to the size of one line of the destination buffer. See [Figure 12-22](#).

Figure 12-22. CCDC 2D Addressing Mode

camisp-107

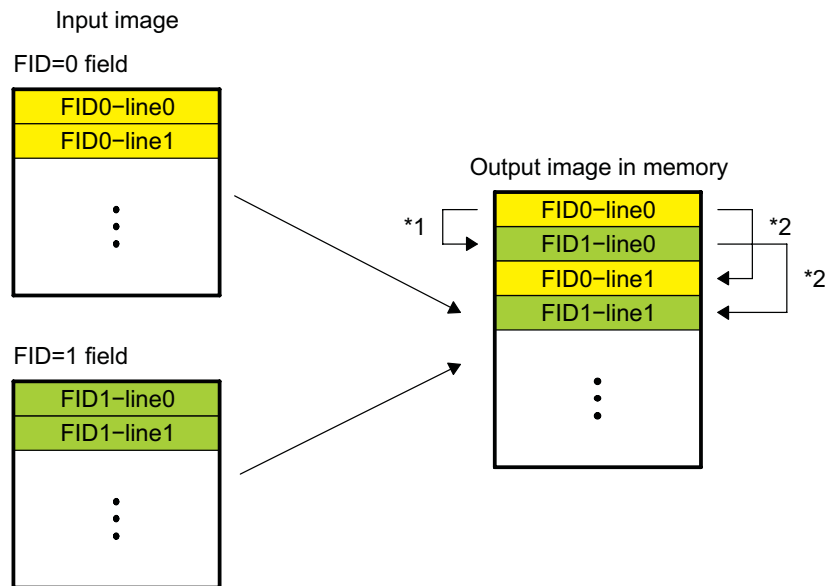

Note:

- This mode can be used only when the source and destination buffers use the same image format.
- 2D addressing is also supported by other camera ISP modules.

Line-output control: Examples

Figure 12-23 and Figure 12-24 show examples of line-output control for frame format conversion and sample formats of input and output images.

Figure 12-23. CCDC/Line-Output Control: Frame Format Conversion

*1 - CCDC_SDOFST[13:12] = 00b, +1 line for FID = 1 line

*2 - CCDC_SDOFST[11:9] = CCDC_SDOFST[8:6] = CCDC_SDOFST[5:3] = CCDC_SDOFST[2:0] = 001b, +2 lines

camisp-050

Figure 12-24. CCDC/Line-Output Control: Sample Formats of Input and Output Images

camisp-051

Output format

The data bits comprising each pixel are stored in the lower bits of a 16-bit memory word and the unused bits are zero-filled. The memory data format is shown in [Table 12-18](#). The format is determined by the [CCDC_SYN_MODE](#) [10:8] DATSIZ field.

If 8-bit data is input, or if A-Law compression is applied, the data can be packed through the [CCDC_SYN_MODE](#) [11] PACK8 setting so that a pixel occupies only 8 bits.

Data is output to memory only when enabled through the [CCDC_SYN_MODE](#) [17] WEN setting. The pixels are ordered in little-endian format.

Table 12-18. Memory Output Format for RAW Data

	Upper word		Lower word	
	MSB(31)	LSB(16)	MSB(15)	LSB(0)
16 bit	Pixel 1		Pixel 0	
15 bit	0	Pixel 1	0	Pixel 0
14 bit	0	Pixel 1	0	Pixel 0
13 bit	0	Pixel 1	0	Pixel 0
12 bit	0	Pixel 1	0	Pixel 0
11 bit	0	Pixel 1	0	Pixel 0
10 bit	0	Pixel 1	0	Pixel 0
9 bit	0	Pixel 1	0	Pixel 0
8 bit	0	Pixel 1	0	Pixel 0
8-bit packed	Pixel 3	Pixel 2	Pixel 1	Pixel 0

Note: YUV data is stored in memory in packed YUV422 mode, using two pixels per 32 bits, as shown in [Table 12-19](#).

Table 12-19. Memory Output Format for YUV Data

Memory Address	Upper word		Lower word	
	MSB(31)	LSB(16)	MSB(15)	LSB(0)
N	Y1	Cr0	Y0	Cb0
N + 1	Y3	Cr1	Y2	Cb1
N + 2	Y5	Cr2	Y4	Cb2

12.4.4.4 DMA

The CCDC module is a master. It has its own address generator and sends addresses and data to the central-resource shared-buffer logic. The central-resource shared-buffer logic arbitrates the data requests and generates the bursts to memory.

12.4.4.5 Memories

The CCDC module has one memory:

- REFORMATTER BUFFER: $3 \times 1376 \times 40$ bits
- LSC PREFETCH BUFFER: 1536×32 bits

12.4.5 IPIPE

12.4.5.1 Preview Engine Features

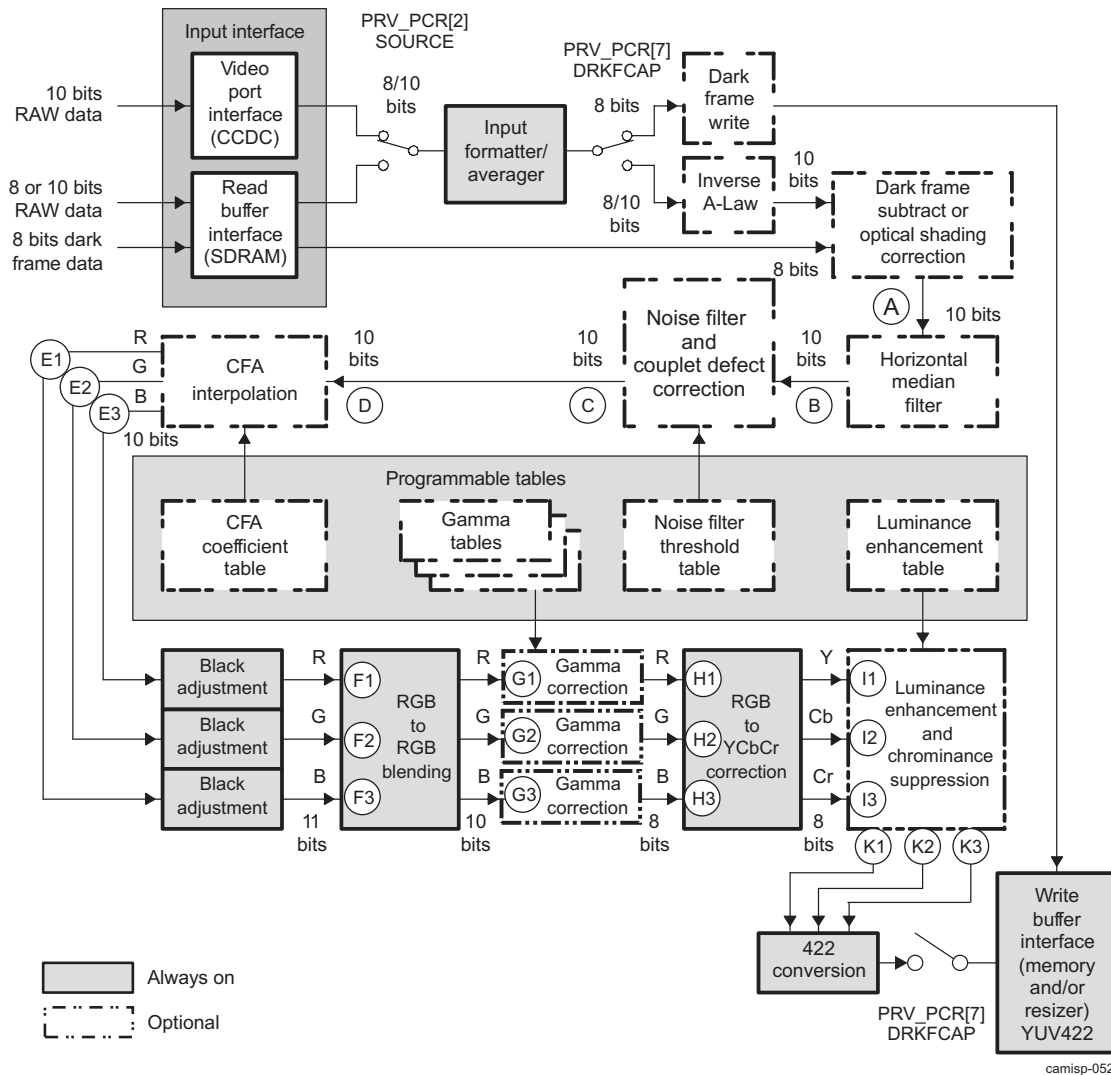

The preview module is responsible for transforming data from a RAW image sensor into YUV422 data that is amenable to still-image encoding, video encoding, or display. It supports the following features:

- Flexible input: Module input data can come from the RAW image sensor (10 bits) or from memory (8 or 10 bits).
- Flexible input formats: Bayer RGB color filter array, complementary-color filter array, Foveon sensors, Honeycomb sensors, SMIA sensors
- Horizontal averaging by a factor of 2, 4, or 8 in the horizontal direction. The preview module can output a maximum of only 3312 pixels horizontally due to fixed memory-line sizes.
- A-Law decompression: Transforms nonlinear 8-bit data to 10-bit linear data. The CCDC module can perform A-Law compression.
- Noise reduction and faulty-pixel correction:
 - Dark-frame capture and subtraction
 - Horizontal median filter
 - Programmable noise filter: 3×3 kernel of same color pixels
 - Couplet faulty-pixel correction
- Digital gain and white balance
- Programmable CFA interpolation that operates on a 5×5 grid
- Programmable RGB-to-RGB blending matrix: 9 coefficients for the 3×3 matrix
- Programmable gamma correction: 1024 entries for each color held in local memory
- Programmable RGB-to-YUV color conversion: 9 coefficients for the 3×3 matrix
- Luminance enhancement (nonlinear), chrominance suppression and offset

12.4.5.1.1 Preview Block Diagram

Figure 12-25 shows the preview engine block diagram.

Figure 12-25. Preview Engine Block Diagram

12.4.5.1.2 Input Interface

The preview engine receives RAW image/video data from the video port interface through the CCDC or from the read buffer interface through the memory (PRV_PCR [2] SOURCE). When the source of input data is the CCDC, the input data is always 10 bits wide. When the source of input data is memory (read buffer interface), the data can be 8 or 10 bits wide. Use the PRV_PCR[4] WIDTH field to set the input data width. The 8 bits can be linear or nonlinear (A-Law compressed).

In addition, the preview engine can fetch a dark frame from memory, with each pixel 8 bits wide.

The frame-input size is configured using the `PRV_HORZ_INFO` and `PRV_VERT_INFO` registers.

If the input source is the CCDC, the input height set in the preview engine must be less than or equal to the output height of the video-port output of the CCDC. The input width must be at least 4 pixels smaller than the CCDC output width (SPH \geq 2; EPH \geq 2 pixels before the last pixel sent from the CCDC).

The input memory address ([PRV_RSDR_ADDR](#)) and line offset ([PRV_RADR_OFFSET](#)) registers should be aligned on 32-byte boundaries when the input source is set to memory. The dark-frame input address ([PRV_DSDR_ADDR](#)) and line offset ([PRV_DRKF_OFFSET](#)) should also be aligned on 32-byte boundaries when the dark-frame subtract function is enabled.

When the input source is memory, the preview engine always operates in one-shot mode. After enabling the preview engine and processing a frame, the enable bit is turned off and it is up to firmware to reenale it to process the next frame from memory.

When the input source is the CCDC, the preview engine can be configured to operate in one-shot mode or continuous mode ([PRV_PCR](#) [3] ONESHOT).

The SBL image data read port is shared between the preview module. When the image is read from memory, the read port must be affected to the preview receiver module by writing 0 into the [ISP_CTRL](#) [27] SBL_SHARED_RPORTA.

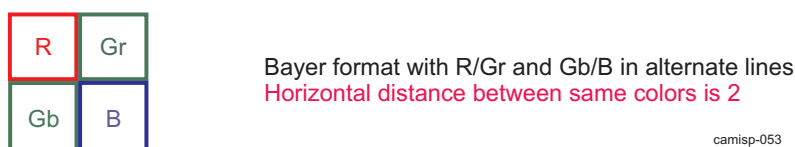

12.4.5.1.3 Input Formatter/Averager

Preview-engine output is limited to 3312 pixels per horizontal line due to line memory-width restrictions in the noise filter and CFA interpolation blocks. To support sensors that output more than 3312 pixels per line, an averager is incorporated to downsample by factors of 1 (no averaging), 2, 4, or 8 in the horizontal direction ([PRV_AVE](#) [1:0] COUNT). The horizontal distance between two consecutive pixels of the same color to be averaged is selectable from among 1, 2, 3, or 4 for both even ([PRV_AVE](#) [3:2] EVENDIST) and odd ([PRV_AVE](#) [5:4] ODDDIST) lines. This must be configured to match the input pattern type.

Valid output of the input formatter/averager is either 8 or 10 bits wide.

[Figure 12-26](#) shows the horizontal distances for different patterns.

Figure 12-26. Horizontal Distances for Different Patterns

12.4.5.1.4 Dark-Frame Write

The preview engine is capable of capturing and saving a dark frame to memory instead of performing conventional processing steps ([PRV_PCR](#) [7] DRKFCAP).

This dark frame can later be subtracted from the RAW image data to eliminate the repeatable baseline noise level in the frame.

Each input pixel is written as an 8-bit value; if the input pixel value is greater than 255, it is saturated to 255. If a dark pixel is greater than 255, it is more likely to be faulty, and can be corrected by the faulty-pixel correction module in the CCDC. If properly corrected, the value must be less than 255 when it reaches the preview engine.

The [PRV_WSDR_ADDR](#) and [PRV_WADD_OFFSET](#) registers must be used to indicate the output address and line offset, respectively, of the dark-frame output in memory.

12.4.5.1.5 Inverse A-Law

To save memory capacity and bandwidth, the CCDC includes an option to apply 10-bit to 8-bit A-Law compression and to pack the sensor data to 1 byte per pixel. To process this data correctly, the inverse A-Law block is provided to decompress the 8-bit nonlinear data back to 10-bit linear data if enabled ([PRV_PCR](#) [5] INVALAW). Even if the inverse A-Law block is not enabled, but the input is still 8 bits ([PRV_PCR](#) [4] WIDTH), the data is left shifted by 2 to make it 10-bit data. If the input is 10 bits wide, no operation is performed on the data.

Note: When A-Law compression in CCDC is enabled during dark-frame write, it must be enabled when the stored dark frame is used.

12.4.5.1.6 Dark-Frame Subtract or Shading Compensation

The preview engine can fetch a dark frame containing 8-bit values from memory (8 bits in input are converted internally to 10 bits by adding two zeros to the left) and subtracting it, pixel by pixel, from the incoming input frame ([PRV_PCR](#) [6] DRKFEN). This function removes pattern noise in the sensor. The output of the dark-frame subtract operation is 10 bits wide (U10Q0).

There must be adequate memory bandwidth if this feature is enabled. If the data fetched from memory arrives late, the [PRV_PCR](#) [31] DRK_FAIL status bit is set to indicate a fail.

Instead of performing the dark-frame subtract, the preview engine can perform lens-shading compensation (if [PRV_PCR](#) [21] SCOMP_EN is set along with [PRV_PCR](#) [6] DRKFEN). In this case, the 8-bit unsigned value fetched from memory is multiplied by the incoming pixel, and the result is right-shifted by the number of bits specified by the [PRV_PCR](#) [24:22] SCOMP_SFT parameter (0-7 bits).

The SBL data read port is shared between the CCDC and preview module. The read port must be affected to the preview module by writing 0 into the [ISP_CTRL](#) [28] SBL_SHARED_RPORTB. Programmers must ensure that the CCDC module does not use this port before switching to the preview module.

12.4.5.1.7 Horizontal Median Filter

The preview engine contains a horizontal median filter that can help reduce temperature-induced noise effects. The horizontal median filtering operation, shown in , calculates the absolute difference between the current pixel (I) and pixel (I-X) and between the current pixel (I) and pixel (I+X). If the absolute difference exceeds a specified threshold and the sign of the differences is the same, the average of pixel (I-X) and pixel (I+X) replaces pixel (I). The horizontal median filter's threshold is configurable ([PRV_HMED](#) [7:0] THRESHOLD), and the horizontal median filter can be either enabled or disabled ([PRV_PCR](#) [8] HMEDEN). The horizontal distance (X) between two consecutive pixels can be either 1 or 2 pixels for both even ([PRV_HMED](#) [8] EVENDIST) and odd ([PRV_HMED](#) [9] ODDDIST) lines. The input and output of the horizontal median filter are 10 bits wide (U10Q0).

Note: Line-width reduction: If the horizontal median filter is enabled, the preview engine reduces the length of the output line of this stage by 4 pixels (2 starting pixels -left edge and 2 ending pixels -right edge). For example, if the input size is 656x490 pixels, the output is 652x490 pixels. There is no truncation of input data line if this block is disabled.

12.4.5.1.8 Noise Filter and Faulty Pixel Correction

12.4.5.1.8.1 Overview

The noise filter and couplet defect correction (CDC) operate on the same 3x3 matrix of same color pixels. Both functions can be enabled separately using the [PRV_PCR](#) [27] DCOREN and [PRV_PCR](#) [9] NFEN bits.

The faulty pixel correction function replaces the central pixel (x0) with one of the neighbors (x1-x8) in the following cases:

- When it has been identified as faulty.
- When the feature is enabled.

The noise filter modifies the central pixel when it is enabled. The neighbors used by the algorithm have not been corrected by the faulty pixel stage. However, they are not being used by the noise filter because they are far apart from the central pixel. In other words, the difference between the pixel intensities is above a user-configurable threshold. The algorithm chooses whether noise filter or faulty pixel correction is used.

- When no faulty pixels are detected, only the noise filter modifies the central pixel.

- When one neighbor is a faulty pixel, the CDC stage does not correct it. However, the faulty pixel is not used by the noise filter because it is far apart from the central pixel.
- When the central pixel is faulty, it is replaced by the CDC stage. The central pixel is then filtered by the noise filter stage,
- When the central pixel and one of its neighbors are faulty, the CDC replaces the central pixel and the noise filter does not use the other faulty pixel.
- However, when the central pixel and two or more neighbors are faulty, no correction can be done by the CDC stage and the noise filter uses faulty pixels. Those defects are not corrected.

12.4.5.1.8.2 Same Color Pixel Extraction and Cropping

The pixel extraction stage assumes that the horizontal and vertical distances between same color pixels is always 2.

Foveon sensors that follow the RGBRGB color pattern have a horizontal distance of 3. Therefore, they are not supported and this function must be disabled when using these sensors.

If either or both features are enabled, the preview engine reduces the output of this stage by 4 pixels in each line (2 starting pixels – left edge and 2 ending pixels – right edge) and 4 lines in each frame (2 starting lines – top edge and 2 ending lines – bottom edge). For example, if the input size is 656x490 pixels, the output is 652x486 pixels. There is no chopping of data if this block is disabled.

12.4.5.1.8.3 Defect Correction

The camera ISP supports single and couplet defect correction. The advantage of those algorithms, compared to the faulty pixel correction implemented inside the CCDC module, is that it does not have to know the positions of the faulty pixels.

The defect-correction algorithms are based on on-the-fly min/max exclusion. Both algorithms are mutually exclusive.

12.4.5.1.8.3.1 Single Defect Correction

Each pixel is compared with the surrounding 8 pixels in the same color plane. If the center pixel is larger than the maximum among them, the output is the second largest value. If the center pixel is the minimum, it is replaced by the second smallest value. If the center pixel is neither the maximum nor minimum, the center pixel is the output.

The single defect correction mode is entered when the following bits are set:

- [PRV_PCR](#) [27] DCOREN = 1
- [PRV_PCR](#) [28] DCOR_METHOD = 0
- [PRV_CDC_THRx](#) [9:0] DETECT = 0
- [PRV_CDC_THRx](#) [25:16] CORRECT = 1023

12.4.5.1.8.3.2 Couplet Defect Correction (CDC)

The defect-correction module also supports couplet defect correction (MinMax2 defect-correction). In MinMax2 defect-correction, the center pixel is compared with the 2nd maximum and the 2nd minimum pixel among the surrounding 8 pixels. If the center pixel is larger than the 2nd maximum signal by more than thrD ([PRV_CDC_THRx](#) [9:0] DETECT x = 0, 1, 2, 3 depending on color), the center pixel is considered as a defect pixel. Then, the center pixel is replaced with the maximum value of surrounding pixels, unless the difference between the maximum pixel and the 2nd maximum value is larger than thrC ([PRV_CDC_THRx](#) [25:16] CORRECT x = 0, 1, 2, 3 depending on color). In this case, the center pixel is replaced with the 2nd maximum pixel.

12.4.5.1.8.4 Noise Filter

The basic concept of the 2D noise filter is *area averaging by excluding far-apart-value neighbors*. This algorithm uses the following two tables:

- Threshold table (10 bits, 32 entries), which is used in the filtering algorithm
- Strength table (5 bits, 32 entries), which stores averaging weight

12.4.5.1.9 White Balance

The white-balance module has a digital gain adjuster and a white-balance adjuster. In the digital gain adjuster (PRV_WB_DGAIN [9:0] DGAIN), RAW data is multiplied by a fixed-value gain, regardless of the color of the pixel to be processed.

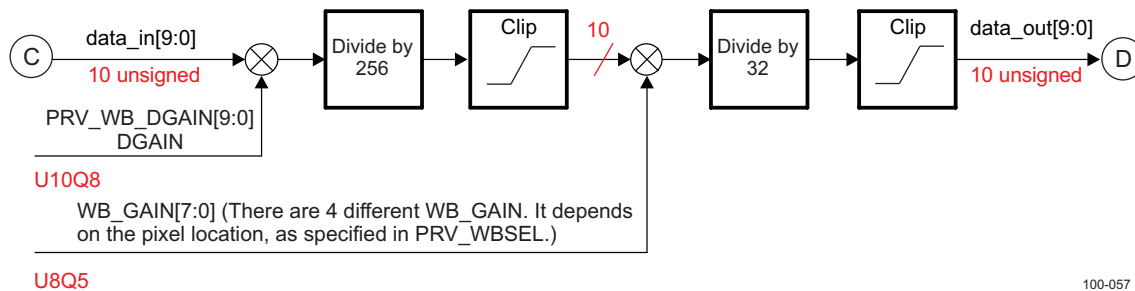

In the white-balance gain adjuster (PRV_WBGAIN), RAW data is multiplied by a selected gain corresponding to the color of the processed pixel.

For non-Foveon sensors (PRV_PCR [14:11] CFAFMT different from 2 or 5), the white-balance gain can be selected from four 8-bit values, depending on the position of the current pixel. First horizontal and vertical positions are computed modulo 4 starting from the first received pixel. This position is used to fetch the white-balance gain index from the PRV_WBSEL register. This index is then used to fetch the corresponding white-balance gain from the PRV_WBGAIN register.

If the input is from a Foveon sensor (PRV_PCR [14:11] CFAFMT equals to 2 or 5), the white-balance gain is selected by using modulo-3 arithmetic. If the Foveon pattern is RGBRGB, modulo-3 arithmetic is used in the horizontal pixel counts. If the Foveon pattern is RRR GGG BBB, modulo-3 arithmetic is used in the vertical line counts.

Figure 12-27 is the block diagram of the white-balance module.

Figure 12-27. White Balance Functional Models

100-057

12.4.5.1.10 CFA Interpolation

The CFA function is responsible for providing full RGB data for each pixel. Depending on sensor type and configuration, interpolation and/or rephasing are required.

The CFA function can be enabled (PRV_PCR [10] CFAEN) and configured to different interpolation modes (PRV_PCR [14:11] CFAFMT).

For example, when CFAFMT=1, the sensor sends 2 samples for each physical location. For odd lines, it sends R, G, and B must be interpolated. For even lines, it sends B, G, and R must be interpolated.

12.4.5.1.10.1 CFA for Bayer Modes

In Bayer modes, the CFA interpolation block is responsible for populating the missing color pixels at a given location, resulting in a 3-color RGB pixel. It does this by interpolating data from neighboring pixels of the same color. See Table 12-20.

Table 12-20. CFA-Supported Bayer Modes

Mode	PRV_PCR [14:11] CFAFMT	Sensor Sent Colors per Location	Interpolated Colors per Location
Generic Bayer	0	1	2
N + 1	1	2	1
N + 2	3	4	0

In the generic mode, CFA interpolation is implemented using programmable filter coefficients that operate on a 5×5 grid:

- Each coefficient is coded in S8Q6 format.
- Each output color , G, and B) has its own set of coefficients.
- There are 4 phases. Each pixel is associated with a phase.
- Different sets of filter coefficients are provided, depending on the tendency (gradient in the data: horizontal, vertical, or neutral).
- So there are 3 color × 4 phase × 3 tendencies × 16 taps = 576 coefficients (each coefficient is 8 bits wide).

Note: Coefficients are based on sensor type. However, users can use a different methods of defining an optimal coefficient set.

12.4.5.1.10.2 CFA Options

If the CFA interpolation block is disabled, the same input pixel is broadcast to all three output pixels.

Note: Image-size reduction: If CFA interpolation is enabled, the preview engine reduces the output of this stage. Two pixels/line in the left, right, top, and bottom edges are truncated in the Bayer/conventional and other modes.

If the CFA format is 2× downsampling in both horizontal and vertical directions, or if the sensor is in Foveon format (serial RGB and RRRR GGGG BBBB patterns), only 2 lines at the top and bottom of the image are truncated. The two left- and right-most pixels are processed.

12.4.5.1.11 Black Adjustment

The CFA interpolation output is three pixels (red, blue, and green values) and this is fed as input to the black-adjustment module, which performs the following calculation for an adjustment of each color level:

$$data_out = data_in + bl_offset$$

12.4.5.1.12 RGB Blending

The RGB2RGB blending module has a general 3×3 square matrix and redefines the RGB data from the CFA interpolation module, which can be used as a function of a color correction. This is programmable (PRV_RGB_MAT1, PRV_RGB_MAT2, PRV_RGB_MAT3, PRV_RGB_MAT4, PRV_RGB_MAT5, PRV_RGB_OFF1, & PRV_RGB_OFF2) so that the color spectrum of the sensor can be adjusted to the human color spectrum. The input is signed 11 bits and the output is unsigned 10 bits. The following calculation is performed in this module:

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \begin{bmatrix} MTX_RR & MTX_GR & MTX_BR \\ MTX_RG & MTX_GG & MTX_BG \\ MTX_RB & MTX_GB & MTX_BB \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} + \begin{bmatrix} MTX_OFFR \\ MTX_OFFG \\ MTX_OFFB \end{bmatrix}$$

camisp-E094

Gains are in S12Q8 format, and offsets are in S10Q0 format.

Note: All blending matrix coefficients are equal to 1 (256 in S12Q8 coding) after reset. The following computation must be performed to bypass the RGB to RGB blending step:

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

camisp-E161

That leads to:

$$\begin{aligned} MTX_{RR} &= MTX_{GG} = MTX_{BB} = 256 \\ others &= 0 \end{aligned}$$

12.4.5.1.13 Gamma Correction

Gamma correction is performed on each of the R, G, and B pixels separately by indexing programmable gamma look-up tables. Each table has 1024 8-bit entries. The input data value is used to index into the table and the table content is the output.

The gamma table can be bypassed ([PRV_PCR](#) [26] GAMMA_BYPASS). In this case, the output of the gamma correction is the 8 MSB of the 10-bit input. The gamma table can be written only while the preview engine is disabled.

12.4.5.1.13.1 RGB-to-YCbCr Conversion

The RGB-to-YCbCr conversion module has a 3×3 square matrix and converts the RGB color space of the image data into the YCbCr color space. In this module, the following calculation is performed using the contents of the [PRV_CSC0](#), [PRV_CSC1](#), [PRV_CSC2](#), and [PRV_CSC_OFFSET](#) registers:

$$\begin{bmatrix} Y \\ Cb \\ Cr \end{bmatrix} = \begin{bmatrix} CSCRY & CSCGY & CSCBY \\ CSCRCB & CSCGCB & CSCBCB \\ CSCRCR & CSCGCR & CSCBCR \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} + \begin{bmatrix} YOFST \\ OFSTCB \\ OFSTCR \end{bmatrix}$$

camisp-E095

Gains are in S10Q8 format, and offsets are in S8Q0 format for chroma and U10Q0 for luma.

Note: Program the following values after reset for correct color conversion:

- [PRV_CSC2](#) [19:10] CSCGCR = 0x39E
- [PRV_CSC2](#) [9:0] CSCRCR = 0x080

12.4.5.1.13.2 Nonlinear Luminance Enhancement

Nonlinear luminance enhancement functions as an edge enhancer (crossed in the horizontal direction). It can be enabled or disabled using the [PRV_PCR](#) [15] YNENHEN parameter. If it is enabled, a look-up table with 127 20-bit entries must be programmed. Each entry contains a 10-bit signed offset value in the MSBs, and a 10-bit signed slope in the LSBs.

[Table 12-21](#) lists the format of each entry.

Table 12-21. Nonlinear Luminance-Enhancement Table Entry Format

MSB	LSB
19	9
10	0
OFFSET	SLOPE

12.4.5.1.13.2.1 Chrominance Suppression

Occasionally, in very bright portions of an image, only one or two of the color channels are saturated, while the remaining channel(s) are not. This can lead to a false-color effect. One common example is the appearance of pink where white should be. Chrominance suppression can be used to correct this issue.

Chrominance suppression can be enabled or disabled using the [PRV_PCR](#) [16] SUPEN parameter. False-color pixels can also be introduced on edges crossed in the horizontal direction by the CFA interpolation function. The luminance value used in the calculation can be configured as the luminance value or the high-pass-filtered version of the luminance value to find the edge information in the horizontal direction ([PRV_CSUP](#) [16] HPYF). The chrominance suppression threshold and gain can be set in the [PRV_CSUP](#) [15:8] CSUPTH (U8Q0) and [PRV_CSUP](#) [7:0] CSUPG (U8Q8) fields, respectively.

12.4.5.1.13.2.2 Contrast and Brightness

The luminance component can be adjusted for contrast (scaling/multiplication) and brightness (offset/addition). Contrast is set in the [PRV_CNT_BRT](#) [15:8] CNT field (U8Q4 precision), and brightness is set in the [PRV_CNT_BRT](#) [7:0] BRT field (U8Q0 precision).

12.4.5.1.13.2.3 Downsampling and Output Clipping

The 4:2:2 conversion module converts image data to YCbCr-4:2:2 format by averaging every other Cb and Cr component in the horizontal direction. Before outputting the data, the preview engine performs clipping on the YCC components separately. The minimum and maximum threshold values for the Y and C values are specified using the [PRV_SETUP_YC](#) register. If no clipping is required, the register must be set to its reset values of 0xFF for the maximum Y and C values, and 0 for the minimum Y and C values.

12.4.5.1.14 Write-Buffer Interface

The output of the preview engine may be passed directly to the resizer ([PRV_PCR](#) [19] RSZPORT) and/or written to memory ([PRV_PCR](#) [20] SDRPORT).

If the output is written to memory, the write address ([PRV_WSDR_ADDR](#)) and line offset ([PRV_WADD_OFFSET](#)) must be on 32-byte boundaries. The output format of the YCC data is programmable by setting the [PRV_PCR](#) [18:17] YCPOS parameter.

The final width and height of the output vary depending on which processing functions are enabled. [Table 12-22](#) indicates how many edge pixels/lines are truncated by enabling certain modules in the preview engine. These values must be subtracted from the input height and width after the averager to determine the size of preview-engine output.

Table 12-22. Image Cropping by Preview Functions

Image Cropping by Preview Functions		
Function	Pix/Line	Lines
Horizontal median filter	4	0
Noise filter	4	4
CFA (Bayer, Fuji, or Sony)	4	4
CFA (Foveon or 2x down sampling)	0	2
Color suppression OR luminance enhancement	2	0
Maximum total	14	8

Note: Different CFA modes are mutually exclusive

12.4.5.2 Resizer

12.4.5.2.1 Features

The resizer module enables image upsampling and downsampling, see [Table 12-23](#). The following features are supported:

- Flexible input sources:
 - Preview module: enables on-the-fly processing.
 - Memory: enables differed processing.
- Flexible input format:
 - YUV422 packed data (16 bits)
 - Color-separate data (8 bits). The data must be contiguous in memory. The input source for the data must be the memory: not available for on-the-fly processing.
 - Same output format as input
- Upsampling: Up to 4×. Enables digital zoom:
 - General polyphase filter:
 - Ratio of 1× to 4×: 4 taps (horizontal and vertical) and 8 phases
- Downsampling: Down to 0.25×:
 - General polyphase filter:
 - Ratio of 0.25× to 0.5×: 7 taps (horizontal and vertical) and 4 phases
 - Ratio of 0.5× to 1×: 4 taps (horizontal and vertical) and 8 phases
- Constraints:
 - The following input width (IW) and output width (OW) constraints must be obeyed due to limited on-chip memory resources.

Table 12-23. Resizer Use Constraints

Resizer Use Constraints			Horizontal Resizer Ratio	
			0.25× to 0.5×	0.5× to 4×
			7 taps	4 taps
Vertical resizer ratio	0.25× to 0.5×	7 taps	OW≤1650	OW≤1650
	0.5× to 4×	4 taps	OW≤3312	OW≤3312

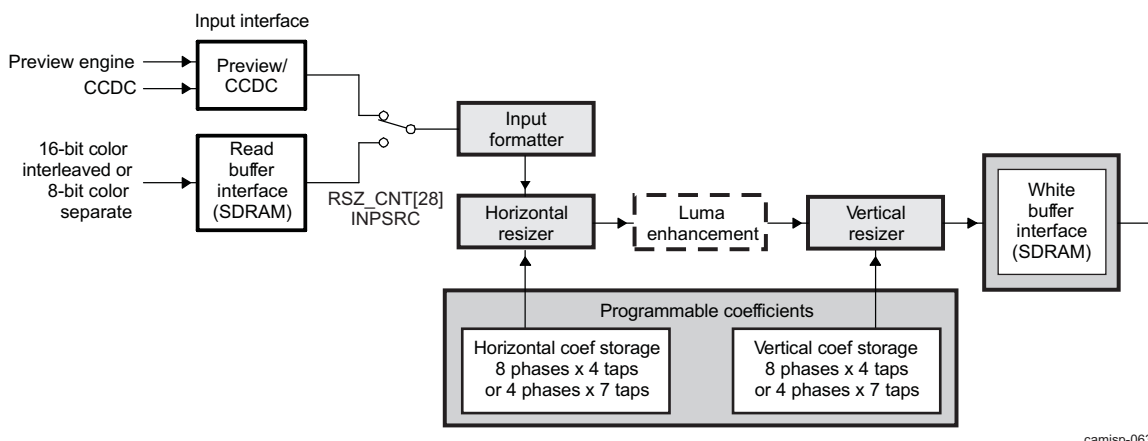

- The horizontal resizer output rate must not exceed half the functional clock; that is, at 166-MHz functional clock, the horizontal resizer output rate must not exceed 83M pixels/s. This limitation applies only for the on-the-fly processing input source.
- Flexible resizing ratios: Independent resizing factors for the horizontal and vertical directions. The applicable ratio is 256/N, with N ranging from 64 to 1024.
- Programmable luminance enhancer
- Continuous and one-shot operation

12.4.5.2.2 Block Diagram

The resizer module performs either upsampling (digital zoom) or downsampling on image/video data within a range of 0.25× to 4× resizing. The input source can be sent to either the preview engine/CCDC or memory, and the output is sent to memory.

The resizer module performs horizontal resizing, then vertical resizing, independently. Between them there is an optional edge-enhancement feature. This process is shown in [Figure 12-28](#).

Figure 12-28. Resizer Process

camisp-063

12.4.5.2.3 Input and Output Interfaces

The input source can be sent to either the preview engine/CCDC or memory ([RSZ_CNT](#) [28] INPSRC). The input width ([RSZ_IN_SIZE](#) [12:0] HORZ) must be at least 32 pixels.

12.4.5.2.3.1 Preview Engine/CCDC Input Mode

In the preview engine/CCDC input mode, internal hardware synchronization signals define input frames. The horizontal starting byte ([RSZ_IN_START](#) [12:0] HORZ_ST) and vertical starting line ([RSZ_IN_START](#) [28:16] VERT_ST) define a starting pixel with respect to the upper-left corner of an input image (signaled through horizontal and vertical synchronization signals). The input width and height in the [RSZ_IN_SIZE](#) register specify the exact input range (relative to the starting pixel) necessary to generate an output frame of specified width/height.

Note: Care must be taken to ensure that the input sizes specified by the [RSZ_IN_START](#) and [RSZ_IN_SIZE](#) registers are less than or equal to the output from the preview engine or CCDC; otherwise, incorrect hardware operation may occur.

[RSZ_SDR_INADD](#) and [RSZ_SDR_INOFF](#) must be programmed to be 0x0 in this mode.

Also, the output ports of the CCDC ([CCDC_SYN_MODE](#) [19] SDR2RSZ) and preview engine ([PRV_PCR](#) [19] RSZPORT) to the resizer must be configured so that only one of them is enabled. If both are enabled, the CCDC gains control of this interface.

If input is from the CCDC, the output of the CCDC must be in YUV422 format (the resizer does not support resizing RAW data from the CCDC).

12.4.5.2.3.2 Memory-Input Mode

In memory-input mode, the memory address in [RSZ_SDR_INADD](#) points to the 32-byte-aligned memory address where the starting pixel resides.

The horizontal starting pixel ([RSZ_IN_START](#) [12:0] HORZ_ST) defines a starting pixel within that 32-byte alignment; HORZ_ST is constrained to 0...15 for the 422 format, and 0...31 for the color-separated format.

The vertical starting pixel ([RSZ_IN_START](#) [28:16] VERT_ST) must be zero in memory-input mode. The [RSZ_SDR_INOFF](#) register specifies the address offset between rows of input data. The input width and height in the [RSZ_IN_SIZE](#) register specify the exact input range (relative to the starting pixel) necessary to generate an output frame of specified width/height.

Figure 12-29 shows the resizer in memory-input mode.

Figure 12-29. Resizer in Memory-Input Mode

camisp-115

12.4.5.2.3.3 Output Interface

In both input modes, the **RSZ_OUT_SIZE** register specifies output width/height, the **RSZ_SDR_OUTADD** register specifies output starting pixel (upper-left corner) memory address, and the **RSZ_SDR_OUTOFF** register specifies memory address offset between the beginning of output rows. The resizer output always goes to memory.

Note: **RSZ_SDR_INADD**, **RSZ_SDR_OUTADD**, **RSZ_SDR_INOFF**, and **RSZ_SDR_OUTOFF** must be 32-byte-aligned; the lower 5 bits of the byte address are assumed zero.

Output-width constraints: The output width (**RSZ_OUT_SIZE** [10:0] HORZ) must be at least 16 pixels, and be even (so that the same number of Cb and Cr components is outputted). Due to the vertical memory size constraint, the output width (**RSZ_OUT_SIZE** [10:0] HORZ) cannot be greater than:

- 3312 pixels if the vertical resizing ratio is between \times and $4\times$ ((**RSZ_CNT** [19:10] VRSZ + 1) = 512)
- 1650 pixels wide if the vertical resizing ratio is between \times and $1/4\times$ ((**RSZ_CNT** [19:10] VRSZ + 1) > 512)

12.4.5.2.4 Horizontal and Vertical Resizing

In the rest of this section:

- HRSZ is used for **RSZ_CNT** [9:0] HRSZ + 1
- VRSZ is used for **RSZ_CNT** [19:10] VRSZ + 1

The resizer module can upsample or downsample image data with independent resizing factors in the horizontal and vertical directions. The HRSZ and VRSZ parameters can range from 64 to 1024 to give a resampling range from $4\times$ to $0.25\times$ (256/HRSZ or 256/VRSZ).

The resizer module uses the same resampling algorithm for the horizontal and vertical directions.

The resizing/resampling algorithm uses a programmable polyphase sample rate converter (resampler). The polyphase filter coefficients are programmable so that any user-specified filter can be implemented.

Figure 12-30 shows a general sample-rate converter where the resampling rate is equal to L/M.

Figure 12-30. Typical Sample-Rate Converter

camisp-E123

L phases are used in a typical polyphase implementation. The resizer module, however, fixes the number of phases to 8 for a resizing range of $\times \sim 4\times$ ($RSZ = 64 \sim 512$), or 4 for a resizing range of $1/4\times \sim 1/2\times$ ($RSZ = 513 \sim 1024$). In this way, the upsampling value (L) is fixed to either 8 or 4, and the downsampling value (M) is based on RSZ. To achieve a resizing ratio of $256/RSZ$, the downsampling value (M) is equal to $(P \times RSZ)/256$, where P is the number of phases. Figure 12-31 shows the resizer functionality.

Figure 12-31. Resizer Functionality

camisp-E124

Figure 12-32 shows a model of the resolution of the noninteger downsampling ratio. The interpolated output from the filter is upsampled and replicated 256/P times before it is downsampled by the RSZ factor.

Figure 12-32. Resizer Approximation Scheme

camisp-E125

This implementation means that a resizing ratio with $256/RSZ$ times the input size can be obtained. However, each output pixel is rounded to the nearest interpolated output of $1/P$ input-pixel precision. The polyphase filter coefficients are programmable so that any user-specified filter can be implemented. It is recommended that coefficient sets be chosen to implement a sample rate converter where a low-pass filter is used, with a cutoff frequency as shown in Figure 12-33.

Figure 12-33. Cutoff Frequency for Low-Pass Filter

$$\omega_c = \min\left(\frac{\pi}{P}, \frac{\pi}{\frac{P \times RSZ}{256}}\right)$$

camisp-E126

If polyphase resampling is used, all upsampling factors can share the same set of coefficients. However, a different coefficient set is required when changing between 8-phase and 4-phase modes, and with different downsampling factors.

32 programmable coefficients are available for the horizontal direction (registers [RSZ_HFILT10](#) to

[RSZ_HFILT3130](#)) and another 32 programmable coefficients are available for the vertical direction (registers [RSZ_VFILT10](#) to [RSZ_VFILT3130](#)). The 32 programmable coefficients are arranged as either 4 taps and 8 phases for the resizing range of $\times \sim 4\times$ ($RSZ = 64 \sim 512$), or 7 taps and 4 phases for a resizing range of $1/4\times \sim 1/2\times$ ($RSZ = 513 \sim 1024$)(RSZ is either $HRSZ$ or $VRSZ$). [Table 12-24](#) shows the arrangement of the 32 filter coefficients. Each tap is arranged in S10Q8 format.

Table 12-24. Arrangement of the Filter Coefficients

Filter Coefficient	0.5x to 4x		0.24x to ~0.5x	
	Phase	Tap	Phase	Tap
0	0	0	0	0
1		1		1
2		2		2
3		3		3
4	1	0		4
5		1		5
6		2		6
7		3		Not used
8	2	0	1	0
9		1		1
10		2		2
11		3		3
12	3	0		4
13		1		5
14		2		6
15		3		Not used
16	4	0		
17		1		
18		2		
19		3		
20	5	0		
21		1		
22		2		
23		3		Not used
24	6	0	3	0
25		1		1
26		2		2
27		3		3
28	7	0		4
29		1		5
30		2		6
31		3		Not used

The indexing scheme of coefficients is oriented for dot-product (or inner product), rather than for impulse response. In other words, the first data point contributing to a particular output is multiplied by the coefficient associated with tap 0, and the last data point is multiplied by the coefficient associated with tap 3 or tap 6 (depending on whether it is 4-tap or 7-tap mode). The normal raster-scan order is used where the upper-left corner gets the (0, 0) coordinate. Pixel 0 is the left-most column of pixels for horizontal resizing, and the top-most row of pixels for vertical resizing. [Figure 12-34](#) shows an example of the alignment of input pixels to tap coefficients using a simple 1:1 resize case (4-tap mode). In this example, only one phase output is necessary.

[Figure 12-34](#) shows the alignment of input pixels to tap coefficients.

Figure 12-34. Alignment of Input Pixels to Tap Coefficients

camisp-116

Figure 12-34 also shows how the first output is computed when all taps are aligned with input pixels. To compute the last several pixels in each line/column, the filter requires more input pixels than the following equation calculates:

$$\text{input size} = \text{output size} \times \text{RSZ} / 256$$

In the former example, where the input size is X and the output size is Y, three extra input pixels are required to generate the correct number of output pixels:

$$X = Y \times 256 / 256 + 3 \text{ (to account for the extra pixels required for filtering)}$$

The input size calculation depends on the starting phase and rounding issues in the algorithm.

Table 12-25 lists the input size calculations derived from the algorithm description in Section 12.4.5.2.5.

The input width and height parameters must be programmed strictly according to these equations; otherwise, incorrect hardware operation may occur.

Table 12-25. Input Size Calculations

	8-Phase, 4-Tap Mode	4-Phase, 7-Tap Mode
RSZ_IN_SIZE[12:0] HORZ	$(32 \times \text{sph} + (\text{ow} - 1) \times \text{hrsz} + 16) \gg 8 + 7$	$(64 \times \text{sph} + (\text{ow} - 1) \times \text{hrsz} + 32) \gg 8 + 7$
RSZ_IN_SIZE[28:16] VERT	$(32 \times \text{spv} + (\text{oh} - 1) \times \text{vrsz} + 16) \gg 8 + 4$	$(64 \times \text{spv} + (\text{oh} - 1) \times \text{vrsz} + 32) \gg 8 + 7$

Where:

sph = Start phase horizontal (**RSZ_CNT** [22:20] HSTPH)

spv = Start phase vertical (**RSZ_CNT** [25:23] VSTPH)

ow = Output width (**RSZ_OUT_SIZE** [10:0] HORZ + extra)

oh = Output height (**RSZ_OUT_SIZE** [26:16] VERT)

hrsz = Horizontal resize value (**RSZ_CNT** [9:0] HRSZ + 1)

vrsz = Vertical resize value (**RSZ_CNT** [19:10] VRSZ + 1)

extra = 0 when **RSZ_YENH** [17:16] ALGO = 0 (edge enhancement disabled)

extra = 4 when **RSZ_YENH** [17:16] ALGO != 0 (edge enhancement enabled)

The horizontal and vertical starting phases can be programmed in the [RSZ_CNT](#) [22:20] HSTPH and [RSZ_CNT](#) [25:23] VSTPH fields, respectively. The chrominance data can be resized using bilinear interpolation or the same algorithm as the luminance data ([RSZ_CNT](#) [29] CBILIN). For more information about how these fields are used in the algorithm, see [Section 12.4.5.2.5, Resampling Algorithm](#).

12.4.5.2.5 Resampling Algorithm

The resizer module uses the same resampling algorithm for the horizontal and vertical directions. For the rest of this section, the horizontal direction is used in describing the resampling algorithm. The algorithm is described first for the 4-tap/8-phase mode, then for the 7-tap/4-phase mode.

[Section 12.4.5.2.5.1](#) and [Section 12.4.5.2.5.2](#) explain the generic algorithm without detailing the differences between color components. [Section 12.4.5.2.5.3](#) describes how interleaved chroma are processed when input is YUV422.

12.4.5.2.5.1 4-Tap/8-Phase Mode

In the 4-tap/8-phase mode, the coefficients for each of the 8 phases may be set to interpolate 8 intermediate pixels between input pixels. For each output pixel calculation, a fine-input pointer with 56 input-pixel precision is incremented by the [RSZ_CNT](#) [9:0] HRSZ +1 value. A coarse-input pointer with 1/8 input-pixel precision (corresponds to one of the 8 phases) is calculated by rounding the fine-input pointer to the nearest 1/8 pixel. The output pixel is calculated by the dot product of the coefficients of the phase filter (selected by the coarse-input pointer) and the appropriate four input pixels. [Figure 12-35](#) shows a pseudo-code description of the resizer algorithm in the 4-tap/8-phase mode.

Figure 12-35. Pseudo-Code Description of the Resizer Algorithm in the 4-Tap/8-Phase Mode

camisp-064

- The starting input pixel location (in whole pixels) (see [Section 12.4.5.2.3, Input and Output Interfaces](#)) and the starting phase (in 1/8 pixel) ([RSZ_CNT](#) [22:20] HSTPH) are programmed through the resizer registers.
- A fine-input pointer is maintained in 1/256-pixel precision.
- A coarse-input pointer and a pixel-input pointer are computed for each output, based on the fine-input pointer.
- The coarse-input pointer is in 1/8 pixel precision. The pixel-input pointer is in whole-pixel precision.
- Initially, fine-input pointer = 256* starting input pixel + 32* starting phase - 256. The fine-input pointer defines the starting 1/8 pixel location covered by the filter waveform.
- For each output pixel:

Coarse-input pointer = /* Rounded to the nearest phase */
(fine-input pointer + 16) >> 5

Pixel-input pointer = /* Rounded up to a whole pixel, when already on an integer pixel, go to next one to simplify coefficient organization */
(coarse-input pointer >> 3) + 1

Coefficient phase = /* 3 LSBs = phase */
(coarse-input pointer & 7)

Output = dot product of the 4 coefficients and the 4 inputs starting with pixel-input pointer
Clip output to 8-bit unsigned for luma, 8-bit signed for chroma

```

fine-input pointer = fine-input pointer
+ (RSZ_CNT [9:0] HRSZ + 1)

/* distance between outputs = 1/resize_factor = (RSZ_CNT [9:0] HRSZ + 1) / 256 = (RSZ_CNT
[9:0] HRSZ + 1) in = 56 precision */

```

- Same algorithm in the horizontal and vertical directions, except with separate initial pixel/phase values and separate RSZ values.

12.4.5.2.5.2 7-Tap/4-Phase Mode

In the 7-tap/4-phase mode, the coefficients for each of the 4 phases may be set to interpolate 4 intermediate pixels between input pixels. For each output pixel calculation, a fine-input pointer with 1/56 input-pixel precision is incremented by the `RSZ_CNT [9:0] HRSZ + 1` value. A coarse-input pointer with = input-pixel precision (corresponds to one of the 4 phases) is calculated by rounding the fine-input pointer to the nearest = pixel. The output pixel is calculated by the dot product of the coefficients of the phase filter (selected by the coarse-input pointer) and the appropriate 7 input pixels. Figure 12-36 shows a pseudo-code description of the resizer algorithm in the 7-tap/4-phase mode.

Figure 12-36. Pseudo-Code Description of the Resizer Algorithm in the 7-Tap/4-Phase Mode

camisp-065

- The starting input-pixel location (in whole pixels) (see Section 12.4.5.2.3, *Input and Output Interfaces*) and the starting phase (in = pixel) (`RSZ_CNT [22:20] HSTPH`) are programmed through the resizer registers.
- A fine-input pointer is maintained in 56 pixel precision.
- A coarse-input pointer and a pixel-input pointer are computed for each output based on the fine-input pointer.
- The coarse-input pointer is in = pixel precision. The pixel-input pointer is in whole-pixel precision.
- Initially, fine-input pointer = $256 * \text{starting input pixel} + 64 * \text{starting phase} - 256$. The fine-input pointer defines the starting = pixel location covered by the filter waveform.
- For each output pixel:

```

Coarse-input pointer =                /* Round to the nearest phase */
(fine-input pointer + 32) >> 6

Pixel-input pointer =                /* Round up to a whole pixel; when already on an
(coarse-input pointer >> 2) + 1      integer pixel, go to next one to simplify coefficient
                                   organization */

Coefficient phase =                  /* 2 LSBs = phase */
(coarse-input pointer & 3)

Output = Dot product of the 7 coefficients and the 7 inputs starting with the pixel-input
pointer

Clip output to 8-bit unsigned for luma, 8-bit signed for chroma

/* It is acceptable to require the 8th coefficients to be filled with zeros by firmware so that 8
coefficients and 8 inputs, the last input being don't care value, are multiply-added */

Fine-input pointer = Fine input pointer + (RSZ_CNT [9:0] HRSZ + 1)

```

```
/* Distance between outputs = 1/resize_factor = (RSZ_CNT [9:0] HRSZ + 1)/256 =
(RSZ_CNT [9:0] HRSZ + 1) in 56 precision */
```

- Same algorithm in both the horizontal and vertical directions, but with separate initial pixel/phase values and separate RSZ values.

Note: The pixel-input pointer, pip, in the algorithm description, points to pixels, not bytes or shorts in the memory. The fine-input pointer, fip, points to a =56 resolution sub-pixel position. The coarse-input point, cip, points to a 1/8 or 1/4 resolution sub-pixel location, depending on the number of phases.

12.4.5.2.5.3 Horizontal Resizing With Interleaved Chroma

Chroma inputs, Cb and Cr, are 8-bit unsigned values that represent 128-biased 8-bit signed values (the signed chroma are called U and V instead of Cb and Cr). During the resizing computation, the chroma values have the 128 bias subtracted to convert to the 8-bit signed format. After vertical resizing, the 128 bias is added back to convert back to 8-bit unsigned format.

Chroma components, which are 2:1 horizontally downsampled with respect to luma, have two methods of horizontal resizing processing: filtering with luma, and bilinear interpolation.

The horizontal resizing with interleaved chroma option can be selected in the [RSZ_CNT](#) [29] CBILIN field independently of the [RSZ_CNT](#) [22:20] HSTPH parameters. However, filtering with luma is only intended for downsampling, and bilinear interpolation is only intended for upsampling.

For horizontal resizing of Y/Cb/Cr in a combined filtering flow, the algorithm is modified as shown in the following algorithm descriptions:

Filter Chroma With Luma (4-Tap/8-Phase Mode):

```
For (l=0; l<output_width; l++) { /* output width depends of input width and resizing factors*/
    Coarse-input pointer = (fine-input pointer + 16) >> 5    /* Round to nearest phase */
    Pixel-input pointer = (coarse-input pointer >> 3) + 1    /* Round up to a whole pixel */
    Coefficient phase = pixel-input pointer & 7               /* 3 LSB = phase */

    if (l & 1 == 0) { /* even output pixel, generate YCbCr */
        Yout = dot product of the 4 coefficients and the 4 Y inputs starting with pixel-input pointer
        Cbout = dot product of the 4 coefficients and the 4 upsampled Cb inputs starting with
        pixel-input pointer
        Crout = dot product of the 4 coefficients and the 4 upsampled Cr inputs starting with
        pixel-input pointer
        Clip outputs to 8-bit unsigned for luma, 8-bit
        signed for chroma
    }
    Else { /* odd output pixel, generate Y only */
        Yout = dot product of the 4 coefficients and the 4 Y inputs starting with pixel-input pointer
        Clip output to 8-bit unsigned
    }
    Fine-input pointer = fine-input pointer + (RSZ_CNT [9:0] HRSZ + 1)
}
}
```

Filter Chroma With Luma (7-Tap/4-Phase Mode):

```

For (l=0; i<output_width; l++) { /* output width depends of input width and resizing factors*/
    Coarse-input pointer = (fine-input pointer + 32) >> 5    /* Round to nearest phase */
    Pixel-input pointer = (coarse-input pointer >> 2) + 1    /* Round up to a whole pixel */
    Coefficient phase = pixel-input pointer & 3              /* 2 LSB = phase */

    if (l & 1 == 0) { /* Even output pixel, generate YCbCr */
        Yout = dot product of the 7 coefficients and the 7 Y inputs starting with pixel-input pointer
        Cbout = dot product of the 7 coefficients and the 7 upsampled Cb inputs starting with
            pixel-input pointer
        Crout = dot product of the 7 coefficients and the 7 upsampled Cr inputs starting with
            pixel-input pointer
        Clip outputs to 8-bit unsigned for luma, 8-bit
            signed for chroma
    }
    Else { /* Odd output pixel, generate Y only */
        Yout = dot product of the 7 coefficients and the 7 Y inputs starting with pixel-input pointer
        Clip output to 8-bit unsigned
    }

    Fine-input pointer = fine-input pointer + (RSZ_CNT [9:0] HRSZ + 1)
}
}

```

Note: The chroma input values are internally replicated to realize 1:2 upsampling to line up with luma input values. Only required chroma outputs are computed; they correspond to even luma outputs.

Bilinear Interpolation (4-Tap or 7-Tap):

For the bilinear interpolation flow of chroma horizontal resizing, the algorithm is adapted as follows. For the bilinear interpolation option, it is not necessary to replicate chroma samples.

```

For (l=0; i<output_width; l++) {
    if (l & 1 == 0) { /* even output pixel, generate YCbCr */
        Coarse-input pointer = ... /*Calculation issued from 4 taps or 7
            taps*/
        Pixel-input pointer = ... /*Calculation issued from 4 taps or 7 taps*/
        Yout = dot product of ... /*Calculation issued from 4 taps or 7
            taps*/
        C_fine_input_pointer = fine_input_pointer + 128*ntaps          /* Points to center of filter
                                                                            kernel */
        Cidx = C_fine_input_pointer >> 9                             /* Truncate to even pixel
                                                                            grid to find left value */
        Cbin[0] = Cb[Cidx]
    }
}

```

```

    Cbin[1] = Cb[Cidx + 1]
    Crin[0] = Cr[Cidx]
    Crin[1] = Cr[Cidx + 1]
    frac = C_fine_input_pointer & 511 /* 9-bit fraction */
    Cbout = ((512 - frac) * Cbin[0] + frac * Cbin[1] + 256) >> 9
    Crout = ((512 - frac) * Crin[0] + frac * Crin[1] + 256) >> 9
    Clip outputs to 8-bit unsigned for luma, 8-bit signed for chroma
    Fine-input pointer = fine-input pointer + (RSZ_CNT [9:0] HRSZ + 1)
}

Else { /* odd output pixel, generate Y only */
    ...
}

}

```

In the former algorithm, fixed-point arithmetic is used. The variable *frac* is an unsigned integer representing the fraction *f*. Thus, 1- *f* becomes 512 - *frac*. After the sum of products, 256, representing 0.5 real-numbers, is added to the sum, and then the sum is right-shifted by 9 bits to get back to the integer chroma representation.

In both algorithm options, the chroma outputs computed are interleaved with luma values to generate the YCbYCr output format (or the alternate format specified in RSZ_CNT [26] YCPOS).

In the vertical resizing stage, the two chroma planes are processed interleaved as one separate image. Because there is no resolution issue vertically, and no horizontal dependency in vertical resizing, the vertical scheme is consistent with conventional processing, and is not analyzed here.

12.4.5.2.5.4 Algorithm Functionality

Table 12-26 is an example of 1:2.56 (hrsz = 100) horizontal resizing that illustrates the address calculation and chroma processing in 4:2:2 format (4-tap 8-phase mode). The starting pixel and phase are assumed to be zero.

Table 12-26. Processing Example for 1:2.56 Horizontal Resize

Output	Y0	Cb0	Cr0	Y1	Y2	Cb2	Cr2	Y3	Y4	Cb4	Cr4	Y5
fip (+= hrsz)		-256		-156		-56		44		144		244
cip (= (fip+16)>>5)		-8		-5		-2		1		5		8
pip (= (cip>>3) + 1)		0		0		0		1		1		2
coef ph (= cip & 7)		0		3		6		1		5		0
Inputs needed (chroma filtered like luma)	Y0	Cb0	Cr0	Y0	Y0	Cb0	Cr0	Y1	Y1	Cb0	Cr0	Y2
	Y1	Cb2	Cr0	Y1	Y1	Cb0	Cr0	Y2	Y2	Cb2	Cr2	Y3
	Y2	Cb2	Cr2	Y2	Y2	Cb2	Cr2	Y3	Y3	Cb2	Cr2	Y4
	Y3	Cb2	Cr2	Y3	Y3	Cb2	Cr2	Y4	Y4	Cb4	Cr4	Y5
Cfip (= fip+512)		256				488				720		
Cidx (= Cfip >> 9)		0				0				1		
Inputs needed for chroma bilinear interpolation		Cb0	Cr0			Cb0	Cr0			Cb2	Cr2	
		Cb2	Cr2			Cb2	Cr2			Cb4	Cr4	

Note the distinction between using {Cb0, Cb0, Cb2, Cb2} and {Cb0, Cb2, Cb2, Cb4} as input to the filter. The 4 filter taps are applied in order, so with the different chroma component repetition, the result is different (even when the coefficient phase is the same).

The Cidx of the chroma bilinear interpolation flow points to the chroma sample in linear array order, so Cidx = 1 means we Cb2 and Cb4 are being grabbed.

12.4.5.2.6 Luma Edge Enhancement

Edge enhancement can be applied to the horizontally resized luminance component before the output of the horizontal stage is sent to the line memories and the vertical stage. The [RSZ_YENH](#) [17:16] ALGO parameter can be set to disable edge enhancement, or to select a 3-tap or a 5-tap horizontal high-pass filter (HPF) for luminance enhancement. The edge enhancement algorithm is as follows:

If edge enhancement is selected, the two left-most and two right-most pixels in each line are not outputted to the line memories and the vertical stage. The [RSZ_OUT_SIZE](#) [10:0] HORZ register is the final output width, up to 1280 pixels when vertical 4-tap mode is used, and up to 640 pixels when vertical 7-tap mode is used. When edge enhancement is enabled, the horizontal resizer output width used to calculate the required input width must be [RSZ_OUT_SIZE](#) [10:0] HORZ + 4.

[RSZ_YENH](#) [7:0] CORE is in U8Q0. [RSZ_YENH](#) [11:8] SLOP is in U4Q4. [RSZ_YENH](#) [15:12] GAIN is in U4Q4.

12.4.6 Statistics Collection Modules (SCMs)

The statistics-collection modules are the H3A and histogram modules that provide statistics on the incoming images to help designers of camera systems.

12.4.6.1 Statistics Collection: H3A

12.4.6.1.1 Features

The H3A module supports control loops for autofocus, auto white balance, and auto exposure by collecting metrics about the imaging/video data. The metrics are used to adjust parameters for processing the imaging/video data. There are two main blocks in the H3A module:

- **Autofocus engine (AF):**
The AF submodule extracts and filters the red, green, and blue data from input image data and provides the accumulation or peaks of the data in a specified region. The specified region is a two-dimensional block of data referred to as a paxel. The AF engine supports the following features:
 - Peak mode in a paxel (a Paxel is defined as a two dimensional block of pixels):
Accumulation of the maximum focus value of each line in a paxel.
 - Accumulation mode
 - Accumulation/Sum Mode (instead of Peak mode). Accumulation of focus value in a paxel.
 - Up to 36 paxels/windows in the horizontal direction and up to 128 paxels/windows in the vertical direction
 - Programmable width and height for the paxel/window
 - Programmable red, green, and blue position within a 2x2 matrix
 - Separate horizontal start for paxel and filtering
 - Programmable vertical line increments within a paxel
 - Parallel IIR filters configured in a dual-biquad configuration with individual coefficients (2 filters with 11 coefficients each)
- **Auto exposure and auto white balance engine (AE/AWB)**
The AE/AWB engine accumulates values and checks for saturated values in a subsampling of the video data. In the case of the AE/AWB, the two-dimensional block of data is referred to as a window.

Thus, other than having different names, paxels and windows are essentially the same. However, the numbers, dimensions, and starting positions of AF paxels and AE/AWB windows are programmable separately. AE/AWB supports the following features:

- Accumulation of clipped pixels along with all nonsaturated pixels
- Up to 36 horizontal windows/paxel and up to 128 vertical windows/paxel
- Separate vertical start coordination and height for a black row of paxels different from the remaining color paxels
- Programmable horizontal and vertical sampling points in a window

12.4.6.1.2 Autofocus Engine

The autofocus engine works by extracting each red, green, and blue pixel from the video stream and subtracting a fixed offset from the pixel value (128 when A-Law is enabled or 512 when A-Law is disabled). The offset value is then passed through two IIR filters, and the absolute values of the filter outputs are the focus values (FV). For each paxel, the pixel values and the two focus value outputs are accumulated for each color and sent to memory. The following sections describe this process in more detail.

Only RAW10 data is supported by the autofocus function. In some cases, RAW8 or RAW12 data can be converted to RAW10 using the data-lane shifter.

12.4.6.1.3 AE/AWB Engine

The AE/AWB engine starts by dividing the frames into windows and further subsampling each window into 2x2 blocks. Then, for each subsampled 2x2 block, each pixel is accumulated. Also, each pixel is compared to a limit set in a register. If any pixels in a 2x2 block are greater than or equal to the limit, the block is not counted in the unsaturated block counter. Pixels greater than the limit are replaced by the limit, and the value of the pixel is accumulated.

12.4.6.2 Statistics Collection: Histogram

12.4.6.2.1 Features

The histogram accepts RAW image/video data from either the video-port interface of the CCDC or from memory, performs a color-separate gain on each pixel (white/channel balance), and bins the pixels according to the amplitude, color, and region specified through the CCDC register settings. It can support either 3 or 4 colors (Foveon or Bayer), and up to 4 regions, simultaneously. [Figure 12-37](#) shows the processing of the histogram module.

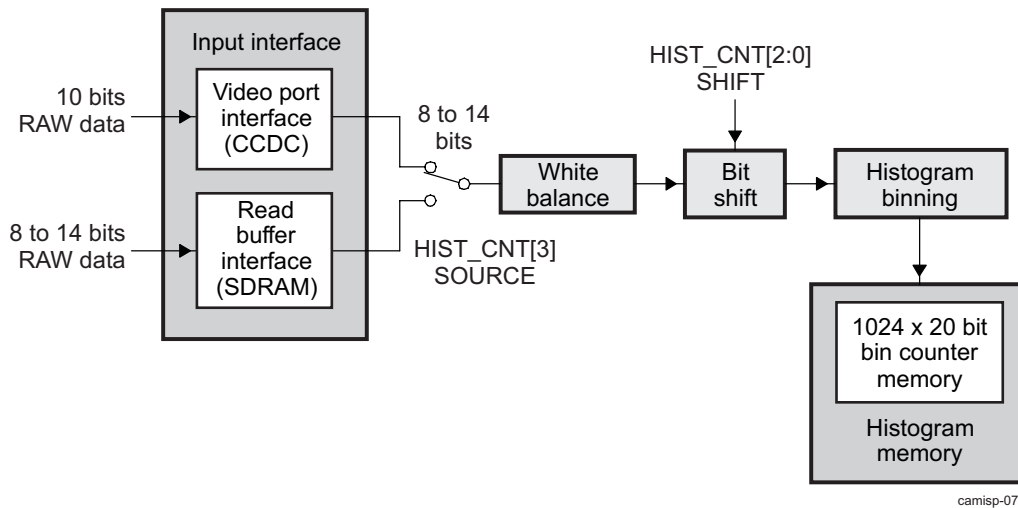

The histogram module is typically used with 3A metrics by the host processor to adjust various parameters for processing image data. The following features are supported:

- Flexible input: Input data can come from the RAW image sensor (through the CCDC module) or from memory.
- Color-separate gain: A digital gain per color component can be applied before histogram computation.
- Histogram computation: The module performs pixel binning of the incoming RAW image data. Each bin collects the number of pixels with values in a range. If no saturation occurs, the sum of the values in every bin is equal to the total number of pixels in the input image. The histogram computation can occur over one frame or be accumulated over multiple frames. The computation occurs on rectangular regions. A histogram is computed for each color component in the image:
 - The RAW image data dynamic can be up to 10 bits (pixel values in the range 0 to 1023).
 - Range: Each bin covers a pixel range. Each bin can cover a maximum of 128 pixel values.
 - Programmable regions: There can be up to 4 regions. The region positions and horizontal and vertical sizes are programmable. When regions overlap, pixels from the overlapped area are accumulated into the highest-priority region only; region0 has the highest priority and region3 the lowest priority.
 - Programmable number of bins: There can be 32, 64, 128, or 256 bins per color and per region. The number of bins depends on the number of regions, because histogram memory size is fixed.

- Color components: A histogram is computed for each color component in the RAW image. There are usually 3 color components in Foveon image sensors and 4 color components in Bayer image sensors.
- Saturation: If the pixel count exceeds $2^{20}-1$, the pixel count is saturated.
- Memory clear: The histogram memory is cleared automatically when it is read.
- Output: The histogram result is stored in a local RAM read by a system initiator, typically the system DMA, to be written to memory.

12.4.6.2.2 Block Diagram

Figure 12-37. Histogram Process

camisp-073

12.4.6.2.3 Input Interface

The histogram receives RAW image/video data from the video port interface through the CCDC (which is interfaced to an external sensor) or from the read buffer interface through memory ([HIST_CNT](#) [3] SOURCE).

The input data is 10 bits wide if the source is the video-port interface. When the input source is from memory, data-bit width can range from 8 to 14 bits. If the input data is 8 bits packed (memory contains two 8-bit pixels for every 16 bits), the [HIST_CNT](#) [8] DATSIZ bit must be set. If memory contains one pixel for every 16 bits, the DATSIZ bit must be cleared.

Likewise, if memory contains one pixel for every 16 bits, the DATSIZ bit must be cleared. The input memory address ([HIST_RADD](#)) and line-offset ([HIST_RADD_OFF](#)) registers are used to specify the location of the input frame in memory. Both of these registers should be aligned on 32-byte boundaries.

The frame-input width and height are configured using the [HIST_H_V_INFO](#) [29:16] HSIZE and [HIST_H_V_INFO](#) [13:0] VSIZE register fields, respectively.

The histogram module supports 4-color Bayer and 3-color Foveon color patterns. The [HIST_CNT](#) [6] CFA field is used to select the color pattern of the input data (Bayer or Foveon).

12.4.6.2.4 White Balance

A white-balance gain can be separately applied to each color channel by programming the fields in the [HIST_WB_GAIN](#) register. [Table 12-27](#) indicates which pixel index in the color pattern corresponds to each field in the WB_GAIN register.

Figure 12-38. Color Pattern Indexes

Bayer	
0	1
2	3

camisp-074

Table 12-27. White Balance Field-to-Pattern Assignments

HIST_WB_GAIN fields	Bayer
WG00	0
WG01	1
WG02	2
WG03	3

Each gain constant is 8 bits wide with 5 bits of decimal precision (U8Q5).

12.4.6.2.5 Histogram Binning

The histogram bins the input data by amplitude, color, and region (see [Figure 12-39](#)). Each bin is a counter, counting the number of pixels of a color in the range associated with the bin. The number of bins can be programmed to 32, 64, 128, or 256 bins in the [HIST_CNT](#) [5:4] BINS field. However, due to limited histogram memory size (1024 words), the number of bins (times 4 colors) limits the number of regions that can be active, as shown in [Table 12-28](#).

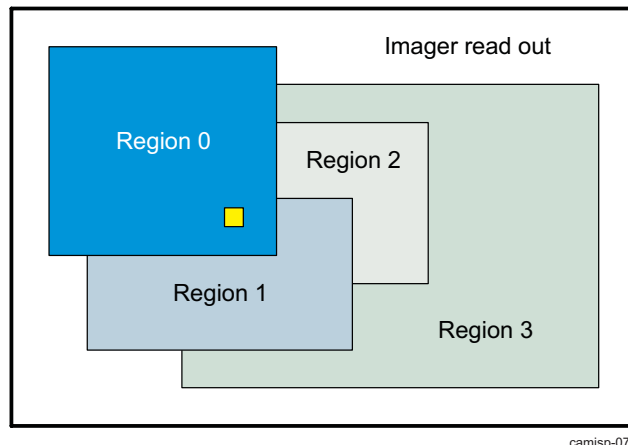

Table 12-28. Regions and Bins for Histogram

Number of Bins	Number of Regions Allowed
256	1
128	2"
64	4
32	4

As indicated by [Table 12-28](#), up to four overlapping regions can be designated within the frame. Each region is defined by the horizontal starting ([HIST_Rn_HORZ](#) [29:16] HSTART) and ending ([HIST_Rn_HORZ](#) [13:0] HEND) pixels, and the vertical starting ([HIST_Rn_VERT](#) [29:16] VSTART) and ending ([HIST_Rn_VERT](#) [13:0] VEND) lines (where n is the region number 0...3).

12.4.6.2.5.1 Region Priority

Up to four regions can be active at any time, but a pixel is binned into only one region. The priority is Region 0 > Region 1 > Region 2 > Region 3. For example, the yellow pixel in [Figure 12-39](#) is binned only for Region 0, although it is present in all four regions.

Figure 12-39. Region Priority

12.4.7 Central-Resource Shared Buffer Logic (SBL)

The central-resource SBL receives data read and write requests from the CCDC, preview, H3A, histogram, and resizer modules. It arbitrates between requestors and constructs bursts to transfer data to and from memory.

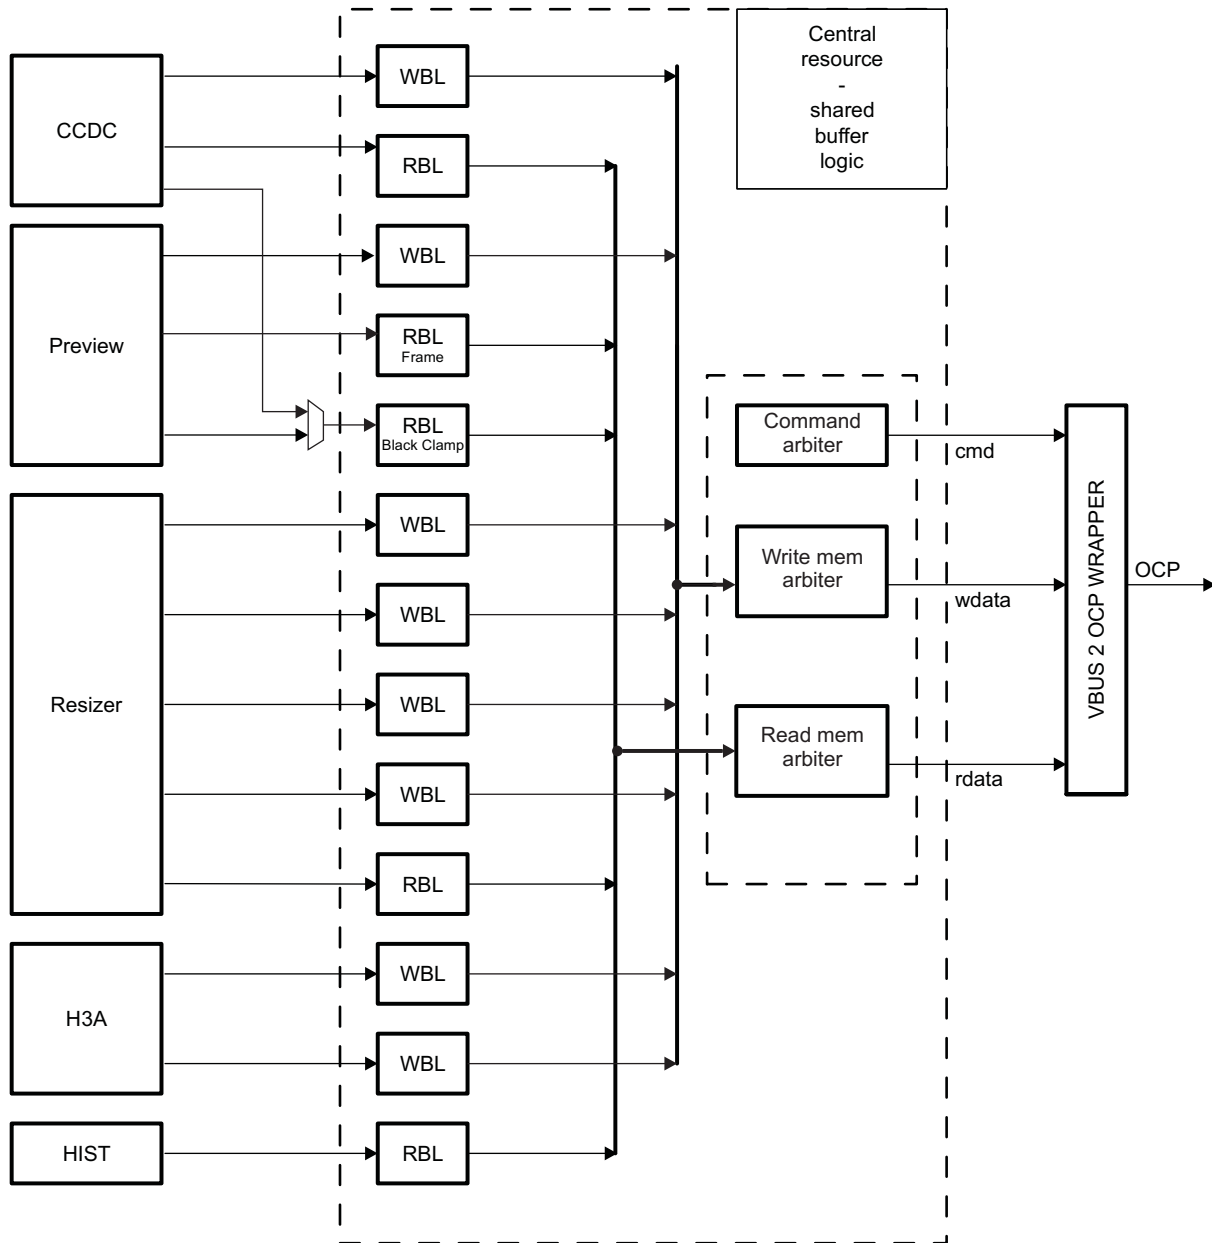

The central-resource SBL performs the following functions:

- Interface to the CCDC module:
 - Collects output data from the CCDC in the write buffer (1 port)
 - Transfers faulty-pixel table data to the CCDC from the read buffer (2 ports)
 - Transfer lens-shading compensation to the CCDC engine from the read buffer. This port is shared with PREVIEW module dark frame subtract port.
- Interface to the preview module:
 - Collects output data from the preview engine in the write buffer (1 port)
 - Transfer input data to the PREVIEW engine from the read buffer (1 ports).
 - Transfer dark frame subtract data to the PREVIEW engine from the read buffer . This port is shared with CCDC lens-shading compensation read port.
- Interface to the H3A module:
 - Collects output data from the H3A in the write buffer (2 ports)
- Interface to the histogram module:
 - Transfers input data to the histogram from the read buffer (1 port)
- Interface to the resizer module:
 - Collects output data from the resizer in the write buffer (4 ports)
 - Transfers input data to the resizer from the read buffer (1 port)
- Requests arbitration between the different initiators. Based on fixed priorities.
- Performs throttle memory read requests for preview, resizer, and histogram to limit bandwidth in memory-to-memory operations

12.4.7.1 Block Diagram

Figure 12-40 shows the central-resource SBL. It comprises WBL and RBL blocks, read and write buffers, and arbitration logic. The VBUSM data-width to the memory is 64 bits.

Figure 12-40. Central-Resource SBL Block Diagram

camisp-078

12.4.7.2 Functional Operations

12.4.7.2.1 Parameters

Table 12-29 summarizes the central-resource SBL parameters. Those parameters are fixed at design time and cannot be changed by users. The functional operations of the central-resource SBL are based on a fixed data size of 256 bytes called a data unit (DU). P0 has the highest priority and P14 has the lowest priority.

Table 12-29. Central Resource SBL Fixed Parameters

Port	Port Direction	Port Priority	Buffer Size Bytes	Description
CCDC	WRITE	P4	1024 = 4DUs	CCDC output port
	READ	P1	512 = 2DUs	CCDC fault pixel correction input port
PREVIEW	WRITE	P9	1024 = 4DUs	PREVIEW output port
	READ	P13	1024 = 4DUs	PREVIEW input port
	READ	P0	1024 = 4DUs	PREVIEW dark-frame input port CCDC lens-shading compensation input port
RESIZER	WRITE	P5	1024 = 4DUs	RESIZER output line 1 port
	WRITE	P6	1024 = 4DUs	RESIZER output line 2 port
	WRITE	P7	1024 = 4DUs	RESIZER output line 3 port
	WRITE	P8	1024 = 4DUs	RESIZER output line 4 port
	READ	P12	1024 = 4DUs	RESIZER input port
H3A	WRITE	P10	512 = 2DUs	H3A output - AF port
	WRITE	P11	512 = 2DUs	H3A output - AE/AWB port
HIST	READ	P14	512 = 2DUs	HIST input port

12.4.7.2.2 Write-Buffer Logic (WBL) and Write Buffer

The central-resource SBL uses multiple WBL blocks to interface between the modules' write ports and the write-buffer memory.

- One WBL is instantiated for each module write port.
- Each WBL collects the module's write port output data and transfers the data to the write-buffer memory. Arbitration occurs between the WBL blocks to access the write-buffer memory.
- Each WBL is responsible for tracking all corresponding DUs in the write-buffer memory. There can be 2 or 4 DUs in the write buffer associated with a WBL.
- A WBL generates a command to memory when:
 - The write data crosses a DU boundary. At this point, the module starts filling a new DU. Also, the WBL generates a command to transfer the previous DU to memory.
 - An end-of-frame occurs. The DU (even if not full) is transferred to memory, and a command is issued.
 - An end-of-line occurs. The DU (even if not full) is transferred to the memory, and a command is issued.

12.4.7.2.3 Read Buffer Logic (RBL) and Read Buffer

The central-resource SBL uses multiple RBL blocks to interface between the modules' read ports and the read-buffer memory.

- One RBL is instantiated for each module read port.
- Each RBL is responsible for accepting input data from the read-buffer memory and for sending the input data to the read port of the corresponding module.
- Each RBL is responsible for tracking all corresponding DUs in the read-buffer memory. There can be 2 or 4 DUs in the read buffer associated with a RBL.
- Unlike the WBL, the RBL is not responsible for issuing the commands to memory; each individual module is responsible for doing this.

Two read ports are shared:

- Between the PREVIEW module dark frame and the CCDC lens-shading compensation input

They can only be used by one module at a given time because there's no arbitration mechanism. Software is responsible of enabling only one of the 2 possible features attached to a port and to select the correct multiplexer configuration using the [ISP_CTRL](#) [27] SBL_SHARED_RPORTA and [ISP_CTRL](#) [28] SBL_SHARED_RPORTB registers.

12.4.7.2.4 Arbitration

The central-resource SBL arbitrates between module requests, based on fixed priorities. Read and write requests are arbitrated independently.

A total of 8 commands can be active at a time. When a new slot opens, the highest-priority transfer enters the command queue.

RBLs/WBLs are ensured access to the read/write buffer memories at least once every other cycle.

Note: The hardware uses burst. All bursts are precise; the total number of transfers in the burst is known at the start of the burst. All writes are posted.

12.4.7.3 Memories

The central-resource shared-buffer module has three memories:

- READ BUFFER: Shared by all modules.
- WRITE BUFFER 0: Used only by the resizer module.
- WRITE BUFFER 1: Shared by all modules except RESIZER.

12.4.7.4 Debug Registers

Some registers are available for debugging data transfers between a module and external memory. The read-only debug registers are divided into two categories:

- 8 global request registers to capture information about any of the 52 module request registers at a given time. Each register provides information about one DU. The number 16 corresponds to the maximum number of outstanding requests, according to the protocol. Each global request register provides the following information:
 - Individual module register command number. For modules with 2 individual requestors, this field displays either 0 or 1. For modules with 4 individual requestors, this field displays 0, 1, 2, or 3.
 - Source or destination module
 - Data-flow direction
 - Valid bit
- 52 individual module request registers (read or write information). Each register provides information about one DU. The number of request registers assigned (2 or 4) depends on memory bandwidth requirements; modules with lower requirements are assigned 2 request registers, while modules with higher bandwidths are assigned 4 request registers.

Table 12-30. Central Resource SBL Number of Request Registers

Port	RD/WR	Nb Request Registers	Description
CCDC	WRITE	4 WR request registers	CCDC output
	READ	2 RD request registers	CCDC fault pixel correction input
PREVIEW	WRITE	4 WR request registers	PREVIEW output
	READ	4 RD request registers	PREVIEW input
	READ	4 RD request registers	PREVIEW dark-frame input
RESIZER	WRITE	4 WR request registers	RESIZER output line 1
	WRITE	4 WR request registers	RESIZER output line 2
	WRITE	4 WR request registers	RESIZER output line 3

Table 12-30. Central Resource SBL Number of Request Registers (continued)

Port	RD/WR	Nb Request Registers	Description
	WRITE	4 WR request registers	RESIZER output line 4
	READ	4 RD request registers	RESIZER input port
H3A	WRITE	2 WR request registers	H3A output - AF port
	WRITE	2 WR request registers	H3A output - AE/AWB port
HIST	READ	2 RD request registers	HIST input

Each write-request register provides the following information:

- Current byte count: Number of bytes in the block of data for this command, up to 256 bytes
- Data ready: Block of data confirmed by the module
- Data sent: Data sent to the destination and waiting for status
- Upper 20 bits of the address

Each read-request register provides the following information:

- Valid: Read requested from the module
- Waiting for data: Command accepted from the source
- Data available: Data received from the source and can be read by the module
- Byte count requested: Up to 256 bytes
- Upper 20 bits of the address

12.4.8 Circular Buffer (CBUFF)

The circular buffer maps a virtual space to a physical space by address translation. It does not change the data or store it locally.

Note: Addresses can be further translated by the MMU.

12.4.8.1 Feature List

The features are listed below:

- 2 independent circular buffers (CBUFF0 and CBUFF1)
- Linear address space (virtual) mapped into a circular space (physical)
- Fully transparent for accesses out of the configured virtual space
- Maximum physical buffer size of 16x16M bytes:
 - Physical space is composed by 2,4,8 or 16 windows
 - Maximum allowed window size is 16M bytes
- Support for multi line write patterns
 - Used together with the resizer in upscale mode. Each buffer must contain at least ceil (vertical zoom factor) images lines
- Support of 2D addressing modes
- Strong error detection mechanisms
- Buffer addresses are 64 bit aligned but window fill level managing is byte accurate
- Read and write accesses are supported

12.4.8.2 Interrupts

All events generated (see [Table 12-11](#) for details) by the circular buffer are merged into a single event at camera ISP level. This event can be mapped to MPU SS by enabling the [ISP_IRQ0ENABLE](#) [21] CBUFF_IRQ bit or to IVA2.2 by enabling the [ISP_IRQ1ENABLE](#) [21] CBUFF_IRQ bit.

12.4.8.3 Functional Description

The circular buffer module (CBUFF) maps a virtual address space to a physical space called circular buffer. The CBUFF module can handle up to 2 independent circular buffers CBUFF0 and CBUFF1.

This section gives an overview of typical utilizations of the module.

12.4.8.3.1 Window Management

This section explains the internal address remapping and windows management algorithm. Internally the module maintains some variables in addition to the configuration registers.

The module manages 2 circular buffers in parallel. Those are called CBUFF0 and CBUFF1.

Table 12-31. Internal Variables

Quantity	Description
CWx	Current window index for buffer x (x=0,1). Possible values are 0 to allowed window count. The current value can be read using the CBUFFx_STATUS [11:8] CW register.
NWx	Next window index for buffer x (x=0,1). Possible values are 0 to allowed window count. The current value can be read using the CBUFFx_STATUS [19:16] NW register.
CPUWx	Window in the physical buffer that can be accessed by the CPU. Possible values are 0 to allowed window count. The current value can be read using the CBUFFx_STATUS [3:0] CPUW register.
FCOx	Start address, in the virtual space, of the current window. This is an internal quantity that cannot be accessed by SW.
OFFSETy	This is an internal quantity that cannot be accessed by SW. y=0: Address offset used when the current window of buffer 0 is accessed y=1: Address offset used when the next window of buffer 0 is accessed y=2: Address offset used when the current window of buffer 1 is accessed y=3: Address offset used when the next window of buffer 1 is accessed
LEVELy	This is an internal quantity that cannot be accessed by SW. y=0: Amount of data, in bytes, read or written in the current window of buffer 0 y=1: Amount of data, in bytes, read or written in the next window of buffer 0 y=2: Amount of data, in bytes, read or written in the current window of buffer 1 y=3: Amount of data, in bytes, read or written in the next window of buffer 1

12.4.8.3.1.1 Startup

The status of a circular buffer (CBUFF0 or CBUFF1) is reset when it is disabled. This does not affect the configuration registers or the [CBUFF_IRQSTATUS](#) register. [Table 12-32](#) shows the internal state after reset.

Table 12-32. Internal State After Reset

Quantity	Description
CWx	0
NWx	1
CPUWx	0
FCOx	CBUFFx_START
OFFSET0	0
OFFSET1	0
OFFSET2,3	0
LEVELy	0

12.4.8.3.1.2 Access Identification

For each access to the virtual space the CBUFF module first checks the address (ADDR) to classify the transaction into one of the following categories listed in [Table 12-33](#).

Table 12-33. Address Identification

ID	Label	Condition
0	CW_CBUFF0	CBUFFx_CTRL [0] ENABLE=1 and ADDR>=FCO0 and ADDRFCO0 + CBUFFx_WINDOWSIZE and ADDR= CBUFFx_END (x = 0)
1	NW_CBUFF0	CBUFFx_CTRL [0] ENABLE=1 (x = 0) and ADDR>=FCO0 + CBUFFx_WINDOWSIZE and ADDRFCO0 + 2* CBUFFx_WINDOWSIZE and ADDR= CBUFFx_END (x = 0)
2	CW_CBUFF1	CBUFFx_CTRL [0] ENABLE=1 and ADDR>=FCO1 and ADDRFCO1 + CBUFFx_WINDOWSIZE and ADDR= CBUFFx_END (x = 1)
3	NW_CBUFF1	CBUFFx_CTRL [0] ENABLE=1 and ADDR>=FCO1 + CBUFFx_WINDOWSIZE and ADDRFCO1 + 2* CBUFFx_WINDOWSIZE and ADDR= CBUFFx_END (x = 1)
4	ERR_CBUFF0	CBUFFx_CTRL [0] ENABLE=1 and ADDR>= CBUFFx_START and ADDR= CBUFFx_END (x = 0)
5	ERR_CBUFF1	CBUFFx_CTRL [0] ENABLE=1 and ADDR>= CBUFFx_START and ADDR= CBUFFx_END (x = 1)
6	TRANSPARENT	Always true

Lower IDs correspond to higher priorities in case multiple conditions are true. For example when the current virtual window of the circular buffer 0 is accessed, at least the tests for categories CW_CBUFF0 and ERR_CBUFF0 are true. The final category is CW_CBUFF0 because it has a higher priority.

Further processing depends on the category:

- TRANSPARENT: Accesses flow through the module, without changing its internal state or any translation.
- ERR_CBUFF0 and ERR_CBUFF1: The module goes into error state for the concerned buffer (CBUFF0 or CBUFF1) and set the [CBUFF_IRQSTATUS](#)[1] IRQ_CBUFF0_INVALID bit (or [CBUFF_IRQSTATUS](#)[4] IRQ_CBUFF1_INVALID). When the module is in error state for CBUFFx, all accesses to that buffer are cancelled. In other words, any access that has an address between [CBUFFx_START](#) and [CBUFFx_END](#) (x = 0) is not transmitted to the interconnect. There are 2 ways to leave the error state
 - HW reset
 - Disable and re-enable the buffer (CBUFF0 or CBUFF1) in error state.
 Accesses outside of the virtual space from the circular buffer in error state are not affected.
- CW_CBUFF0, NW_CBUFF0, CW_CBUFF1 and NW_CBUFF1: The internal state is updated and address translation is performed when the performed access type (read or write) is compatible with the current mode (read or write). Otherwise an IRQ_CBUFFx_INVALID event is set and CBUFFx goes to the error state.

12.4.8.3.1.3 Address Translation

An offset is selected depending on the access category (check section [Section 12.4.8.3.1.1](#)) and the internal state of the accessed buffer. [Table 12-34](#) lists possible cases.

Table 12-34. Address Translation

Condition	Address Translation
CBUFFx_CTRL [0] ENABLE=1 and ADDR >= CBUFFx_START and ADDR = CBUFFx_END and CBUFF0 in error state (x = 0)	Access cancelled
CBUFFx_CTRL [0] ENABLE=1 and ADDR >= CBUFFx_START and ADDR = CBUFFx_END and CBUFF1 in error state (x = 1)	Access cancelled
Category = CW_CBUFF0	ADDROUT = ADDRIN-OFFSET0
Category = NW_CBUFF0	ADDROUT = ADDRIN-OFFSET1
Category = CW_CBUFF1	ADDROUT = ADDRIN-OFFSET2
Category = NW_CBUFF1	ADDROUT = ADDRIN-OFFSET3
Category = ERR_CBUFF0	Access cancelled
Category = ERR_CBUFF1	Access cancelled
Category = TRANSPARENT	ADDROUT = ADDRIN

12.4.8.3.1.4 Window Fill Level

Each time an access is performed into an active window (CW_CBUFF0, NW_CBUFF0, CW_CBUFF1 or NW_CBUFF1) the window level is updated. The corresponding LEVELy is incremented according to the BYTEEN input of the interconnect port. All possible BYTEEN patterns are supported. [Table 12-35](#) shows some examples. The basic idea is to count the number of ones in the BYTEEN input.

Table 12-35. Window Level Increment

BYTEEN	LEVELy Increment	Comment
0x00	+0	No access
0x01	+1	8 bit access
0x02	+1	8 bit access
0x03	+2	16 bit access
...
0x07	+3	24 bit access
...
0x0F	+4	32 bit access
...
0xF0	+4	32 bit access
...
0xFF	+8	64 bit access

The window level is compared to [CBUFFx_THRESHOLD](#). As listed in [Table 12-36](#), the following situations may occur:

Table 12-36. Window Level Comparison

Condition	Description
LEVEL0 >= CBUFFx_THRESHOLD (x = 0)	Current window of buffer 0 full. Internal window indexes, levels and offsets are updated
LEVEL1 >= CBUFFx_THRESHOLD (x = 0)	Next window of buffer 0 full. An IRQ_CBUFF0_INVALID error event is set and CBUFF0 enters the error state
LEVEL2 >= CBUFFx_THRESHOLD (x = 1)	Current window of buffer 1 full.
LEVEL3 >= CBUFFx_THRESHOLD (x = 1)	Next window of buffer 1 full. An IRQ_CBUFF1_INVALID error event is set and CBUFF1 enters the error state

12.4.8.3.1.5 Window Pointer and Offset Update

When the current window of a circular buffer (CBUFFx, x=0 or 1) is full:

- The "next window" becomes the "current window"
 - $CWx \leftarrow NW$
 - $LEVEL(2*x) \leftarrow LEVEL(2*x+1)$
 - $OFFSET(2*x) \leftarrow OFFSET(2*x+1)$
 - $FCOx = FCOx + CBUFFx_WINDOWSIZE$
- A new "next window" is opened. The update is done in a circular manner: the first window in the physical space is reused after the last one
 - $NW \leftarrow (NW+1) \text{ modulo } WC$
 - $LEVEL(2*x+1) \leftarrow 0$
 - When the "next window" is moved from the last buffer to the first:
 - $OFFSET(2*x+1) = OFFSET(2*x+1) + WCx * CBUFFx_WINDOWSIZE$

Note: WC is the window count defined by the CBUFFx_CTRL[9:8] WCOUNT register.

12.4.8.3.2 CPU Interaction

The CBUFF module sets an IRQ_CBUFFx_READY event to inform the CPU that it can access the CPUx window in the physical buffer. The CBUFF module cannot monitor CPU accesses to the physical buffer. The CPU must indicate when it has completed the processing of the CPUWx window by writing the CBUFFx_CTRL[2] DONE bit. This increments the CPU window index CPUWx by one modulo the window count.

The behavior depends if read or write mode has been selected using the CBUFFx_CTRL[1] RWMODE bit.

12.4.9 MMU Logic

12.4.9.1 MMU Features

The camera ISP MMU contains a translation lookaside buffer (TLB) that holds translations and properties for current pages. This TLB can be managed statically through the configuration slave port, or by the internal hardware table-walking logic (TWL), which can autonomously traverse the page table on a TLB miss. The TWL can be enabled or disabled (MMU_CNTL [2] TWLENABLE).

On a TLB miss, the initiator is stalled until a valid address translation is found. If no valid translation is found, a translation fault interrupt is generated to the processor. It is a nonrecoverable situation, which leads to the camera ISP being reset by the processor software.

The MMU provides up to 4G bytes of virtual memory.

12.4.9.2 MMU Functional Description

For a detailed description of MMU, see the *Memory Management Units* chapter.

Note: In the camera ISP MMU, the endianness feature is available for write, but conversion for read is not possible.

12.5 Camera ISP Basic Programming Model

12.5.1 Programming the Timing CTRL Module

Note: All the following settings must be done before enabling the Timing control module.

12.5.1.1 Timing Generator

The cam_xclka clock frequency is set through the [TCTRL_CTRL](#) [4:0] DIVA bit field. The cam_xclkb clock frequency is set through the [TCTRL_CTRL](#) [9:5] DIVB bit field. One can change the divisor values at any time.

For divisor values 0, 1, and 31, the divider is not enabled. For all other values:

- cam_xclka = cam_mclk/[TCTRL_CTRL](#) [4:0] DIVA
- cam_xclkb = cam_mclk/[TCTRL_CTRL](#) [9:5] DIVB

12.5.1.2 Camera-Control Signal Generator

Enabling of the SHUTTER, PRESTROBE or STROBE signals generation and activates the counters:

- [TCTRL_CTRL](#) [21] SHUTEN= 1
- [TCTRL_CTRL](#) [22] PSTRBEN= 1
- [TCTRL_CTRL](#) [23] STRBEN = 1

Two configurations apply:

- The control signals are based on the vertical synchronization information coming from the camera module or from the externally generated cam_global_reset signal.
- The control signals are based on the internally generated cam_global_reset.

12.5.1.2.1 Vertical Synchro-Based Control-Signal Generation or Externally-Generated cam_global_reset

Before enabling the control-signal generation, the following registers must be set:

- Select the input that triggers the control signals. The trigger signal can come from the PARALLEL or the externally-generated cam_global_reset signal.
 - [TCTRL_CTRL](#) [28:27] INSEL
- The signal must be set to INPUT:
 - [TCTRL_CTRL](#) [31] GRESETDIR = 0x0
 - Writes to [TCTRL_CTRL](#) [29] GRESETEN bit do not trigger the PRESTROBE, STROBE, and SHUTTER signals, and do not generate the cam_global_reset signal.
- The following bits are cleared automatically to 0 after the signal assertion:
 - [TCTRL_CTRL](#) [21] SHUTEN
 - [TCTRL_CTRL](#) [22] PSTRBEN
 - [TCTRL_CTRL](#) [23] STRBEN
- The following bits set the polarity of the SHUTTER, STROBE/PRESTROBE, and cam_global_reset signals. The signals can be active high or active low:
 - [TCTRL_CTRL](#) [24] SHUTPOL
 - [TCTRL_CTRL](#) [26] STRBPSTRBPOL
 - [TCTRL_CTRL](#) [30] GRESETPOL
- The following bit sets the clock divisor value, which generates the CNTCLK clock:
 - [TCTRL_CTRL](#) [18:10] DIVC

The clock is set by CNTCLK = cam_mclk/[TCTRL_CTRL](#) [18:10] DIVC. The possible values are 0 to 511. Setting DIVC = 0 disables the CNTCLK clock generation.
- The frame counters are set with (possible values are 0 to 63 frames):

- [TCTRL_FRAME](#) [5:0] SHUT
- [TCTRL_FRAME](#) [11:6] PSTRB
- [TCTRL_FRAME](#) [17:12] STRB

Note: If the value is zero, the Timing Control module does not delay any frame in input.

- The delay counters are set with:
 - [TCTRL_SHUT_DELAY](#)
 - [TCTRL_PSTRB_DELAY](#)
 - [TCTRL_STRB_DELAY](#)

The possible values are 0 to $2^{25} - 1$ cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is $(2^{25} - 1) \times 2.366 \text{ us} = 79 \text{ s}$ ([TCTRL_CTRL](#) [18:10] DIVC = 511).
- The signal durations are set with:
 - [TCTRL_SHUT_LENGTH](#)
 - [TCTRL_PSTRB_LENGTH](#)
 - [TCTRL_STRB_LENGTH](#)

The possible values are 0 to $2^{24} - 1$ cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is $(2^{24} - 1) \times 2.366 \text{ us} = 39.69 \text{ s}$ ([TCTRL_CTRL](#) [18:10] DIVC = 511).

12.5.1.2.2 Internally-Generated cam_global_reset-Based Control-Signal Generation

Before enabling the cam_global_reset control-signal generation by writing [TCTRL_CTRL](#) [29] GRESETEN = 1, the following registers must be set:

Note: Setting [TCTRL_CTRL](#) [21] SHUTEN, [TCTRL_CTRL](#) [22] PSTRBEN, [TCTRL_CTRL](#) [23] STRBEN, and [TCTRL_CTRL](#) [29] GRESETEN to 1 simultaneously leads to unpredictable behavior. The [TCTRL_CTRL](#) [21] SHUTEN, [TCTRL_CTRL](#) [22] PSTRBEN, [TCTRL_CTRL](#) [23] STRBEN must be set before [TCTRL_CTRL](#) [29] GRESETEN is enabled.

- The signal must be set to OUTPUT:
 - [TCTRL_CTRL](#) [31] GRESETDIR = 0x1
 - Vertical synchronization events do not trigger the PRESTROBE, STROBE, and SHUTTER signals.
- The following bits are cleared automatically to 0 after the signal assertion:
 - [TCTRL_CTRL](#) [21] SHUTEN
 - [TCTRL_CTRL](#) [22] PSTRBEN
 - [TCTRL_CTRL](#) [23] STRBEN
 - [TCTRL_CTRL](#) [29] GRESETEN
- The following bits set the polarity of the SHUTTER, STROBE/PRESTROBE, and cam_global_reset signals. The signals can be active high or active low:
 - [TCTRL_CTRL](#) [24] SHUTPOL
 - [TCTRL_CTRL](#) [26] STRBPSTRBPOL
 - [TCTRL_CTRL](#) [30] GRESETPOL
- The following bit sets the clock divisor value, which generates the CNTCLK clock:
 - [TCTRL_CTRL](#) [18:10] DIVC

The clock is set by $\text{CNTCLK} = \text{cam_mclk} / \text{TCTRL_CTRL} [18:10] \text{ DIVC}$. The possible values are 0 to 511. Setting DIVC = 0 disables the CNTCLK clock generation.
- The frame counters bit fields are ignored:
 - [TCTRL_FRAME](#) [5:0] SHUT
 - [TCTRL_FRAME](#) [11:6] PSTRB
 - [TCTRL_FRAME](#) [17:12] STRB
- The delay counters are set with:
 - [TCTRL_SHUT_DELAY](#)

- [TCTRL_PSTRB_DELAY](#)
- [TCTRL_STRB_DELAY](#)

The possible values are 0 to 225 -1 cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is $(225 - 1) \times 2.366 \text{ us} = 79 \text{ s}$ ([TCTRL_CTRL \[18:10\] DIVC = 511](#)).

- The signal durations are set with:

- [TCTRL_SHUT_LENGTH](#)
- [TCTRL_PSTRB_LENGTH](#)
- [TCTRL_STRB_LENGTH](#)

The possible values are 0 to 224 -1 cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is $(224 - 1) \times 2.366 \text{ us} = 39.69 \text{ s}$ ([TCTRL_CTRL \[18:11\] DIVC = 511](#)).

- The cam_global_reset assertion time is set by [TCTRL_GRESET_LENGTH](#). The possible values are 0 to 224 -1 cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is $(224 - 1) \times 2.366 \text{ us} = 39.69 \text{ s}$ ([TCTRL_CTRL \[18:11\] DIVC = 511](#)).

12.5.2 Programming the CCDC

This section discusses issues related to the software control of the CCDC. It lists which registers are required to be programmed in different modes, and describes how to enable and disable the CCDC, how to check the status of the CCDC, the different register access types, and programming constraints.

12.5.2.1 CCDC Hardware Setup/Initialization

This section discusses the configuration of the CCDC required before image processing can begin.

12.5.2.1.1 Reset Behavior

On hardware reset of the camera ISP, all registers in the CCDC are reset to their reset values.

12.5.2.1.2 Register Setup

Before enabling the CCDC, the hardware must be correctly configured through register writes.

[Table 12-37](#) identifies the register parameters that must be programmed before enabling the CCDC.

Table 12-37. CCDC Required Configuration Parameters

Function	Configuration Required
External pin signal configuration	CCDC_SYN_MODE [0] VDHOUT
	CCDC_SYN_MODE [16] VHDEN
	CCDC_SYN_MODE [2] VDPOL
	CCDC_SYN_MODE [3] HDPOL
	CCDC_SYN_MODE [7] FLDMODE
	CCDC_SYN_MODE [1] FLDOUT
	CCDC_SYN_MODE [4] FLDPOL
	CCDC_SYN_MODE [5] EXWEN
	CCDC_SYN_MODE [6] DATAPOL
	CCDC_CFG [15] VDLC = 1
	ISP_CTRL [3:2] PAR_BRIDGE
	ISP_CTRL [7:6] SHIFT
	ISP_CTRL [4] PAR_CLK_POL
Input mode	CCDC_REC656IF [0] R656ON
	CCDC_SYN_MODE [13 :12] INPMOD

12.5.2.1.3 Pixel Selection (Framing) Register Dependencies

There are three locations in the data flow where the Valid Frame Data can be defined:

- Data Formatter Input Pixel Selection
- Video Port Output Pixel Selection
- Output Formatter Pixel Selection

Care must be taken to ensure that the frame definitions correspond to the output of the upstream frame definitions. When the video port is enabled, [CCDC_VP_OUT](#) [30:17] VERT_NUM must be less than [CCDC_FMT_VERT](#) [12:0] FMTLNV.

Two data paths through the CCDC affect the programming of the pixel-selection registers, depending on the value of the [CCDC_SYN_MODE](#) [18] VP2SDR bit:

- VP2SDR = 0: The input data bypasses the data formatter/video port. In this case, only the memory output frame parameters apply. This data path is represented by the white arrow in [Figure 12-41](#).
- VP2SDR = 1: The input data passes through the data formatter/video port. In this case, both data formatter frame definitions apply to the video-port output, and all three frame definitions apply to the memory output. This data path is represented by the green shaded arrow in [Figure 12-41](#).

Figure 12-41. Dependencies Among Framing Settings in Data Flow

camisp-084

12.5.2.2 Enable/Disable Hardware

All required registers mentioned in the previous section must be programmed before setting the [CCDC_PCR](#) [0] ENABLE bit.

The CCDC always operates in continuous mode. In other words, after enabling the CCDC, it processes sequential frames until the ENABLE bit is cleared by software. When this happens, the frame being processed completes before the CCDC is disabled.

When the CCDC is in master mode (HS/VS signals set to outputs), fetching and processing of the frame begin immediately on setting the [CCDC_PCR](#) [0] ENABLE bit.

When the CCDC is in slave mode (HS/VS signals set to inputs), processing of the frame depends on the input timing of the external sensor/decoder. To ensure that data from the external device is not missed, the CCDC must be enabled before data transmission from the external device. In this way, the CCDC waits for data from the external device.

On setting the [CCDC_FPC](#) [15] FPCEN bit, the CCDC begins to fetch and buffer the faulty-pixel table from memory. If faulty-pixel correction is used, the [CCDC_FPC](#) [15] FPCEN bit must be set before the [CCDC_PCR](#) [0] ENABLE bit, but after the faulty-pixel table is placed in memory and the [CCDC_FPC](#) [14:0] FPNUM and [CCDC_FPC_ADDR](#) registers are set.

12.5.2.3 Events and Status Checking

The CCDC can generate three different interrupts: [CCDC_VD0_IRQ](#), [CCDC_VD1_IRQ](#), and [CCDC_VD2_IRQ](#).

The [CCDC_SYN_MODE](#) [16] VDHEN bit must be enabled to receive any of the CCDC [CCDC_VDx_IRQ](#) interrupts.

12.5.2.3.1 Interrupts

The CCDC module has 3 programmable events: [CCDC_VD0_IRQ](#), [CCDC_VD1_IRQ](#), and [CCDC_VD2_IRQ](#), and one error event [CCDC_ERR_IRQ](#). Event generation is detailed in [Section 12.5.2.3.2](#) and [Section 12.5.2.3.3](#).

CCDC module events can be mapped to the ARM or to the DSP:

- The [CCDC_VD0_IRQ](#), [CCDC_VD1_IRQ](#), [CCDC_VD2_IRQ](#) and [CCDC_ERR_IRQ](#) bits in the [ISP_IRQ0ENABLE](#) register control whether the CCDC module events trigger an interrupt to the ARM. The [ISP_IRQ0STATUS](#) register indicates which event(s) triggered the interrupt. An event is cleared by writing a 1 in its corresponding bit in the [ISP_IRQ0STATUS](#) register. To clear the [CCDC_ERR_IRQ](#) interrupt, clear the [CCDC_FPC](#) [16] FPERR bit before clearing the [ISP_IRQ0STATUS](#) [11] [CCDC_ERR_IRQ](#) bit.
- The [CCDC_VD0_IRQ](#), [CCDC_VD1_IRQ](#), [CCDC_VD2_IRQ](#) and [CCDC_ERR_IRQ](#) bits in the [ISP_IRQ1ENABLE](#) register control whether the CCDC module events trigger an interrupt to the DSP. The [ISP_IRQ1STATUS](#) register indicates which event(s) triggered the interrupt. An event is cleared by writing a 1 in its corresponding bit in the [ISP_IRQ1STATUS](#) register. To clear the [CCDC_ERR_IRQ](#) interrupt, clear the [CCDC_FPC](#) [16] FPERR bit before clearing the [ISP_IRQ1STATUS](#) [11] [CCDC_ERR_IRQ](#) bit.

12.5.2.3.2 CCDC_VD0_IRQ and CCDC_VD1_IRQ Interrupts

As shown in [Figure 12-42](#), [CCDC_VD0_IRQ](#) and [CCDC_VD1_IRQ](#) interrupts occur relative to the VS pulse. The trigger timing is selected by using the [CCDC_SYN_MODE](#) [2] VDPOL setting. [CCDC_VD0_IRQ](#) and [CCDC_VD1_IRQ](#) occur after receiving the number of horizontal lines (HS pulse signals) set in the [CCDC_VDINT](#) [30:16] VDINT0 and [CCDC_VDINT](#) [14:0] VDINT1 register fields, respectively.

Note: In the case of BT.656 input mode, there is VS at the beginning of each field. Therefore, there are two interrupts for each frame (one for each field).

If [CCDC_SYN_MODE](#) [2] VDPOL is 0, the CCDC_VD0_IRQ and CCDC_VD1_IRQ HS counters begin counting HS pulses from the rising edge of the external VS, as shown in [Figure 12-42](#).

Figure 12-42. CCDC_VD0_IRQ/CCDC_VD1_IRQ Interrupt Behavior When VDPOL = 0

If [CCDC_SYN_MODE](#) [2] VDPOL is 1, the CCDC_VD0_IRQ and CCDC_VD1_IRQ HS counters begin counting HS pulses from the falling edge of the external VS.

Figure 12-43. CCDC_VD0_IRQ/CCDC_VD1_IRQ Interrupt Behavior When VDPOL = 1

12.5.2.3.3 CCDC_VD2_IRQ Interrupt

In addition to the CCDC_VD0_IRQ and CCDC_VD1_IRQ interrupts, the CCDC has an interrupt called CCDC_VD2_IRQ. This interrupt always occurs at the falling edge of the WEN signal (through external pin). There are no registers in the CCDC module to configure this interrupt, see [Figure 12-44](#).

Figure 12-44. CCDC_VD2_IRQ Interrupt Behavior

12.5.2.3.4 Status Checking

The [CCDC_PCR](#) [1] BUSY status bit is set when the start of frame occurs (if the [CCDC_PCR](#) [0] ENABLE bit is 1 at that time). It is automatically reset to 0 at the end of a frame. The [CCDC_PCR](#) [1] BUSY status bit may be polled to determine end-of-frame status.

The [CCDC_FPC](#) [16] FPERR status bit is set when faulty-pixel data fetched from memory arrives late. This bit can be reset by writing a 1 to the bit.

12.5.2.4 Register Accessibility During Frame Processing

There are three types of register access in the CCDC:

- Shadowed registers: In the CCDC, two register fields are shadowed in different ways. Shadowed registers can be read and written at any time, but the written values take effect (are latched) only at certain times, based on some event. Reads return the most recent write, even though the settings are not used until the specific event occurs. The shadowed registers are:
 - [CCDC_PCR](#) [0] ENABLE
 - Written values take effect only at the start of a frame event (rising edge of VD if [CCDC_SYN_MODE](#) [2] VDPOL is positive, or falling edge of VD if [CCDC_SYN_MODE](#) [2] VDPOL is negative).
 - [CCDC_SDR_ADDR](#)

- When [CCDC_CFG](#) [15] VDLC is set to 0, written values take effect only at the start of a frame event (rising edge of VD if [CCDC_SYN_MODE](#) [2] VDPOL is positive, or falling edge of VD if [CCDC_SYN_MODE](#) [2] VDPOL is negative). When [CCDC_CFG](#) [15] VDLC is set to 1, written values take effect only at the start of the frame being output to memory (when the input has reached the [CCDC_HORZ_INFO](#) [30:16] SPH pixel of the [CCDC_VERT_START](#) [30:16] SLV0 or [CCDC_VERT_START](#) [14:0] SLV1 line of each field).
- Busy-writable registers: These registers/fields can be read or written even if the module is busy. Changes to the underlying settings occur instantaneously.
All register fields in the CCDC not formerly listed as shadowed or below as optionally shadowed/busy-writable are busy-writable registers.
- Optionally Shadowed/Busy-Writable registers: All registers/fields listed below can be set as either shadow registers or busy-writable registers:
 - When [CCDC_CFG](#) [15] VDLC is 0, these registers are shadowed.
 - When [CCDC_CFG](#) [15] VDLC is 1, these registers are busy-writable.

Note: [CCDC_CFG](#) [15] VDLC must be set to 1 by software if the CCDC is to be used; therefore, these registers are busy-writable. If [CCDC_CFG](#) [15] VDLC remains set to 0 (default), indeterminate results may occur for ANY register access in the CCDC, not just those listed below.

- Optionally shadowed or busy-writable registers
 - [CCDC_SYN_MODE](#) [19] SDR2RSZ
 - [CCDC_SYN_MODE](#) [18] VP2SDR
 - [CCDC_SYN_MODE](#) [16] VDHEN
 - [CCDC_SYN_MODE](#) [17] WEN
 - [CCDC_SYN_MODE](#) [14] LPF
 - [CCDC_HD_VD_WID](#)
 - [CCDC_PIX_LINES](#)
 - [CCDC_HORZ_INFO](#)
 - [CCDC_VERT_START](#)
 - [CCDC_VERT_LINES](#)
 - [CCDC_CULLING](#)
 - [CCDC_HSIZE_OFF](#)
 - [CCDC_SDOFST](#)
 - [CCDC_CLAMP](#) [31] CLAMPEN
 - [CCDC_FMTCFG](#) [0] FMTEN
 - [CCDC_LSC_CONFIG](#)
 - [CCDC_LSC_INITIAL](#)
 - [CCDC_LSC_TABLE_BASE](#)
 - [CCDC_LSC_TABLE_OFFSET](#)

12.5.2.5 Interframe Operations

Between frames, it may be necessary to enable/disable functions or modify memory pointers. Since the [CCDC_PCR](#) register and memory pointer registers are shadowed, these modifications can take place any time before the end of the frame, and the data is latched in for the next frame. The MPU subsystem can perform these changes on receiving an interrupt.

12.5.2.6 CCDC Operations

12.5.2.6.1 Image-Sensor Configuration

12.5.2.6.1.1 Input-Mode Selection

The CCDC module supports two modes: SYNC mode and ITU-R BT.656 mode. Specific settings correspond to each mode.

- SYNC mode:
 - In this mode, the input data can be either raw data or YCbCr data. Setting [CCDC_SYN_MODE](#).INPMODE = 0 selects raw data, and [CCDC_SYN_MODE](#) [13:12] INPMODE = 1 or 2 selects YCbCr data on 16 or 8 bits. If [CCDC_SYN_MODE](#)[13:12] INPMODE = 0, the cam_d signal width is selected through [CCDC_SYN_MODE](#) [10:8] DATSIZ: the possible values are 8, 10, 11, and 12 bits.
 - If [CCDC_SYN_MODE](#) [13:12] INPMODE = 1, the cam_d signal width is 8 bits, but the internal CCDC module data path is configured to 16 bits. It is mandatory to enable the 8- to 16-bit bridge by setting [ISP_CTRL](#) [3:2] PAR_BRIDGE = 2 or 3. The [ISP_CTRL](#) [3:2] PAR_BRIDGE bit also controls how the 8-bit data is mapped onto the 16-bit data.
 - The value set in [CCDC_SYN_MODE](#) [10:8] DATSIZ does not matter. The position of the Y component can be set with the [CCDC_CFG](#) [11] Y8POS bit.
 - If [CCDC_SYN_MODE](#) [13:12] INPMODE = 2, the cam_d signal width is 8 bits. The value set in [CCDC_SYN_MODE](#) [10:8] DATSIZ does not matter. The position of the Y component can be set with the [CCDC_CFG](#) [11] Y8POS bit.
 - The internal timing generator must be enabled with [CCDC_SYN_MODE](#) [16] VDHDEN = 1.
- ITU mode:
 - In this mode, the data follows the protocol set by the ITU-R BT.656 protocol. To select it, set [CCDC_REC656IF](#) [0] R656ON = 1. When this mode is selected, the values set in [CCDC_SYN_MODE](#) [13:12] INPMODE and [CCDC_SYN_MODE](#) [10:8] DATSIZ do not matter.
 - To select the 8-bit or 10-bit protocol, set the [CCDC_CFG](#) [5] BW656 bit field. Data line cam_d [7:0] are used for 8-bit YCbCr and cam_d [9:0] are used for 10-bit YCbCr.
 - FVH error correction is enabled by setting [CCDC_REC656IF](#) [1] ECCFVH = 1.
 - The internal timing generator must be enabled with [CCDC_SYN_MODE](#) [16] VDHDEN = 1.

12.5.2.6.1.2 Timing Generator and Frame Settings

The polarities of the cam_hs, cam_vs and cam_fld signals are controlled by the [CCDC_SYN_MODE](#) [3] HDPOL, [CCDC_SYN_MODE](#) [2] VDPOL, and [CCDC_SYN_MODE](#) [4] FLDPOL bit fields. The polarities can be positive or negative.

The pixel data is presented on cam_d one pixel for every cam_pclk rising edge or falling edge. It is controlled with the [ISP_CTRL](#) [4] PAR_CLK_POL bit.

The [CCDC_SYN_MODE](#) [7] FLDMODE bit fields set the image-sensor type to progressive or interlaced mode. When the sensor is interlaced, the [CCDC_SYN_MODE](#) [15] FLDSTAT status bit indicates whether the current frame is odd or even.

The polarity of the cam_d signal can also be controlled with the [CCDC_SYN_MODE](#) [6] DATAPOL bit field. The polarity can be normal mode or one's complement mode.

Furthermore, the directions of the cam_fld and cam_hs/cam_vs signals are controlled by the [CCDC_SYN_MODE](#) [1] FLDOOUT and [CCDC_SYN_MODE](#) [0] VDHDOUT bits. If [CCDC_SYN_MODE](#) [0] VDHDOUT is set as an output, the [CCDC_PIX_LINES](#) register controls the length of the cam_hs and cam_vs signals.

If [CCDC_SYN_MODE](#) [0] VDHDOUT = 1:

- The HS sync pulse width is given by [CCDC_HD_VD_WID](#) [27:16] HDW. The VS sync pulse width is given by [CCDC_HD_VD](#) [11:0] VDW.
- The HS period is given by [CCDC_PIX_LINES](#) [31:16] PPLN. The VS period is given by [CCDC_PIX_LINES](#) [15:0] HLPF x 2.

Figure 12-45 shows the HS/VS sync pulse output timings.

Figure 12-45. HS/VS Sync Pulse Output Timings

camisp-117

12.5.2.6.1.3 Mosaic Filter Settings

The CCDC module supports image sensors with R, G, and B primary color mosaic filters and Ye, Cy, Mg, and G complementary color mosaic filters. The mosaic filter layout pattern is controlled by the [CCDC_COLPTN](#) register. Each bit field in this register controls the color associated to one pixel in a 4x4 region area. The 4x4 area repeats horizontally and vertically.

[Figure 12-46](#) shows configuration examples of the [CCDC_COLPTN](#) register. It is assumed that CP0LPC0 is the first pixel output and CP3LPC3 is the last pixel output during frame readout.

camisp-088

12.5.2.6.2 Image-Signal Processing

12.5.2.6.2.1 Digital Clamp

Digital clamp is enabled only if optical black clamping is disabled: [CCDC_CLAMP](#) [31] CLAMPEN = 0. The digital clamp DC value to be subtracted from the raw image data ([CCDC_SYN_MODE](#) [13:12] INPMOD = 0) or from the luminance ([CCDC_SYN_MODE](#) [13:12] INPMOD = 0 or [CCDC_REC656IF](#) [0] R656ON = 1) is set with the [CCDC_DCSUB](#) register. The DC value can range from 0 to 212-1. The reset value is 0.

12.5.2.6.2.2 Optical Black Clamping

Optical black clamping is enabled by setting [CCDC_CLAMP](#) [31] CLAMPEN to 1. When enabled, an average of black-pixel samples is computed over a window. If the window's height is 2N, the average value multiplied by a programmable gain factor is subtracted from the raw image data for the following 2N lines. Every 2N lines, a new average value is computed. For the first 2N lines, 0 is subtracted.

The window's size and horizontal position are controlled by the [CCDC_CLAMP](#) register. The window's vertical position is set to line 0 and cannot be modified:

- [CCDC_CLAMP](#) [30:28] OBSLEN sets the horizontal size of the window (1, 2, 4 or 8 pixels).
- [CCDC_CLAMP](#) [27:25] OBSLN sets the vertical size of the window (2N = 1, 2, 4 or 8 lines).
- [CCDC_CLAMP](#) [24:10] OBST sets the horizontal start position of the upper-left corner of the window. It is specified from the start of the HS sync pulse in pixel clocks.

The gain factor is set by the [CCDC_CLAMP](#) [4:0] OBGAIN bit field. Its fixed-point representation is U5Q4; the range is 0 to 1.9375. The gain factor reset value is 1.

If optical-black clamping is disabled, digital clamp is enabled.

12.5.2.6.2.3 Black Compensation

Black compensation applies an offset to the raw image data. The offset is applied according to the phase and color for each phase. The black compensation offsets are controlled by the [CCDC_BLKCOMP](#) register. All offsets are coded in S8Q0 representation (two's complement); the range is -128 to +127.

12.5.2.6.2.4 Faulty-Pixel Correction

Faulty-pixel correction is enabled by setting [CCDC_FPC](#) [15] FPCEN to 1. Before activating faulty-pixel correction, set the number of faulty pixels to be corrected in a frame with the [CCDC_FPC](#) [14:0] FPNUM bit field, set the faulty-pixel LUT in memory, and set the [CCDC_FPC_ADDR](#) register to the LUT address. The address should be aligned to a 64-bit byte boundary; the 6 LSBs are ignored. Reading the register always shows the 6 LSBs as 0.

If the CCDC module cannot fetch the required faulty-pixel entry in time, an error is set in the [CCDC_FPC](#) [16] FPERR bit. After the bit is set, no more faulty pixels are corrected in the frame. The bit is automatically cleared on the end of the frame and the feature reenabled for the following frame.

12.5.2.6.2.5 Lens Shading Compensation

Lens Shading Compensation operates either on a single frame or continuously depending on firmware programming. Upon power-on reset, the LSC module is disabled and input pixels are copied to the output, bypassing any shading operation.

Prior to enabling the LSC module the configuration registers must be initialized.

The SBL data read port is shared between the CCDC shading compensation and PREVIEW dark frame subtract features. The read port must be affected to the PREVIEW module by writing 1 into the [ISP_CTRL](#) [28] SBL_SHARED_RPORTB. Programmers must ensure that the PREVIEW module does not use this port before switching to CCDC module.

The following registers define the gain map organization. They must be configured for correct operation:

- [CCDC_LSC_TABLE_OFFSET](#): Rows length of the gain
- [CCDC_LSC_CONFIG](#) [10:8] GAIN_MODE_N: Vertical downsampling factor
- [CCDC_LSC_CONFIG](#) [14:12] GAIN_MODE_M: Horizontal downsampling factor
- [CCDC_LSC_CONFIG](#) [3:1] GAIN_FORMAT: Gain map samples coding

Firmware chooses the position of the LSC module in the data flow using the [CCDC_LSC_CONFIG](#) [6] AFTER_REFORMATTER register. Image framing is set using the registers listed below:

- Before data reformatter. Framing is applied to the image received from the sensor.
 - [CCDC_FMT_HORZ](#)[28:16] FMTSPH: First horizontal pixel from HS sync pulse
 - [CCDC_FMT_HORZ](#)[12:0] FMTLNH: Number of pixels in horizontal direction
 - [CCDC_FMT_VERT](#)[28:16] FMTSLV: First line from VS sync pulse
 - [CCDC_FMT_VERT](#)[12:0] FMTLNV: Number of lines
- After data reformatter. Framing is applied to the image received from data formatter. Therefore the frame size depends on data reformatter settings.
 - [CCDC_VP_OUT](#)[30:17] VERT_NUM: Number of lines
 - [CCDC_VP_OUT](#)[16:4] HORZ_NUM: Number of pixels in horizontal direction
 - [CCDC_VP_OUT](#)[3:0] HORZ_ST: First horizontal pixel

[CCDC_LSC_TABLE_BASE](#) must point to the first used gain sample. The first pixels phase is defined by the [CCDC_LSC_INITIAL](#) [5:0] X and [CCDC_LSC_INITIAL](#) [21:16] Y registers. They must be consistent with the gain map organization and the defined framing.

When [CCDC_LSC_CONFIG](#) [0] ENABLE bit is written 1, the LSC module starts operation by prefetching needed gain entries from external memory, and when the active region starts, appropriate gains are applied to the image pixels. Refer to for more details on gain map organization.

When the LSC module reaches the last N lines of the input image (with respect to starting gain map point, which may or may not coincide with starting of active region of image), it detects the [CCDC_LSC_CONFIG](#) [0] ENABLE bit. If [CCDC_LSC_CONFIG](#) [0] ENABLE = 1, it starts prefetching gain entries for the next frame and wait for the active region of next frame to arrive. If [CCDC_LSC_CONFIG](#) [0] ENABLE = 0, it stops LSC operation once the active region is passed, and goes into idle until [CCDC_LSC_CONFIG](#) [0] ENABLE is written 1 again. To provide a mechanism for firmware to recover from LSC module waiting for input image indefinitely, if [CCDC_LSC_CONFIG](#) [0] ENABLE is written 0 after it has started gain map prefetching, but before LSC gets to the next active region, LSC operation is aborted and turned idle, with any prefetched gain entries are discarded. This can happen before or after the next start of frame.

LSC registers are optionally shadowed. When they are shadowed they can be modified at any time. The new value is taken into account for the next frame. Otherwise the module must be disabled ([CCDC_LSC_CONFIG](#) [0] ENABLE=0) prior to changing non shadowed registers.

12.5.2.6.2.6 Data Formatter

The data formatter transforms movie mode readout patterns into Bayer readout patterns. It is enabled by setting [CCDC_FMTCFG](#) [0] FMTEN to 1.

The [CCDC_FMT_HORZ](#) and [CCDC_FMT_VERT](#) registers set a clip window at the input of the data reformatter.

The data formatter converts a single line of movie mode sensor into multiple Bayer lines; it is capable of transforming 1 input line into 1, 2, 3, or 4 output lines. The number of lines generated from one input line is set by the [CCDC_FMTCFG](#) [3:2] LNUM bit field. The following limitations apply:

- The maximum number of pixels that can be supported in an output line if the input line is transformed into 1 output line is 4x1376 (1376 is the limit of the line memory).
- The maximum number of pixels that can be supported in an output line if the input line is transformed into 2 output lines is 2x1376.
- The maximum number of pixels that can be supported in an output line if the input line is transformed into 3 output lines is 1376.
- The maximum number of pixels that can be supported in an output line if the input line is transformed into 4 output lines is 1376.

The data reformatter gets its flexibility from up to 8 different addresses and a program that can contain up to 16 entries each for the odd and even lines. The program length for even fields is set with the [CCDC_FMTCFG](#) [11:8] PLEN_EVEN bit field. The program length for odd fields is set with the [CCDC_FMTCFG](#) [7:4] PLEN_ODD bit fields. Each entry refers to one of the 8 addresses and supports autoincrement and autodecrement.

- The 8 addresses are controlled by the [CCDC_FMT_ADDRx](#) registers (x = 0 to 7).
- The 16 program entries for even lines are controlled by the [CCDC_PRGEVEN0](#) and [CCDC_PRGEVEN1](#) registers. The 16 program entries for odd lines are controlled by the [CCDC_PRGODD0](#) and [CCDC_PRGODD1](#) registers.

Modulo addressing is used to access the program entries. Even input lines use the even program and odd input lines use the odd program. Each new pixel in a line uses one program entry.

The [CCDC_VP_OUT](#) register sets the frame size at the output of the video port.

Example 1: Conventional readout pattern: 1 input line = 1 output line

The following input-to-output mapping (see [Table 12-39](#)) corresponds to a conventional readout pattern. One input line corresponds to 1 output line; the output can be as large as 4x1376 pixels.

Table 12-39. Conventional Readout Pattern 1 to 1

Input	Pixels order in input line								
Line [I]	0	1	2	3	[...]	5500	5501	5502	5503
Output	Pixels order in output line								
Line [I]	0	1	2	3	[...]	5500	5501	5502	5503

To obtain this mapping between the input and output pixels, the following settings apply:

- [CCDC_FMTCFG](#) [3:2] LNUM = 0 Converts to 1 line
- [CCDC_FMTCFG](#) [11:8] PLEN_EVEN = 0 1 program entry
- [CCDC_FMTCFG](#) [7:4] PLEN_ODD = 0 1 program entry
- [CCDC_FMT_ADDRx](#) [25:24] LINE (x = 0) = 0 Init ADDR0 pointer to 0th line
- [CCDC_FMT_ADDRx](#) [12:0] INIT (x = 0) = 0 Init ADDR0 index to 0th pixel
- [CCDC_PRGEVEN0](#) [3:0] EVEN0 = 0 Even prog entry 0: ADDR0++
- [CCDC_PRGODD0](#) [3:0] ODD0 = 0 Odd prog entry 0: ADDR0++
- [CCDC_VP_OUT](#) [3:0] HORZ_ST = 0 Horizontal start

- **CCDC_VP_OUT** [16:4] **HORZ_NUM** = 0 Horizontal size

The program for even and odd lines is executed as follows. Since there is only one program entry, this instruction is executed repeatedly.

```
ADDR0= (0, 0)
While not end_of_line
{
Write
    incoming pixel to ADDR0
ADDR0+=(1,0)
}
```

Example 2: Dual readout pattern: 1 input line = 1 output line

The following input-to-output mapping (see [Table 12-40](#)) corresponds to a conventional dual readout pattern. One input line corresponds to 1 output line; the output can be as large as 4x1376 pixels.

Table 12-40. Dual Readout Pattern 1 to 1

Input	Pixels order in input line								
Line [I]	0	1	2	3	[...]	4092	4093	4094	4095
Output	Pixels order in output line								
Line [I]	0	2	4	6	[...]	7	5	3	1

To obtain this mapping between the input and output pixels, the following settings apply:

- **CCDC_FMTCFG** [3:2] **LNUM** = 0 Converts to 1 line
- **CCDC_FMTCFG** [11:8] **PLEN_EVEN** = 1 2 program entry
- **CCDC_FMTCFG** [7:4] **PLEN_ODD** = 1 2 program entry
- **CCDC_FMT_ADDRx** [25:24] **LINE** (x = 0) = 0 Init ADDR0 pointer to 0th line
- **CCDC_FMT_ADDRx** [12:0] **INIT** (x = 0) = 0 Init ADDR0 index to 0th pixel
- **CCDC_FMT_ADDRx** [25:24] **LINE** (x = 1) = 0 Init ADDR1 pointer to 0th line
- **CCDC_FMT_ADDRx** [12:0] **INIT** (x = 1) = 4095 Init ADDR1 index to 4095th pixel
- **CCDC_PRGEVEN0** [3:0] **EVEN0** = 0 Even prog entry 0: ADDR0++
- **CCDC_PRGEVEN0** [7:4] **EVEN1** = 3 Even prog entry 1: ADDR1- -
- **CCDC_PRGODD0** [3:0] **ODD0** = 0 Even prog entry 0: ADDR0++
- **CCDC_PRGODD0** [7:4] **ODD1** = 3 Even prog entry 1: ADDR1- -
- **CCDC_VP_OUT** [3:0] **HORZ_ST** = 0 Horizontal start
- **CCDC_VP_OUT** [16:4] **HORZ_NUM** = 0 Horizontal size

```
ADDR0=(0,0)
ADDR1=(4095,0)
While not
    end_of_line
{
Write incoming pixel to ADDR0
ADDR0+= (1,0)
Write incoming pixel to ADDR1
ADDR1 -= (1,0)
}
```

Example 3: Dual readout pattern: 1 input line = 3 output line

The following input-to-output mapping (see [Table 12-41](#)) corresponds to a complex pattern. One input line corresponds to 3 output lines; the output can be as large as 1376 pixels.

Table 12-41. Dual Readout Pattern 1 to 3

Input	Pixels order in input line								
Line [i]	0	1	2	3	4	5	6	7	8
	9	10	11	[...]					
Output	Pixels order in output line								
Line [3i]			0	6	[...]	23	17	11	5
Line [3i + 1]		2	8	14	[...]	15	9	3	
Line [3i + 2]	4	10	16	22	[...]	7	1		

To obtain this mapping between the input and output pixels, the following settings apply:

- **CCDC_FMTCFG** [3:2] LNUM = 2 Converts to 3 lines
- **CCDC_FMTCFG** [11:8] PLEN_EVEN = 5 6 program entries
- **CCDC_FMTCFG** [7:4] PLEN_ODD = 5 6 program entries
- **CCDC_FMT_ADDRx** [25:24] LINE (x = 0) = 0 Init ADDR0 pointer to 0th line
- **CCDC_FMT_ADDRx** [12:0] INIT (x = 0) = 2 Init ADDR0 index to 2nd pixel
- **CCDC_FMT_ADDRx** [25:24] LINE (x = 1) = 2 Init ADDR1 pointer to 2nd line
- **CCDC_FMT_ADDRx** [12:0] INIT (x = 1) = 855 Init ADDR1 index to 855th pixel
- **CCDC_FMT_ADDRx** [25:24] LINE (x = 2) = 1 Init ADDR2 pointer to first line
- **CCDC_FMT_ADDRx** [12:0] INIT (x = 2) = 1 Init ADDR2 index to first pixel
- **CCDC_FMT_ADDRx** [25:24] LINE (x = 3) = 1 Init ADDR3 pointer to first line
- **CCDC_FMT_ADDRx** [12:0] INIT (x = 3) = 856 Init ADDR3 index to 856th pixel
- **CCDC_FMT_ADDRx** [25:24] LINE (x = 4) = 2 Init ADDR4 pointer to second line
- **CCDC_FMT_ADDRx** [12:0] INIT (x = 4) = 0 Init ADDR4 index to 0th pixel
- **CCDC_FMT_ADDRx** [25:24] LINE (x = 5) = 0 Init ADDR5 pointer to 0th line
- **CCDC_FMT_ADDRx** [12:0] INIT (x = 5) = 857 Init ADDR5 index to 857th pixel
- **CCDC_PRGEVEN0** [3:0] EVEN0 = 0 Even prog entry 0: ADDR0++
- **CCDC_PRGEVEN0** [7:4] EVEN1 = 3 Even prog entry 1: ADDR1- -
- **CCDC_PRGEVEN0** [11:8] EVEN2 = 4 Even prog entry 2: ADDR2++
- **CCDC_PRGEVEN0** [15:12] EVEN3 = 7 Even prog entry 3: ADDR3- -
- **CCDC_PRGEVEN0** [19:16] EVEN4 = 8 Even prog entry 4: ADDR4++
- **CCDC_PRGEVEN0** [23:20] EVEN5 = 11 Even prog entry 4: ADDR5- -
- **CCDC_PRGODD0** [3:0] ODD0 = 0 Even prog entry 0: ADDR0++
- **CCDC_PRGODD0** [7:4] ODD1 = 3 Even prog entry 1: ADDR1- -
- **CCDC_PRGODD0** [11:8] ODD2 = 4 Even prog entry 2: ADDR2++
- **CCDC_PRGODD0** [15:12] ODD3 = 7 Even prog entry 3: ADDR3- -
- **CCDC_PRGODD0** [19:16] ODD4 = 8 Even prog entry 4: ADDR4++
- **CCDC_PRGODD0** [23:20] ODD5 = 11 Even prog entry 4: ADDR5- -
- **CCDC_VP_OUT** [3:0] HORZ_ST = 2 Horizontal start, excludes first 2 pixels
- **CCDC_VP_OUT** [16:4] HORZ_NUM = 854 Horizontal size

```

ADDR0=(2,0)
ADDR1=(855,2)
ADDR2=(1,1)
ADDR3=(856,1)
ADDR4=(0,2)
ADDR5=(857,0)
While
    not end_of_line
{
Write incoming pixel to
    ADDR0
ADDR0 += (1, 0)
Write incoming pixel to
    ADDR1
ADDR1 -= (1, 0)
Write incoming pixel to
    ADDR2
ADDR2 += (1, 0)
Write incoming pixel to
    ADDR3
ADDR3 -= (1, 0)
Write incoming pixel to
    ADDR4
ADDR4 += (1, 0)
Write incoming pixel to
    ADDR5
ADDR5 -= (1, 0)
}

```

Video Port

The 10-bit video-port output is enabled with [CCDC_FMTCFG](#) [15] VPEN = 1. Since the input data can be up to 12 bits, one has to select which 10 bits are selected with [CCDC_FMTCFG](#) [14:12] VPIN.

The output of the video port goes to the Preview module. At the output of the video port, the data rate is resynchronized; the [CCDC_FMTCFG](#) [18:16] VPIF_FRQ bit field selects the video-output data rate (from L3/2 MHz to L3/6 MHz). If [CCDC_FMTCFG](#) [18:16] VPIF_FRQ frequency is set too low compared to the input pixel clock, overflow can occur.

12.5.2.6.2.7 Output Formatter

12.5.2.6.2.7.1 Low-Pass Filter

The low-pass filter is enabled with the [CCDC_SYN_MODE](#) [14] LPF bit. When enabled, two pixels each in the left and right edges of each line are cropped from the output.

12.5.2.6.2.7.2 A-Law Compression

A-Law compression is enabled by setting [CCDC_ALAW](#) [3] CCDTBL to 1. The A-Law table is fixed, so no setup is required. When the input is wider than 10 bits, the [CCDC_ALAW](#) [2:0] GWDI bit is used to select which 10 bits of the 12 possible bits are selected for compression. See [Table 12-42](#).

Table 12-42. CCDC_ALAW [2:0] GWDI

GWDI	Description
4	Bits 11 to 2
5	Bits 10 to 1
6	Bits 9 to 0
Others	Reserved

12.5.2.6.2.7.3 Culling

Culling performs a horizontal and vertical decimation function. The horizontal and vertical culling patterns are set by the [CCDC_CULLING](#) register.

- The 8-bit [CCDC_CULLING](#) [31:24] CULHEVN and [CCDC_CULLING](#) [23:16] CULHODD bit fields set the horizontal culling pattern for even and odd lines. A 1 means that the pixel is retained; a 0 means that the pixel is skipped. The same number of retained pixels must be set for even and odd lines.
- The 8-bit [CCDC_CULLING](#) [7:0] CULV bit field sets the vertical culling pattern. The LSB represents the top line and the MSB represents the bottom line. A 1 means that the line is retained; a 0 means that the line is skipped.

12.5.2.6.2.7.4 Data Packing

Pixel data are stored to memory in little-endian format (bytes at lower addresses have lower significance). By default, pixel data are stored in 16-bit words; unused bits are filled with zeros.

If the input data is 8 bits, or if A-Law compression is enabled, one can store the data into 8-bit words by setting [CCDC_SYN_MODE](#) [11] PACK8 to 1.

If the input data is 12, 11, 10, or 9 bits, and A-Law compression is not enabled, the 8 MSBs are stored to memory.

[Figure 12-47](#) shows data packing and pixel ordering.

Figure 12-47. Data Packing - Pixel Ordering

	3 1	2 4	1 5	0 7	0 0
12 bits	0	pix 1	0	pix 0	
11 bits	0	pix 1	0	pix 0	
10 bits	0	pix 1	0	pix 0	
9 bits	0	pix 1	0	pix 0	
8 bits	0	pix 1	0	pix 0	
8 bits packed	pix3	pix 2	pix 1	pix 0	

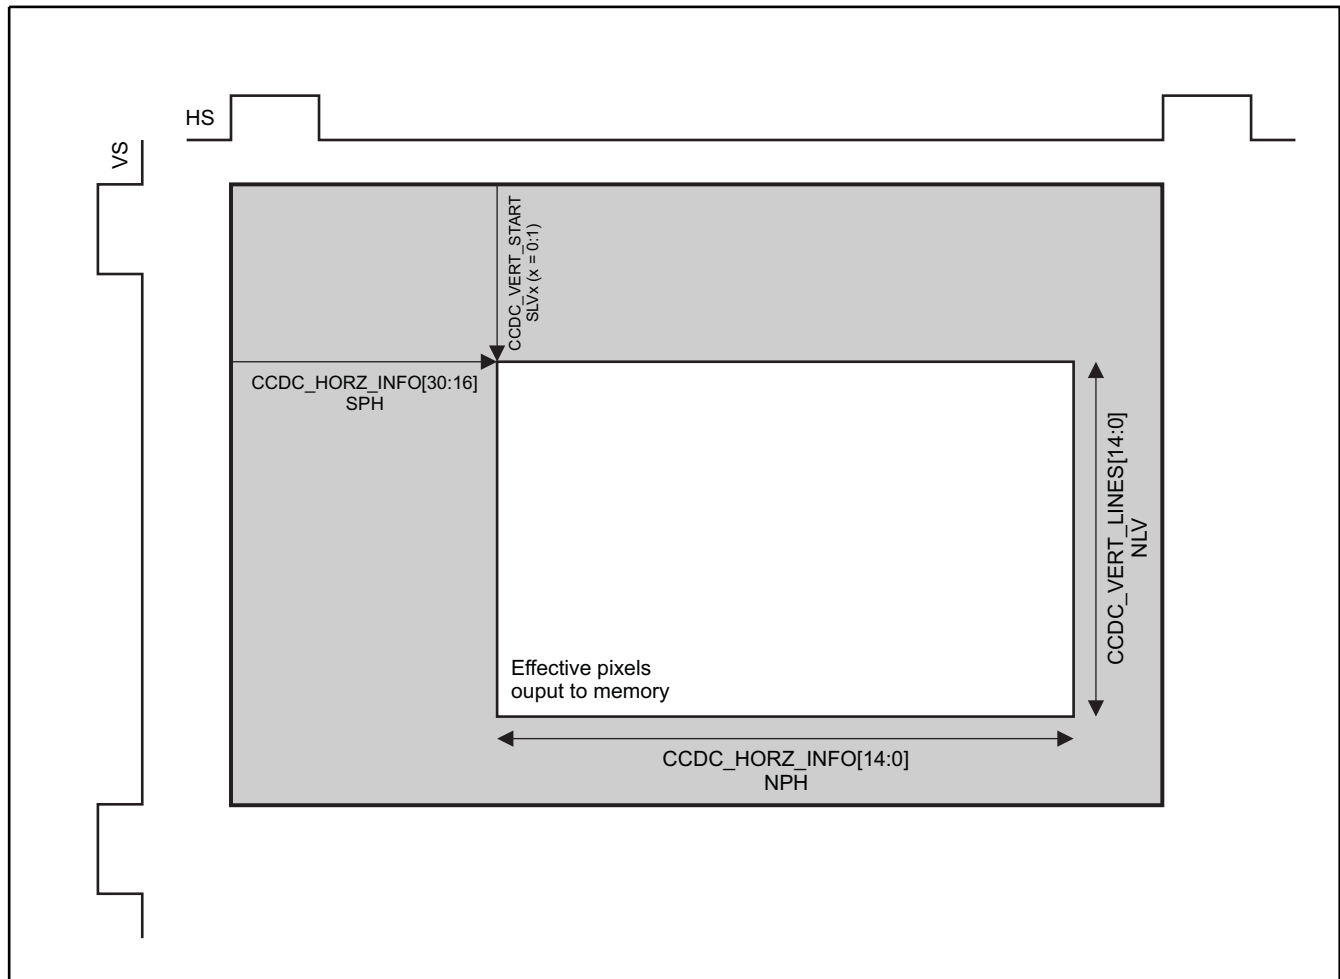

camisp-118

12.5.2.6.2.7.5 Clipping Window

Before data is stored in memory, one can set a clipping window; only a selected sensor area is stored to memory. [Figure 12-48](#) shows the settings; only the white area is stored to memory.

- The valid-data horizontal start position is controlled with the [CCDC_HORZ_INFO](#) [30:16] SPH bit field. The valid-data vertical start position is controlled with the [CCDC_VERT_START](#) register. If the sensor is interlaced, the vertical start position for even and odd fields can be configured independently with the [CCDC_VERT_START](#) register. If the sensor is progressive, the [CCDC_VERT_START](#) [14:0] SLV1 bit field is ignored.
- The valid-data horizontal size is controlled with the [CCDC_HORZ_INFO](#) [14:0] NPH bit field. The horizontal size must be a multiple of 16 pixels. The valid-data vertical size is controlled with the [CCDC_VERT_LINES](#) [14:0] NLV register.

Figure 12-48. Clipping Window Before Output to Memory

camisp-119

12.5.2.6.2.7.6 Output to Memory

The output formatter memory write enable is controlled by the [CCDC_SYN_MODE](#) [17] WEN bit. The output of the data reformatter can be written to memory by setting [CCDC_SYN_MODE](#) [18] VP2SDR to 1.

The pixel data at the output of the output formatter is written to the address given by the [CCDC_SDR_ADDR](#) register. The address should be aligned on a 32-byte boundary. The 5 LSBs are ignored. Reading the register always shows the 5 LSBs as 0.

A destination pitch can be set with the [CCDC_HSIZE_OFF](#) register. The offset must be a multiple of 32 bytes. The 5 LSBs are ignored. Reading the register always shows the 5 LSBs as 0. It is required for the pixel line length to be a multiple of 32 bytes to be stored in memory without holes.

The [CCDC_SDOFST](#) register controls how the pixels are stored to memory.

Data to be written to memory can be qualified by the external `cam_wen` signal. This feature can be enabled by setting the [CCDC_SYN_MODE](#) [5] EXWEN bit. The [CCDC_CFG](#) [8] WENLOG bit configures how the `cam_wen` signal is used with the internally generated valid signal.

The data can be swapped on a byte basis with the [CCDC_CFG](#) [12] BSWD bit.

If [CCDC_SYN_MODE](#) [13:12] INPMOD = 1, the MSB of the 8-bit chroma component can be inverted by setting [CCDC_CFG](#) [13] MSBINVI to 1.

12.5.2.7 Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the CCDIC. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- If the memory output port is enabled, the memory output line offset and address should be on 32-byte boundaries.
- If faulty-pixel correction is enabled, the [CCDC_FPC_ADDR](#) address should be on a 64-byte boundary.
- External WEN cannot be used when the VP2SDR path is enabled.
- If the formatter is enabled, in line-alternating mode, the vertical start and end number should be even.
- The horizontal number for the video port must be $\leq 1376 \times 4$.
- If the video port is enabled, [CCDC_VP_OUT](#) [30:17] VERT_NUM must be [CCDC_FMT_VERT](#) [12:0] FMTLNV.
- The video port must be enabled if the formatter is enabled.
- In YCC input mode:
 - The [CCDC_COLPTN](#) must be set to 0s.
 - The [CCDC_BLKCMP](#) must be set to 0s.
 - Faulty-pixel correction must be disabled.
 - The video port must be disabled.
 - The formatter must be disabled.
 - The VP2SDR must be disabled.
 - The low-pass filter must be disabled.
 - The A-Law must be disabled.
- In RAW input mode, the resizer output path should not be enabled.

12.5.3 Programming the Preview Engine

This section discusses issues related to software control of the preview engine. It lists which registers are required to be programmed in different modes, how to enable and disable the preview engine, and how to check the status of the preview engine; discusses the different register access types; and enumerates programming constraints.

12.5.3.1 Preview Hardware Setup/Initialization

This section discusses the configuration of the preview engine required before image processing can begin.

12.5.3.1.1 Reset Behavior

On hardware reset of the camera ISP, all registers in the preview engine are reset to their reset values. However, since the preview engine programmable tables (gamma, noise filter, luminance enhancer, and CFA coefficients) are stored in internal memory, their contents do not have reset values. If the reset is a chip-level power-on reset (reset after power is applied), the contents of these tables are unknown. If the reset is a camera ISP module reset (when power remains active), the contents of these tables remain the same as before the reset.

12.5.3.1.2 Register Setup

Before enabling the preview engine, the hardware must be correctly configured through register writes. [Table 12-43](#) identifies the register parameters that must be programmed before enabling the preview engine.

Table 12-43. Preview Engine Required Configuration Parameters

Function	Configuration Required
Function enable/disable	PRV_PCR [5] INVALAW PRV_PCR [7] DRKFCAP PRV_PCR [6] DRKFEN PRV_PCR [21] SCOMP_EN PRV_PCR [8] HMEDEN PRV_PCR [9] NFEN PRV_PCR [10] CFAEN PRV_PCR [26] GAMMA_BYPASS PRV_PCR [15] YNENHEN PRV_PCR [16] SUPEN PRV_PCR [27] DCOREN
I/O ports	PRV_PCR [2] SOURCE PRV_PCR [20] SDRPORT PRV_PCR [19] RSZPORT
Input size	PRV_HORZ_INFO PRV_VERT_INFO
Averager	PRV_AVE
White balance	PRV_PCR [14:11] CFAFMT PRV_WB_DGAIN PRV_WBGAIN PRV_WBSEL
Black adjustment	PRV_BLKADJOFF
RGB-to-RGB blending	PRV_RGB_MAT1 to PRV_RGB_MAT5 PRV_RGB_OFF1 to PRV_RGB_OFF2
RGB-to-YCbCr conversion	PRV_CSC0 to PRV_CSC2
Contrast and brightness	PRV_CNT_BRT
YCC output format	PRV_SETUP_YC PRV_PCR [18:17] YCPOS

The [PRV_PCR](#) register contains control bits that enable or disable optional functions and module I/O ports. If an optional function or port is enabled, there may be more registers or configuration information required for the preview engine to operate correctly.

[Table 12-44](#) can be read as:

If (**Condition** is TRUE) then

Configuration required parameters must be programmed.

Table 12-44. Preview Engine Conditional Configuration Parameters

Function	Condition	Configuration Required
Read from CCDC	PRV_PCR [2] SOURCE = 0x0	PRV_PCR [3] ONESHOT
Read from memory	PRV_PCR [2] SOURCE = 0x1	PRV_PCR [4] WIDTH PRV_RSDR_ADDR PRV_RADR_OFFSET ISP_CTRL [27] SBL_SHARED_RPORTA
Dark frame subtract	PRV_PCR [6] DRKFEN = 0x1	PRV_DSDR_ADDR PRV_DRKF_OFFSET ISP_CTRL [28] SBL_SHARED_RPORTB Dark frame must be in memory

Table 12-44. Preview Engine Conditional Configuration Parameters (continued)

Function	Condition	Configuration Required
Shading correction	PRV_PCR [21] SCOMP_EN = 0x1 && PRV_PCR [6] DRKFEN = 0x1	PRV_PCR [24:22] SCOMP_SFT PRV_DSDR_ADDR PRV_DRKF_OFFSET Dark frame must be in memory
Horizontal median filter	PRV_PCR [8] HMEDEN = 0x1	PRV_HMED
Noise filter	PRV_PCR [9] NFEN = 0x1	PRV_NF [1:0] SPR Setup Noise Filter Tables
Defect correction	PRV_PCR [27] DCOREN = 0x1	PRV_PCR [28] DCOR_METHOD PRV_CDC_THRx (x = 0 to 3)
CFA interpolation	PRV_PCR [10] CFAEN = 0x1	PRV_CFA Setup CFA Coefficient Table
Gamma correction	PRV_PCR [26] GAMMA_BYPASS = 0x0	Setup Gamma Correction Tables
Luminance enhancement	PRV_PCR [15] YNENHEN = 0x1	Setup Luminance Enhancement Table
Chrominance suppression	PRV_PCR [16] SUPEN = 0x1	PRV_CSUP
Write to memory	PRV_PCR [20] SDRPORT = 0x1	PRV_WSDR_ADDR PRV_WADD_OFFSET

12.5.3.1.3 Table Setup

The three gamma memories, noise filter threshold memory, noise filter strength memory, luminance enhancer memory, and the CFA coefficient memory must be filled in before the operation of the preview engine, if their respective functions are enabled.

Two registers allow memory contents to be read and written:

- The address register is used to select the specific table entry: [PRV_SET_TBL_ADDR](#).
- The data register contains the data to be written to the specified location: [PRV_SET_TBL_DATA](#).

While the data register is 20 bits wide, only the 8 LSB data is used for the gamma, noise filter, and CFA filter tap memories. [Table 12-45](#) identifies the addressing range for each memory provided in the preview engine.

Table 12-45. Preview Engine Memory Address Ranges

Start	End	Bit Width	Memory
0x0000	0x03FF	8	Red gamma table
0x0400	0x07FF	8	Green gamma table
0x0800	0x0BFF	8	Blue gamma table
0x0C00	0x0C1F	10	NF threshold table 32x10
0x0C20	0x0C3F	5	NF strength table 32x5
0x1000	0x107F	20	Non-linear enhancement table
0x1400	0x163F	8	CFA filter coefficient table

The preview engine supports linear increments on reads and writes automatically. The following examples show how the programmer can read/write the memory. If data is read/written, the address pointer is automatically incremented. For random/noncontiguous reads/writes, [PRV_SET_TBL_ADDR](#) register must be modified.

Note: The address is not autoincremented when the preview engine is busy and users try to read/write the tables.

Example:

Read/write all the entries of the CFA table (using linear increment):

- WRITE (SET_TBL_ADDR, 0x1400);
- READ (SET_TBL_DATA, 0xvalue1);
- WRITE (SET_TBL_DATA, 0xvalue2);
- READ (SET_TBL_DATA, 0xvalue3);
- Etc. . . .
- READ (SET_TBL_DATA, 0xvalue163F);

Read/write selective entries of the tables (have to program the address separately for each read/write)

- WRITE (SET_TBL_ADDR, 11);
- READ (SET_TBL_DATA, value11);
- WRITE (SET_TBL_ADDR, 564);
- WRITE (SET_TBL_DATA, value564);

12.5.3.2 Enable/Disable Hardware

Setting the [PRV_PCR](#) [0] ENABLE bit to 0x1 enables the preview engine. This must be done after all required registers and tables are programmed.

When the input source is the memory, the preview engine always operates in one-shot mode. In other words, after enabling the preview engine, the ENABLE bit is automatically turned off (set to 0) and only a single frame is processed from memory. In this mode, fetching and processing of the frame begin immediately on setting the ENABLE bit.

When the input source is the CCDC, the preview engine can be configured to operate in either one-shot mode or continuous mode ([PRV_PCR](#) [3] ONESHOT). Processing of the frame is depends on the timing of the CCDC. To ensure that data from the CCDC is not missed, the preview engine must be enabled before the CCDC so that it waits for CCDC data.

Note: In one-shot mode, on setting the ENABLE bit, the processing of the frame begins and the ENABLE, ONESHOT, and SOURCE bits are reset to their reset values.

When the preview engine is in continuous mode, it can be disabled by clearing the ENABLE bit during the processing of the last frame. The disable is latched in at the end of the frame in which it is written.

12.5.3.3 Events and Status Checking

The preview engine generates an interrupt at the end of each frame.

The status of this interrupt can be checked by reading the [ISP_IRQ0STATUS](#) register (or [ISP_IRQ1STATUS](#)). When the read of the register [ISP_IRQ0STATUS](#) occurs (or [ISP_IRQ1STATUS](#)), the register is not automatically reset. To reset the interrupt, a 1 must be written to the PRV_DONE_IRQ bit.

Each event that generates an interrupt can be individually mapped to ARM or DSP using the [ISP_IRQ0ENABLE](#) register (or [ISP_IRQ1ENABLE](#)). When a particular event is not enabled (for example [ISP_IRQ0ENABLE](#)[x] = 0), the correspondent status ([ISP_IRQ0STATUS](#) [x] = 1) bit is flagged if the correspondent event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

The [PRV_PCR](#) [1] BUSY status bit is set when the start of frame occurs (if the [PRV_PCR](#) [0] ENABLE bit is 1 at that time). It is automatically reset to 0 at the end of a frame. The [PRV_PCR](#) [1] BUSY status bit may be polled to determine end-of-frame status.

The [PRV_PCR](#) [31] DRK_FAIL status bit is set when dark-frame data fetched from memory arrives late. This bit can be reset by writing a 1 to the bit.

12.5.3.4 Register Accessibility During Frame Processing

There are three types of register access in the preview engine.

- Shadow registers: These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame. Reads return the most recent write, even though the settings are not used until the next start of frame.

The shadowed registers are:

- [PRV_PCR](#)
- [PRV_RSDR_ADDR](#)
- [PRV_RADR_OFFSET](#)
- [PRV_DSDR_ADDR](#)
- [PRV_DRKF_OFFSET](#)
- [PRV_WSDR_ADDR](#)
- [PRV_WADD_OFFSET](#)

- Busy-writable registers: These registers/fields can be read or written even if the module is busy. Changes to the underlying settings occur instantaneously.

The busy-writable registers are:

- [PRV_WB_DGAIN](#)
- [PRV_WBGAIN](#)

- Busy-lock registers:
 - All registers EXCEPT the shadow and busy-writable registers belong to this category. Busy-lock registers cannot be written when the module is busy. Writes are allowed, but no change occurs in the registers (blocked writes from hardware perspective, but allowed writes from software perspective).
 - After the [PRV_PCR](#) [1] BUSY bit is reset to 0, busy-lock registers can be written.
 - The [PRV_SET_TBL_DATA](#) register cannot be read when the preview engine is busy, because this register is mapped to memories internally. Such reads return indeterminate data. Byte enables are not implemented for reading preview engine memories.

The ideal procedure for changing the preview engine registers is:

IF ([PRV_PCR](#) [1] BUSY == 0) OR IF
(EOF interrupt occurs)

DISABLE PREVIEW ENGINE

CHANGE REGISTERS

ENABLE PREVIEW ENGINE

12.5.3.5 Interframe Operations

Between frames, it may be necessary to enable/disable functions or modify memory pointers. Since the [PRV_PCR](#) register and memory pointer registers are shadowed, these modifications can occur any time before the end of the frame, and the data is latched in for the next frame. The MPU Subsystem can perform these changes on receiving an interrupt.

12.5.3.6 Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the preview engine. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- A frame can only be read from memory when the SBL read port is affected to the PREVIEW module ([ISP_CTRL](#) [27] SBL_SHARED_RPORTA=0)
- The shading compensation feature can only be used when the SBL read port is affected to the PREVIEW module ([ISP_CTRL](#) [28] SBL_SHARED_RPORTB=0)
- The first input pixel must be the RED pixel, for the register names to be aligned with the appropriate colors.
- If the memory output port is enabled, the memory output line offset and address should be on 32-byte boundaries.
- The output width must be less than or equal to 3312.
- The output width must be even.
- Input to the horizontal median filter must be even.
- The horizontal median filter and noise filter should not be enabled for Foveon formatted input.
- Defect correction can only be used when noise filter is enabled
- Input height must be smaller than CCDC output height.
- The input width of the preview engine must be a multiple of the average count multiplied by the least common multiple of the odd distance and even distance of the averager.
 - ([PRV_HORZ_INFO](#) [13:0] EPH - [HORZ_INFO](#) [29:16] SPH + 1) MOD ((1 [PRV_AVE](#) [1:0] COUNT)*LeastCommonMultiple([PRV_AVE](#) [5:4] ODDDIST+1, [PRV_AVE](#) [3:2] EVENDIST+1)) = 0
- Input width must be at least 4 pixels smaller than CCDC output width:
 - [PRV_HORZ_INFO](#) [29:16] SPH at least 2 pixels before last pixel from CCDC
 - [PRV_HORZ_INFO](#) [13:0] EPH at least 2 pixels before last pixel from CCDC

12.5.4 Programming the Resizer

This section discusses issues related to software control of the resizer. It lists which registers are required to be programmed in different modes, how to enable and disable the resizer, and how to check the status of the resizer; discusses the different register access types; and enumerates programming constraints.

12.5.4.1 Resizer Hardware Setup/Initialization

This section discusses the configuration of the resizer required before image processing can begin.

12.5.4.1.1 Reset Behavior

On hardware reset of the camera ISP, all registers in the resizer are reset to their reset values.

12.5.4.1.2 Register Setup

Before enabling the resizer, the hardware must be correctly configured through register writes.

[Table 12-46](#) identifies the register parameters that must be programmed before enabling the resizer.

Table 12-46. Resizer Required Configuration Parameters

Function	Configuration Required
Resizer control parameters	RSZ_CNT
I/O sizes	RSZ_OUT_SIZE
	RSZ_IN_START
	RSZ_IN_SIZE

Table 12-46. Resizer Required Configuration Parameters (continued)

Function	Configuration Required
Memory addresses	RSZ_SDR_INADD RSZ_SDR_INOFF RSZ_SDR_OUTADD RSZ_SDR_OUTOFF
Filter coefficients	RSZ_HFILT10 to RSZ_HFILT3130 RSZ_VFILT10 to RSZ_VFILT3130
Edge enhancement	RSZ_YENH [17:16] ALG0

The edge-enhancement function is optional:

- If it is disabled, the rest of the [RSZ_YENH](#) register does not need to be programmed.
- If it is enabled, the edge-enhancement parameters in [Table 12-47](#) must be programmed so that the edge-enhancement function operates correctly.

[Table 12-47](#) can be read as:

If (**Condition** is TRUE) then

Configuration required parameters must be programmed.

Table 12-47. Resizer Conditional Configuration Parameters

Function	Condition	Configuration Required
Edge enhancement	RSZ_YENH [17:16] ALG0 = 0x1 or 0x2	RSZ_YENH [15:12] GAIN RSZ_YENH [11:8] SLOP RSZ_YENH [7:0] CORE

12.5.4.2 Enable/Disable Hardware

Setting the [RSZ_PCR](#) [0] ENABLE bit to 0x1 enables the resizer. This must be done after all required registers are programmed.

When the input source is memory, the resizer always operates in one-shot mode. In other words, after enabling the resizer, the [RSZ_PCR](#) [0] ENABLE bit is automatically turned off (set to 0) and only a single frame is processed from memory.

In this mode, fetching and processing of the frame begin immediately on setting the [RSZ_PCR](#) [0] ENABLE bit.

When the input source is the CCDC or preview engine, the Resizer can be configured to operate in either one-shot mode, or continuous mode ([RSZ_PCR](#) [2] ONESHOT). Processing of the frame depends on the timing of the CCDC/Preview. To ensure that data from the CCDC or preview engine is not missed, the resizer must be enabled before to these upstream modules, so it waits for data from the CCDC or the preview engine.

When the resizer is started during an ongoing frame the enable is latched at the end of the frame it was written in.

When the Resizer is in continuous mode, it can be disabled by clearing the ENABLE bit during the processing of the last frame. The disable is latched in at the end of the frame it was written in.

12.5.4.3 Events and Status Checking

The resizer generates an interrupt event at the end of each frame.

The status of this interrupt can be checked by reading the [ISP_IRQ0STATUS](#) register (or [ISP_IRQ1STATUS](#)). When the read of the register [ISP_IRQ0STATUS](#) occurs (or [ISP_IRQ1STATUS](#)), the register is not automatically reset. To reset the interrupt, a 1 must be written to the [RSZ_DONE_IRQ](#) bit.

Each event that generates an interrupt can be individually mapped to ARM or DSP using the [ISP_IRQ0ENABLE](#) register (or [ISP_IRQ1ENABLE](#)). When a particular event is not enabled (for example [ISP_IRQ0ENABLE\[x\] = 0](#)), the correspondent status ([ISP_IRQ0STATUS\[x\] = 1](#)) bit is flagged, if the correspondent event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

The [RSZ_PCR \[1\]](#) BUSY status bit is set when the start of frame occurs (if the [RSZ_PCR \[0\]](#) ENABLE bit is 1 at that time). It is automatically reset to 0 at the end of a frame. The [RSZ_PCR \[1\]](#) BUSY status bit may be polled to determine end-of-frame status in oneshot mode. [Figure 12-49](#) shows the firmware/hardware interaction. Configuration registers and filter coefficients are programmed in-between or before busy periods, before writing ENABLE to 0x1.

Figure 12-49. Firmware Interactions for Memory-Input Resizing

Note: The [SBL_SDR_REQ_EXP \[19:10\]](#) RSZ_EXP bit field enables the spreading of non-real time read requests over time. It is useful to avoid overflow situations when the resizer module is programmed to work from memory to memory.

12.5.4.4 Register Accessibility During Frame Processing

There are two types of register access in the resizer.

- Shadow registers: These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame. Note that reads return the most recent write, even though the settings are not used until the next start of frame.
The shadowed registers are:
 - [RSZ_PCR](#)
 - [RSZ_SDR_INADD](#)
 - [RSZ_SDR_INOFF](#)
 - [RSZ_SDR_OUTADD](#)
 - [RSZ_SDR_OUTOFF](#)
- Busy-lock registers
 - All registers EXCEPT the shadowed registers belong to this category.
 - Busy-lock registers cannot be written when the module is busy. Writes are allowed, but no change occurs in the registers (blocked writes from hardware perspective; allowed write from software perspective).
 - After the [RSZ_PCR \[1\]](#) BUSY bit is reset to 0, the busy-lock registers can be written.

The ideal procedure for changing the resizer registers is:

```
IF (RSZ\_PCR \[1\] BUSY == 0) OR IF
(EOF interrupt occurs)
    DISABLE RESIZER
    CHANGE REGISTERS
```

ENABLE RESIZER

12.5.4.5 Inter-Frame Operations

Between frames, it may be necessary to modify the memory pointers before processing the next frame. Since the [RSZ_PCR](#) [0] ENABLE bit and memory pointer registers are shadowed, these modifications can occur any time before the end of the frame, and the data is get latched in for the next frame. The MPU Subsystem can perform these changes on receiving an interrupt.

Note: The firmware is responsible for computing and uploading the filter coefficients. If polyphase resampling is used, a different set is required when changing between 4-tap and 7-tap modes, and with different downsampling factors; all upsampling factors can share the same set of coefficients. Do not change any busy-lock registers while the resizer is operating. Specifically, when back-to-back resizes require changes in any busy-lock registers (such as the coefficients, resizing ratios, input and output sizes), users must wait for the first resize to complete. The following section describes some scenarios where this is required.

12.5.4.5.1 Multiple Passes for Large Resizing Operations

The resizer supports multiple passes of processing for large resizing operations. "Large" has meanings:

- Wider output than 3312 pixels: This works only in memory input mode. Input can be partitioned into multiple resizer blocks, and each block is separately resized and stitched together. Having input/output memory line offsets, input starting pixel and starting phase are essential to make this work. The basic idea is to begin subsequent slices at exactly where previous images leave off. The starting phase and pixel registers can be programmed to this exact location.
- Larger than 4x upsampling: Resizing can be applied in multiple passes. For example, 10x upsampling can be realized by first a 4x upsampling, then a 2.5x upsampling. The first pass can be performed on-the-fly with the preview engine. The second pass can be performed only with input from memory, and for 10x digital zoom; there is time outside the active picture region to perform the second pass.
- Larger than 4:1 downsampling: Although it is rarely necessary to generate a very small image from a large image, this is supported by the hardware. For example, 10x downsampling can be realized first with 4x downsampling on-the-fly with the preview engine, then 2.5x downsampling in the memory-input path. There may not be much time outside the active data region for the second pass, but since the image is already reduced to 1/16 of its original size, not much time is necessary. Typically, sensor or video input has 10 ~ 20 % of usable vertical blanking.

For all these scenarios, the second pass can be configured and initiated from an interrupt service routine triggered by the resizer end-of-frame interrupt: [ISP_IRQ0ENABLE](#) [24] RSZ_DONE_IRQ (or [ISP_IRQ1ENABLE](#)).

12.5.4.5.2 Processing Time Calculation

The time calculated below is the time it takes for all resizes where the input source is memory (second pass when doing a 10x resize in preview mode; in the case of a 10x resize in preview mode, the first pass is hidden behind the time it takes to capture and process the image from the sensor based on cam_pclk and the number of lines resized).

The following equation can be used to determine the processing time of the resizer when the input is from memory and therefore how much time it takes before it can switch back to preview input mode:

$$\text{Time} = [W \times \text{bytes_per_pixel} \times \text{input height}] / \text{CAM_FCLK}$$

Where:

/* If the input is YUV422 and horizontal downsampling is performed: */

if (([RSZ_CNT](#) [27] INPTYP == 0) && (([RSZ_CNT](#) [9:0] HRSZ + 1) > 256))

```
W = average (input_width, output width); /* output width includes extra 4 pixels if edge enhancement is enabled*/
```

```
else
```

```
W = max(input width, output width); /*output width includes extra 4 pixels if edge enhancement is enabled*/
```

```
input_width = RSZ_IN_SIZE[12:0]HORZ
```

```
output_width = RSZ_OUT_SIZE[10:0]HORZ
```

```
input_height = RSZ_IN_SIZE[28:16]VERT
```

$$\text{bytes_per_pixel} = \begin{cases} 1, & \text{when } \text{RSZ_CNT}[27]\text{INPTYP} = 1 \text{ (color separate)} \\ 2, & \text{when } \text{RSZ_CNT}[27]\text{INPTYP} = 0 \text{ (YUV422)} \end{cases}$$

camisp-E097

This time is the baseline steady state calculation of the hardware and does not include the time it takes for the hardware to fetch the first input and fill the pipeline. It also does not include the time spent from the last output from the resizer to get back to memory when the resizer interrupt occurs.

However, these beginning and ending times are relatively negligible.

Depending on real-time constraints, this processing time may be much faster than is required. (data fetches can be delayed from memory to free more bandwidth for use by other system peripherals; see [Section 12.5.7.5.2, Input from Memory](#).)

12.5.4.6 Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the resizer. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- Vertical and horizontal resize ratio values must be within the following range: [64..1024].
- Output width:
 - Must be within the maximum limit:
 - width 3312 (if vertical resize value is in range: $(\text{RSZ_CNT}[19:10] \text{ VRSZ} + 1) = [64..512]$)
 - width 1650 (if vertical resize value is in range: $(\text{RSZ_CNT}[19:10] \text{ VRSZ} + 1) = [513..1024]$)
 - Must be even
 - Must be a multiple of 16 bytes (for vertical upsizing)
- When input is from preview engine/CCDC:
 - The input height and width must be \leq the output of the preview engine/CCDC.
 - The input address and offset must be zero.
 - The input can not be color-separated data.
- If the source is memory:
 - The vertical start pixel must be zero.
 - The horizontal start pixel must be within the range: 0:15 for color interleaved, 0:31 for color separate data.
 - The memory output line offset and address must be on 32-byte boundaries.
- Input height and width MUST adhere to the equations in [Table 12-48](#).

Table 12-48. How to Set Input Height and Width

	8-phase, 4-tap mode	4-phase, 7-tap mode
RSZ_IN_SIZE [12:0] HORZ	$(32 * \text{sph} + (\text{ow} - 1) * \text{hrs} + 16) \gg 8 + 7$	$(64 * \text{sph} + (\text{ow} - 1) * \text{hrs} + 32) \gg 8 + 7$
RSZ_IN_SIZE [28:16] VERT	$(32 * \text{spv} + (\text{oh} - 1) * \text{vrs} + 16) \gg 8 + 4$	$(64 * \text{spv} + (\text{oh} - 1) * \text{vrs} + 32) \gg 8 + 7$

Where:

- sph = Start phase horizontal ([RSZ_CNT](#) [22:20] HSTPH)
- spv = Start phase vertical ([RSZ_CNT](#) [25:23] VSTPH)
- ow = Output width ([RSZ_OUT_SIZE](#) [10:0] HORZ + extra)
- oh = Output height ([RSZ_OUT_SIZE](#) [26:16] VERT)
- hrsz = Horizontal resize value ([RSZ_CNT](#) [9:0] HRSZ + 1)
- vrsz = Vertical resize value ([RSZ_CNT](#) [19:10] VRSZ +1)
- extra = 0 when [RSZ_YENH](#) [17:16] ALGO = 0 (edge enhancement disabled)
- extra = 4 when [RSZ_YENH](#) [17:16] ALGO != 0 (edge enhancement enabled)

Note: Normally, (for example, for a QVGA display or encoded PAL video), the output size, not the input size, matters. The image provided by preview/CCDC/memory must have an adequate output size: at least [RSZ_IN_SIZE](#)[12:0] HORZ x [RSZ_IN_SIZE](#) [28:16] VERT. If the image is bigger, the resizer can crop extra pixels.

The phase is usually computed to keep the center of the image at the same location. This permits a natural-looking continuous digital zoom.

For this reason, [Table 12-48](#) explains how to compute [RSZ_IN_SIZE](#) [12:0] HORZ , [RSZ_IN_SIZE](#) [28:16] VERT, not how to compute the output size.

12.5.5 Programming the H3A

This section discusses issues related to software control of the H3A module. It lists which registers are required to be programmed in different modes, how to enable and disable the H3A, and how to check the status of the H3A; discusses the different register access types; and enumerates programming constraints.

12.5.5.1 Hardware Setup/Initialization

This section discusses the configuration of the H3A required before image processing can begin.

12.5.5.1.1 Reset Behavior

On hardware reset of the camera ISP, all registers in the H3A are reset (set to their reset values).

12.5.5.1.2 Register Setup

For register configuration, the AF engine and the AEW engine of the H3A can be independently be configured. Because there are separate enable bits for each engine, so this section discusses the AF engine and the AEW engine separately.

12.5.5.1.2.1 AF Engine

Before enabling the AF engine, the hardware must be correctly configured through register writes. [Table 12-49](#) identifies the register parameters that must be programmed before enabling the AF engine of the H3A.

Table 12-49. AF Engine Required Configuration Parameters

Function	Configuration Required
AF optional preprocessing	H3A_PCR [2] AF_MED_EN
	H3A_PCR [1] AF_ALAW_EN

Table 12-49. AF Engine Required Configuration Parameters (continued)

Function	Configuration Required
AF mode configuration	H3A_PCR [13:11] RGBPOS H3A_PCR [14] FVMODE
Paxel start and size information	H3A_AFPAX1 H3A_AFPAX2 H3A_AFPAXSTART H3A_AFIIRSH
Memory address	H3A_AFBUFST
Filter coefficients	H3A_AFCOEF010 to H3A_AFCOEF1010

The horizontal median filter function is optional.

If it is disabled, the [H3A_PCR](#) [10:3] MED_TH does not need to be programmed.

However, if it is enabled, the [H3A_PCR](#) [10:3] MED_TH parameter must be programmed so that the horizontal median filter function operates correctly.

[Table 12-50](#) can be read as:

If (**Condition** is TRUE) then

Configuration required parameters must be programmed

Table 12-50. AF Engine Conditional Configuration Parameters

Function	Condition	Configuration Required
Horizontal median filter	H3A_PCR [2] AF_MED_EN	H3A_PCR [10:3] MED_TH

12.5.5.1.2.2 AEW Engine

Before enabling the AEW engine, the hardware must be correctly configured through register writes.

[Table 12-51](#) identifies the register parameters that must be programmed before enabling the AEW engine of the H3A.

Table 12-51. AEW Engine Required Configuration Parameters

Function	Configuration Required
AEW optional preprocessing	H3A_PCR [17] AEW_ALAW_EN
Saturation limit	H3A_PCR [31:22] AVE2LMT
Window start and size information	H3A_AEWWIN1 H3A_AEWINSTART H3A_AEWINBLK H3A_AEWSUBWIN
Memory address	H3A_AEWBUFST

12.5.5.2 Enable/Disable Hardware

Setting the [H3A_PCR](#) [0] AF_EN bit enables the AF engine, and the [H3A_PCR](#) [16] AEW_EN bit enables the AEW engine. This should be done after all required registers are programmed.

The H3A always operates in continuous mode. Since the input to the H3A module is the video-port interface of the CCDC, processing of the frame depends on the timing signals from the CCDC. To ensure that data from the CCDC is not missed, the H3A should be enabled before the CCDC so that it waits for CCDC data.

The AF engine or the AEW engine can be disabled by clearing the [H3A_PCR](#) [0] AF_EN or [H3A_PCR](#) [16] AEW_EN bit, respectively, during the processing of the last frame. The disable is latched in at the end of the frame in which it is written.

12.5.5.3 Event and Status Checking

Both the AF engine and the AEW engine generate an interrupt at the end of processing each frame. These interrupt events can be sent to CAM_IRQ0 or CAM_IRQ1 by setting the H3A_AWB_DONE_IRQ or H3A_AF_DONE_IRQ bits in the [ISP_IRQ0ENABLE](#) enable register (or [ISP_IRQ1ENABLE](#)).

The status of these interrupts can be checked by reading the [ISP_IRQ0STATUS](#) register (or [ISP_IRQ1STATUS](#)). When the read of the register [ISP_IRQ0STATUS](#) occurs (or [ISP_IRQ1STATUS](#)), the register is not automatically reset. To reset the interrupt, a 1 must be written to the corresponding bit.

Each event that generates an interrupt can be individually mapped to ARM or DSP using the [ISP_IRQ0ENABLE](#) register (or [ISP_IRQ1ENABLE](#)). When a particular event is not enabled (for example [ISP_IRQ0ENABLE](#)[x] = 0), the correspondent status ([ISP_IRQ0STATUS](#) [x] = 1) bit is flagged if the correspondent event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

12.5.5.4 Register Accessibility During Frame Processing

There are two types of register access in the H3A module:

- Shadow registers: These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame. Reads return the most recent write, even though the settings are not used until the next start of frame.
The shadowed registers are:
 - [H3A_PCR](#)
 - [H3A_AFBUFST](#)
 - [H3A_AEWBUFST](#)
- Busy-lock registers:
 - All registers EXCEPT the shadowed registers belong to this category.
 - Busy-lock registers cannot be written when the module is busy. Writes are allowed, but no change occurs in the registers (blocked writes from hardware perspective, but allowed writes from software perspective).
 - After the busy bit in the PCR register is reset to 0, the busy-lock registers can be written ([H3A_PCR](#) [15] BUSYAF for AF registers and [H3A_PCR](#) [18] BUSYAEAWB for AE/AWB registers).

The ideal procedure for changing the H3A registers is:

```
IF (H3A\_PCR [15] BUSYAF == 0 OR H3A\_PCR [18] BUSYAEAWB == 0) OR IF (EOF interrupt occurs)
    DISABLE AF or AE/AWB
    CHANGE REGISTERS AF or AE/AWB
    ENABLE AF or AE/AWB
```

12.5.5.5 Interframe Operations

Between frames, it may be necessary to modify the memory pointers before processing the next frame. Since the [H3A_PCR](#) and memory pointer registers are shadowed, these modifications can occur any time before the end of the frame, and the data is latched in for the next frame. The MPU subsystem can perform these changes on receiving an interrupt.

12.5.5.6 Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the H3A. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- The H3A should not be enabled for Foveon formatted input.
- The output addresses must be on 64-byte boundaries.
- AF Engine:
 - The paxel horizontal start value must be greater than or equal to the IIR horizontal start position.
 - The width and height of the paxels must be even numbers.
 - The minimum width of the autofocus paxel must be 6 pixels.
 - Paxels cannot overlap the last pixel in a line.
 - Paxels must be adjacent to one another.
- AEW Engine:
 - The width and height of the windows must be even numbers.
 - Subsampling windows can only start on even numbers.
 - The minimum width of the AE/AWB windows is 6 pixels.

12.5.6 Programming the Histogram

This section discusses issues related to software control of the histogram module. It lists which registers are required to be programmed in different modes, how to enable and disable the histogram, and how to check the status of the histogram; discusses the different register access types; and enumerates programming constraints.

12.5.6.1 Hardware Setup/Initialization

This section discusses the configuration of the histogram required before image processing can begin.

12.5.6.1.1 Reset Behavior

On hardware reset of the camera ISP, all registers in the histogram are reset to their reset values. However, since the histogram output memory is stored in internal memory, its contents do not have reset values. If the reset is a chip-level power-on reset (reset after power is applied), the contents of this memory are unknown. If the reset is a camera ISP module reset (when power remains active), the contents of this memory remain the same as before the reset.

12.5.6.1.2 Reset of Histogram Output Memory

Clear the output memory before enabling the histogram. This can be done two ways:

- Writing zeros to the memory through software
- If the [HIST_CNT](#) [7] CLR bit is set, reading the memory causes it to be reset after the read.

Reads and writes to the output memory are blocked when the [HIST_PCR](#) [1] BUSY bit is 1.

12.5.6.1.3 Register Setup

Before enabling the histogram module, the hardware must be correctly configured through register writes. [Table 12-52](#) identifies the register parameters that must be programmed before enabling the histogram.

Table 12-52. Histogram Required Configuration Parameters

Function	Configuration Required
Histogram Control Bits	HIST_CNT [3] SOURCE HIST_CNT [6] CFA HIST_CNT [5:4] BINS HIST_CNT [2:0] SHIFT HIST_CNT [7] CLR
White Balance Gain	HIST_WB_GAIN
Region n Size and position (n = 0)	HIST_Rn_HORZ HIST_Rn_VERT

[Table 12-53](#) can be read as:

If (**Condition** is TRUE) then

Configuration required parameters should be programmed

Table 12-53. Histogram Conditional Configuration Parameters

Function	Condition	Configuration Required
Input from memory	HIST_CNT [3] SOURCE = 0x1	HIST_CNT [8] DATSIZ HIST_RADD HIST_RADD_OFF HIST_H_V_INFO
Less than 256 bins	HIST_CNT [5:4] BINS 3	HIST_Rn_HORZ (n = 1) HIST_Rn_VERT (n = 1)
Less than 128 bins	HIST_CNT [5:4] BINS 2	HIST_Rn_HORZ (n = 2) HIST_Rn_VERT (n = 2) HIST_Rn_HORZ (n = 3) HIST_Rn_VERT (n = 3)

12.5.6.2 Enable/Disable Hardware

Setting the [HIST_PCR](#) [0] ENABLE bit enables the histogram module. This must be done after all required registers are programmed and the output memory has been cleared.

When the input source is the memory, the histogram module always operates in one-shot mode. In other words, after enabling the histogram, the ENABLE bit is automatically turned off (set to 0) and only a single frame is processed from memory. In this mode, fetching and processing of the frame begin immediately on setting the ENABLE bit.

When the input source is the CCDC, the histogram always operates in continuous mode. Processing of the frame depends on the timing of the CCDC. To ensure that data from the CCDC is not missed, the histogram must be enabled before CCDC so it waits for CCDC data..

When the histogram is in continuous mode, it can be disabled by clearing the ENABLE bit during the processing of the last frame. The disable is latched in at the end of the frame in which it is written.

12.5.6.3 Event and Status Checking

The histogram generates an interrupt at the end of each frame.

The status of this interrupt can be checked by reading the [ISP_IRQ0STATUS](#) register (or [ISP_IRQ1STATUS](#)). When the read of the register [ISP_IRQ0STATUS](#) occurs (or [ISP_IRQ1STATUS](#)), the register is not automatically reset. To reset the interrupt, a 1 must be written to the HIST_DONE_IRQ bit.

Each event that generates an interrupt can be individually mapped to ARM or DSP using the [ISP_IRQ0ENABLE](#) register (or [ISP_IRQ1ENABLE](#)). When a particular event is not enabled (for example [ISP_IRQ0ENABLE\[x\] = 0](#)), the corresponding status ([ISP_IRQ0STATUS \[x\] = 1](#)) bit is flagged if the corresponding event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

The [HIST_PCR \[1\] BUSY](#) status bit is set when the start of frame occurs (if the [HIST_PCR \[0\] ENABLE](#) bit is 1 at that time). It is automatically reset to 0 at the end of a frame. The [HIST_PCR \[1\] BUSY](#) status bit may be polled to determine the end-of-frame status.

12.5.6.4 Register Accessibility During Frame Processing

There are two types of register access in the histogram module.

- Shadow registers: These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame. Reads return the most recent write, even though the settings are not used until the next start of frame.

The shadowed registers are:

- [HIST_PCR](#)
- [HIST_RADD](#)
- [HIST_RADD_OFF](#)

- Busy-lock registers
 - All registers EXCEPT the shadowed registers belong to this category.
 - Busy-lock registers cannot be written when the module is busy. Writes are allowed, but no change occurs in the registers (blocked writes from hardware perspective; allowed write from software perspective).
 - After the [HIST_PCR \[1\] BUSY](#) bit is reset to 0, the busy-lock registers can be written.
 - The [HIST_DATA](#) register cannot be read when the histogram is busy, because since this register is mapped to memories internally. Such reads return indeterminate data. Byte enables are not implemented for reading the histogram memory.

The ideal procedure for changing the histogram registers is:

IF ([HIST_PCR \[1\] BUSY](#) == 0) OR IF (EOF interrupt occurs)

DISABLE HISTOGRAM

CHANGE REGISTERS

ENABLE HISTOGRAM

12.5.6.5 Interframe Operations

Between frames read from memory, it may be necessary to modify the input memory pointers before processing the next frame. Since the [H3A_PCR](#) and memory pointer registers are shadowed, these modifications can take place any time before the end of the frame, and the data is latched in for the next frame. The MPU Subsystem can perform these changes on receiving an interrupt.

If continuous frames are processed without clearing the histogram output memory, the bin counters contain the counts of however many images are processed since they were last cleared. To read the bin counters for each frame, the bin counters must be read after each frame is completed, but before the next frame begins (since the counters cannot be read while the [HIST_PCR \[1\] BUSY](#) bit is 1).

If the input source is memory (one-shot mode), the [HIST_PCR \[0\] ENABLE](#) bit must be set once for the frame, and after the frame is completed, the bin counters can be read/cleared before enabling the next frame.

When the input source is the video-port interface of the CCDC (continuous mode), the [HIST_PCR \[0\] ENABLE](#) bit must be set to enable processing of the frame, and cleared after the frame processing begins (the disable is latched in at the end of the frame). This procedure allows only one frame to be processed. After the frame is completed, the bin counters can be read/cleared before enabling the histogram for the next frame.

12.5.6.6 Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the histogram. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- The input address and line offset must be on 32-byte boundaries.
- A region dimension of 1 (horizontal or vertical or both) is not allowed.

12.5.7 Programming the Central-Resource SBL

This section discusses issues related to the software control of the central-resource SBL. It lists which registers are required to be programmed in different modes, describes how to check the status of the central resource SBL overflow bits, and enumerates programming constraints.

The central-resource SBL controls data interactions between the camera ISP modules and the interface to memory. A small number of registers configure maximum data-read bandwidth in memory-to-memory operations.

12.5.7.1 Hardware Setup/Initialization

This section discusses the configuration of the central-resource SBL required before image processing can begin.

12.5.7.1.1 Reset Behavior

On hardware reset of the camera ISP, all registers in the SBL are reset to their reset values.

12.5.7.1.2 Register Setup

Before enabling any of the camera ISP modules, the hardware must be correctly configured through register writes to the camera ISP registers. If the preview engine, resizer, or the histogram is reading from memory, the [SBL_SDR_REQ_EXP](#) register must be programmed. The values programmed in each of the three fields (PRV_EXP, RSZ_EXP, HIST_EXP) determines the number of clock cycles required to allow two consecutive read requests from the module.

12.5.7.2 Enable/Disable Hardware

The central-resource SBL functionality is always enabled, unless the PRCM idles the clocks to the camera ISP.

12.5.7.3 Event and Status Checking

The SBL generates one interrupt for the write buffer overflow events listed below. Software must check which overflow event has raised the interrupt request, by reading the [SBL_PCR](#) register.

See [Table 12-54](#).

Table 12-54. SBL Write-Buffer Overflow Events

Bit	Event Description
SBL_PCR [24] CCDCPRV_2_RSZ_OVF	CCDC/PREVIEW to RESIZER input overflow This bit is set if the RESIZER input source is sent to CCDC/PREVIEW engine when the active data (to be resized) has already showed up at the resizer interface. In such a case, resizing for this frame cannot take place and the bit is set. This scenario can happen when a resize of > 4x is required per frame. Therefore, the RESIZER must operate in two passes. In the first pass, the input data from CCDC/PREVIEW is directly resized and written to memory. In the second pass, the resized data from the first pass is resized again. The next frame from the CCDC/PREVIEW engine should start only after the second pass on the previous frame is complete. This bit indicates the failure status.
SBL_PCR [23] CCDC_WBL_OVF	CCDC write-buffer memory overflow
SBL_PCR [22] PRV_WBL_OVF	PREVIEW write-buffer memory overflow
SBL_PCR [21] RSZ1_WBL_OVF	RESIZER line 1 write-buffer memory overflow
SBL_PCR [20] RSZ2_WBL_OVF	RESIZER line 2 write-buffer memory overflow
SBL_PCR [19] RSZ3_WBL_OVF	RESIZER line 3 write-buffer memory overflow
SBL_PCR [18] RSZ4_WBL_OVF	RESIZER line 4 write-buffer memory overflow
SBL_PCR [17] H3A_AF_WBL_OVF	H3A AF write-buffer memory overflow
SBL_PCR [16] H3A_AEAWB_WBL_OVF	H3A AE/AWB write-buffer memory overflow

The status of this interrupt can be checked by reading the [ISP_IRQ0STATUS](#) register (or [ISP_IRQ1STATUS](#)). When the read of the register [ISP_IRQ0STATUS](#) occurs (or [ISP_IRQ1STATUS](#)), the register is not automatically reset. To reset the interrupt, a 1 must be written:

- To the corresponding bit(s) in the [SBL_PCR](#) registers
- To the OVF_IRQ bit in the [ISP_IRQ0STATUS](#) register (or [ISP_IRQ1STATUS](#))

Each event that generates an interrupt can be individually mapped to ARM or DSP using the [ISP_IRQ0ENABLE](#) register (or [ISP_IRQ1ENABLE](#)). When a particular event is not enabled (for example [ISP_IRQ0ENABLE](#)[x] = 0), the correspondent status ([ISP_IRQ0STATUS](#) [x] = 1) bit is flagged if the correspondent event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

The SBL flags no read buffer logic underflow events. These are signaled by the reading module. [Table 12-55](#) lists the read port and corresponding events if they exist.

Table 12-55. SBL Read-Buffer Underflow Events

Read port	Description
CCDC faulty pixel	When faulty-pixel correction is used, the pixel frequency is imposed by the camera clock. This imposes read-time constraints to the faulty-pixel table read. When the table read was too slow, the CCDC_FPC [16] FPERR bit is set to 1 and no more faulty pixels are processed for that frame. This error generates an interrupt that can be mapped to DSP or ARM by setting the CCDC_ERR_IRQ bit in the ISP_IRQ0ENABLE register (or ISP_IRQ1ENABLE). To clear this interrupt, clear the CCDC_FPC [16] FPERR bit before clearing the ISP_IRQ0STATUS [11] CCDC_ERR_IRQ bit (or ISP_IRQ1STATUS).
CCDC lens-shading compensation	There must be adequate memory bandwidth if this feature is enabled. If the data fetched from memory arrives late, then the CCDC_LSC_PREFETCH_ERROR event is triggered and an interrupt generated.
Preview dark frame	There must be adequate memory bandwidth if this feature is enabled. If the data fetched from memory arrives late, the PRV_PCR [31] DRK_FAIL status bit is set to indicate a fail. No interrupt is generated by this event.

Table 12-55. SBL Read-Buffer Underflow Events (continued)

Read port	Description
Preview image from memory	No error can occur on this port because the preview module stops processing when no image data is ready.
Resizer image from memory	No error can occur on this port because the resizer module stops processing when no image data is ready.
Histogram image from memory	No error can occur on this port because the histogram module stops processing when no image data is ready.

12.5.7.4 Register Accessibility During Frame Processing

The central resource SBL registers are all busy-writable registers.

- Busy-writable registers
 - These registers/fields can be read or written even if the module is busy. Changes to the underlying settings occur instantaneously.

12.5.7.5 Camera ISP Bandwidth Adjustments

For memory-to-memory operation, the camera ISP processes data at the highest possible data rate. If this processing returns results long before real-time deadlines, the performance of other peripherals in the system may be negatively affected. The camera ISP offers two kinds of adjustments that can slow down data processing in this situation. One can be made when the sensor input to the CCDC is the input source, and the other can be made when the memory is the source of the input image.

12.5.7.5.1 Input From CCDC Video-Port Interface

The video-port interface delivers data at a rate independent of the pixel clock when the data reformatter is enabled. By default, this rate is set to 83 MHz, which is fast enough to support a parallel interface clock of 75 MHz. When the pixel clock is at a lower frequency, it is unnecessary for the video-port interface to operate at such a high frequency. The [CCDC_FMTCFG \[18:16\] VPIF_FRQ](#) field of the CCDC can be programmed to reduce the rate at which the video port delivers new data to the other modules (Preview, H3A, and histogram). In effect, this register indirectly controls the output bandwidth of the preview engine, resizer, and H3A. Depending on the input sensor clock, Users can set this field appropriately and balance the bandwidth requirements to memory. [Figure 12-50](#) demonstrates how this register can expand processing time per line for lower PCLK frequencies.

Figure 12-50. Video-Port Interface Bandwidth Balancing

camisp-091

12.5.7.5.2 Input From Memory

When the input image is from memory, data is fetched from memory and processed at a steady state rate of 166 MB/sec. Depending on the image size and real-time deadline for each frame, this may be much faster than necessary. Such activity can also starve other processes in the system. The [SBL_SDR_REQ_EXP](#) register can be programmed to control the rate at which a camera ISP module (Preview, resizer, or histogram) reads the input frame from memory. This indirectly controls the output bandwidth of the preview engine and resizer. Depending on the size of the images and the real-time deadlines, users can set this field appropriately and balance the bandwidth requirements to memory. [Figure 12-51](#) demonstrates how this register can expand processing time for lower real-time requirements.

Figure 12-51. Memory Read Bandwidth Balancing

12.5.8 Programming the Circular Buffer (CBUFF)

12.5.8.1 Hardware Setup/Initialization

This section discusses the configuration of the circular buffer required before address translation can begin.

12.5.8.2 Reset Behavior

Upon hardware reset of the circular buffer, all of the registers in the circular buffer are reset to their reset values.

12.5.8.3 Register Setup

All registers of the circular buffer to be used (CBUFFx, x=0 or 1) have to be initialized for correct operation.

The [CBUFFx_START](#) and [CBUFFx_END](#) register define the virtual address range managed by the circular buffer. It usually corresponds to the address region where one image frame is written by the camera ISP.

The window count and size are set through the [CBUFFx_CTRL](#) [9:8] WCOUNT and [CBUFFx_WINDOWSIZE](#) registers. The window size usually depends on the utilization of the buffer. 8 or 16 video lines correspond to a current size for JPEG video compression. A higher window count provides better latency related overflow protection.

When the camera ISP accesses data in an incremental addressing scheme, the next window is never used. In this case the overflow event generation, when the processor window falls into the "next window", can be disabled by setting the [CBUFFx_CTRL](#) [3] ALLOW_NW_EQ_CPUW flag.

When the 2D addressing capability isn't used the [CBUFFx_THRESHOLD](#) register is set to the window size. Otherwise it is set to a smaller value depending on the buffer organization. For example, when each window corresponds to 8 lines by 4096 pixel but the camera ISP only send lines of 2560 pixels the [CBUFFx_WINDOWSIZE](#)=8*4096 and [CBUFFx_THRESHOLD](#)=8*2560.

When the register setup is completed the module is enabled using the [CBUFFx_CTRL](#) [0] EN bit.

It can be disabled by clearing the [CBUFFx_CTRL](#) [0] EN bit. This must only be done when there are no more outstanding requests to the virtual space managed by CBUFFx. All internal FSMs and counters of the circular buffer are reset when it is disabled. Pending interrupts are not affected.

12.5.8.4 Event and status Checking

12.5.8.4.1 Interrupts

All events generated by the circular buffer are mapped to an unique event at camera ISP level: CBUFF_IRQ,

The CBUFF module event can be mapped to the MPU SS or to the IVA SS.

The CBUFF_IRQ bit in the [ISP_IRQ0ENABLE](#) [21] CBUFF_IRQ register control whether the CBUFF module event triggers an interrupt to the MPU SS. The CBUFF_IRQ bit in the [ISP_IRQ0ENABLE](#) [21] CBUFF_IRQ register control whether the CBUFF module event triggers an interrupt to the IVA2.2 SS.

When an event has been triggered the [ISP_IRQ0STATUS](#) [21] CBUFF_IRQ bit is set (or [ISP_IRQ1STATUS](#)). SW must then read the [CBUFF_IRQSTATUS](#) register to know which circular buffer event has triggered the interrupt. SW must clear the event first in the circular buffer module by writing 1 to the proper bit in [CBUFF_IRQSTATUS](#) register and then clear the event at camera ISP level by writing 1 to the [ISP_IRQ0STATUS](#) [21] CBUFF_IRQ bit (or [ISP_IRQ1STATUS](#)). If another event is pending at circular buffer level, the CBUFF_IRQ interrupt is triggered again.

12.5.8.4.2 Status Checking

The event status can be checked through the CBUFFx_READY_IRQ, CBUFFx_INVALID_IRQ and CBUFFx_OVR_IRQ bits in the [CBUFF_IRQSTATUS](#) registers.

In addition to those status bits the circular buffer module provides read only access to the "current window", "next window" and "CPU windows" indexes through the [CBUFFx_STATUS](#) register. The "CPU window" index can for example be used by the processor to compute the address of the physical buffer. Those indexes can also be used to evaluate latency margins.

12.5.8.5 Register Accessibility During Frame Processing

All registers are Busy-writeable registers. These registers/fields can be read or written even if the module is busy. Changes to the underlying settings takes place instantaneously. However the module behavior is unpredictable when registers are changed during processing.

For correct operation software must follow the following steps:

- Disable all accesses to the virtual space managed by CBUFFx. For example when the circular buffer relocates data provided by the CCDC module SW must disable the CCDC module and check SBL status registers to make sure there are no more outstanding transactions.
- Disable circular buffer x by clearing the [CBUFFx_CTRL](#) [0] ENABLE bit.
- Change the configuration.
- Re-enable CBUFFx by setting the [CBUFFx_CTRL](#) [0] ENABLE bit.

12.5.8.6 Operations

A CBUFFx_READY_IRQ event is generated each time processor can read data from the circular buffer. Processor can clear the event when it starts processing the data to avoid masking of other events. Processor can keep trace of the location on the data internally or use the circular buffer registers to compute it.

The formula used is:

$$\text{ADDR} = \text{CBUFFx_STATUS} [3:0] \text{ CPUW} \times \text{CBUFFx_WINDOWSIZE} + \text{CBUFFx_START}$$

When processor is done with processing, it must free the buffer by setting the [CBUFFx_CTRL \[2\] DONE](#) bit. Otherwise an overflow event may occur.

Note that the circular buffer does not keep trace of end of frame events. They have to be managed by the processor using the end of frame event of the module that writes into the circular buffer. At the end of the frame there may remain data in the "current write" and "next write" windows. For example, when the window size is set to 8 lines and the image size is 20 lines only 2 window ready events are generated for a linear addressing scheme. The remaining 4 lines can be read after the end of frame event.

No automatic reset of the CBUFF FSM occurs at the end of the camera ISP frame. Software must reset the CBUFF by clearing the [CBUFFx_CTRL \[0\] ENABLE](#) bit when the frame has been completely processed. A new frame can only start when [CBUFFx_CTRL \[0\] ENABLE](#) has been set.

12.6 Camera ISP Registers

Table 12-56. Physical Addresses of CAMERA_ISP

Module Name	Base address (hex)	Size
ISP	0x480B C000	512 bytes
ISP_CBUFF	0x480B C100	256 bytes
ISP_CCDC	0x480B C600	512 bytes

RESERVED																MIDDLE_MODE		RESERVED										SOFT_RESET	AUTO_IDLE		

Bits	Field Name	Description	Type	Reset
31:14	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00000
13:12	MIDDLE_MODE	Master interface power management, handshake protocol. 0x0: Force-standby: the hardware signal is only asserted to the power and reset clock manager when the module is disabled. 0x1: No-standby: the hardware signal is never asserted to the power and reset clock manager. 0x2: Smart-standby: the hardware signal is asserted to the power and reset clock manager based on the internal activity of the module. The ISP clocks are not disabled during smart standby.	RW	0x0
11:2	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x000
1	SOFT_RESET	Software reset. Set the bit to 1 to trigger the module reset. The bit is automatically reset by the HW. During reads return 0. 0x0: Normal mode. 0x1: The module is reset.	RW	0x0
0	AUTO_IDLE	Internal interface clock gating strategy 0x0: interface clock is free running 0x1: Automatic interface clock gating strategy is applied based on the Interconnect interface activity.	RW	0x1

Bits	Field Name	Description	Type	Reset
31	HS_VS_IRQ	HS or VS synchro event This event is triggered if a rising or falling edge is detected on the HS or VS signal. The rising or falling edge and the HS or VS signal selection is chosen with the ISP_CTRL.SYNC_DETECT bit field. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
30	SEC_ERR_IRQ	Security error event. The event is triggered when a privilege violation error occurs. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
29	OCP_ERR_IRQ	ISP Interconnect error. This event is triggered when an Interconnect error occurs: SResp = ERR. The cause may be a security violation. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
28	MMU_ERR_IRQ	MMU error. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
27:26	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
25	OVF_IRQ	Central Resource SBL overflow This event is triggered when one of the buffer in the central resource SBL overflows. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
24	RSZ_DONE_IRQ	RESIZER module - resizer processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
23:22	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
21	CBUFF_IRQ	Circular buffer interrupt 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0

Bits	Field Name	Description	Type	Reset
20	PRV_DONE_IRQ	PREVIEW module - processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
19	CCDC_LSC_PREFETCH_ERROR	The prefetch error indicates when the gain table was read too slowly from SDRAM. When this event is pending the module goes into transparent mode (output=input). Normal operation can be resumed at the start of the next frame after 1) clearing this event 2) disabling the LSC module 3) enabling it 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
18	CCDC_LSC_PREFETCH_COMPLETED	Indicates current state of the prefetch buffer. Can be used to start sending the data once the buffer is full to minimize the risk of an underflow. This event is triggered when the buffer contains 3 full paxel rows. It can be used to minimize buffer underflow risks. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
17	CCDC_LSC_DONE	The event is triggered when the internal state of LSC toggles from BUSY to IDLE. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
16	HIST_DONE_IRQ	HIST module - processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
15:14	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
13	H3A_AWB_DONE_IRQ	H3A module - auto exposure and auto white balance processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
12	H3A_AF_DONE_IRQ	H3A module - autofocus processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
11	CCDC_ERR_IRQ	CCDC module - faulty pixel correction memory underflow 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
10	CCDC_VD2_IRQ	CCDC module - programmable event 2 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
9	CCDC_VD1_IRQ	CCDC module - programmable event 1. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
8	CCDC_VD0_IRQ	CCDC module - programmable event 0. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0

Bits	Field Name	Description	Type	Reset
7:0	RESERVED	Reserved bit field. Write the reset value.	RW	0x0

Bits	Field Name	Description	Type	Reset
31	HS_VS_IRQ	HS or VS synchro event This event is triggered if a rising or falling edge is detected on the HS or VS signal. The rising or falling edge and the HS or VS signal selection is chosen with the ISP_CTRL.SYNC_DETECT bit field. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
30	SEC_ERR_IRQ	Security error event. The event is triggered when a privilege violation error occurs. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
29	OCP_ERR_IRQ	ISP Interconnect error. This event is triggered when an Interconnect error occurs: SResp = ERR. The cause may be a security violation. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
28	MMU_ERR_IRQ	MMU error. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
27:26	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
25	OVF_IRQ	Central Resource SBL overflow This event is triggered when one of the buffer in the central resource SBL overflows. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
24	RSZ_DONE_IRQ	RESIZER module - resizer processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
23:22	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
21	CBUFF_IRQ	Circular buffer interrupt 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
20	PRV_DONE_IRQ	PREVIEW module - processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
19	CCDC_LSC_PREFETCH_ERROR	The prefetch error indicates when the gain table was read too slowly from SDRAM. When this event is pending the module goes into transparent mode (output=input). Normal operation can be resumed at the start of the next frame after 1) clearing this event 2) disabling the LSC module 3) enabling it 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0

Bits	Field Name	Description	Type	Reset
18	CCDC_LSC_PREFETCH_COMPLETED	Indicates current state of the prefetch buffer. Can be used to start sending the data once the buffer is full to minimize the risk of an underflow. This event is triggered when the buffer contains 3 full paxel rows. It can be used to minimize buffer underflow risks. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
17	CCDC_LSC_DONE	The event is triggered when the internal state of LSC toggles from BUSY to IDLE. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
16	HIST_DONE_IRQ	HIST module - processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
15:14	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
13	H3A_AWB_DONE_IRQ	H3A module - auto exposure and auto white balance processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
12	H3A_AF_DONE_IRQ	H3A module - autofocus processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
11	CCDC_ERR_IRQ	CCDC module - faulty pixel correction memory underflow 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
10	CCDC_VD2_IRQ	CCDC module - programmable event 2 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0

Table 12-77. TCTRL_GRESET_LENGTH

Address Offset	0x0000 0030																																
Physical Address	0x480B C030																Instance	ISP															
Description	TIMING CONTROL - GLOBAL SHUTTER LENGTH REGISTER This register is used by the TIMING CTRL module to generate the cam_global_reset signal.																																
Type	RW																																
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
RESERVED								LENGTH																									

Bits	Field Name	Description	Type	Reset
31:24	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
23:0	LENGTH	Sets the length of the cam_global_reset signal assertion in cycles of the CNTCLK clock. The CNTCLK frequency is generated with the TCTRL_CTRL.DIVC bit field. After signal assertion, the TCTRL_CTRL.GRESETEN bit is automatically cleared. The possible values are 0 to 2^24-1 cycles. The polarity of the cam_global_reset signal is set by the TCTRL_CTRL.GRESETPOL bit.	RW	0x000000

Bits	Field Name		Description		Type	Reset																																																																																											
31:25	COUNTER		Sets the number of PRESTROBE pulses after the original pulse. If this bit is set to 0, the PRESTROBE signal behavior is only controlled by TCTRL_FRAME.STRB , TCTRL_PSTRB_DELAY and TCTRL_PSTRB_LENGTH . If TCTRL_PSTRB_LENGTH =0, there is no replay. This bit is useful when one wants to enable red-eye removal.		RW	0x00																																																																																											
24:0	DELAY		Sets the delay for the PRESTROBE signal re-assertion in cycles of the CNTCLK clock. The CNTCLK frequency is generated with the TCTRL_CTRL.DIVC bit field. The possible values are 0 to 2^25-1 cycles. If TCTRL_PSTRB_LENGTH =0, there is no replay. This bit field must not be set to 0 if the COUNTER is set to a value different of 0. This bit is useful when one wants to enable red-eye removal.		RW	0x0000000

12.6.2.9 ISP_CTRL

Table 12-81. ISP_CTRL

Address Offset	0x0000 0040		
Physical Address	0x480B C040	Instance	ISP
Description	CONTROL REGISTER After reset, the parallel interface is selected and only the CCDC module data write port is enabled.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FLUSH	JPEG_FLUSH	CCDC_WEN_POL	SBL_SHARED_RPORTB	RESERVED				SBL_AUTOIDLE	SBL_WR0_RAM_EN	SBL_WR1_RAM_EN	SBL_RD_RAM_EN	PREV_RAM_EN	CCDC_RAM_EN	SYNC_DETECT	RSZ_CLK_EN	PRV_CLK_EN	HIST_CLK_EN	H3A_CLK_EN	CBUFF_AUTOGATING	CCDC_CLK_EN	SHIFT	RESERVED	PAR_CLK_POL	PAR_BRIDGE	PAR_SER_CLK_SEL						

Bits	Field Name	Description	Type	Reset
31	FLUSH	CCDC memory flush Writing 1 in this bit flushes the CCDC memories in the central resource SBL. The SBL memories are always flushed by the end of frame. However, there are cases where the end of frame cannot be detected.	RW	0x0
30	JPEG_FLUSH	JPEG flush When a camera module outputs a JPEG bit stream, this bit must be set because the bit stream length may not be a multiple of 32 bits. Enabling this bit ensures that no data stay in the design internal FIFOs.	RW	0x0
29	CCDC_WEN_POL	Sets the polarity of the CCDC WEN bit. 0x0: Active low 0x1: Active high	RW	0x0
28	SBL_SHARED_RPORTB	Controls SBL shared read port B access 0x0: Read port used by preview module dark frame read 0x1: Read port used by CCDC module lens-shading compensation data read	RW	0x0
27:22	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
21	SBL_AUTOIDLE	Sets the SBL autoidle mode 0x0: Disabled 0x1: Enabled	RW	0x1
20	SBL_WR0_RAM_EN	This bit controls the SBL module WRITE0 RAM used by the RESIZER module. If the RESIZER module is disabled, this bit should be set to 0 to save power. 0x0: RAM is disabled 0x1: RAM is enabled	RW	0x0
19	SBL_WR1_RAM_EN	This bit controls the SBL module WRITE1 RAM. If the RESIZER module is the only module enabled to perform memory to memory resize operations, this bit should be set to 0 to save power. 0x0: RAM is disabled 0x1: RAM is enabled	RW	0x0
18	SBL_RD_RAM_EN	This bit controls the SBL module READ RAM. If no read requests are generated, this bit should be set to 0 to save power. 0x0: RAM is disabled 0x1: RAM is enabled	RW	0x0
17	PREV_RAM_EN	This bit controls the PREVIEW module RAM. If the PREVIEW module is not used, this bit should be set to 0 to save power. 0x0: RAM is disabled 0x1: RAM is enabled	RW	0x0

Bits	Field Name	Description	Type	Reset
16	CCDC_RAM_EN	This bit controls the CCDC module RAM. If the CCDC module is not used, the bit should be set to 0 to save power. 0x0: RAM is disabled 0x1: RAM is enabled	RW	0x0
15:14	SYNC_DETECT	HS or VS synchronization signal detection It is sometimes necessary to detect the rising or falling edge of the horizontal and vertical synchro signals. When such event is detected, an interrupt is triggered if ISP_IRQ0ENABLE.HS_VS_IRQ = 1 or ISP_IRQ0ENABLE.HS_VS_IRQ = 1. 0x0: HS falling edge 0x1: HS rising edge 0x2: VS falling edge 0x3: VS rising edge	RW	0x0
13	RSZ_CLK_EN	RSZ module clock enable. This bit controls the clock distribution to the RSZ module. 0x0: Disable clock. The module is not active. However, accesses on the module slave port to configure it are still possible. 0x1: Enable clock. The module is fully functional.	RW	0x0
12	PRV_CLK_EN	PRV module clock enable. This bit controls the clock distribution to the PRV module. 0x0: Disable clock. The module is not active. However, accesses on the module slave port to configure it are still possible. 0x1: Enable clock. The module is fully functional.	RW	0x0
11	HIST_CLK_EN	HIST module clock enable. This bit controls the clock distribution to the HIST module. 0x0: Disable clock. The module is not active. However, accesses on the module slave port to configure it are still possible. 0x1: Enable clock. The module is fully functional.	RW	0x0
10	H3A_CLK_EN	H3A module clock enable. This bit controls the clock distribution to the H3A module. 0x0: Disable clock. The module is not active. However, accesses on the module slave port to configure it are still possible. 0x1: Enable clock. The module is fully functional.	RW	0x0
9	CBUFF_AUTOGATING	CBUFF module autogating feature control 0x0: CBUFF autogating feature is disabled. The CBUFF internal clock is free running. 0x1: CBUFF autogating feature is enabled. The CBUFF internal clock is only enabled when it is requested by the CBUFF module.	RW	0x0
8	CCDC_CLK_EN	CCDC module clock enable. This bit controls the clock distribution to the CCDC module. 0x0: Disable clock. The module is not active. However, accesses on the module slave port to configure it are still possible. 0x1: Enable clock. The module is fully functional.	RW	0x0

Bits	Field Name	Description	Type	Reset
7:6	SHIFT	<p>Data lane shifter</p> <p>The parallel interface is a 12-bit interface. The CAMERA ISP has 14 data lanes but the full imaging pipeline only supports 10 bits. There are 2 main utilizations of the data lane shifter</p> <p>1) Dynamic reduction: For example data from a 12 bit sensor can be converted into 10bit.</p> <p>2) When a camera module as fewer than 12 data lanes, the ISP requires the pins to be connected on the least significant lanes. An issue occurs when a n-bit camera parallel interface can work in a m-bit mode with m<n. The ISP expects the m bits to be on the least significant data lanes whereas it is not correct.</p> <p>The data lane shifter takes place before the CCDC module</p> <p>0x0: No shift. CAMEXT[13:0] -> CAM [13:0]</p> <p>0x1: Shift by 2. CAMEXT[13:2] -> CAM [11:0]</p> <p>0x2: Shift by 4 CAMEXT[13:4] -> CAM [9:0]</p> <p>0x3: Shift by 6 CAMEXT[13:6] -> CAM [7:0]</p>	RW	0x0
5	RESERVED	<p>Write 0s for future compatibility. Reads returns 0.</p>	RW	0x0
4	PAR_CLK_POL	<p>This bit sets the pixel clock polarity on the parallel interface. The pixel clock is used for latching the pixel data into the CCDC module.</p> <p>0x0: Clock not inverted. The data are sampled on the rising edge of the clock.</p> <p>0x1: Clock inverted. The data are sampled on the falling edge of the clock.</p>	RW	0x0
3:2	PAR_BRIDGE	<p>This bit field controls the 8 to 16-bit bridge at the input of the CCDC module.</p> <p>0x0: The bridge is disabled: no conversion.</p> <p>0x1: Reserved</p> <p>0x2: The bridge is enabled. The first byte is written to cam_d[7:0], the second byte is written to cam_d[15:8]</p> <p>0x3: The bridge is enabled. The first byte is written to cam_d[15:8], the second byte is written to cam_d[7:0]</p>	RW	0x0
1:0	PAR_SER_CLK_SEL	<p>Selects the serial or parallel interface as the input to the preview hardware.</p> <p>0x0: Selects the 12-bit parallel interface as the input to the CCDC module.</p> <p>0x1: Reserved.</p> <p>0x2: Reserved.</p>	RW	0x0

Table 12-85. TCTRL_CTRL

Address Offset		0x0000 0050																Instance		ISP											
Physical Address		0x480B C050																													
Description		TIMING CONTROL - CONTROL REGISTER																													
Type		RW																													
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GRESETDIR	GRESETPOL	GRESETEN	INSEL		STRBPSTRBPOL	RESERVED	SHUTPOL	STRBEN	PSTRBEN	SHUTEN	RESERVED	DIVC					DIVB				DIVA										

Bits	Field Name	Description	Type	Reset
31	GRESETDIR	Sets the direction of the cam_global_reset signal. 0x0: INPUT. cam_global_reset is an input to the TIMING CONTROL module. cam_global_reset is externally generated. 0x1: OUTPUT. cam_global_reset is an output of the TIMING CONTROL module. cam_global_reset is internally generated. If GRESETEN is set to 1, the internally generated cam_global_reset triggers the generation of the PRESTROBE, STROBE and SHUTTER signals. The frame counters are ignored.	RW	0x0
30	GRESETPOL	Sets the polarity of the global reset signal: cam_global_reset. It applies whatever the direction of the cam_global_reset signal: input or output. 0x0: active high 0x1: active low	RW	0x0
29	GRESETEN	Triggers the generation of the cam_global_reset signal. The signal is asserted immediately. If enabled, the cam_global_reset signal is asserted for TCTRL_GRESET_LENGTH cycles. After the signal assertion, the enable bit is automatically cleared to 0. The polarity of the cam_global_reset signal is set with TCTRL_CTRL.GRESETPOL . Enabling this bit triggers the generation of the cam_shutter and cam_strobe signals (if previously enabled). The frame counters must be set to 0 when this bit is set to 1 and GRESETDIR is set a OUTPUT.	RW	0x0
28:27	INSEL	Sets the mode that triggers the SHUTTER, PRESTROBE and STROBE signals. 0x0: Video Port. The VS sync pulse at the input of the CCDC module is used to count the frames. The source of the VS pulse is selected by the ISP_CTRL [1:0] PAR_SER_CLK_SEL register. 0x1: Reserved. 0x2: Reserved. 0x3: GRESET. The cam_global_reset input signal triggers the SHUTTER, PRESTROBE and STROBE signals. In this mode, there are no frame counters. The delay counters start decrementing as soon as the cam_global_reset signal is asserted. The polarity of the cam_global_reset signal is set with TCTRL_CTRL.GRESETPOL .	RW	0x0
26	STRBPSTRBPOL	Sets the polarity of the strobe and prestrobe signals. 0x0: Active high 0x1: Active low	RW	0x0
25	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0

Bits	Field Name	Description	Type	Reset
24	SHUTPOL	Sets the polarity of the mechanical shutter signal: cam_shutter 0x0: Active high 0x1: Active low	RW	0x0
23	STRBEN	Flash strobe signal enable. If enabled, the STROBE signal is asserted after TCTRL_FRAME .STRB frames have been received and a delay of TCTRL_STRB_DELAY cycles have passed. The STROBE signal is asserted for TCTRL_STRB_LENGTH cycles. After the signal assertion, the enable bit is automatically cleared to 0. This signal must not be disabled by software.	RW	0x0
22	PSTRBEN	Flash prestrobe signal enable. If enabled, the PRESTROBE signal is asserted after TCTRL_FRAME .PSTRB frames have been received and a delay of TCTRL_PSTRB_DELAY cycles have passed. The PRESTROBE signal is asserted for TCTRL_PSTRB_LENGTH cycles. After the signal assertion, the enable bit is automatically cleared to 0. This signal must not be disabled by software.	RW	0x0
21	SHUTEN	Mechanical shutter signal enable. If enabled, the SHUTTER signal is asserted after TCTRL_FRAME .SHUT frames have been received and a delay of TCTRL_SHUT_DELAY cycles have passed. The SHUTTER signal is asserted for TCTRL_SHUT_LENGTH cycles. After the signal assertion, the enable bit is automatically cleared to 0. This signal must not be disabled by software.	RW	0x0
20:19	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
18:10	DIVC	Sets the clock divisor value for the CNTCLK clock generation based on the CAM_MCLK input clock. CNTCLK is an internal clock used by the TIMING CTRL module counters. Usually, CNTCLK = CAM_MCLK/DIVC, except for some particular values shown hereafter. 0x0: No clock. CNTCLK is gated.	RW	0x000
9:5	DIVB	Sets the clock divisor value for the cam_xclkb clock generation based on the CAM_MCLK input clock. Usually, cam_xclkb = CAM_MCLK/DIVB, except for some particular values shown hereafter. This bit field is not reset by a soft reset; a hard reset is required. It enables to keep the clock configuration stable through a soft reset. 0x0: cam_xclkb = stable low level. Divider disabled. 0x1: cam_xclkb = stable high level. Divider disabled. 0x1F: cam_xclkb = cam_xclk. Bypass.	RW	0x00
4:0	DIVA	Sets the clock divisor value for the cam_xclka clock generation based on the CAM_MCLK input clock. Usually, cam_xclka = CAM_MCLK/DIVA, except for some particular values shown hereafter. This bit field is not reset by a soft reset; a hard reset is required. It enables to keep the clock configuration stable through a soft reset. 0x0: cam_xclka = stable low level. Divider disabled. 0x1: cam_xclka = stable high level. Divider disabled. 0x1F: cam_xclka = cam_xclk. Bypass.	RW	0x00

Description	TIMING CONTROL - STROBE LENGTH REGISTER This register is used by the TIMING CTRL module to generate the STROBE signal.																														
Type	RW																														
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								LENGTH																							
Bits		Field Name						Description															Type		Reset						
31:24		RESERVED						Write 0s for future compatibility. Reads returns 0.															RW		0x00						
23:0		LENGTH						Sets the length of the cam_strobe signal assertion in cycles of the CNTCLK clock. The CNTCLK frequency is generated with the TCTRL_CTRL.DIVC bit field. After signal assertion, the TCTRL_CTRL.STRBEN bit is automatically cleared. The possible values are 0 to 2^24-1 cycles.															RW		0x000000

12.6.3.5 CBUFFx_CTRL

Table 12-109. CBUFFx_CTRL

Address Offset	0x0000 0020 + (0x4 * x)	Index	x = 0 to 1
Physical Address	0x480B C120 + (0x4 * x)	Instance	ISP_CBUFF
Description	Circular buffer x control register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																WCOUNT		BCF				ALLOW_NW_EQ_CPUW	DONE	RWMODE	ENABLE						

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x000000
9:8	WCOUNT	Window count 0x0: 2 windows 0x1: 4 windows 0x2: 8 windows 0x3: 16 windows	RW	0x0
7:4	BCF	This register controls the bandwidth control feedback loop output. Functionality depends on subsystem integration. 0: Control loop disabled. Data read from memory is free running. 1-15: The control feedback loop signal is asserted when the window count available for ISP is below (<) the threshold. In other words at least (>=) BCF windows are available for ISP access when this signal is released.	RW	0x0
3	ALLOW_NW_EQ_CPUW	Allow NW=CPUW. Better buffer utilization when ISP does not use the next write window. 0x0: When the CPUW and the NW pointers designate the same window and accesses are effectively performed to those windows an overflow event occurs. This happens when - the CPU has received an READY IRQ for that window indicating that it can be accessed and - the ISP performs an access to that window. ISP accesses are tracked based on OCPI activity. 0x1: When the CPUW and the CW pointers designate the same window and accesses are effectively performed to those windows an overflow event occurs. This happens when - the CPU has received an READY IRQ for that window indicating that it can be accessed and - the ISP performs an access to that window. ISP accesses are tracked based on OCPI activity.	RW	0x0
2	DONE	Write this bit to 1 to indicate the CPU has finished processing its physical buffer. This bit is automatically cleared by hardware, reads always return 0. 0x0: No effect. 0x1: The CPU has completely processed the CPUW physical buffer.	W	0x0
1	RWMODE	Selects read or write mode 0x0: Write mode. HW writes and CPU reads the physical space. CPU accesses are out of CBUFF module's scope, therefore only writes are permitted between CBUFF0_START and CBUFF0_END. 0x1: Read mode. HW reads and CPU writes the physical space. CPU accesses are out of CBUFF module's scope; therefore only reads are permitted between CBUFF0_START and CBUFF0_END.	RW	0x0
0	ENABLE	Enable/disable 0x0: Disables the circular buffer 0; this resets the internal state of circular buffer 0. All accesses received on OCPI are transmitted to OCPO without modification. Disabling the module takes effect immediately. It is SW responsibility to ensure that no more accesses to CBUFF0 are outstanding before disabling the module. Otherwise memory corruption may occur. 0x1: Enable the circular buffer 0. All accesses between CBUFF0_START and CBUFF0_END are processed by the module.	RW	0x0

12.6.4.3 CCDC_SYN_MODE

Table 12-125. CCDC_SYN_MODE

Address Offset	0x0000 0008																														
Physical Address	0x480B C608															Instance	ISP_CCDC														
Description	SYNC and mode set register																														
Type	RW																														

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED												SDR2RSZ	VP2SDR	WEN	VDHLEN	FLDSTAT	LPF	INPMOD	PACK8	DATSIZ			FLDMODE	DATAPOL	EXWEN	FLDPOL	HDPOL	VPOL	FLDOUT	VDHOUT	

Bits	Field Name	Description	Type	Reset
31:20	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x000
19	SDR2RSZ	Memory port output into the RESIZER input. Controls whether or not the memory port output data are forwarded to the RESIZER module input port. This does not depend on the state of the CCDC_SYN_MODE.WEN bit. This bit must only be set if the CCDC module receives directly YUV422 data. The input frame size to the RESIZER module is the same as the output frame size to the memory port. The data are simultaneously written to memory if the WEN bit is set while sending the same data to the RESIZER module. The PREVIEW module can also write to the RESIZER module: this bit takes precedence over the PREVIEW module settings. This bit is latched by the VS sync pulse. 0x0: Disable 0x1: Enable	RW	0x0
18	VP2SDR	Video port output enable to the output formatter.. Controls whether the video port data is forwarded to the output formatter or not. If CCDC_SYN_MODE.WEN = 1, the video port data is written to memory. Note that if field is set, then SDRAM line (VERT_START.SLVx) and pixel start (HORZ_INFO.SPH) are with respect to the video port output (and not the original input) This bit field is latched by the VS sync pulse. 0x0: Disable 0x1: Enable	RW	0x0
17	WEN	Data write enable. Controls whether the CCDC module output data are written to memory or not. This bit field is latched by the VS sync pulse. 0x0: Disable 0x1: Enable	RW	0x0
16	VDHDEN	Timing generator enable. If HS/VS sync pulses are defined as output signals, activates the internal timing generator. If HS/VS sync pulses are defined as input signals, activates internal timing generator to synchronize with HS/VS. This bit must be set to 1 when HS and VS signals are used. 0x0: Disable 0x1: Enable	RW	0x0
15	FLDSTAT	cam_fld signal status. This bit field applies only if the CCDC module is configured to work in interlaced mode: CCDC_SYN_MODE.FLDMODE = "interlaced". It indicates the status of the current field. 0x0: Odd field 0x1: Even field	R	0x0
14	LPF	Three-tap low pass (antialiasing) filter enable. This bit field is latched by the VS sync pulse. 0x0: Filter is disabled. 0x1: Filter is enabled.	RW	0x0

Bits	Field Name	Description	Type	Reset
13:12	INPMOD	cam_d format in SYNC mode. Sets the data input format. 0x0: Raw data 0x1: YCbCr data on 16 bits. It is required to enable the 8 to 16-bit bridge in the ISP_CTRL register. 0x2: YCbCr data on 8 bits.	RW	0x0
11	PACK8	Data packing. Sets the data packing configuration when the data is written to memory. 0x0: Normal mode: 16 bits/pixel. 0x1: Pack mode: 8 bits/pixel.	RW	0x0
10:8	DATSIZ	cam_d signal width in SYNC mode. Valid only when CCDC_SYN_MODE .INPMOD = "raw data". 0x0: cam_d is 8 bits but the 8 to 16-bit bridge is enabled in the ISP_CTRL register. 0x4: cam_d is 12 bits 0x5: cam_d is 11 bits 0x6: cam_d is 10 bits 0x7: cam_d is 8 bits	RW	0x0
7	FLDMODE	cam_fld signal mode. 0x0: Progressive mode. cam_fld not used. 0x1: Interlaced mode. cam_fld used.	RW	0x0
6	DATAPOL	cam_d signal polarity. 0x0: Normal 0x1: One's complement	RW	0x0
5	EXWEN	External write enable selection. The cam_wen signal can be used as an external memory write-enable signal. The data is stored to memory only if cam_hs, cam_vs and cam_wen signals are asserted. 0x0: cam_wen is not used. 0x1: cam_wen is used	RW	0x0
4	FLDPOL	cam_fld signal polarity. 0x0: Positive 0x1: Negative	RW	0x0
3	HDPOL	Sets the cam_hs signal polarity. 0x0: Positive 0x1: Negative	RW	0x0
2	VDPOL	cam_vs signal polarity 0x0: Positive 0x1: Negative	RW	0x0
1	FLDOUT	cam_fld signal direction. 0x0: Input 0x1: Output	RW	0x0
0	VDHDOUT	cam_hs and cam_vs signal directions. 0x0: Input 0x1: Output	RW	0x0

12.6.4.17 CCDC_FPC

Table 12-153. CCDC_FPC

Address Offset	0x0000 0040																																															
Physical Address	0x480B C640																Instance																ISP_CCDC															
Description	FAULT PIXEL CORRECTION REGISTER																																															
Type	RW																																															

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
RESERVED																FPERR	FPEN	FPNUM															

Bits	Field Name	Description	Type	Reset
31:17	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0000
16	FPERR	<p>Fault pixel correction error</p> <p>This bit is set when the CCDc module is unable to fetch the required fault pixel table entry in time. Write 1 to clear the error or end_of_frame clears it automatically for the next frame.</p> <p>For example, the current pixel being processed has coordinates of 256/512 (256th line and 512th pixel in that line) and it must be corrected. If the entry in the fault pixel table that must be used has coordinates 256/256, then the current pixel cannot be corrected since the correct entry is not loaded in time.</p> <p>Note that there is no error recovery mechanism in the CCDc; if this bit is set at anytime in a frame, there are no more fault pixels corrected in that frame. Firmware is responsible for making sure that there is enough bandwidth in the system to allow for loading of the fault pixel table. Alternately, decreasing the frequency of the fault pixels to be corrected enhances the chances of this bit not being set.</p> <p>0x0: No error</p> <p>0x1: Error</p>	RW	0x0
15	FPCEN	<p>Fault pixel correction enable.</p> <p>Upon setting this bit, and as long as it remains enabled, the fault pixel logic continues to request data and just start over for next frame once the last data of current frame has been received. As soon as the register is set the data are fetched. To disable fault pixel correction, users can write a 0 at any time. However, the disabling only applies after the current frame is processed (busy bit for current frame is 0)</p> <p>This bit should only be written after the FPC_ADDR register below has been set. Also, the other fields in this register have to be set prior to enabling this bit. The required process is:</p> <p>Write(FPC_ADDR)</p> <p>Write(FPC) with this bit (FPC.FPCEN) turned off</p> <p>Write(FPC) with this bit (FPC.FPCEN) turned on while other fields are same as previous write</p> <p>0x0: Disable</p> <p>0x1: Enable</p>	RW	0x0
14:0	FPNUM	<p>Number of fault pixels to be corrected in the frame</p> <p>This field should not be changed when the FPCEN is enabled at any time</p>	RW	0x0000

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0000
15	VDLC	Enable latching function registers on the internal VS sync pulse. If this bit is set, all the register fields that are VS pulse latched take on new values immediately. Care should be taken not to alter fields that can cause undesired behavior to the output data NOTE: In OMAP35x, this bit must be set to 1 by software if the CCDC is to be used. If CCDCFG.VDLC remains set to 0 (default), indeterminate results may occur for ANY register access in the CCDC. For details, see Section 12.5, Basic Programming Model . 0x0: Latched on VS 0x1: Not latched on VS	RW	0x0
14	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
13	MSBINVI	MSB of chroma input signal stored to memory inverted. 0x0: Normal 0x1: MSB inverted	RW	0x0
12	BSWD	Byte swap data stored to memory. 0x0: Normal 0x1: Swap bytes	RW	0x0
11	Y8POS	Location of Y color component when YCbCr 8-bit data is input. 0x0: Even pixel 0x1: Odd pixel	RW	0x0
10:9	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
8	WENLOG	Valid area settings 0x0: Internal valid signal and WEN signal are ANDed logically. 0x1: Internal valid signal and WEN signal are ORed logically.	RW	0x0
7:6	FIDMD	Settings of field identification detection function. 0x0: FLD signal is latched at the VS timing. The external Field signal is latched when the VD is active and the active edge of the HD signal 0x1: FLD signal is not latched. The field signal is not latched at all 0x2: FLD signal is latched at edge of VS. The field signal is latched on the active edge of the VD signal 0x3: FLD signal is latched on phase of VS and HS. The field signal is latched when the VD signal is active and the HD signal is inactive (opposite phase)	RW	0x0

Bits	Field Name	Description	Type	Reset
5	BW656	The data width in ITU-R BT656 input mode. This bit field takes precedence over the CCDC_SYN_MODE .INPMOD and CCDC_DATSIZ bit fields if the ITU mode is enabled with CCDC_REC656IF .R656ON = 1. 0x0: 8 bits 0x1: 10 bits	RW	0x0
4	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
3	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0

RESERVED								VPIF_FRQ				VPEN	VPIN		PLEN_EVEN	
															PLEN_ODD	
															LNUM	LNALT
																FMTEN

Bits	Field Name	Description	Type	Reset
31:19	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0000
18:16	VPIF_FRQ	Video port data ready frequency. This field allows the firmware to control the rate at which the video port delivers new data to the other modules (PREVIEW, H3A, and HIST modules). In effect, this register controls the raw output bandwidth of the PREVIEW, H3A, and HIST. Depending on the input sensor clock, users can set this field appropriately and balance the bandwidth requirements to memory. Given a pixel clock, one must set this bit field with the higher divisor value to lower the memory bandwidth requirement. 0x0: 0x1: 1/3.5 0x2: 1/4.5 0x3: 1/5.5 0x4: 1/6.5	RW	0x0
15	VPEN	Video port enable. This bit must be enabled to send data to the PREVIEW, H3A and HIST modules. 0x0: Disable 0x1: Enable	RW	0x0
14:12	VPIN	10-bit input select for video port. 0x3: bits 12-3 0x4: bits 11-2 0x5: bits 10-1 0x6: bits 9-0	RW	0x4
11:8	PLEN_EVEN	Number of program entries in even line minus 1. If the desired number of program entries is 8, then the value must be set to 7.	RW	0x0
7:4	PLEN_ODD	Number of program entries in odd line minus 1. If the desired number of program entries is 8, then the value must be set to 7.	RW	0x0
3:2	LNUM	Number of output lines from 1 input line 0x0: 1 line 0x1: 2 lines 0x2: 3 lines 0x3: 4 lines	RW	0x0
1	LNALT	Line alternating mode enable. In Line Alternating Mode, even and odd lines are swapped. 0th line output as 1st line and 1st line output as 0th line, and so on. If this bit field is set, the start and number of lines for the formatter (FMTVERT below) must be even. The FMTEN field below must be set in addition for this field to function 0x0: Enable. Normal mode 0x1: Disable. Line alternating mode	RW	0x0
0	FMTEN	Formatter enable. This bit is latched by the VS sync pulse. 0x0: Disable 0x1: Enable	RW	0x0

12.6.4.31 CCDC_VP_OUT

Table 12-181. CCDC_VP_OUT

Address Offset	0x0000 0094	Instance	ISP_CCDC
Physical Address	0x480B C694		
Description	VIDEO PORT OUTPUT REGISTER		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED	VERT_NUM																HORZ_NUM								HORZ_ST						

Bits	Field Name	Description	Type	Reset
31	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
30:17	VERT_NUM	Number of vertical lines to clock out the video. If the data reformatter is turned off, then the number of lines that can be clocked out of the video port must be at least 1 line less than the number of lines input from the sensor. If the data reformatter is turned on, then the number of lines that can be clocked out of the video port must be less than (CCDC_FMT_VERT .FMTLNV - 1) * (CCDC_FMTCFG .LNUM + 1) The video port output VS pulse is generated right from the first video port input VS itself.	RW	0x0000
16:4	HORZ_NUM	Number of horizontal pixel to clock out the video port. The minimum value allowed is 2 pixels. The maximum offset allowed is 1376 if original input is broken down to 4 lines. The maximum offset allowed is 1376 if original input is broken down to 3 lines. The maximum offset allowed is 2*1376 if original input is broken down to 2 lines. The maximum offset allowed is 4*1376 if original input is broken down to 1 line.	RW	0x0000

Bits	Field Name	Description	Type	Reset
3:0	HORZ_ST	Horizontal start pixel in each output line. The maximum value allowed is 15. The video port output HSYNC pulse is generated from this position on for each line. To be able to select an offset higher than 15, the input settings to the data reformatter must be configured appropriately. The purpose of this parameter is to allow for sensors that can read out a parallelogram image rather than a rectangular image.	RW	0x0

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Write 0s for future compatibility. Reads return zero.	RW	0x00000
14:12	GAIN_MODE_M	Define the horizontal dimension of a paxel. Possible values are listed below 0x2: Paxel is 4 pixels tall (M=4) 0x3: Paxel is 8 pixels tall (M=8) 0x4: Paxel is 16 pixels tall (M=16) 0x5: Paxel is 32 pixels tall (M=32) 0x6: Paxel is 64 pixels tall (M=64)	RW	0x6
11	RESERVED	Write 0s for future compatibility. Reads return zero.	R	0x0

Bits	Field Name	Description	Type	Reset
10:8	GAIN_MODE_N	Define the vertical dimension of a paxel. Possible values are listed below 0x2: Paxel is 4 pixels tall (N=4) 0x3: Paxel is 8 pixels tall (N=8) 0x4: Paxel is 16 pixels tall (N=16) 0x5: Paxel is 32 pixels tall (N=32) 0x6: Paxel is 64 pixels tall (N=64)	RW	0x6
7	BUSY	Module busy or idle 0x0: The module is idle 0x1: The module is busy	R	0x0
6	AFTER_REFORMATTER	Chooses if lens-shading compensation is done before or after data reformatting 0x0: Lens-shading is done before data reformatting. H3A, HIST and PREVIEW receives shading compensated data 0x1: Data received by H3A isn't compensated. Data received by PREVIEW and HIST is compensated.	RW	0x0
5:4	RESERVED	Write 0s for future compatibility. Reads return zero.	RW	0x0
3:1	GAIN_FORMAT	Sets gain table format 0x0: Coded as 8-bit fraction Range from 0 to 255/256 0x1: Coded as 8-bit fraction + 1.0 of base. Range from 1 to 1+255/256 0x2: Coded as 1-bit integer, 7-bit fraction. Range from 0 to 1+127/128 0x3: Coded as 1-bit integer, 7-bit fraction + 1.0 Range from 1 to 2+127/128 0x4: Coded as 2-bit integer, 6-bit fraction Range from 0 to 3+63/64 0x5: Coded as 2-bit integer, 6-bit fraction + 1.0 Range from 1 to 4+63/64 0x6: Coded as 3-bit integer, 5-bit fraction Range from 0 to 7+31/32 0x7: Coded as 3-bit integer, 5-bit fraction + 1.0 Range from 1 to 8+31/32	RW	0x0
0	ENABLE	Enables/disables LSC 0x0: Disables the module at the end of the current frame. Video data is transmitted without modification when LSC is disabled. The BUSY bit can be used to poll when access to SBL buffer can be used by the preview module. 0x1: Enables the module. Module starts fetching the gain table as soon it is started. Firmware has to make sure it has been correctly initialized before starting the module. Data processing is only effective at the start of the next frame. Note that preview module dark frame subtract must be disabled because there is only one shared read port.	RW	0x0

12.6.7.2 PRV_PCR

Table 12-263. PRV_PCR

Address Offset		0x0000 0004																Instance		ISP_PREVIEW											
Physical Address		0x480B CE04																													
Description		PERIPHERAL CONTROL REGISTER All the fields in this register can be altered even when the PREVIEW module is busy. Changes take place only for the next frame.																													
Type		RW																													
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DRK_FAIL	RESERVED		DCOR_METHOD	DCOREN	GAMMA_BYPASS	RESERVED		SCOMP_SFT		SCOMP_EN	SDRPORT	RSZPORT	YCPOS		SUPEN	YNENHEN	CFAFMT				CFAEN	NFEN	HMEDEN	DRKFCAP	DRKFEN	INVALAW	WIDTH	ONESHOT	SOURCE	BUSY	ENABLE

Bits	Field Name	Description	Type	Reset
31	DRK_FAIL	Dark frame subtract fail status. Write 1 to clear this bit. Reset to zero for the next frame. When the error is triggered, dark frame subtract is abandoned for the current frame, dark frame subtract resumes for next frame (but bit is not cleared unless explicitly done by firmware). 0x0: No error 0x1: Error	RW	0x0
30:29	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
28	DCOR_METHOD	Defect correction method. 0x0: MinMax 0x1: MinMax2 (Couplet defect correction)	RW	0x0
27	DCOREN	Defect correction enable This bit enables or disables the defect correction. The PRV_PCR.DCOR_METHOD and PRV_CDC_THRx registers must be configured for correct operation. 0x0: Disable defect correction 0x1: Enable defect correction	RW	0x0
26	GAMMA_BYPASS	Bypass, the output is set to the 8 MSB of the 10-bit input. 0x0: No bypass. 0x1: Bypass, the output is set to the 8 MSB of the 10-bit input.	RW	0x0

Bits	Field Name	Description	Type	Reset
25	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
24:22	SCOMP_SFT	Shading compensation shift value after multiplication. The right-shift range is 0 to 7.	RW	0x0
21	SCOMP_EN	Shading compensation enable instead of dark frame The 8-bit value loaded from memory is multiplied by the current pixel instead of subtracting it. Note that the dark frame subtract (DRKFEN) must be enabled in addition to this bit being active to perform shading compensation. 0x0: Disable. Dark frame subtract can be used. 0x1: Enable. Dark frame subtract cannot be used.	RW	0x0
20	SDRPORT	PREVIEW module memory output port enable. This bit enables or disables the data transfer from the PREVIEW module to the memory. 0x0: Disable 0x1: Enable	RW	0x1
19	RSZPORT	RESIZER module output port enable. This bit enables or disables the data transfer between the PREVIEW and RESIZER modules. Controls whether or not SDRAM output data is forwarded to the resizer input port. This control bit does not depend on the state of the former SDRPORT bit. Data is simultaneously written to SDRAM (if SDRPORT bit is set) while sending the same data to the resizer as input. Note that the CCDC is also capable of directly writing to the resizer input port. The CCDC setting takes precedence over the preview engine setting. 0x0: Disable 0x1: Enable	RW	0x0
18:17	YCPOS	(CRYCBY) Cr0(31:24) Y1(23:16) Cb0(15:8) Y0(7:0) 0x0: (YCRYCB) Y1(31:24) Cr0(23:16) Y0(15:8) Cb0(7:0) 0x1: (YCBYCR) Y1(31:24) Cb0(23:16) Y0(15:8) Cr0(7:0) 0x2: (CBYCRY) Cb0(31:24) Y1(23:16) Cr(15:8) Y0(7:0) 0x3: (CRYCBY) Cr0(31:24) Y1(23:16) Cb0(15:8) Y0(7:0)	RW	0x0
16	SUPEN	Color suppression. 0x0: Disable 0x1: Enable	RW	0x0
15	YNENHEN	Non-linear enhancer 0x0: Disable 0x1: Enable	RW	0x0
14:11	CFAFMT	CFA format 0x0: Mode 0: conventional Bayer. 0x1: Mode 1: horizontal 2x downsample. 0x2: Mode 2: bypass CFA stage (RGB Foveon) 0x3: Mode 3: horizontal and vertical 2x downsample. 0x4: Mode 4: Fuji Honeycom movie mode sensor. 0x5: Mode5: bypass CFA stage (RRRR GGGG BBBB Foveon).	RW	0x0
10	CFAEN	CFA enable 0x0: Disable 0x1: Enable	RW	0x0
9	NFEN	Noise filter enable 0x0: Disable 0x1: Enable	RW	0x0

Bits	Field Name	Description	Type	Reset
8	HMEDEN	Horizontal median filter enable. 0x0: Disable 0x1: Enable	RW	0x0
7	DRKFCAP	Dark frame capture enable. 0x0: Normal processing. 0x1: Capture dark frame.	RW	0x0
6	DRKFEN	Subtract dark frame enable. 0x0: Disable 0x1: Enable	RW	0x0
5	INVALAW	Inverse A-Law enable. 0x0: Disable 0x1: Enable	RW	0x0
4	WIDTH	Input data width selection. 0x0: 10-bit mode 0x1: 8-bit mode	RW	0x0
3	ONESHOT	One-shot mode selection. If this bit is set to 1, it is reset to 0 after the ENABLE bit is asserted. 0x0: Continuous mode (through the video port). 0x1: One shot mode.	RW	0x0
2	SOURCE	Input source selection. If this bit is set to 1, it is reset to 0 after the ENABLE bit is asserted. 0x0: Video port (through the CCDC) 0x1: Memory.	RW	0x0
1	BUSY	Busy bit. 0x0: PREVIEW module not busy. 0x1: PREVIEW module busy.	R	0x0
0	ENABLE	Enable bit. If the ONESHOT or SOURCE bit is 1, this bit is reset to 0 after it is asserted 0x0: PREVIEW module disabled. 0x1: PREVIEW module enabled.	RW	0x0

RADR																															

Bits	Field Name	Description	Type	Reset
31:0	RADR	32-bit read address. Specifies the 32-bit address in memory of the input frame. The lower 5 bits of this register are always treated as 0s. The offset should be aligned on a 32-byte boundary. This field can be altered even when the PREVIEW module is busy. The change takes place only for the next frame (next VS pulse). However, note that reading this register always gives the latest value.	RW	0x00000000

12.6.8.5 RSZ_IN_START

Table 12-339. RSZ_IN_START

Address Offset	0x0000 0010																																
Physical Address	0x480B D010																Instance	ISP_RESIZER															
Description	INPUT CONFIGURATION REGISTER This register must be used when the input pixel data comes from the PREVIEW module. must be set to 0 is the input pixel data comes from memory.																																
Type	RW																																
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
RESERVED				VERT_ST												RESERVED				HORZ_ST													
Bits	Field Name		Description																			Type		Reset									
31:29	RESERVED		Write 0s for future compatibility. Reads returns 0.																			RW		0x0									
28:16	VERT_ST		Vertical start line. This field makes sense when the resizer obtains its input from the preview engine/CCDC When the resizer gets its input from SDRAM, this field must be set to 0																			RW		0x0000									

Bits	Field Name	Description	Type	Reset
15:13	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
12:0	HORZ_ST	Horizontal start pixel. Pixels are coded on 16 bits for YUV and 8 bits for color separate data. When the resizer gets its input from SDRAM, this field must be set to <= 15 for YUV 16-bit data and <= 31 for 8-bit color separate data Horizontal starting pixel value is in number of pixels if input is from SDRAM. If the input to the resizer is from CCDC/preview engine, this field must be programmed as follows: (1) Program this field using number of bytes (twice number of pixels). (2) Change the lowest bit to reflect start position in pixels (effectively change from a value 0 to a value 1 if required)	RW	0x0000

Table 12-419. SBL_PCR

Address Offset	0x0000 0004																																																																																																
Physical Address	0x480B D204																Instance	ISP_SBL																																																																															
Description	PERIPHERAL CONTROL REGISTER Note on the overflow bits: the overflow does not prevent the modules to make further requests. The only way to clear the overflow is to reset the bit. After an overflow, the data are corrupted and the application layer should disregard the data. No software reset is required after an overflow. If the overflow condition is cleared, the data continue to be acquired normally.

31:25	RESERVED							Write 0s for future compatibility. Reads returns 0.																RW							0x00																																																																		
24	CCDCPRV_2_RSZ_OVF							CCDC/PRV to RESIZER input overflow This bit is set if the RESIZER input source is set to CCDC/PREVIEW engine when the active data (to be resized) has already showed up at the resizer interface. In such a case, resizing for this frame cannot take place and the bit is set. This scenario can happen when a resize of > 4x is required per frame. Therefore, the RESIZER needs to operate in two passes. In the first pass the input data from CCDC/PREVIEW is directly resized and written to memory. In the second pass, the resized data from the first pass is resized again. The next frame from the CCDC/PREVIEW engine should only start after the second pass on the previous frame is complete. This bit indicated the failure status. Software has to write 1 to clear the bit. 0x0: No overflow 0x1: Overflow																RW							0x0																																																																		

Bits	Field Name	Description	Type	Reset

2D/3D Graphics Accelerator (SGX)

This chapter describes the 2D/3D graphics accelerator (SGX) for the device.

Note: SGX is not available on all devices. See Chapter 1, the *OMAP35x Family* section, to check availability of this feature.

Note: The SGX is an instantiation of the POWERVR™ SGX from Imagination Technologies™ Ltd. This document contains materials that are Copyright © 2003-2007 Imagination Technologies Ltd. POWERVR, and Imagination Technologies are trademarks or registered trademarks of Imagination Technologies Ltd. All such materials and trademarks are used under license from Imagination Technologies Ltd.

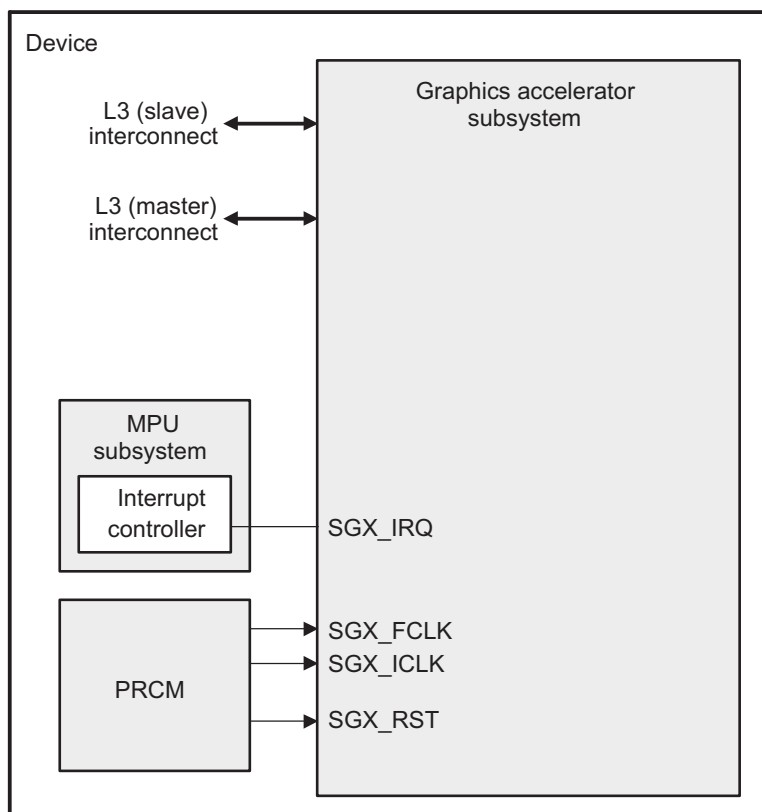

Topic	Page
13.1 SGX Overview	1728
13.2 SGX Integration	1731
13.3 SGX Functional Description	1733
13.4 SGX Registers	1735
13.5 Revision History	1736

13.1 SGX Overview

The 2D/3D graphics accelerator (SGX) subsystem accelerates 2-dimensional (2D) and 3-dimensional (3D) graphics applications. The SGX subsystem is based on the SGX core from Imagination Technologies. SGX is a new generation of programmable PowerVR graphic cores. Targeted applications include feature phones, PDA, hand-held games, PND (portable navigation devices), MID (mobile Internet devices), automotive, and medical instrumentation.

Figure 13-1 shows the SGX subsystem in the device.

Figure 13-1. Graphics Accelerator Highlight

sgx-001

The SGX graphics accelerator efficiently processes a number of various multimedia data types concurrently:

- Pixel data
- Vertex data

This is achieved using a multithreaded architecture using two levels of scheduling and data partitioning enabling zero overhead task switching.

The SGX subsystem is connected by a 64-bit master and a 32-bit slave interface to the L3 interconnect.

13.1.1 PowerVR SGX Main Features

- 2D graphics, 3D graphics, vector graphics, and programmable GPU functions
- Tile-based architecture
- Universal scalable shader engine (USSE) – multithreaded engine incorporating pixel and vertex shader functionality
- Advanced shader feature set – in excess of Microsoft VS3.0, PS3.0, and OGL2.0

- Industry standard API support - OpenGL-ES 1.1 and 2.0, OpenVG 1.0.1
- Fine-grained task switching, load balancing, and power management
- Advanced geometry direct memory access (DMA) driven operation for minimum CPU interaction
- Programmable high-quality image anti-aliasing
- PowerVR SGX core MMU for address translation from the core virtual address to the external physical address (up to 4GB address range)
- Fully virtualized memory addressing for OS operation in a unified memory architecture
- 2D operations via the 3D pipeline

13.1.2 SGX 3D features

- Deferred pixel shading
- On-chip tile floating point depth buffer
- 8-bit stencil with on-chip tile stencil buffer
- 8 parallel depth/stencil tests per clock
- Scissor test
- Texture support:
 - Cube map
 - Projected textures
 - 2D textures
 - nonsquare textures
- Texture formats:
 - RGBA 8888,565,1555
 - Monochromatic 8, 16, 16f, 32f, 32int
 - Dual channel, 8:8, 16:16, 16f:16f
 - Compressed textures PVR-TC1, PVR-TC2, ETC1
 - Programmable support for all YUV formats
- Resolution support:
 - Frame buffer maximum size = 2048 x 2048
 - Texture maximum size = 2048 x 2048
- Texture filtering:
 - Bilinear, tri-linear, anisotropic
 - Independent minimum and maximum control
- Anti-aliasing:
 - 4x multisampling
 - Up to 16x full scene anti-aliasing
 - Programmable sample positions
- Indexed primitive list support
 - Bus mastered
- Programmable vertex DMA
- Render to texture:
 - Including twiddled formats
 - Auto MipMap generation
- Multiple on-chip render targets (MRT). Note: Performance is limited when the on-chip memory is not available.

13.1.3 Universal Scalable Shader Engine – Key Features

The (USSE) is the engine core of the PowerVR SGX architecture and supports a broad range of instructions.

- Single programming model:

- Multithreaded with 16 simultaneous execution threads and up to 64 simultaneous data instances
- Zero-cost swapping in, and out, of threads
- Cached program execution model
- Dedicated pixel processing instructions
- Dedicated video encode/decode instructions
- SIMD execution unit supporting operations in:
 - 32-bit IEEE float
 - 2-way 16-bit fixed point
 - 4-way 8-bit integer
 - 32-bit bit-wise (logical only)
- Static and dynamic flow control:
 - Subroutine calls
 - Loops
 - Conditional branches
 - Zero-cost instruction predication
- Procedural geometry:
 - Allows generation of primitives
 - Effective geometry compression
 - High-order surface support
- External data access:
 - Permits reads from main memory using cache
 - Permits writes to main memory
 - Data fence facility
 - Dependent texture reads

13.2 SGX Integration

Figure 13-2 highlights the SGX subsystem integration in the device.

Figure 13-2. SGX Subsystem Integration

13.2.1 Clocking, Reset, and Power-Management Scheme

13.2.1.1 Clocks

The SGX subsystem operates from two clocks: an interface clock (SGX_ICLK) and a functional clock (SGX_FCLK). The power, reset, and clock management (PRCM) module generates and distributes both clocks inside the device. The SGX clock tree is depicted in the *SGX Power Domain Clocking Scheme* section in the *Power, Reset, and Clock Management* chapter.

Table 13-1. Clock Descriptions

Signal Name	I/O ⁽¹⁾	Description
SGX_FCLK	I	Functional clock (two possible clock sources) -> Functional clock domain
SGX_ICLK	I	Interface clock (L3 interconnect clock domain) -> Interface clock domain

⁽¹⁾ I = Input, O = Output,

- The SGX_ICLK interface clock manages the data transfer on the L3 master and slave ports. The source of SGX_ICLK is the PRCM clock (SGX_L3_ICLK), which belongs to the SGX clock domain and runs at the L3 interconnect clock speed. The SGX_ICLK frequency is selected based on the whole device L3 interconnect clock frequency. For more information on the interface clock, see *Power, Reset, and Clock Management* chapter.
- When no longer required by the SGX subsystem, SGX_ICLK can be disabled by software at the PRCM level by setting the PRCM.CM_ICLKEN_SGX[0] EN_SGX bit to 0. For more information, see

SGX Power Domain Clock Controls section in the *Power, Reset, and Clock Management* chapter.

Note: SGX_ICLK is cut only if the SGX is ready to go into idle state. For more information, see *Power, Reset, and Clock Management* chapter.

- SGX_FCLK is the functional clock and is used inside the SGX subsystem to generate SGX and 3D domain clock signals.

The source of SGX_FCLK is either the PRCM clock (SGX_L3_FCLK, which is derived from SGX_ICLK) or the peripheral DPLL clock DPLL4_M2X2_CLK as depicted in the *SGX Power Domain Clocking Scheme* section of the *Power, Reset, and Clock Management* chapter. Selection is made at the PRCM level by setting the PRCM.CM_CLKSEL_SGX[2:0] CLKSEL_SGX bit field. A divider of 3, 4, or 6 is applied to the SGX_FCLK frequency with regard to the PRCM SGX_L3_FCLK frequency. By default the SGX_FCLK clock is SGX_L3_FCLK / 3.

Whether SGX_FCLK is provided by SGX_L3_FCLK or DPLL4_M2X2_CLK, its gating depends on the PRCM.CM_FCLKEN_SGX[1] EN_SGX bit. Clearing this bit to 0 indicates that both SGX clocks are no longer needed and can be cut at the PRCM level, if the module is ready to enter the idle state. For more information, see the *SGX Power Domain* section in the *Power, Reset, and Clock Management* chapter.

13.2.1.2 Resets

The SGX subsystem has its own reset domain. Global reset of the SGX is performed by activating the SGX_RST signal in the SGX_RST domain. Software controls the release of SGX_RST using the PRCM.RM_RSTCTRL_SGX[0] SGX_RST bit.

13.2.1.3 Power Management

The SGX subsystem has its own power domain (SGX power domain). See the *Power, Reset, and Clock Management* chapter, for additional information about the SGX power domain.

As described in [Section 13.2, SGX Integration](#), the SGX subsystem receives two clock signals from the PRCM module. The functional clock is either a division of the interface clock with a ratio of 1:3, 1:4, or 1:6, or a 96-MHz clock issued from a DPLL4. The functional clock is used inside the SGX to generate clock signals to the multiple internal module SGX clock domains. The division ratio depends on the PRCM registers setting. For more information, see the *Power, Reset, and Clock Management* chapter.

Three power-management modes are defined:

- Deep power sleep (All clocks are gated.)
- Idle (3D clocks are gated.)
- 3D (No clock is gated.)

The SGX handles the automatic clock gating performed on the multiple internal module clock domains.

13.2.2 Hardware Requests

13.2.2.1 Interrupt Request

The SGX subsystem can generate one interrupt (SGX_IRQ) to the MPU subsystem interrupt controller mapped on M_IRQ_21.

13.3 SGX Functional Description

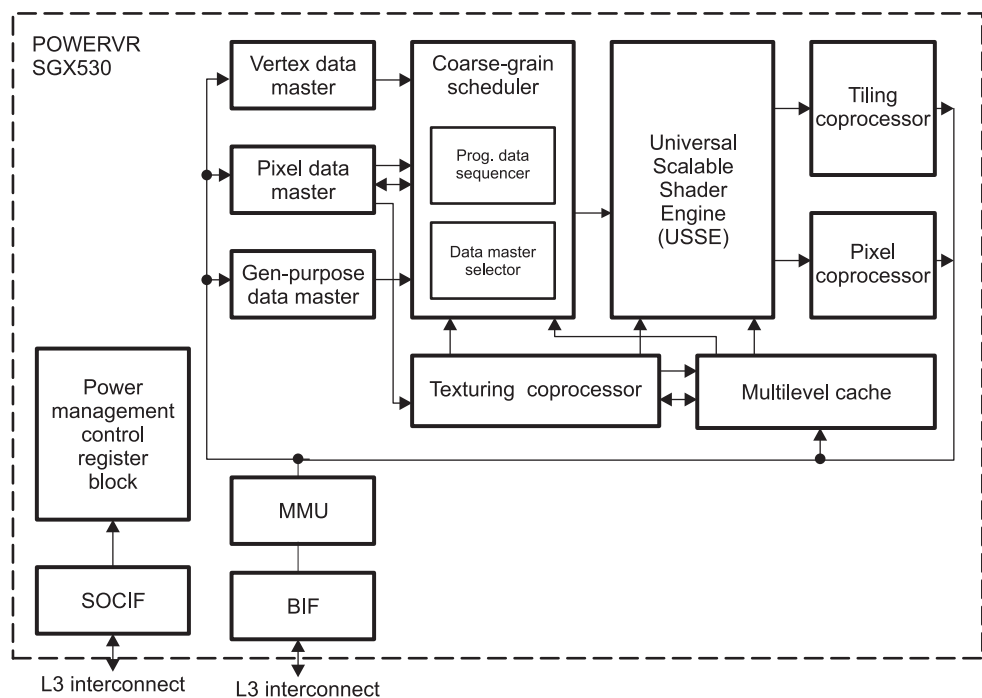

13.3.1 SGX Block Diagram

The SGX subsystem is based on the PowerVR SGX cores from Imagination Technologies. The architecture uses both programmable and hard coded pipelines to perform various processing tasks required in 2D and 3D. The SGX architecture comprises the following elements:

- Coarse grain scheduler
 - Programmable Data Sequencer (PDS)
 - Data Master Selector (DMS)
- Vertex data master (VDM)
- Pixel data master (PDM)
- General-purpose data master
- USSE
- Tiling coprocessor
- Pixel coprocessor
- Texturing coprocessor
- Multilevel cache

Figure 13-3 shows a block diagram of the SGX cores.

Figure 13-3. SGX Block Diagram

sgx-003

13.3.2 SGX Elements Description

The coarse grain scheduler (CGS) is the main system controller for the PowerVR SGX Architecture. It consists of two stages, the DMS and the PDS. The DMS processes requests from the data masters and determines which tasks can be executed given the resource requirements. The PDS then controls the loading and processing of data on the USSE.

There are three data masters in the SGX core:

- The VDM is the initiator of transform and lighting processing within the system. The VDM reads an input control stream, which contains triangle index data, and state data. The state data indicates the PDS program, size of the vertices and the amount of USSE output buffer resource available to the VDM. The triangle data is parsed to determine unique indices that must be processed by the USSE. These are grouped together according to the configuration provided by the driver and presented to the DMS.
- The PDM is the initiator of rasterization processing within the system. Each pixel pipeline processes pixels for a different half of a given tile which allows for optimum efficiency within each pipe due to locality of data. For each task it determines the amount of resource required within the USSE. It merges this with the state address and issues a request for execution on the USSE to the DMS.
- The general-purpose data master responds to events within the system (such as end of a pass of triangles from the ISP, end of a tile from the ISP, end of render, or parameter stream breakpoint event). Each event causes either an interrupt to the host or synchronized execution of a program on the PDS. The program may, or may not cause a subsequent task to be executed on the USSE.

The USSE is a programmable processing unit. Although general in nature, its instructions and features are optimized for three types of task: processing vertices (vertex shading), processing pixels (pixel shading), and video/imaging processing.

The multilevel cache is a 2-level cache consisting of two modules: the main cache and the mux/arbitrator/demux/decompression unit (MADD). The MADD is a wrapper around the main cache module designed to manage and format requests to and from the cache, as well as providing Level 0 caching for texture and USSE requests. The MADD can accept requests from the PDS, USSE, and texture address generator modules. Arbitration is performed between the three data streams; any required texture decompression is also performed.

The texturing coprocessor performs texture address generation and formatting of texture data. It receives requests from either the iterators or USSE modules and translates these into requests into the multilevel cache. Data returned from the cache are then formatted according to the texture format selected and sent to the USSE for pixel-shading operations.

To process pixels in a tiled manner, the screen is divided into tiles and arranged as groups of tiles by the tiling coprocessor. An inherent advantage of tiling architecture is that a large amount of vertex data can be rejected at this stage, thus reducing both the memory storage requirements and the amount of pixel processing to be performed.

The pixel coprocessor is the final stage of the pixel-processing pipeline and controls the format of the final pixel data sent to the memory. It supplies the USSE with an address into the output buffer, and the USSE returns the relevant pixel data. The address order is determined by the frame buffer mode. The pixel coprocessor contains a dithering and packing function.

13.4 SGX Registers

[Table 13-2](#) describes the SGX memory mapping in the device.

Table 13-2. Instance Summary

Module Name	Start Address	End Address	Size
SGX	0x5000 0000	0x5000 FFFF	64K bytes

13.4.1 SGX Register Mapping Summary

CAUTION

The SGX registers are limited to 32-bit data accesses; 8- and 16-bit accesses are not allowed because they can corrupt register content.

13.4.2 SGX Register Description

For more information about register descriptions, contact your TI representative.

13.5 Revision History

Table 13-3 lists the changes made since the previous version of this document.

Table 13-3. Document Revision History

Reference	Additions/Modifications/Deletions
Section 13.1	Removed 3rd sentence, 1st paragraph.
Section 13.1	Added to last sentence, 1st paragraph.

IVA2.2 Subsystem

This chapter describes the image video and audio accelerator (IVA2.2) subsystem for the OMAP35x Applications Processor.

Topic	Page
14.1 IVA2.2 Subsystem Overview	1738
14.2 IVA2.2 Subsystem Integration	1740
14.3 IVA2.2 Subsystem Functional Description	1751
14.4 IVA2.2 Subsystem Basic Programming Model	1783
14.5 IVA2.2 Subsystem Registers	1828
14.6 Revision History	2050

14.1 IVA2.2 Subsystem Overview

The device includes the high-performance Texas Instruments image video and audio accelerator (IVA2.2), based on the TMS320DMC64X+ VLIW digital signal processor (DSP) core.

The internal architecture is an assembly of the following components:

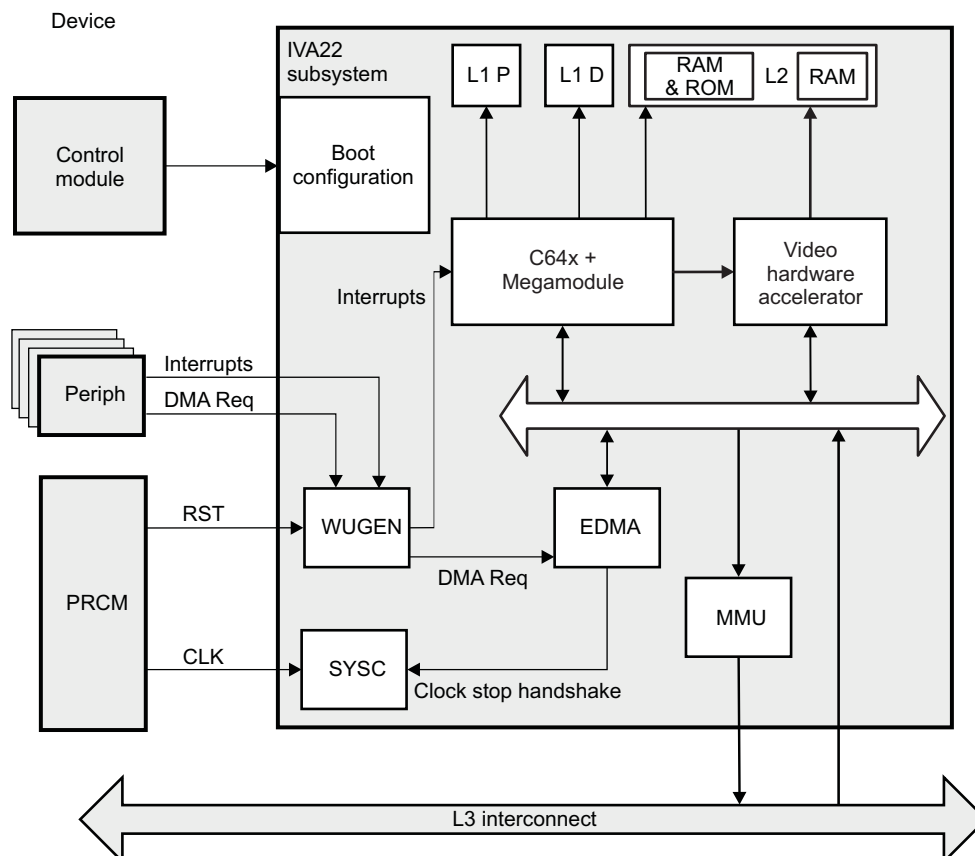

- High-performance TI DSP (TMS320DMC64X+) integrated in a megacell, including local L1/L2 cache and memory controllers
- L1 RAM and L2 RAM and ROM
- Video hardware accelerator
- Dedicated enhanced data memory access (EDMA) engine to download/upload data from/to memories and peripherals external to the sub-chip
- Dedicated memory management unit (MMU) for accessing level 3 (L3) interconnect address space
- Local interconnect network
- Dedicated modules SYSC and WUGEN in charge of power management, clock generation, and connection to the power, reset, and clock manager (PRCM) module

For information about C64x to C64x+ core migration, see the *TMS320C64x to TMS320C64x+ CPU Migration Guide* application note [SPRAA84A](#).

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

[Figure 14-1](#) shows the IVA2.2 subsystem top-level architecture.

Figure 14-1. IVA2.2 Subsystem Highlight

14.1.1 IVA2.2 Subsystem Key Features

The IVA2.2 subsystem has the following main features:

- 32-bit fixed-point media processor
- VLIW architecture based on programmable enhanced version of C64x DSP core
- 8 instructions/cycle, 8 execution units:
 - Optimized instruction set for video and image processing
 - Eight 8 x 8 or 16 x 16 MAC per cycle
 - Eight SAD per cycle
 - Eight interpolations (a + b + 1) >> 1 per cycle
 - Two (32-bit x 32-bit > 64-bit) multiply operations per cycle
- Low-power processor and megacell:
 - Dynamically mixed 32-bit and 16-bit instruction sets
 - Software pipelined loop (SPLOOP) instruction buffer
 - Separate power domain
 - Supported multiple power-down states
- 2-level memory subsystem hierarchy:
 - L1P (program):
 - 32KB direct-mapped cache-32-byte cache line, configurable as cache or memory-mapped (possible values are: 0KB cache/32KB memory, 4KB/28KB, 8KB/24KB, 16KB/16KB, or 32KB/0KB)
 - L1D (data):
 - 32KB 2-way set associative cache-64-byte cache line, configurable as cache or

- memory-mapped (possible values are: 0KB cache/32KB memory, 4KB/28KB, 8KB/24KB, 16KB/16KB, or 32KB/0KB)
 - 48-KB memory-mapped SRAM
- L2 (program and data):
 - 64KB 2-way set associative cache-128-byte cache line, configurable as cache or memory-mapped (possible values are: 0KB cache/64KB memory, 32KB/32KB, or 64KB/0KB)
 - 32-KB memory-mapped SRAM
 - 16-KB ROM
- Video hardware accelerator
- Private direct memory access (DMA) controller:
 - 128 logical channels
 - 1D/2D addressing
 - Chaining capability
 - Fully pipelined, two 64-bit read ports, two 64-bit write ports
 - Single-access 32-byte or 64-byte incrementing bursts
- Level 1 (L1) interrupt controller
- Local IVA digital phase-locked loop (DPLL) supplying IVA subsystem clocking
- 32-entry MMU for seamless integration in high-level operating system (OS) environment
- IVA2.2 system interfaces:
 - 64-bit L3 port shared for external memory accesses:
 - Multithreaded link shared by DSP core and DMA accesses
 - Interface with the L3 interconnect that can be synchronous or asynchronous for clock decoupling between IVA2.2 and L3
 - Incrementing burst support
 - Critical line first, to reduce line-fetch latency to the processor
 - Host port interface (HPI) for MMU programming and access to IVA2.2 internal memories. Can be synchronous or asynchronous.
 - System interfaces: clocking, power management
- C-friendly environment (state-of-the-art C-compiler for VLIW architecture)
- Texas Instruments low-overhead DSP-BIOS operating system

14.2 IVA2.2 Subsystem Integration

IVA hardware accelerators are not available on all devices. See Chapter 1, *OMAP35x Family* section, to check availability of this feature.

[Figure 14-2](#) shows IVA2.2 subsystem integration in the device.

Figure 14-2. IVA2.2 Subsystem Integration

14.2.1 Clocking, Reset, and Power-Management Scheme

14.2.1.1 Clocks

14.2.1.1.1 IVA2.2 Clocks

The IVA2.2 subsystem receives one single-clock signal (DPLL2_ALWON_FCLK) from the PRCM.

Note: When the IVA2.2 subsystem does not require an internal clock, the internal clocks can be disabled at the PRCM level by setting the PRCM.CM_FCLKEN_IVA2 EN_IVA2 bit to 0.

From this clock (DPLL2_ALWON_FCLK) and by using the DPLL2 module in the IVA2.2, three internal clocks are generated by the IVA2.2 system control module (SYSC):

- CD0_CLK: Fastest IVA2.2 subsystem functional clock, dedicated to the DSP. Its frequency can be adjusted at the PRCM level by setting the PRCM.CM_CLKSEL1_PLL_IVA2 and PRCM.CM_CLKSEL2_PLL_IVA2 registers.
- CD1_CLK: Divide-by-two of the CD0_CLK clock
- CD2_CLK: Divide-by-two of the CD0_CLK clock

Generation of these three clocks is handled internally to the IVA2.2 subsystem by the SYSC module under direct control of the PRCM.

Table 14-1 lists the clock domains in the IVA2.2 subsystem and shows the roles of the clocks.

Table 14-1. IVA2.2 Internal Clock

CD0	CD0_CLK	DSP core + PMC + DMC
CD1	CD1_CLK	UMC + power-down + interrupt controller
CD2	CD2_CLK	EMC + IDMA + C64x + Megamodule external interfaces + local interconnect + EDMA + MMU

Note: The internal clocks can be shut down by the PRCM module after the handshake protocol is complete. To configure the PRCM so that internal clocks are hardware-supervised, set the PRCM.CM_AUTOIDLE_PLL_IVA2[2:0] AUTO_IVA2_DPLL field to 0x1. For more information, see the *Power, Reset, and Clock Management* chapter.

CAUTION

Clock configurations depend on core voltage, please refer to your device-specific data manual for a description of the supported voltage levels and maximum clock frequencies.

14.2.1.2 Resets

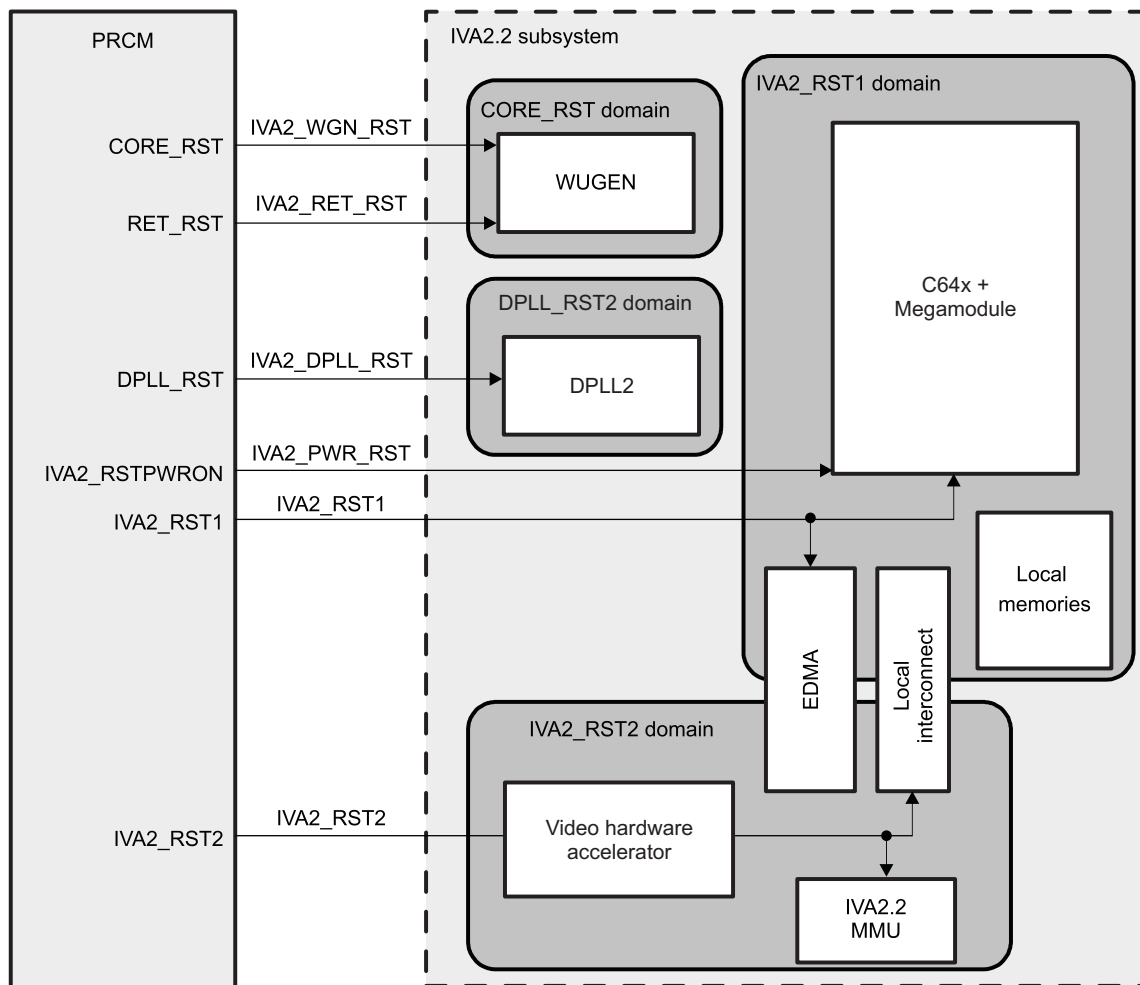

14.2.1.2.1 Hardware Resets

Figure 14-3 shows the seven hardware input reset signals at the boundary of the IVA2.2 subsystem:

- IVA2_RST1, connected to the C64x + Megamodule and EDMA modules
- IVA2_RST2, connected to the MMU and the local interconnect
- CORE_RST, connected to the IVA2.2 subsystem wake-up generator (WUGEN) module
- RET_RST, connected to the subsystem WUGEN retention logic to reset registers that keep their value across a warm reset sequence
- IVA2_RSTPWON, which performs a power-on initialization of IVA2.2 logic

- DPLL2_RST, connected to the DPLL2 module

Figure 14-3. IVA2.2 Subsystem Resets

After chip power on, the IVA2.2 subsystem is kept under reset and only the DPLL2_RST and the RET_RST are released from reset. Then only the WUGEN is released from reset, as part of the core domain. The IVA2.2 remains under reset until the microprocessor unit (MPU) clears the PRCM.RM_RSTCTRL_IVA2[1] RST2_IVA2 bit. On this action, the PRCM switches on the IVA2.2 power domain, sets the clocks back, and releases the power-on reset. When the IVA2.2 power-on sequence completes (hardware handshake), the PRCM releases the IVA2_RST2 reset. At this stage, the C64x + Megamodule is kept under reset (unless the MPU also cleared the PRCM.RM_RSTCTRL_IVA2[0] RST1_IVA2 bit); the MPU can upload some code and data in the C64x+ memory. When the MPU has uploaded the code in the C64x+ memory, the MPU clears the RST1_IVA2 bit, releasing the C64x + Megamodule from reset.

The MPU can apply a software reset to the IVA2.2. For a software reset to be safe, the IVA2.2 must be in clock-off mode (DSP in idle mode with clocks shut down by the PRCM; for information about the clock-off state transition, see [Section 14.4.6.3, Power-Down and Wake-Up Management](#).) For instance, the MPU can use a mailbox interrupt to ask the IVA2.2 to go to IDLE state. In that case, only IVA2_RST1 and/or IVA2_RST2 and/or IVA2_RST3 are applied, depending on which bits are set, and CORE_RST and IVA2_RSTPWON are never applied.

The IVA2.2 can also program the PRCM to go to OFF state automatically when the IVA2.2 is idle. Then, in response to a wake-up event (for example, an interrupt), the PRCM can switch on the IVA2.2 power domain, set the clocks back, and release the power-on reset. When the IVA2.2 power-on sequence completes (hardware handshake), the PRCM releases the IVA2_RST1 and IVA2_RST2 resets (RST1 and RST2 SW bits are assumed to be clear). CORE_RST can be applied only if the device is coming out of CHIP OFF state (CORE power domain also in OFF state). In this case, CORE_RST is released at the same time as the IVA power-on reset.

For some detected severe issues (security, watchdog) or if the user applies an external system reset, the IVA2.2 can receive a warm reset. IVA2_RST1, IVA2_RST2, DPLL_RST, RET_RST, and CORE_RST are applied. When the warm reset source is released, IVA2_RST1, IVA2_RST2, and CORE_RST are released. Power-on reset is not applied in this case.

The DPLL and retention logic resets (IDPLL_RST and RET_RST) are activated only on whole-device under reset and on power up from core retention.

14.2.1.2.2 Software Resets

IVA2.2 subsystem reset signals are sourced from the PRCM module. Some modules of the DSP subsystem can also be reset by software control.

The IVA2_RST1 signal maps to the PRCM.RM_RSTCTL_IVA2_RST1_IVA2 bit and the IVA2_RST2 signal maps to the PRCM.RM_RSTCTL_IVA2_RST2_IVA2 bit in the PRCM register RM_RSTCTRL_IVA2. Writing these three bit fields lets the software reset the IVA2.2 subsystem.

Note: Software reset can be applied only while the IVA2.2 subsystem is in clock-off mode.

The WUGEN reset signal (CORE_RST) is reset with the CORE power domain, which is reset at the occurrence of either global cold or global warm reset events. For more information about global reset sources, see the *Power, Reset, and Clock Management* chapter.

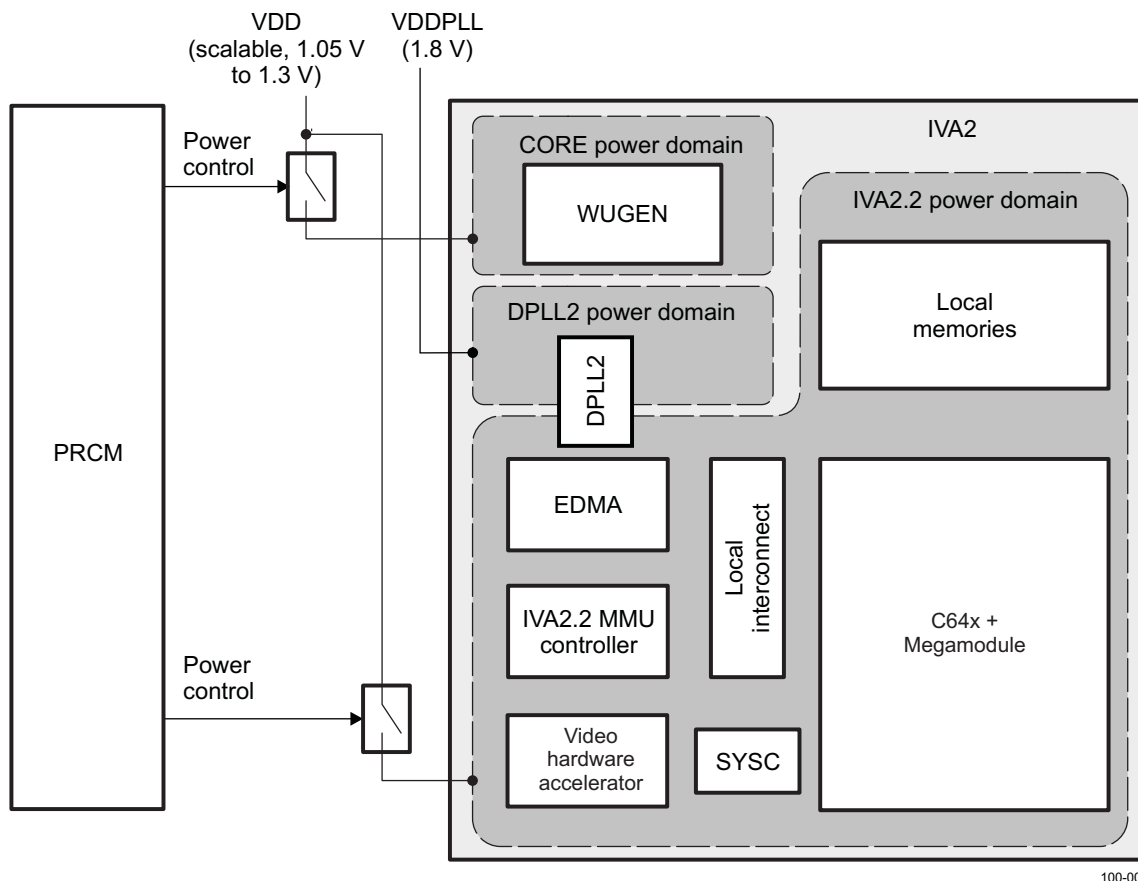

For more information about software resets, see [Section 14.4.6.2, Reset Management](#).

14.2.1.3 Power Domain

The IVA2.2 subsystem comprises three power domains that can be shared with other subsystems at the chip level (see [Figure 14-4](#)):

- DSP power domain: Everything specified in the IVA2.2 subsystem, except the wake-up generator
- CORE power domain: Includes the WUGEN
- DPLL2 power domain: Includes the DPLL.2

Figure 14-4. IVA2.2 Power Domain

100-004

The DSP power domain can be powered off if the CORE power domain is powered on. The PRCM ensures that the DSP power domain is always powered off when the CORE power domain is powered off.

The CORE power domain includes several other system-level components of the device. The WUGEN module is included in the CORE power domain to enable the powered-off DSP subsystem to be awakened after receiving an interrupt, a DMA request, or an L3 slave port access.

When the device enters off mode, the PRM asserts a signal that is distributed to the DPLL to safely isolate the DPLL cell and to set the DPLL cell in sleep mode to reduce power consumption.

Memory voltage can be reduced locally when memory is not being used, to reduce memory leakage:

- If IVA2.2 is not active, this is controlled by the PRCM.PM_PWSTCTRL_IVA2 register by setting the MEMONSTATE and/or MEMRETSTATE bit fields.

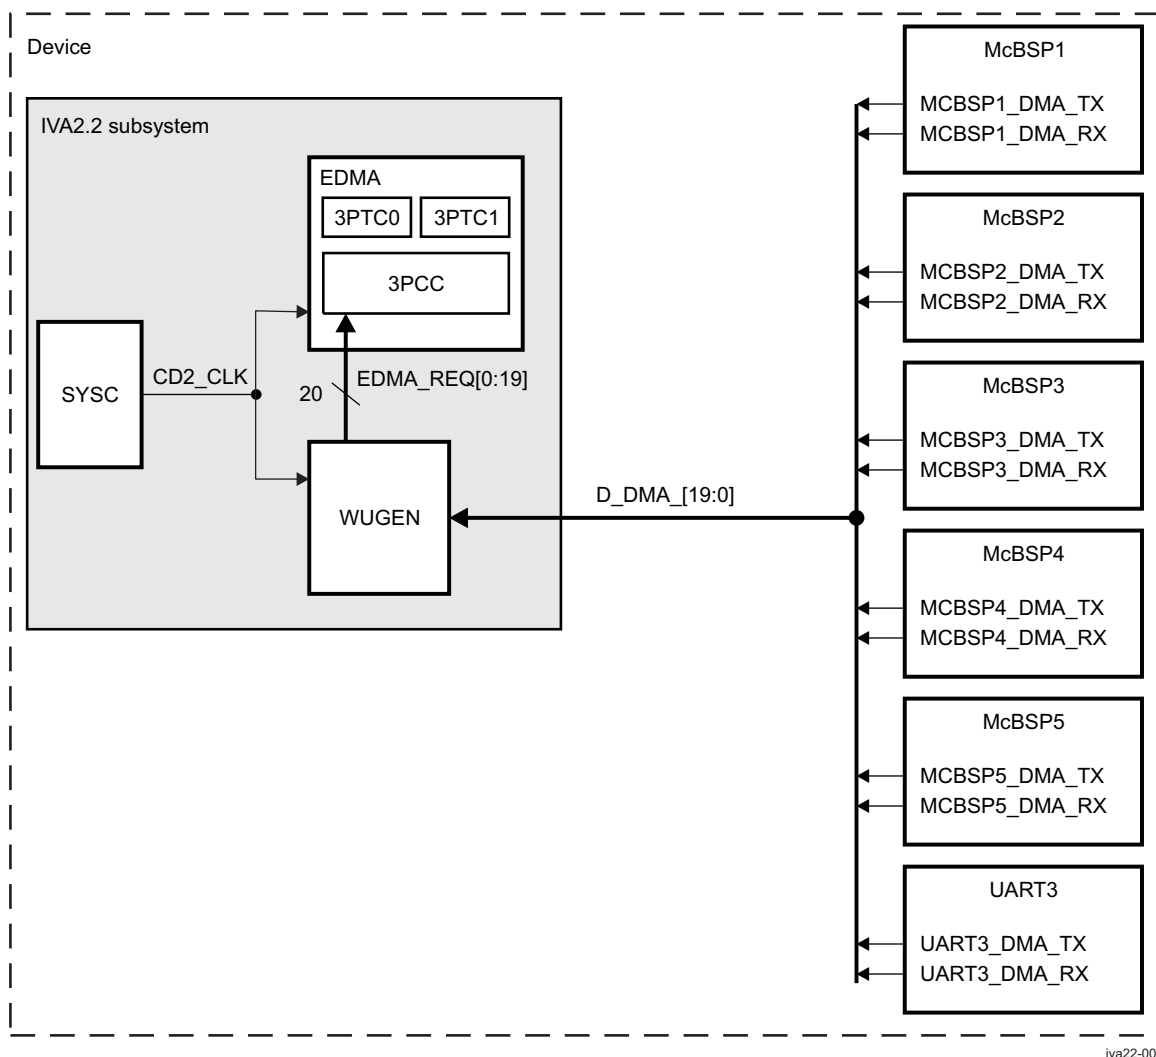

For a detailed description of power domains and controls in the device, see the *Power, Reset, and Clock Management* chapter.

14.2.2 Hardware Requests

14.2.2.1 DMA Requests

The IVA2.2 subsystem receives 14 DMA requests from specific peripherals, such as the McBSP module and the UART module (see [Figure 14-5](#)).

Figure 14-5. IVA2.2 EDMA Requests

For a description of the EDMA controller, see [Section 14.3.2.1, EDMA](#).

[Table 14-2](#) lists EDMA request mappings to the IVA2.2 subsystem EDMA controller.

Table 14-2. IVA2.2 Subsystem EDMA Request Mappings

DMA	Source	Description
D_DMA_0	MCBSP1_DMA_TX	MCBSP module 1 - transmit request
D_DMA_1	MCBSP1_DMA_RX	MCBSP module 1 - receive request
D_DMA_2	MCBSP2_DMA_TX	MCBSP module 2 - transmit request
D_DMA_3	MCBSP2_DMA_RX	MCBSP module 2 - receive request
D_DMA_4	MCBSP3_DMA_TX	MCBSP module 3 - transmit request
D_DMA_5	MCBSP3_DMA_RX	MCBSP module 3 - receive request
D_DMA_6	MCBSP4_DMA_TX	MCBSP module 4 - transmit request

Table 14-2. IVA2.2 Subsystem EDMA Request Mappings (continued)

DMA	Source	Description
D_DMA_7	MCBSP4_DMA_RX	MCBSP module 4 - receive request
D_DMA_8	MCBSP5_DMA_TX	MCBSP module 5 - transmit request
D_DMA_9	MCBSP5_DMA_RX	MCBSP module 5 - receive request
D_DMA_10	UART3_DMA_TX	UART module 3 - transmit request
D_DMA_11	UART3_DMA_RX	UART module 3 - receive request
D_DMA_12	Reserved	
D_DMA_13	Reserved	
D_DMA_14	Reserved	
D_DMA_15	Reserved	
D_DMA_16	Reserved	
D_DMA_17	Reserved	
D_DMA_18	Reserved	
D_DMA_19	Reserved	

Note: All EDMA requests are shared DMA requests; they are also mapped on the system DMA (sDMA). For more information, see the *DMA* chapter.

For more information about EDMA request management, see [Section 14.4.3.3, Programming an EDMA Transfer](#).

14.2.2.2 Interrupt Requests

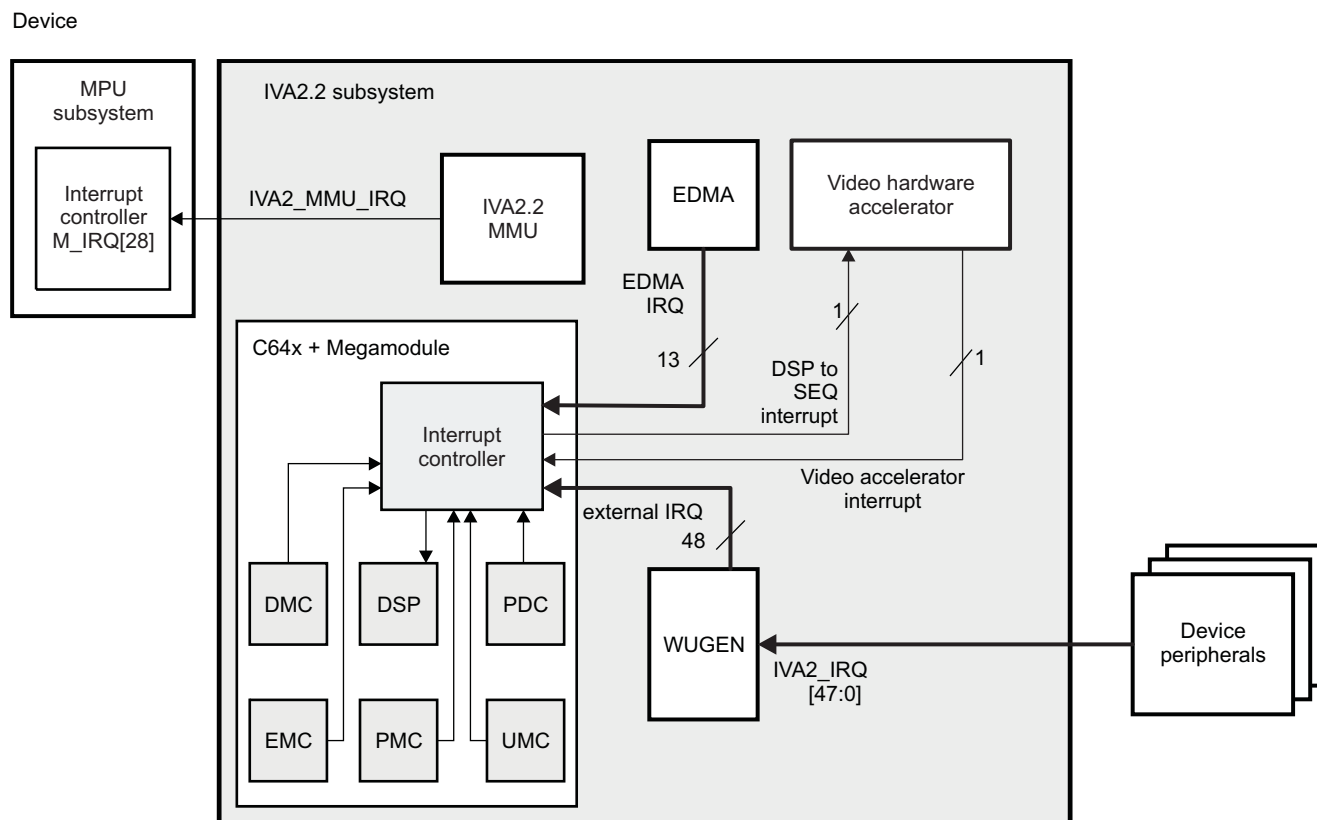

The IVA2.2 subsystem manages three types of interrupts (see [Figure 14-6](#)):

- Internal interrupts: Requests generated by modules in the IVA2.2 subsystem or in the C64x + Megamodule included in the IVA2.2 subsystem
- External interrupts: Requests generated by peripherals external to the IVA2.2 subsystem, like SPI, display subsystem, or camera subsystem. Peripherals that generate interrupts at the IVA2.2 level use the IVA2_IRQ[47:0] input lines of the IVA2.2 subsystem.
- MMU interrupt: The IVA2.2 MMU can generate an interrupt to an external host outside the IVA2.2 subsystem. As shown in [Figure 14-2](#), the interrupt line of the MMU, IVA2_MMU_IRQ, is connected to M_IRQ_28 of the MPU subsystem interrupt controller.

For more information about the functionality of the IVA2.2 MMU, see [Section 14.3, IVA2.2 Subsystem Functional Description](#).

To manage and expand the interrupt capabilities of the C64x + Megamodule (internal and external interrupt requests), the IVA2.2 subsystem includes two levels of interrupt control (see [Figure 14-6](#)):

- One interrupt controller (INTC), integrated in the C64x + Megamodule. This module controls all interrupt requests (internal and external) except the MMU interrupt.
For more information about the INTC, see [Section 14.3.1.6, Memory Protection Overview](#).
- One WUGEN: Responsible at the IVA2.2 subsystem level for detecting wake-up events (interrupts, DMA requests, and slave port access) when the IVA2.2 is powered down. The WUGEN also handles formatting interrupts from device peripherals to the C64x + Megamodule INTC.

Figure 14-6. IVA2.2 Interrupt Management

In addition to interrupt sources internal to the IVA2.2 subsystem, several interrupt sources coming from device peripherals are connected to the C64x + Megamodule INTC, but not directly.

These external interrupt sources are first resynchronized in the WUGEN module, synchronously with the CD2 clock domain clock (CD2_CLK). Then the resynchronized versions are connected to the INTC.

Table 14-3 lists the global interrupt mappings of the IVA2.2 subsystem.

Table 14-3. IVA2.2 Interrupt Mappings

EVT	Interrupts/Events	IVA2.2 Pin Name	Interrupt Source	Interrupt Description
0	EVT0	N/A (internal)	GEM INT CTL	Output of event combiner 0, for events 4-31
1	EVT1	N/A (internal)	GEM INT CTL	Output of event combiner 1, for events 32-63
2	EVT2	N/A (internal)	GEM INT CTL	Output of event combiner 2, for events 64-95
3	EVT3	N/A (internal)	GEM INT CTL	Output of event combiner 3, for events 96-127

⁽¹⁾ EVT94 is used by the DSP to generate an interrupt to the sequencer by means of the HOST_MBX in the SEQ_IRQSTATE register.

The interrupts generated by the WUGEN module (interrupts from device peripherals) are programmable using a set of registers accessible by the user.

Events related to these external interrupts can be masked by writing to the IVA2.WUGEN_MEVTSET0 or IVA2.WUGEN_MEVTSET1 registers. The interrupts can also be individually unmasked by using the IVA2.WUGEN_MEVTCCLR0 or IVA2.WUGEN_MEVTCCLR1 registers. By default (after power on), these external interrupts are masked in WUGEN.

All other interrupts are directly managed by the IVA2.2 DSP INTC, and the DSP registers are set. For information about the DSP INTC, see the documents listed in [Section 14.3.1.8, Other DSP Reference Documents](#).

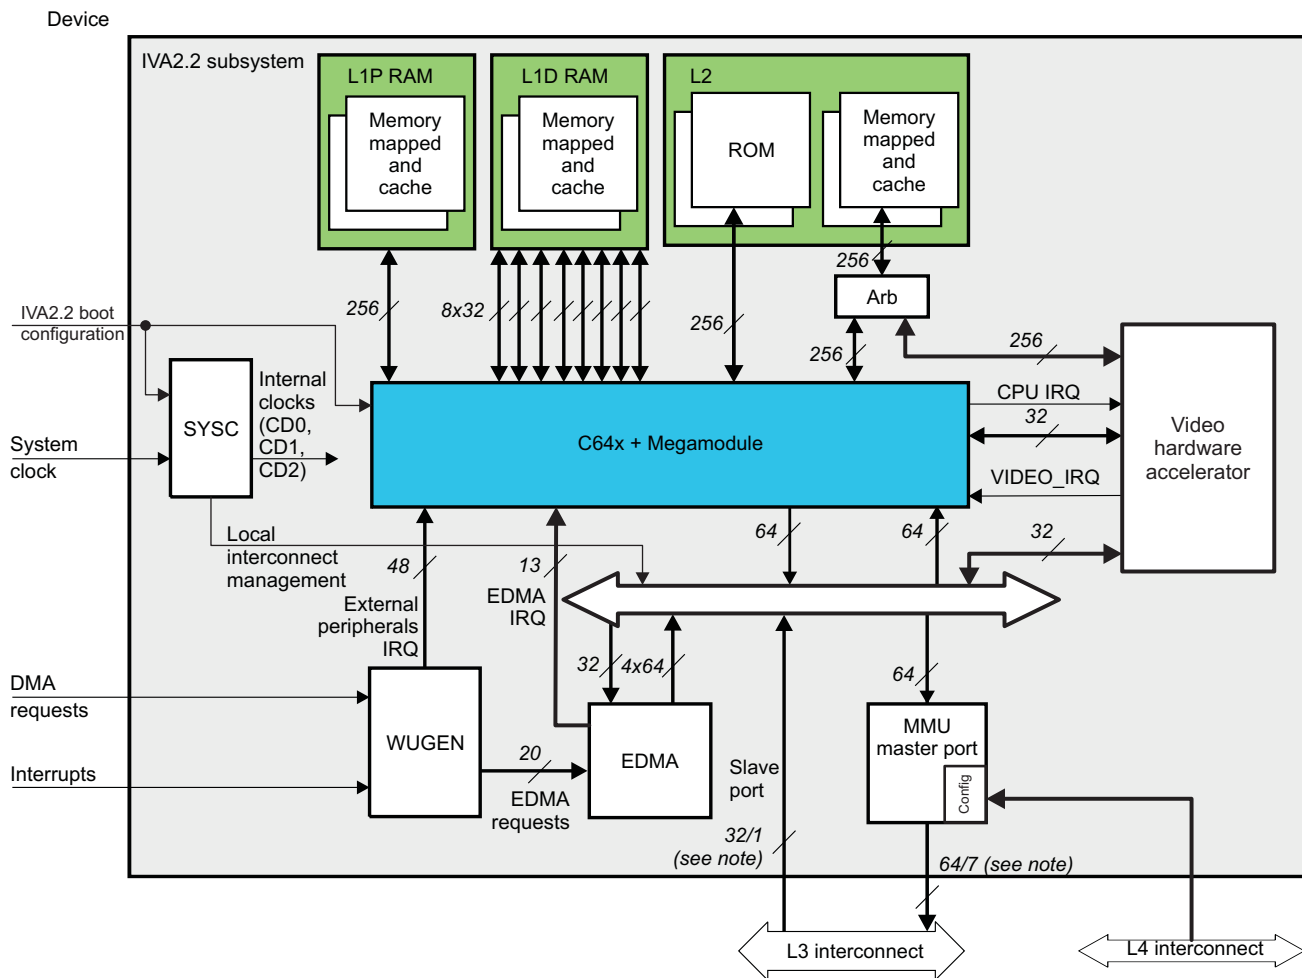

14.3 IVA2.2 Subsystem Functional Description

IVA hardware accelerators are not available on all devices. See Chapter 1, *OMAP35x Family* section, to check availability of this feature.

The IVA2.2 subsystem is composed of a C64x + Megamodule coupled with several submodules that enable its integration in the device architecture. The IVA2.2 subsystem provides one slave port and one master port; both ports are connected to the L3 interconnect.

Figure 14-7 is a block diagram of the IVA2.2 subsystem.

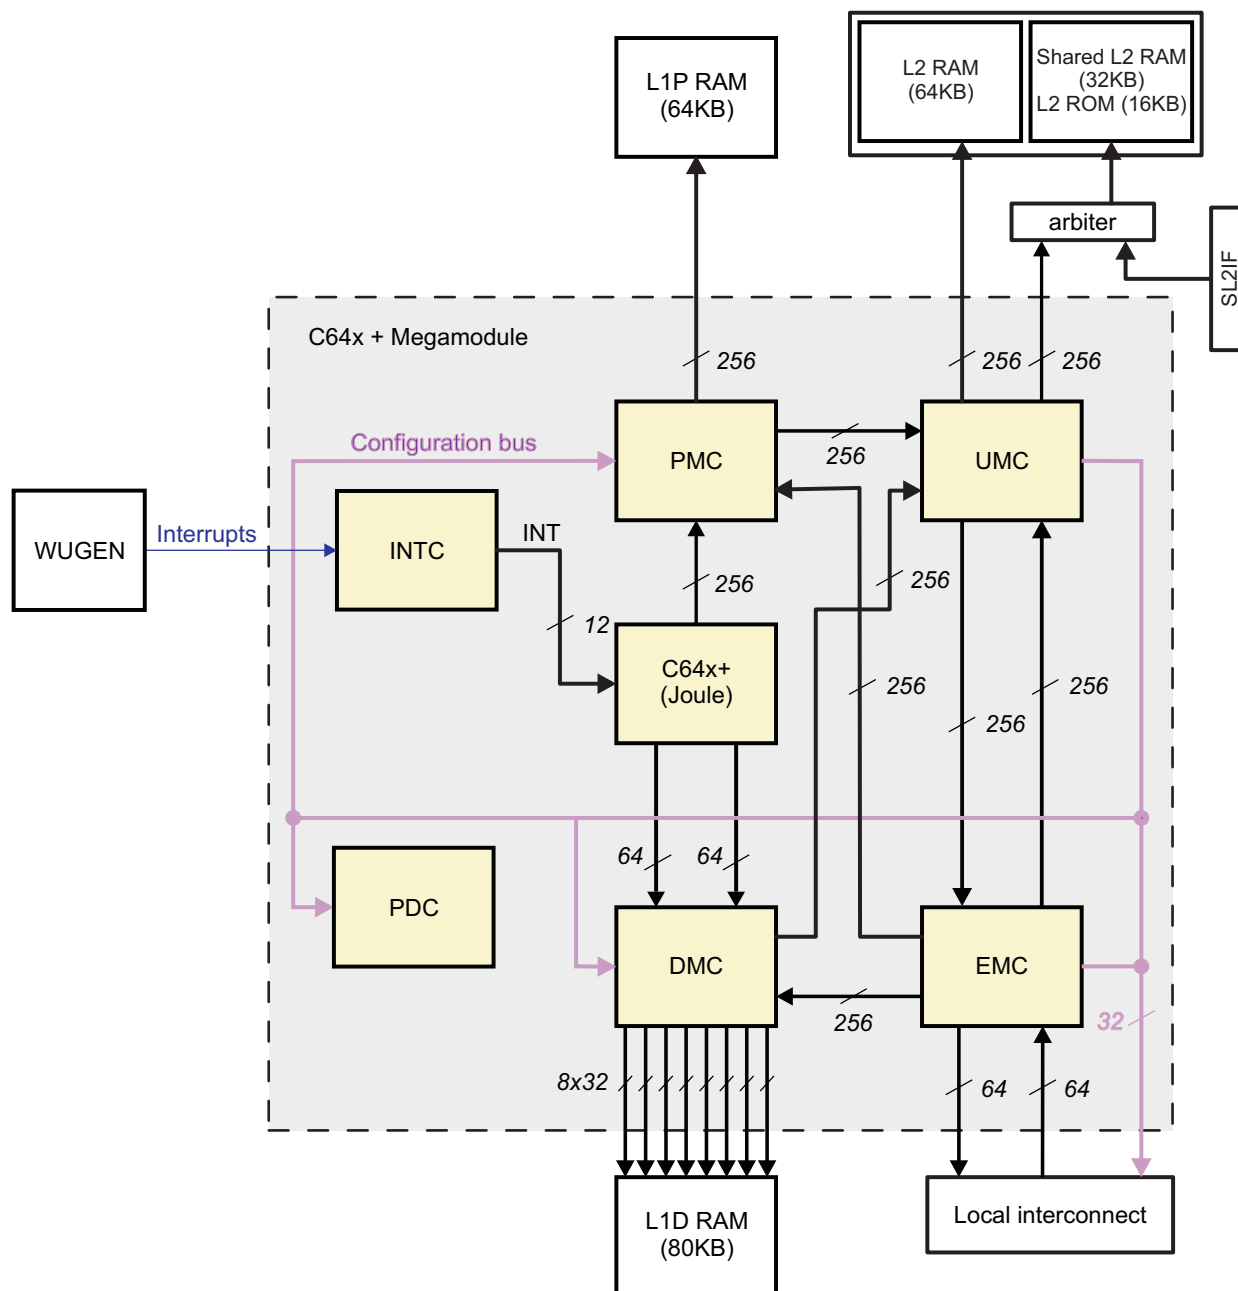

Figure 14-7. IVA2.2 Subsystem Block Diagram

14.3.1 C64x + Megamodule

The C64x + Megamodule is a class of derivative sections of the generalized embedded megacell (GEM). C64x + Megamodule is a hardware-configurable megacell module that comprises a Joule version of the C64x+, an L1 program memory controller (PMC), an L1 data memory controller (DMC), a unified memory controller (UMC), an extended memory controller (EMC), an INTC, and a power-down controller (PDC).

Figure 14-8 is a block diagram of the C64x + Megamodule.

Figure 14-8. C64x + Megamodule Block Diagram

14.3.1.1 DSP Overview

The C64x+ is an extension of the first C64x DSP section (also named Kelvin).

The C64x features the following:

- 32-bit fixed-point media processor
- VLIW architecture
- 8 instructions/cycle, 8 execution units
 - Optimized instruction set for video and image processing
 - Eight 8 x 8 or 16 x 16 MAC per cycle
 - Eight SAD per cycle

- Eight interpolations $(a + b + 1) \gg 1$ per cycle
- Two (32-bit x 32-bit > 64-bit) multiply operations per cycle

In addition to existing C64x features, the C64x+ includes the following:

- SPLOOP
- Compact instructions
- Extended function support
- Exception handling
- Privilege mode support
- HLOS time-stamp counter register

C64x+ operates to up to 365 MHz in the context of IVA2.2.

CAUTION

Clock configurations depend on core voltage, please refer to your device-specific data manual for a description of the supported voltage levels and maximum clock frequencies.

For information about C64x+ DSP, see the Joule reference manual.

14.3.1.2 Program Memory Controller Overview

The PMC is the C64x + Megamodule component that delivers program fetch packets when they are requested by the DSP.

The PMC supports the following features:

- One 256-bit fetch packet per cycle (sustainable)
- 32KB 0-wait state least-significant bit (LSB)-banked SRAM
- L1 program cache controller - 32KB maximum
- Software-programmable allocation of SRAM to cache or memory-mapped SRAM
- DMA transfer from/to SRAM
- Fair priority-based arbitration between DSP, DMA, and cache controller for access to the SRAM
- Block and global program-initiated cache coherence support (invalidate)
- Freeze mode support

In the IVA2.2 subsystem, the PMC controls the 32-KB SRAM typically used as cache RAM. However, the allocation of SRAM can be software-configured to keep a section of the memory as memory-mapped SRAM.

For more information, see [Section 14.4.5, Memory Management](#).

14.3.1.3 DMC Overview

The DMC is the C64x + Megamodule component that reads or writes data from/to local memories, as requested by the DSP.

The DMC supports the following features:

- Two 64-bit memory accesses per cycle (sustainable)
- A memory access pair can be any combination of read and write, with no incurred penalty.
- 80KB 0-wait state LSB-banked SRAM
- L1 data cache controller (capabilities listed in [Table 14-8](#)) - 32KB maximum
- Software-programmable allocation of SRAM to cache or memory-mapped SRAM
- DMA transfer from/to SRAM
- Fair priority-based arbitration between DSP, DMA, and cache controller for access to the SRAM
- Hardware coherence maintenance with L2 (snooping)

- Block and global program-initiated cache coherence support (write-back, invalidate, and write-back-invalidate)
- Freeze and bypass mode support
- Per-page memory-protection attribute check support

The DMC operates to up to 365 MHz in the context of the IVA2.2. The DMC always operates at the same frequency as the DSP.

CAUTION

Clock configurations depend on core voltage, please refer to your device-specific data manual for a description of the supported voltage levels and maximum clock frequencies.

14.3.1.4 UMC Overview

The UMC is the C64x + Megamodule component that reads or writes program and data from/to memory, as requested by the DMC and/or the PMC.

The UMC supports the following features:

- 64KB low-latency state SRAM (first port)
- 32KB low-latency state memory-mapped only SRAM (second port)
- 16KB low-latency ROM (second port)
- L2 unified cache controller (capabilities listed in [Table 14-9](#)) - 64KB maximum
- Software-programmable allocation of SRAM to cache or memory-mapped SRAM
- DMA transfer from/to SRAM and from ROM
- Fair priority-based arbitration between DSP, DMA, and cache controller for access to the SRAM
- Block and global program-initiated cache coherence support (write-back, invalidate, and write-back-invalidate)
- Freeze and bypass modes support
- Per-page memory protection attribute check support
- Emulation support
- Long-distance access support (noncacheable data accesses)
- Page-based memory automatic power-down (to clock-off state) and wake-up support

The UMC contains the interfaces to L2 memory, the L1D, the L1P, and the EMC. The EMC houses the interfaces to the EDMA and internal data memory access (IDMA) engines, and thus allows the UMC and ultimately the CPU to communicate with peripherals and external memory.

The UMC has two L2 memory ports, each of which is 256 bits wide. Although accesses to the two ports are initiated serially for each requestor, only one new access is initiated per UMC clock cycle, to avoid memory-bank conflicts between the ports.

The UMC has three requestor ports: the PMC, the DMC, and the EMC. Peripheral configuration and DMA/IDMA interfacing are handled by the EMC. The PMC interface to the UMC consists of a 256-bit read-only path (L1P fetch only). The DMC and the EMC interface to the UMC, and each has separate 256-bit read and write paths of its own.

The UMC operates to up to 182.5 MHz in the context of the IVA2.2. The UMC always operates at half the frequency of the DSP.

CAUTION

Clock configurations depend on core voltage, please refer to your device-specific data manual for a description of the supported voltage levels and maximum clock frequencies.

14.3.1.5 EMC Overview

The EMC is the megacell component that reads or writes program and data external memory and configuration registers, as requested by the UMC.

The EMC supports the following features:

- IDMA
- 64-bit slave port for accesses from an external DMA engine and/or host to L1 or L2 memory
- 64-bit master port to serve accesses from the UMC to external memory or configuration registers

The EMC operates to up to 182.5 MHz in the context the of the IVA2.2. The EMC can operate at half or one third the frequency of the DSP.

CAUTION

Clock configurations depend on core voltage, please refer to your device-specific data manual for a description of the supported voltage levels and maximum clock frequencies.

14.3.1.6 Memory Protection Overview

The C64x + Megamodule memory protection architecture divides the memory map into pages. Each page has an associated set of permissions.

Memory protection provides many benefits to a system:

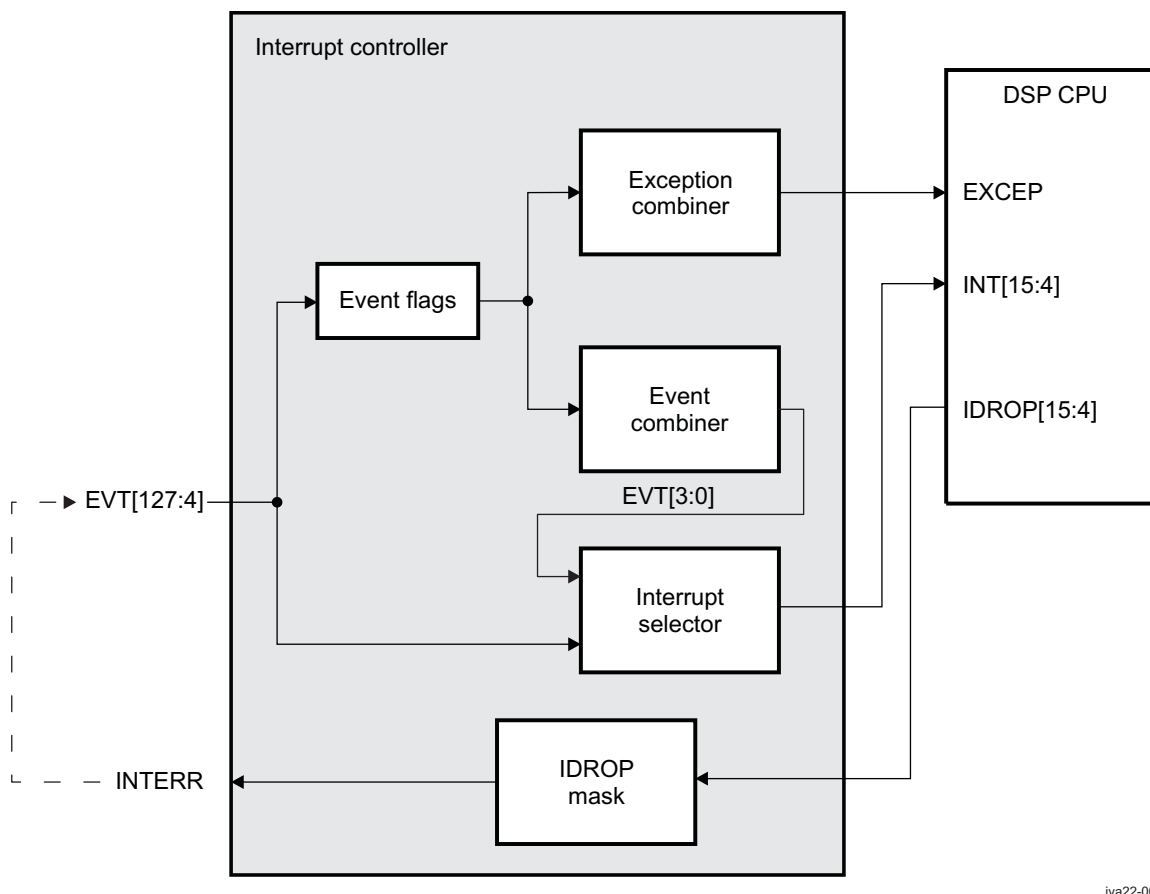

- Protects operating system data structures from poorly behaving code
- Helps in debugging by providing information about illegal memory accesses
- Prevents unauthorized access to sensitive data (provides device security)
- Allows the OS to enforce clearly defined boundaries between supervisor and user mode accesses, leading to greater system robustness

Memory protection is implemented for the PMC, DMC, UMC, and EMC, and also for the IDMA and EDMA modules.

14.3.1.7 INTC

The C64x + Megamodule INTC detects, potentially combines, and routes up to 128 system events (internal and external) to the DSP CPU interrupt lines. [Table 14-5](#) lists the global interrupt mappings of the IVA2.2 subsystem (internal and external interrupts).

The DSP CPU has 12 maskable interrupts and one exception input. The INTC includes an interrupt selector, an exception combiner, and an event combiner. The interrupt selector allows the routing of any of the 128 system events (or a combination of them) to the 12 maskable interrupts of the DSP CPU, and software determines the priorities of those system events. To handle potential conflicts, the 12 CPU interrupts have fixed priorities. The exception combiner allows the combination of any of the 128 system events to the single exception input of the DSP CPU (see [Figure 14-9](#)).

Figure 14-9. C64x + Megamodule INTC Block Diagram

iva22-009

Note: Not all of the 128 event inputs of the INTC are connected to an internal or external event line. [Table 14-3](#) lists the global interrupt mapping of the DSP INTC. Some interrupts at the IVA2.2 boundary are reserved for future use or are not used by the IVA2.2 subsystem. For information about the DSP core INTC, see the C64x+ DSP documents listed in [Section 14.3.1.8, Other DSP Reference Documents](#).

14.3.1.7.1 Event Type

The interrupt controller provides three types of interrupt sources to the DSP CPU:

- Single event
 - A single system event can be directly routed to a CPU interrupt input.
 - A dropped system event is supported through the CPU dropped interrupt reporting mechanism; that is, if the CPU misses the interrupt input, the system event is missed.
- Combined event
 - Up to four event combiners
 - Each combiner allows up to 32 system events to be logically ORed into a single event that can be routed to the DSP CPU.
- Exception event: This event is considered a single event, but it is directly connected to the exception input of the DSP CPU.

14.3.1.7.2 Event Behavior

- Single event source: The interrupt selector routes 1 of 124 events to a DSP CPU interrupt, as programmed in the interrupt selector registers (IC.INTMUX_i registers (where i is 1 to 3). Logic in the CPU and the INTC combine to detect instances where an interrupt request is asserted before an earlier interrupt request was serviced. The INTC records the interrupt number of the first interrupt and keeps this information until directed to release the interrupt, either through reset or by application software. This record can be used as an additional system event to notify the application of an interrupt failure. Interrupts that qualify for dropped detection are defined through an IDROP mask that sets the IC.INTDMASK register. The masked IDROP event output (EVT96; see Table 14-3) is available as a system event that can be selected as either a DSP CPU interrupt or an exception event.
- Combined source: The event combiners create a combined event from the logical OR of 32 system-event flags qualified by a mask provided through programmable registers (IC.EVTMASK_i where i = 0 to 3). The combination of the event flags creates an event that is asserted when any of the event flags included in its generation is active. Software must clear the event flags (IC.EVTCLR_i where i = 0 to 3) to de-assert a combined event.

Note: The use of event flags makes it impossible for the CPU to detect the dropping of independent system events; therefore, dropped interrupt capability is not directly supported for combined events.

The interrupt event combiners create four shared interrupt sources:

- EVT0: Logical OR of EVTFLAG_i[31:04] (i = 0) masked by EVTMASK_i[31:04] (i = 0)
- EVT1: Logical OR of EVTFLAG_i[63:32] (i = 1) masked by EVTMASK_i[63:32] (i = 1)
- EVT2: Logical OR of EVTFLAG_i[95:64] (i = 2) masked by EVTMASK_i[95:64] (i = 2)
- EVT3: Logical OR of EVTFLAG_i[127:96] (i = 3) masked by EVTMASK_i[127:96] (i = 3)

EVTFLAG_i are the event flag registers and EVTMASK_i are the event mask registers. These combined events are presented to the interrupt selection logic.

- Exception event source: As with the event combiner, the exception combiner allows multiple system events to be grouped as a single event input to the CPU, and the combiner provides mask registers to remove undesirable events. Because only one exception is input to the CPU, all mask registers work together to combine up to 128 events as a single EXCEP output. This lets the CPU service all available system exceptions.

The shared exception source is created as follows:

EXCEP: Logical OR of EF[127:04] masked by XM[127:04]

Where EF[i * 32 + j] = EVTFLAG_i[j] and XM[i * 32 + j] = EXPMASK_i[j] (i = 0, 1, 2, 3 and j = 0 to 31).

The logic is similar to that of the event combiners, except that only one combined event is routed to EXCEP.

14.3.1.7.3 Event Detection

The INTC contains a set of status and control registers to manage the status of system events received by the controller. These include set, flag, and clear registers covering all 128 system events. Enabling of the events is managed in the CPU for direct mapped interrupts, in the event combiner for combined events, and in the exception combiner for system exceptions. Events to the interrupt controller can be enabled/disabled only at the event source.

The event flag registers (IC.EVTFLAG_i where i = 0 to 3) capture every system event received, regardless of its destination: event combiner, exception combiner, or interrupt selector. Events that are not masked by either the event combiner or the exception combiner are captured in the IC.EVTFLAG_i (where i = 0 to 3) register corresponding to the event, and are used to determine when the combined event is generated. Events that are masked by either the event combiner or the exception combiner are captured in the IC.EVTFLAG_i register, but do not affect when the DSP CPU interrupt is generated.

The event flags in the IC.EVTFLAG_i registers retain the value of 1 for any event received. These registers are read-only and must be cleared through the write-only IC.EVTCLR_i registers. The IC.EVTSET_i registers can be used to manually set bits in the IC.EVTFLAG_i registers, including those that are masked.

Note: Because external events are maintained by the peripheral until they are explicitly cleared by software, drop event detection does not work for external events (interrupts from peripherals external to the IVA2.2 subsystem).

14.3.1.7.4 Event Selection

The DSP CPU has 12 available maskable interrupts. The interrupt selector allows any of the 128 system events, either from the event inputs or from the event combiners, to be routed to any of the 12 CPU interrupt inputs (see [Figure 14-10](#)).

Figure 14-10. Interrupt Selector Block Diagram

iva22-010

The user can choose which of the 128 input events is mapped to each of the 12 CPU interrupts by writing the event number in the bit field corresponding to the CPU interrupt in the [INTMUXi](#) register. CPU priority is fixed. This event -> interrupt mapping allows software to define the priority of the event. For more information, see [Section 14.4](#), *IVA2.2 Subsystem Basic Programming Model*.

14.3.1.7.5 Event Combination

The event combiner allows multiple system events to be combined as single event for routing to the interrupt selector. This allows the CPU to service all available system events, even though only 12 are available.

A set of event mask registers (IC.[EVTMASKi](#) where $i = 0$ to 3), is used to program the event combiner. These registers allow up to 32 events to be combined as a single event output that is used as a single DSP CPU interrupt. The event mask bits in the [EVTMASKi](#) registers act as enablers for the received system events combined on the event outputs. There are four event outputs to the interrupt selector (EVT[3:0]).

By default, every system event is unmasked and combined with its associated EVT_x. To mask out an event source (for example, to disable an event from being combined), the corresponding mask bit (the IC.[EVTMASKi](#)[y] EMy bit for EVT_y) must be set to 1.

Note: Because the event masks for events 0 through 3 are combined events and thus cannot contribute to the generation of a combined event, they are reserved.

For more information, see [Section 14.4.4, Interrupt Management](#).

14.3.1.7.6 Interrupt Event Error

The INTC can generate a system event internally routed to system event input EVT96. This event is generated when a DSP CPU interrupt is received while the interrupt flag (IFR, internal DSP register) is already set in the CPU. This signals possible problems in the code, such as whether interrupts were disabled for an extended time, or whether pipelined (noninterruptible) code sections were too long.

Note: The same strategy of register settings (events, event set, event clear, event mask) is used in the WUGEN (which is not really an INTC), which enables defining wake-up events so that they can wake up the IVA2.2 subsystem. For more information, see [Section 14.3.4, Wake-Up Generator](#).

For more information, see [Section 14.4.4, Interrupt Management](#). See [Section 14.4, IVA2.2 Subsystem Basic Programming Model](#), for information on associated programming.

14.3.1.7.7 PDC Overview

The C64x + Megamodule PDC allows power management under software control. Different power-down states are defined and can be reached during a period of DSP inactivity. The PDC ensures handshakes with C64x + Megamodule modules so that they go to power-down state in the correct order, on request from the user, and publishes the relevant standby status to the IVA2.2 SYSC module.

The power-down attributes of the C64x + Megamodule components are mapped through the PDC, through the SYS.PDCCMD register.

For information about power-down settings, see [Section 14.4.6.3, Power-Down and Wake-Up Management](#).

14.3.1.8 Other DSP Reference Documents

For more information about the C64x + Megamodule architecture, the instruction set, and the DSP core interrupt controller, and for a complete description of the DSP memory-mapped registers, see the following documents:

- *TMS320C64x+ DSP Megamodule Reference Guide* (TI literature number SPRU871C) describes the C64x+ megamodule peripherals.
- *TMS320C64x/C64x+ DSP CPU and Instruction Set Reference Guide* (TI literature number SPRU732)
- *High-Speed DSP Systems Design Reference Guide* (TI literature number SPRU889) provides recommendations for meeting the many challenges of high-speed DSP system design. These recommendations include information about DSP audio, video, and communications systems for the C5000 and C6000 DSP platforms.

14.3.2 DMA Engines

14.3.2.1 EDMA

The IVA2.2 subsystem has an EDMA to transfer instructions and data from/to any external memory connected to the L3 interconnect to/from the C64x + Megamodule L1D and L2 and, potentially, L1P (if not configured as full cache) local memories. The EDMA can also perform transfers from external memory to external memory and from C64x + Megamodule internal memory to C64x + Megamodule internal memory, with some performance loss caused by resource sharing between the read and write ports. For C64x + Megamodule internal memory to internal memory, use the IDMA.

For the IDMA functional description and a description of IDMA relative programming, see [Section 14.3.2.3, IDMA](#), and [Section 14.4.3.2, Internal Memory-to-Memory Transfer \(IDMA\)](#), respectively.

The EDMA is based on two primary components:

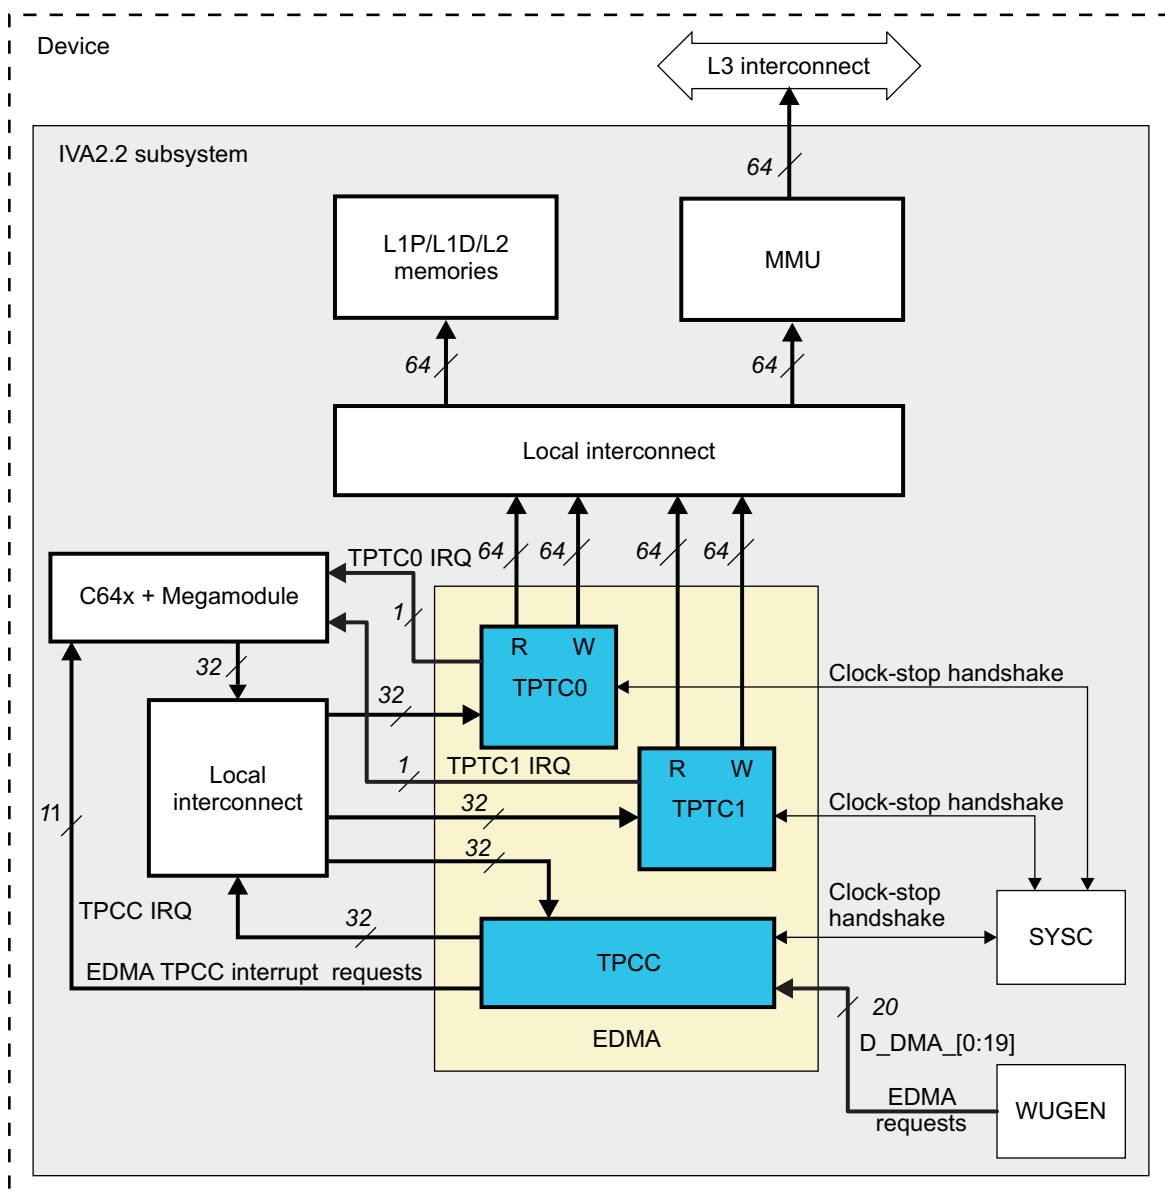

- Third-party DMA channel controller (TPCC)
- Third-party DMA transfer controller (TPTC)

There are two instances of the TPTC in the IVA2.2 subsystem.

[Figure 14-11](#) shows how the EDMA is integrated in the IVA2.2 subsystem:

- Code running on the DSP can configure the EDMA; through the C64x + Megamodule configuration port and the local interconnect, the code can program DMA transfers and software-trigger them by writing to the TPCC configuration registers.
- Preprogrammed DMA transfers can be triggered by external events, referred to in this chapter as DMA requests.
- The TPCC schedules DMA transfers to the TPTC DMA engines (TPTC0 and TPTC1) through dedicated local interconnect 32-bit configuration ports.
- Each TPTC issues concurrent traffic on the local interconnect through dedicated read and write 64-bit ports.
- Interrupts generated by the EDMA are routed to the DSP INTC.
- Power-management handshakes are exchanged between EDMA components and the SYSC module.

Figure 14-11. IVA2.2 EDMA Overview

14.3.2.1.1 Third-Party Channel Controller

The TPCC is the DMA transfer scheduler responsible for scheduling, arbitrating, and issuing user-programmed transfers to the two TPTCs.

14.3.2.1.1.1 TPCC Features

The TPCC features are as follows:

- Parameter RAM (PaRAM entries) holding up to 128 transfer contexts, with the following capabilities:
 - Ping-pong and circular buffering
 - Channel chaining
 - Auto-reloading

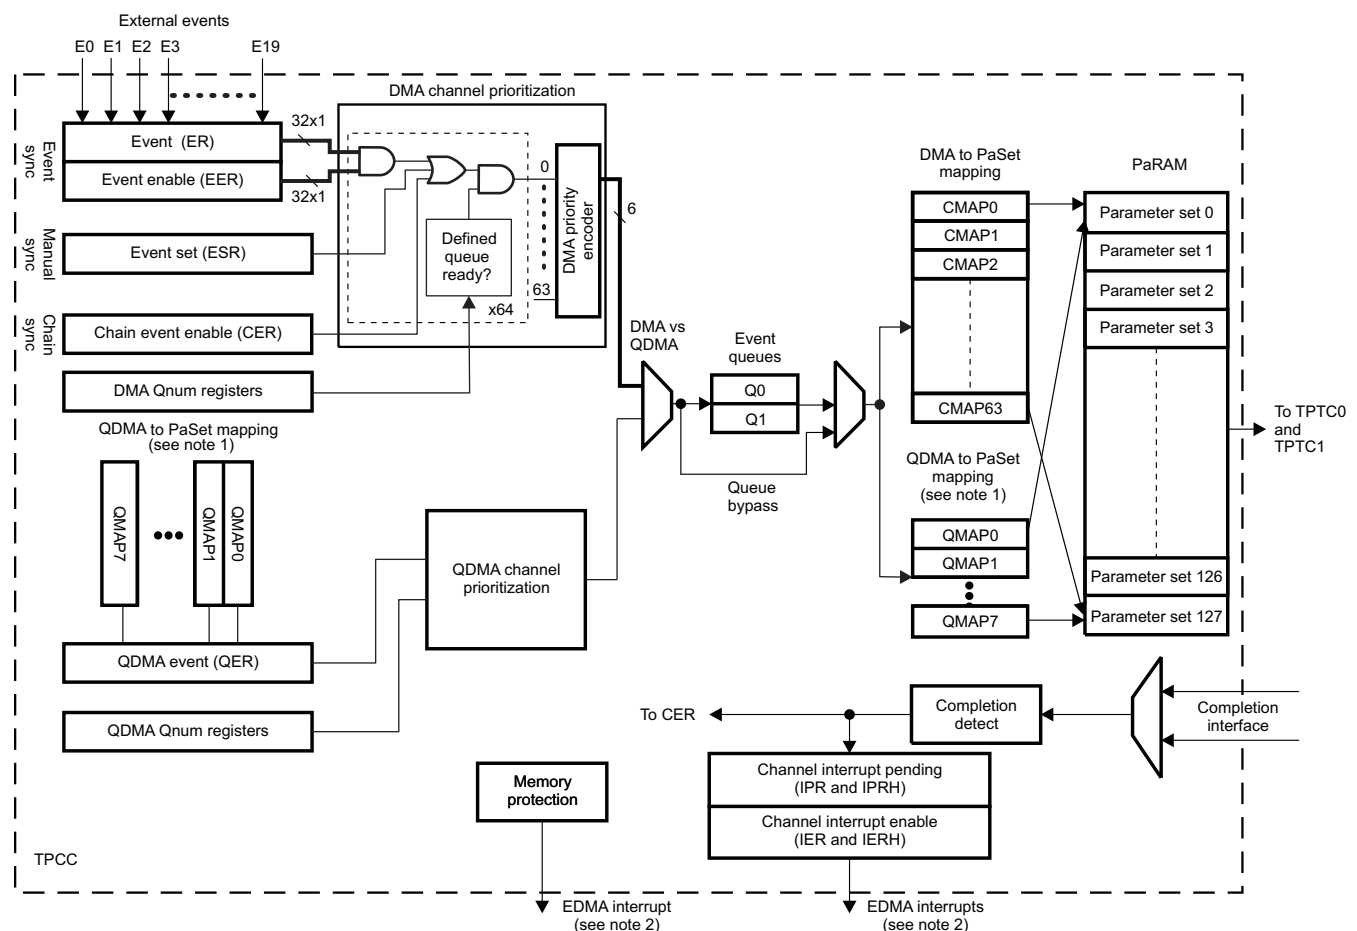

Each PaRAM entry can be used as a DMA entry (up to 64), QDMA entry (up to 8), or link entry (remaining):

- Up to 64 DMA logical channels:

- 64 channels can be triggered explicitly by the DSP CPU (DMA entry).
- 64 channels can be triggered by 20 external events (see Table 14-2).
- All channels can be triggered by completion of a previous transfer in a user-programmed chain of transfers (linked entry).
- 8 channels can be triggered automatically and indirectly by the CPU using the IDMA, reducing CPU offload for DMA configuration (QDMA entry).
- 12 interrupt lines connected to the DSP CPU
- Boundaries for synchronization with the CPU are programmable.
- Two queues holding events waiting for submission to TPTC
- Memory protection
- Each transfer can be programmed to a priority level (three possible levels).

Figure 14-12 is a block diagram of the TPCC.

Figure 14-12. TPCC Block Diagram

iva22-012

Notes:

1. Although it is depicted twice in Figure 14-12, there is only one physical register set for the QDMA to PaRAM set mapping block.
2. For more information, see Table 14-3.

A channel is a specific event that can cause a transfer to be submitted to the TPTCs as a transfer request. The TPCC supports up to 64 DMA channels and up to 8 QDMA channels. These channels are identical, except for the ways they are triggered:

- DMA channels can be triggered by external events (such as McBSP TX Evt and McBSP RX Evt) by the software writing 1 to a given bit location or channel, by the event set register, or through chaining.
- QDMA channels are triggered automatically (auto-triggered) by the CPU using the IDMA. QDMAs allow a minimum number of linear writes (optimized for the C64x + Megamodule IDMA feature) to be issued to the TPCC to force a series of transfers to occur.

The TPCC arbitrates among all pending DMA/QDMA events with a fixed 64:1 and 4:1 priority encoder for DMA and QDMA events, respectively (a low channel number corresponds to a high priority). DMA events are always higher priority than QDMA events. The higher-priority event is placed in the event queue to await submission to the transfer controller, which occurs at the earliest opportunity. Each event queue is serviced in FIFO order, with a maximum of 16 queued events per event queue. If more than one TPTC is ready to be programmed with a transmission request (TR), the event queues are serviced with fixed priority, Q0 higher than Q1. When an event is ready to be queued and both the event queue and the TC channel are empty, the event bypasses the event queue and goes directly to the PaRAM processing logic for submission to the appropriate TC. If the TR bus/PaRAM processing is busy, the bypass path is not used. The bypass is not used to dequeue for a higher-priority event.

Events are extracted from the event queue when the TPTC is available for a new TR to be programmed into the TPTC (signaled with the empty signal, indicating an empty program register set). As an event is extracted from the event queue, the associated PaRAM entry is processed and submitted to the TPTC as a TR. The TPCC updates the appropriate counts and addresses in the PaRAM entry in anticipation of the next trigger event for that PaRAM entry. The PaRAM entry consists of eight words of DMA context, including source address, destination address, count, indexes, etc.

14.3.2.1.1.2 DMA Versus QDMA

The only difference between a QDMA and a DMA transfer is the specific means of generating/recognizing TR synchronization. From the user point of view, DMA and QDMA transfer types can be combined to perform various types of transfers.

DMA channel TR synchronization can be generated from one of three sources:

- Event-triggered: The event register ([TPCC_ER](#)) channel *n* bit is set as the result of an external event. An external event is latched in the event register. If the corresponding event is enabled through the event enable register ([TPCC_EER](#)), this is recognized as a TR synchronization.
- Manually triggered: The event set register channel *n* bit is set manually to the event set register ([TPCC_ESR](#) and [TPCC_ESRH](#) registers) for channel *n* ([TPCC_ESR\[n\]](#) En bit or [TPCC_ESRH\[n\]](#) En bit). Manually set events do not need to be enabled to be recognized as a TR synchronization.
- Chain-triggered: The chain event register channel *n* ([TPCC_CER](#) and [TPCC_CERH](#) registers) bit is set when a chaining completion code is detected on the completion interface for channel *n*. Chain events do not need to be enabled. If a chain trigger is detected, this is always recognized as a TR synchronization.

QDMA TR synchronization occurs one of two ways:

- Auto-triggered: The QDMA event register channel *n* ([TPCC_QER](#) and [TPCC_QERH\[n\]](#) En) bit is set when a CPU write address matches the address defined by the QDMA mapping register for channel *n* ([TPCC_QCHMAPj](#)) and the QDMA channel is enabled ([TPCC_QEER\[n\]](#) En bit field).
- Link-triggered: The [TPCC_QER\[n\]](#) En bit is set when a link update is performed on a PaRAM address that matches the [TPCC_QCHMAPj](#) setting, and the [TPCC_QEER\[n\]](#) En bit is set.

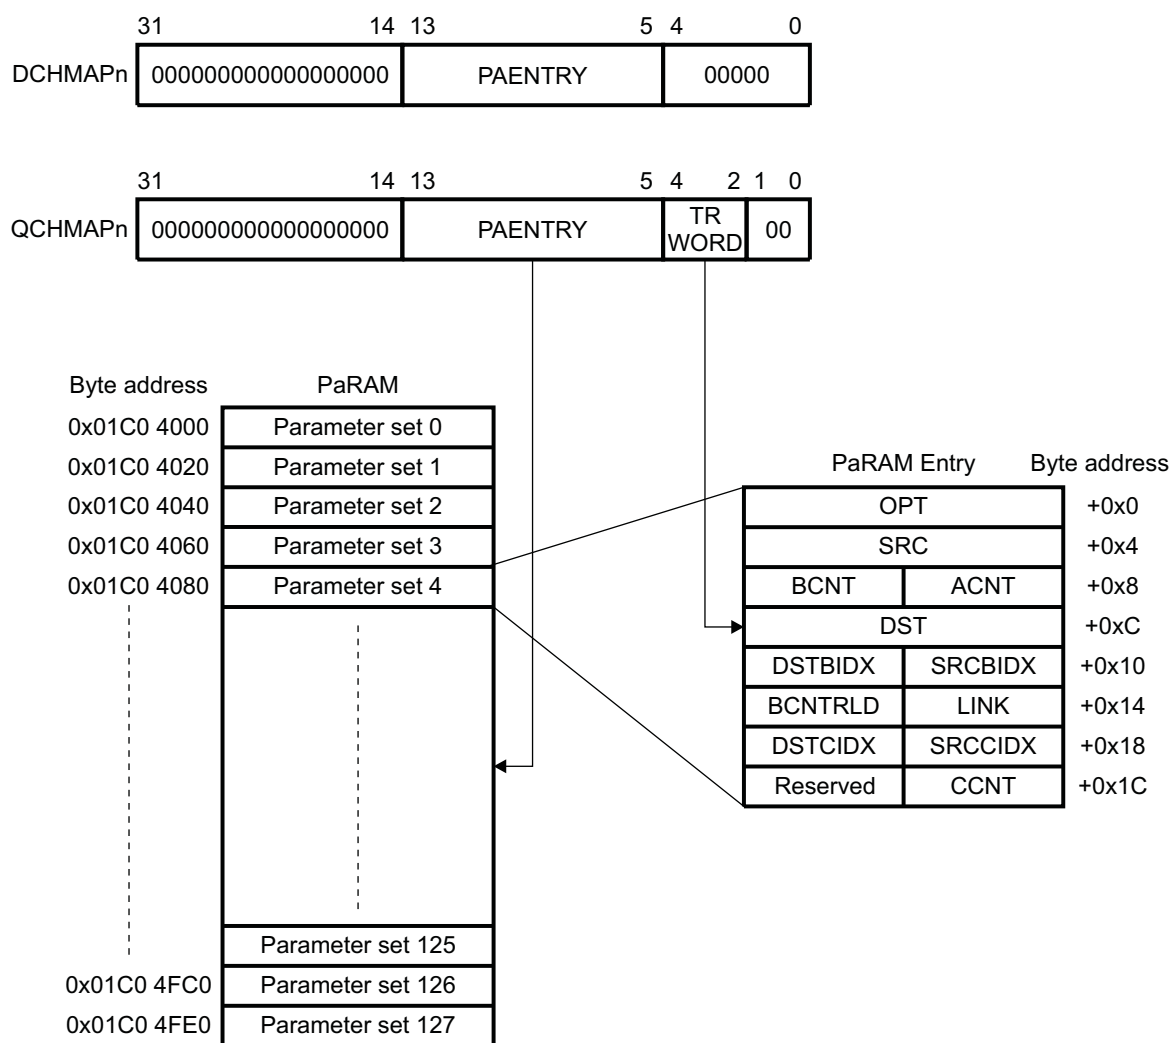

There is a subtle difference between each trigger type and the associated enablers. Event assertion always results in the [TPCC_ER\[n\]](#) En bit being set, regardless of the state of the enable ([TPCC_EER.En](#)). It is recognized as a TR synchronization only if enabled. Chain triggering always sets the [TPCC_CER\[n\]](#) En bit and is always treated as a TR synchronization. Manual triggering always sets the [TPCC_ESR\[n\]](#) En bit and is always treated as a TR synchronization. Auto-triggering (QDMA) sets only the event register [TPCC_QER\[n\]](#) En bit only if the corresponding event is enabled ([TPCC_QEER\[n\]](#) En); when the [TPCC_QER\[n\]](#) En bit is set, it is always treated as a TR synchronization.

For more information, see [Section 14.4, IVA2.2 Subsystem Basic Programming Model](#).

14.3.2.1.1.3 DMA/QDMA Channel Mapping and PaRAM Entry

The DMA and QDMA channel mapping registers ([TPCC_DCHMAPi](#) and [TPCC_QCHMAPj](#)) allow each DMA and QDMA channel to be mapped to arbitrary locations in the PaRAM memory map. The entry is designated with a 9-bit PAENTRY ([TPCC_DCHMAPi](#)[13:5] PAENTRY and [TPCC_QCHMAPj](#)[13:5] PAENTRY bit fields) PaRAM entry number that defines the entry number in a 128-entry maximum PaRAM (see [Figure 14-13](#)). [TPCC_QCHMAPj](#)[4:2] TRWORD points to the trigger word of the PaRAM entry defined by PAENTRY. A write to the trigger word results in a QDMA event being recognized.

Figure 14-13. DMA/QDMA Channel Mapping and PaRAM Entry

iva22-013

Note: Each parameter entry of PaRAM is organized as eight 32-bit words or 32 bytes, as shown in [Figure 14-13](#).

The location of fields in each entry, as well as bit positions in the options field, must match the TR packet format as closely as possible to the requirements of the TPTC0 and TPTC1 programming. Each PaRAM entry consists of 16-bit and 32-bit parameters that correspond to the transfer geometry. For more information about the parameters, see [Section 14.3.2.1.1.2, DMA Versus QDMA](#).

14.3.2.1.1.4 Types of TPCC Transfers

The TPCC streamlines transfers into an orthogonal transfer structure that is always defined by three dimensions. Of the three dimensions, only two synchronization types are supported: 1D synchronized transfers and 2D synchronized transfers; 3D synchronized transfers can be logically achieved by chaining.

The following terms are used:

- 1-dimension (1D) transfer or array: ACNT contiguous bytes transfer. For information about the 1D transfer programming model, see [Section 14.3.2.1.1.5, Transfer Synchronization](#).
- 2-dimension (2D) transfer or frame: BCNT arrays of ACNT bytes transfer. Each array transfer in 2D transfer is separated from the other transfers by an index programmed through the TPCC.SBIDX or TPCC.DBIDX registers.
- 3-dimension (3D) or block: CCNT frames of BCNT arrays of ACNT bytes. Each transfer in the third dimension is separated from the previous transfer by an index programmed by the TPCC.SCIDX or TPCC.DCIDX registers. The reference point for the index depends on the synchronization type.

14.3.2.1.1.5 Transfer Synchronization

In a 1D synchronized transfer, each TPCC TR synchronization triggers the transfer of the first dimension of ACNT bytes, or one array of ACNT bytes. In other words, each TR packet consists of transfer information for only one array. Arrays can be separated by SBIDX and DBIDX, as shown in [Figure 14-13](#), where the start address of array N equals the start address of array 1 plus SRC or DST BIDX. Frames can be separated by SCIDX and DCIDX. For 1D synchronized transfers, after the frame is exhausted, the address is updated by adding (S|D)CIDX to the beginning address of the last array in the frame.

Contrast this to the (S|D)CIDX update in 2D synchronized transfers, which are referenced from the beginning address of the first array in the previous frame. For information about parameter updates, see [Section 14.3.8, Error Reporting](#).

In a 2D synchronized transfer, each TR synchronization triggers the transfer of two dimensions or one frame. In other words, each TR packet conveys information for one entire frame of BCNT arrays of ACNT bytes. Arrays can be separated by SBIDX and DBIDX, as shown in [Figure 14-15](#). Frames can be separated by SCIDX and DCIDX. For 2D synchronized transfers, after a TR for the frame is submitted, the address is updated by adding (S|D)CIDX to the beginning address of the beginning array in the frame. Contrast this to the (S|D)BIDX update in 1D synchronized transfers. For information about parameter updates, see [Section 14.3.8, Error Reporting](#).

14.3.2.1.1.6 DMA Channel Prioritization

If multiple trigger sources (event trigger/chain trigger/manual trigger) for a single channel are active at the same time, the TPCC services events in the following order:

1. Event trigger (through event register [ER])
2. Chain trigger (through chain event register [CER])
3. Manual trigger (through event set register [ESR])

14.3.2.1.1.7 Transfer Completion

Transfer completion can be used for two different mechanisms in the TPCC:

- Generating chained events
- Generating interrupts to an external processor

The underlying mechanism for both features is the same. The user programs the PaRAM Options field with a specific transfer completion code ([TPCC_OPTm\[17:12\] TCC](#)) and indicates whether that completion code is to be used to generate a chained event and/or to generate an interrupt on completion of a transfer (either or both can be done). The user can selectively program whether completion signaling is enabled for the final TR of a PaRAM set, for all except the final TR of a PaRAM set, or for all TRs of a PaRAM set. The specific TCC value (6-bit binary value) programmed by the user dictates which bit of the 64-bit CER and/or interrupt pending register (IPR) is used.

There is no direct correlation between the TCC value used for a specific PaRAM entry and the channel number for that entry. Software controls the allocation of TCC values. There is always a 1:1 relationship between the TCC value and the IPR bit and/or the CER bit set when that transfer completes. For example, completion of the PaRAM entry for channel 0 can chain-trigger the PaRAM entry for channel 1.

14.3.2.1.2 Third-Party Transfer Controller

The TPTC is the DMA transfer engine that generates transfers as programmed in dedicated working registers, using two dedicated master ports: a read-only port and a write-only port.

Note: The port data bus width of the instances of the TPTC is fixed at 64 bits.

14.3.2.1.2.1 TPTC Features

The TPTC features are as follows:

- Pipelined transfers (multiple in-flight transfers)
- Background programming
- 2D or 1D transfer
- Increment addressing modes
- Clock-stop handshaking with the SYSC controller
- Programmable tracking of transfer completion
- 2D qualifications of transfers to allow 2D bandwidth optimization

Two instances of the TPTC generate concurrent traffic on the IVA2.2 local interconnect. Each TC controller consists of the following components:

- DMA program register set: Stores the context for the DMA transfer that is loaded into the active register set on completion of the current active register set. The CPU or TPCC programs the program register set, not the active register set. For typical stand-alone operation, the CPU programs the program register while the TC services the active register set. The program register set includes ownership control that synchronizes the CPU software and the DMA.
- Source DMA active register set: Stores the context (src/dst/cnt/etc) for the DMA transfer request in progress in the read controller. The active register set is split into independent source and distant register halves, because the source local interconnect controller and distant local interconnect controller operate independently of each other.
- Distant DMA register set: Stores the context (src/dst/cnt/etc) for the DMA transfer request in progress, or pending, in the write controller. The pending register sets are required to allow the source controller to begin processing a new TR while the distant register set is still processing the previous TR.
- Channel FIFO: Temporary holding buffer for in-flight data. The read return data of the source peripheral is stored in the data FIFO and then written to the destination peripheral by the write command/data bus.
- Read controller/local interconnect read interface: The local interconnect read interface issues optimally sized read commands to the source peripheral, based on a burst size of 64 bytes and the available landing space in the channel FIFO.
- Write controller/local interconnect write interface: The local interconnect write interface issues optimally sized write commands to the destination peripheral, based on a burst size of 64 bytes and available data in the channel FIFO.
- Completion interface: The completion interface sends completion information to the TPCC for posting interrupts in the TPCC.
- Configuration port: Slave interface that provides read/write access to program registers, and provides read access to all memory-mapped TC registers. For information about TPTC registers, see [Section 14.5, IVA2.2 Subsystem Registers](#).

[Table 14-4](#) lists the hardware settings.

[Figure 14-14](#) shows the internal structure of the TPTC and its connection to the TPCC.

Figure 14-14. TPTC Block Diagram

iva22-014

The primary responsibility of the TPTC is to perform read and write transfers through the local interconnect to the slave peripherals, as programmed in the active and program register sets:

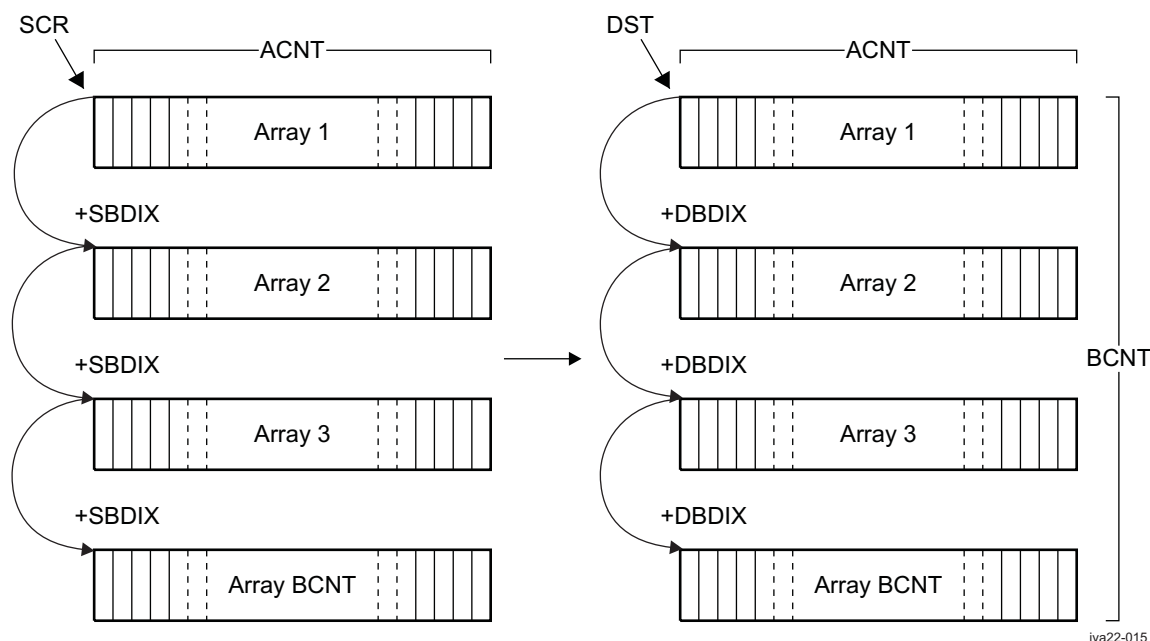

- In the TC stand-alone use model, the user directly programs the program and active register sets for a given channel (TPTC0 or TPTC1). Because of the TPCC, this mode is not the use case targeted for device applications, so it is not emphasized in this chapter. For information about its programming model, see [Section 14.4.3.6.6, Direct Configuration to Transfer Channel \(Not Recommended\)](#).
- In the TC external-control use model, the user does not directly program the active and program register sets. Instead, the TPCC is the user interface to the EDMA system, and the TPTCs (TPTC0 and TPTC1) are slaves to the TPCC. This is the use case of the EDMA in device applications.

14.3.2.1.2.2 Transfer Geometry

The TPTC supports a transfer geometry fully defined by the registers summarized here (see [Figure 14-15](#)).

- OPTx = options, (where x = 0, 1)
 - SAM = Source address mode, controls whether the source array is from incrementing addresses or from a single FIFO address
 - DAM = Distant address mode, controls whether the destination array is to an incrementing address or to a single FIFO address
 - FWID = Controls the width of the FIFO
- SRC = Source address
- DST = Distant address
- CNT = BCNT, ACNT
 - ACNT = Number of bytes in each array
 - BCNT = Number of arrays in each TR
- BIDX = DBIDX, SBIDX
 - SBIDX = Source B-dimension index, defines the address offset between starting addresses of each source array
 - DBIDX = Distant B-dimension index, defines the address offset between starting addresses of each destination array

Figure 14-15. Transfer Geometry

Note: Many Texas Instruments DMA controllers employ a concept of element size and element indexing. To maintain orthogonality, the concept of element size has been dropped. An element-indexed transfer is logically achieved by programming ACNT to the size of the element and BCNT to the number of elements that must be transferred.

14.3.2.1.2.3 Tracking Transfers

Each TPTC channel consists of three register sets: a program register set, a source-active register set, and a distant FIFO register set. The status of each of these register sets is indicated by the PROGBUSY, SRCACTV, DSTACTV, and WSACTV status bits, which are user-readable in the `TPTCj_TCSTAT` register.

The program register set (`TPTCj_POPT`, `TPTCj_PSRC`, `TPTCj_PCNT`, `TPTCj_PDST`, `TPTCj_PBDIX`, and `TPTCj_PMPPRXY`) is never modified by the TPTC, because they are simply holding registers processed by the active register sets. The source active register set (`TPTCj_SAOPT`, `TPTCj_SASRC`, `TPTCj_SACNT`, `TPTCj_SADST`, `TPTCj_SABIDX`, `TPTCj_SAMPPRXY`, `TPTCj_SACNTRLD`, `TPTCj_SASRCBREF`, and `TPTCj_SADSTBREF`) tracks commands for the source side of the transfer, and the distant FIFO register set (`TPTCj_DFOPTi`, `TPTCj_DFSRCi`, `TPTCj_DFCNTi`, `TPTCj_DFDSTi`, `TPTCj_DFBIDXi`, and `TPTCj_DFMPPRXYi`) tracks commands for the distant side of the transfer.

As the source and distant controllers process a TR, the SRC, DST, and CNT fields must be continuously updated as commands are issued. A reference value for these registers is also maintained. The active register set uses the reference address (SRCBREF and/or DSTBREF) to calculate the addresses of the subsequent arrays in a transfer. This is required because subsequent arrays are defined as an offset from the starting address of the current array. Similarly, when a new array begins, the CNT must be restored (from CNTRLD) to the originally programmed value and decremented as the new array is processed.

The following summarizes register use for the active register sets:

- Static fields
 - OPT
 - BIDX = DBIDX/SBIDX
- Dynamic fields
 - SRC = Source address of the next read command to be issued
 - Tracked by source active register set
 - DST = Distant address of the next write command to be issued

- Tracked by distant FIFO register set
 - CNT = BCNT/ACNT
 - BCNT = Number of arrays remaining to be transferred. This includes the current array; that is, BCNT is decremented after all commands for an array are issued (or at least after all read or write commands are scheduled).
 - ACNT = Number of bytes remaining to be transferred
 - Tracked independently in source and distant FIFO register sets
 - Reference fields
 - CNTRLD = ACNTRLD only
 - CNTRLD.ACNTRLD is set with the initial CNT.ACNT value. The reload value is copied into CNT.ACNT when CNT.ACNT decrements to 0.
 - Tracked independently in source and distant FIFO register sets
- Because a command is complete when BCNT decrements to 0, there is no BCNT reload value.
- SRCBREF = Source address reference points to the starting address of the array being read. The starting address of the next array is calculated as SRCBREF + SBIDX.
 - Tracked by source active register set
 - DSTBREF = Distant address reference points to the starting address of the array being written. The starting address of the next array is calculated as DSTBREF + DBIDX.
 - Tracked by distant FIFO register set

14.3.2.1.2.4 Completion Interface to TPCC

The TPCC can request that the TPTC send completion information to the TPCC when a TR completes. Completion status is requested in the TR options registers ([TPTCj_DFOPTi\[20\]](#) TCINTEN and [TPTCj_DFOPTi\[22\]](#) TCCHEN bits, and [TPTCj_DFOPTi\[17:12\]](#) TCC where i = 0 to 3 when j = 0 and i = 0 or 1 when j = 1).

If TCINTEN or TCCHEN is set to 1, the TPTC must return completion information on completion of the entire TR. The TPCC uses completion information for chaining (enabled by TCCHEN) or for posting interrupts (enabled by TCINTEN).

The TPTC generates status conditions based on completion of a transfer ([TPTCj_INTSTAT\[1\]](#) TRDONE bit) and based on the program register set transitioning to the downstream registers ([TPTCj_INTSTAT\[0\]](#) PROGEMPTY bit).

These two conditions can be enabled by the corresponding bits in the [TPTCj_INTEN](#) register to generate an interrupt to the DSP CPU through the TCERRINTx interrupt line (TCERRINT0 for TPTC0 and TCERRINT1 for TPTC1). For the event mapping of these interrupt lines, see [Table 14-2](#).

Note: Status bits TRDONE and PROGEMPTY are always available and are stored in the [TPTCj_INTSTAT](#) register regardless of use model and regardless of whether the corresponding bits are enabled. Typically, these bits are not used in the TPCC use model. They are used in a stand-alone use model in which the user directly programs the TC.

For more information about EDMA completion and its programming model, see [Section 14.4.3.1, Transfers From/to Device Memories/Peripherals \(EDMA\)](#).

14.3.2.1.3 EDMA Hardware Parameters

[Table 14-4](#) lists the hardware parameter settings for the IVA2.2 subsystem.

Table 14-4. IVA2.2 EDMA Hardware Parameters

Module		Parameter	IVA2.2
EDMA	TC	FIFO size for TC0	256 bytes
		FIFO size for TC1	128 bytes
		Data bus width	64 bits
		TR pipelining depth TC0	4
		TR pipelining depth TC1	2
		Endianness	Little
		Burst size	64
	CC	Number of DMA channels	64
		Number of QDMA channels	8
		Number of PaRAM entries	128
		Number of Event Qs	2
		Number of TPTCs	2

Note: The TR pipelining depth controls the number of read TRs for a given transfer channel that can be serviced by the source transfer controller without being serviced by the distant transfer controller. This dictates the amount of storage required in the distant queue channel registers for in-flight TRs

The user cannot directly program burst size, as with the sDMA, but must rely on the ACNT/BCNT and issue 1D synchronization transfers to do so.

14.3.2.2 EDMA Access to Video Hardware Accelerator

To improve performance and to offload themselves, the C64x + Megamodule and sequencer can both program the EDMA in IVA2.2 to transfer memory to/from the video accelerator to/from external memories. The C64x + Megamodule programs the EDMA through the IVA2.2 local interconnect.

The DMA accesses the video hardware accelerator with the memory mappings listed in [Table 14-5](#).

Table 14-5. EDMA Memory Mapping for the Video Hardware Accelerator

Device Name	Start Address (Hex)	End Address (Hex)	Size (in Kbytes)
Video Hardware Accelerator Registers	0x0000 0000	0x000F 7FFF	992
Video interconnect CFG	0x000F 8000	0x000F BFFF	16
Reserved	0x000F C000	0x000F FFFF	16
Other MEMS and PERIPHS	0x0010 0000	0xFFFF FFFF	4,193,280

14.3.2.3 IDMA

The IDMA is a simple DMA engine that performs block transfers between any two memory locations local to the C64x + Megamodule. A local memory has a controller that is included in the C64x + Megamodule. Local memory can be L1P, L1D, or L2 memories or C64x + Megamodule port configuration for an offloaded configuration. The IDMA controller consists of two DMA channels (channel 0 and channel 1) that can be independently programmed (a dedicated set of registers) to perform block moves between internal C64x + Megamodule resources.

IDMA channel 0 is used only to configure registers of IVA2.2 modules connected to the C64x + Megamodule configuration port, and it is useful for the DMA PaRAM entries.

To allow an easy configuration of IVA2.2 modules, the IDMA channel contains five registers: status, mask, source address, destination address, and window count.

For information about the use of channel 0 for an offloaded configuration, see [Section 14.4.3.6.5, Offloaded Configuration \(Using IDMA\)](#).

IDMA channel 1 allows transfers between any two C64x + Megamodule local internal memories (L2, L1P, L1D). Channel 1 is intended for background transfers in internal memory, such as block moves between the relatively high-latency L2 and the zero-latency L1D SRAM. This lets the CPU process data directly within L1D with minimal CPU impact.

For more information, see [Section 14.4.3.2, Internal Memory-to-Memory Transfer \(IDMA\)](#).

14.3.3 MMU

The IVA2.2 MMU communicates accesses from the DSP core of the IVA2.2 subsystem to the L3 interconnect, mapping the 4G bytes of the DSP virtual addresses to any place in the 4G-byte address space of the device.

At reset, the MMU is disabled, and the IVA2.2 DSP CPU can access device global memory mapping from the 0x1100 0000 address. The range of addresses 0x00000000 to 0x10FF FFFF is reachable only by the DSP CPU, because it performs its own internal memory-mapping function. For more information, see the *Memory Mapping* chapter.

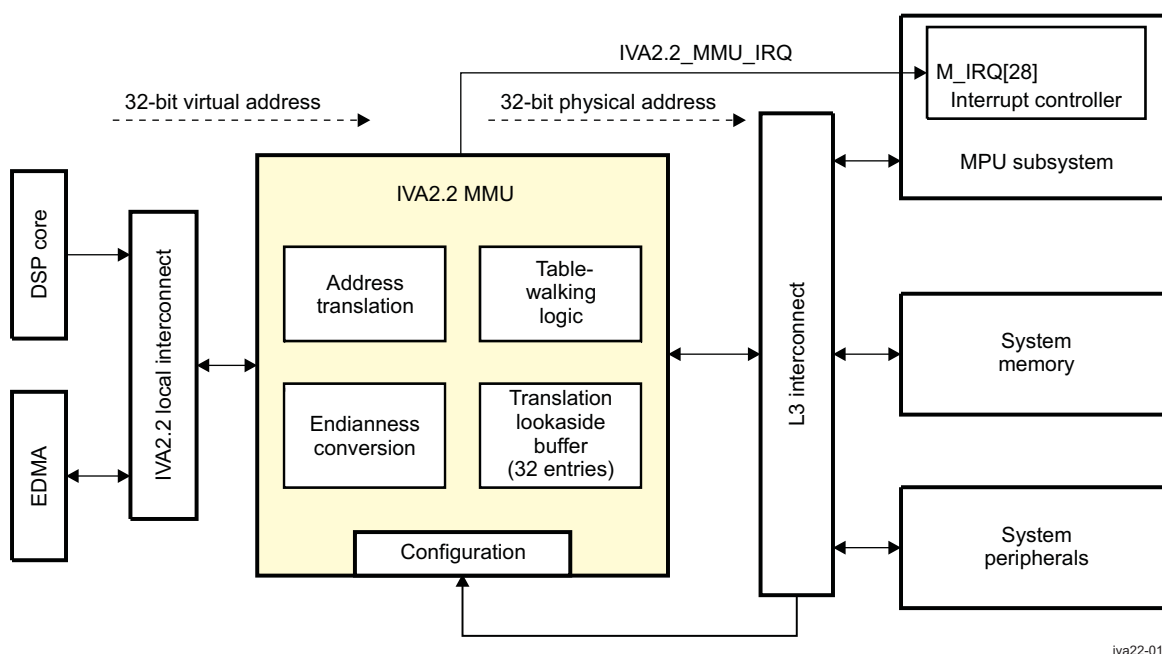

The IVA2.2 MMU main features are:

- 32 entries/fully associative translation look-aside buffer (TLB)
- One interrupt line to the MPU
- 32-bit virtual addresses, 32-bit physical addresses
- 4-KB and 64-KB pages, 1-MB section, 16-MB super-section
- Predefined (static), software-driven (interrupt-based) or table-driven (hardware table-walker) software translation strategies

Note: The endianness conversion capability of the MMU module is not used in the IVA2.2 subsystem (the DSP is configured as a little-endian processor in the device). With this configuration, the MMU2.MMU_RAM[9] ENDIANNESS bit setting is ignored, even if the user changes the value.

Figure 14-16 shows the integration and functionality of the IVA2.2 MMU module.

Figure 14-16. IVA2.2 MMU Block Diagram

iva22-016

14.3.3.1 MMU VA-to-PA Translation

The IVA2.2 MMU translates the 32-bit DSP external addresses to physical addresses in the 32-bit MPU address space. Address translation is performed by a translation table structure (TTB) that maps the most-significant bits (MSBs) of the DSP byte address to another set of MSBs of a 32-bit MPU byte address. The least-significant bits (LSBs) of the DSP-generated byte address are used as page/section indices in the address translations and are not altered when forming the new 32-bit physical address. The TTB translations are expedited by a TLB that serves as a cache of recently used page translations. The address mapping can be programmed at the TTB level or by writing the TLB entries directly. The IVA2.2 MMU contains 32 TLB entries that can be configured to remap 4-KB, 64-KB, 1-MB, or 16-MB segments of memory.

The TLB can be managed statically or dynamically (through the use of interrupts) by the MPU OS, but the MMU also includes hardware table-walking logic that lets the MMU autonomously traverse the page table on a TLB miss. On a TLB miss, the translation table-walking logic automatically retrieves the information from the translation table stored in physical memory and updates the TLB cache.

Figure 14-17 shows the TTB structure in detail.

Figure 14-17. IVA2.2 MMU Translation Table Hierarchy

iva22-017

Note: The MMU passes the lower bits of the virtual address unchanged.

14.3.3.2 MMU Configuration

If the IVA2.2 MMU requires software intervention, the MPU services the event; IVA2.2 MMU service requests are signaled to the MPU with a dedicated interrupt, M_IRQ[28].

Generally, the MMU is initialized at boot time, but it can also be dynamically reprogrammed. Typically, the MMU is programmed by the MPU through the IVA2.2 slave port on the L3 interconnect when a new task is created on the IVA2.2 subsystem. But the DSP also has access to the MMU configuration registers for the save and restore process. At reset, MMU is disabled and DSP virtual addresses are passed directly through as physical addresses (not translated). IVA2.2 MMU configuration registers are at system base address 0x5D00 0000.

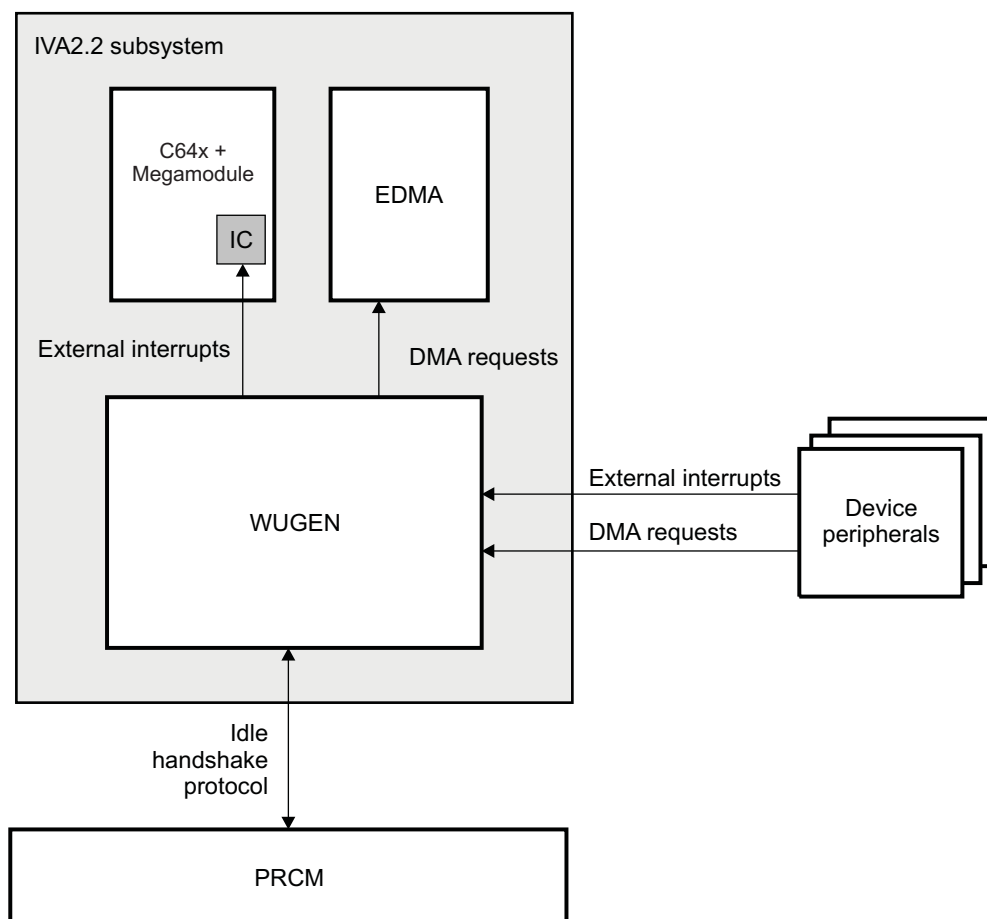

For more information about the functionality of the IVA2.2 subsystem MMU module, including interrupts, register descriptions, and programming model, see the *Memory Management Units* chapter.

14.3.4 Wake-Up Generator

The wake-up generator (WUGEN) controls the following:

- Implementing the IVA2.2 idle handshake protocol with the PRCM
- Resynchronizing interrupts and DMA requests from device peripherals external to the IVA2.2 subsystem
- Blocking the interrupts and DMA requests to the IVA2.2 on clean boundaries, when the WUGEN is asked to go into IDLE state
- Detecting the enabled wake-up interrupts and DMA requests and generating a wake-up event to the PRCM
- Formatting interrupts to C64x + Megamodule interrupt format

[Figure 14-18](#) shows the WUGEN in the IVA2.2 subsystem and its interactions with other submodules.

Figure 14-18. IVA2.2 WUGEN Description

14.3.4.1 Interrupts, DMA Requests, and Event Management

Interrupts and DMA requests are generated the same way in the WUGEN module. In this section, both are called events.

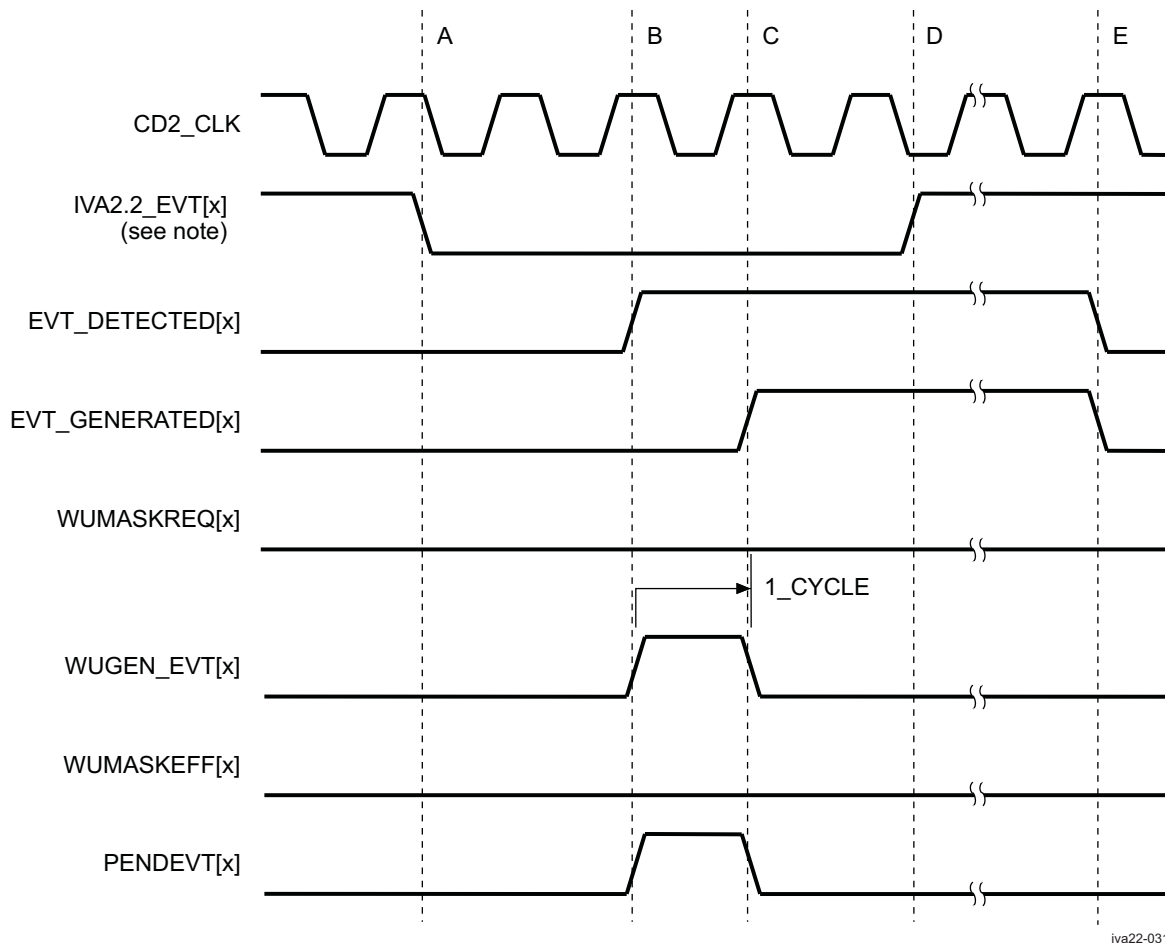

To manage interrupts, DMA requests, and slave port accesses from external modules, the WUGEN module uses several sets of user-programmable registers:

- The [WUGEN_MEVT0](#), [WUGEN_MEVT1](#), and [WUGEN_MEVT2](#) registers define individual mask bits for external asynchronous events (interrupts, DMA requests, slave port access). This register is read-only, only by the DSP. To modify the value of the individual mask, write 1 to the associated bits of [WUGEN_MEVTCLR0](#), [WUGEN_MEVTCLR1](#), and [WUGEN_MEVTCLR2](#) (to clear) and [WUGEN_MEVTSET0](#), [WUGEN_MEVTSET1](#), and [WUGEN_MEVTSET2](#) (to set).
- The [WUGEN_PENDEVT0](#), [WUGEN_PENDEVT1](#), and [WUGEN_PENDEVT2](#) registers are read-only registers that track which external events are pending in the WUGEN module and are not yet generated to the C64x + Megamodule interrupt controller (INTC) or to the EDMA. If an event is masked, this information is stable until the corresponding mask bit is cleared. If an event is unmasked, this information may not be stable, and therefore corresponds to a transitive period of processing the event in the WUGEN module.

14.3.4.1.1 Event Generation

Figure 14-19 shows event-generation steps in the WUGEN.

Figure 14-19. WUGEN Event Generation

iva22-031

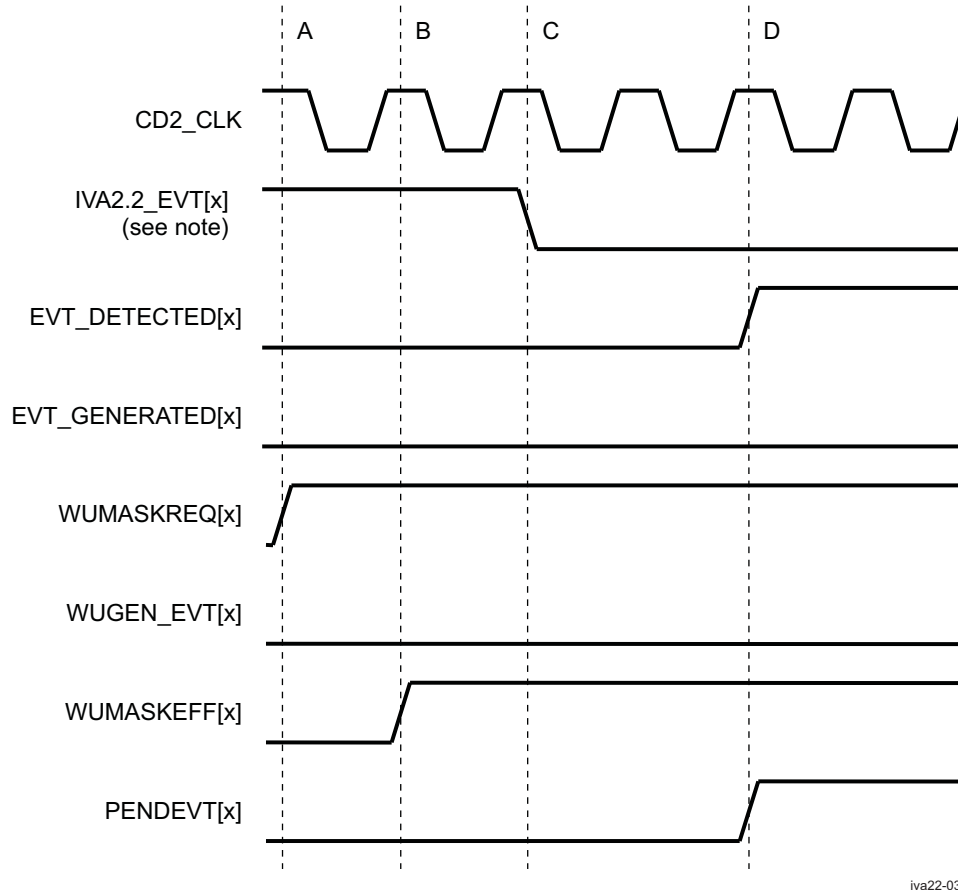

Note: IVA2.2_EVT[x] refers to either IVA2.2nIRQ[x] or IVA2.2_nDMAREQ[x].

- An asynchronous event is asserted.
- The event is resynchronized and detected. Because the event is not masked, it is propagated to C64x + Megamodule/EDMA.
- The event-pending flag is cleared because the event was generated. The event to C64x + Megamodule/EDMA is de-asserted after one WUGEN clock cycle.
- After some time, the source of the event is released (probably because it cleared in the corresponding interrupt status register).
- The release of the event is detected and clears the internal EVT_GENERATED flag for that interrupt.

14.3.4.1.2 Individual Event Masking

To mask individual events, write 1 in the [WUGEN_MEVTSET0](#), [WUGEN_MEVTSET1](#), or [WUGEN_MEVTSET2](#) register of the WUGEN module. These registers are used to mask interrupts and DMA requests.

Figure 14-20 shows the mechanism of event masking in the WUGEN module.

Figure 14-20. WUGEN Event Masking

iva22-032

Note: IVA2.2_EVT[x] refers to either IVA2.2_nIRQ[x] or IVA2.2_nDMAREQ[x].

- The user sets the corresponding bit in the mask. Event generation is disabled.
- Event mask completion is reflected in the IVA2.2.WUGEN_MEVT0 to IVA2.2.WUGEN_MEVT2 registers (where i = 0 to 2) for reads.
- An asynchronous event is asserted.
- The event is resynchronized and detected. Because the event is masked, it is not propagated to C64x + Megamodule/EDMA. The event-pending flag is kept active (sticky) until the mask is removed.

14.3.4.1.3 Individual Event Mask Clear

To unmask individual events, write 1 in the WUGEN_MEVTCLR0, WUGEN_MEVTCLR1, or WUGEN_MEVTCLR2 register of the WUGEN module.

Figure 14-21 shows the event-mask-clear mechanism in the WUGEN module.

Figure 14-21. WUGEN Event Mask Clear

iva22-033

Note: IVA2.2_EVT[x] refers to either IVA2.2_nIRQ[x] or IVA2.2_nDMAREQ[x].

- An asynchronous event is asserted.
- The event is resynchronized and detected. Because the event is masked, it is not propagated to C64x + Megamodule/EDMA. The event-pending flag is kept active (sticky) until the mask is removed.
- After some time, clear the corresponding bit in the WUGEN mask. The event is automatically generated to C64x + Megamodule if the event is still seen as active. If the event is not seen as active, nothing happens.
- In both cases, the event-pending flag is cleared.

For more information about interrupts and the EDMA programming model, see [Section 14.4.4, Interrupt Management](#), and [Section 14.4.3.1, Transfers From/to Device Memories/Peripherals \(EDMA\)](#).

14.3.4.2 Idle Handshake

After reset, the WUGEN waits for a request. If the user executes the DSP IDLE instruction to put the DSP in standby state, the SYSC initiates a clock-off handshake with the WUGEN.

14.3.5 SYSC Module

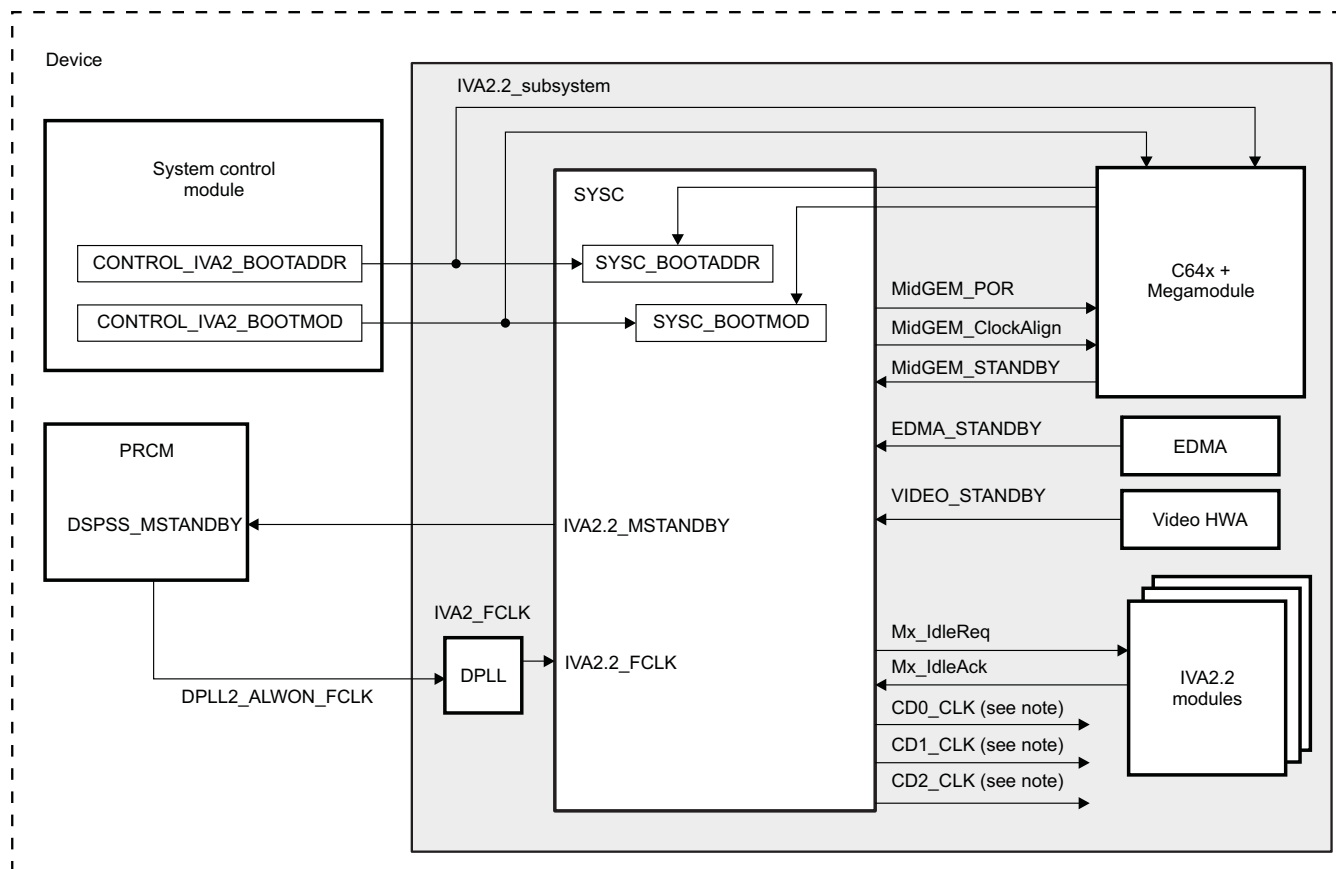

The SYSC module of the IVA2.2 subsystem controls the following functions:

- Generation of the divided clocks to all components of the IVA2.2 subsystem
- Synchronization of the IVA2.2 divided clocks and the C64x + Megamodule internal-divided clocks
- PRCM power handshaking

- Sequencing of clock-to-off transition for the IVA2.2 modules
- Reset input resynchronization of the active-to-nonactive transition to the CD2_CLK clock
- IVA2.2 boot configuration and its access from the DSP

Figure 14-22 is the block diagram of the SYSC in the IVA2.2 subsystem.

Figure 14-22. SYSC Block Diagram

Note: For more information, see [Section 14.2.1, Clocking, Reset, and Power-Management Scheme](#).

14.3.5.1 Divided Clock Generation

The SYSC module generates the divided clocks used by the modules in the IVA2.2 subsystem. The SYSC generates three clocks:

- CD0_CLK
- CD1_CLK
- CD2_CLK

Based on the IVA2.2_FCLK clock, these three clocks are configured from the PRCM. For details, see [Section 14.2.1, Clocking, Reset, and Power-Management Scheme](#).

14.3.5.2 Clock Management, Power-Down, and Wake-Up

The SYSC ensures correct generation of the clocks described in [Figure 14-22](#). The SYSC also allows management of the clock gating of the EDMA, video accelerator, and C64x + Megamodule if the user wants to lead some dynamic power aspects.

The SYSC module controls the transition to IVA2.2 subsystem standby state and standby signal generation (IVA2.2_MSTANDBY signal in [Figure 14-22](#)) to the PRCM. Using the signals DSP_MEGACELL_STANDBY, EDMA_STANDBY, VIDEO_STANDBY, Mx_IdleReq, and Mx_IdleAck, the SYSC manages and controls the correct power-down transition of the IVA2.2 subsystem and its submodules to ensure that the IVA2.2 internal clocks can be cut. For information about the IVA2.2 power-down transition and its programming model, see [Section 14.4.6.3, Power-Down and Wake-Up Management](#).

External events can also occur at the IVA2.2 boundary (access to IVA2.2 using the slave access port or external nonmasked events), requiring the restart of the IVA2.2 clocks (in case of IVA2.2 standby state). The WUGEN module controls the asynchronous generation of a wake-up signal to the PRCM; this signal restarts IVA2.2 PLL clock generation, allowing the SYSC to regenerate the IVA2.2 internal clocks.

14.3.5.3 Boot Configuration

The IVA_SYSC.SYSC_BOOTADDR and IVA_SYSC.SYSC_BOOTMOD registers are the boot-time configuration registers. These read-only registers are accessible only by the DSP, and their values are determined when the IVA2.2 subsystem is released from reset by the PRCM.

The values of these registers are driven externally by two system control module registers, SYSC_GENERAL1.CONTROL_IVA2_BOOTADDR and SYSC_GENERAL1.CONTROL_IVA2_BOOTMOD, which are read-write accessible by the MPU subsystem for MPU-driven IVA2.2 boot sequence and/or by the IVA2.2 DSP for autonomous boot. For more information, see [Section 14.4.1, IVA2.2 Boot](#).

Note: If the values of the SYSC_GENERAL1.CONTROL_IVA2_BOOTADDR and SYSC_GENERAL1.CONTROL_IVA2_BOOTMOD registers change, the new IVA2.2.SYSC_BOOTADDR and IVA2.2.SYSC_BOOTMOD register values are not updated until the next reset.

For more information, see [Section 14.4.1, IVA2.2 Boot](#).

14.3.5.4 Interconnect Optimization

The IVA2.2.SYSC_LICFG0 and IVA2.2.SYSC_LICFG1 registers are local interconnect configuration registers. They are read-write accessible by the DSP only. Setting these registers enables or disables interconnect optimization.

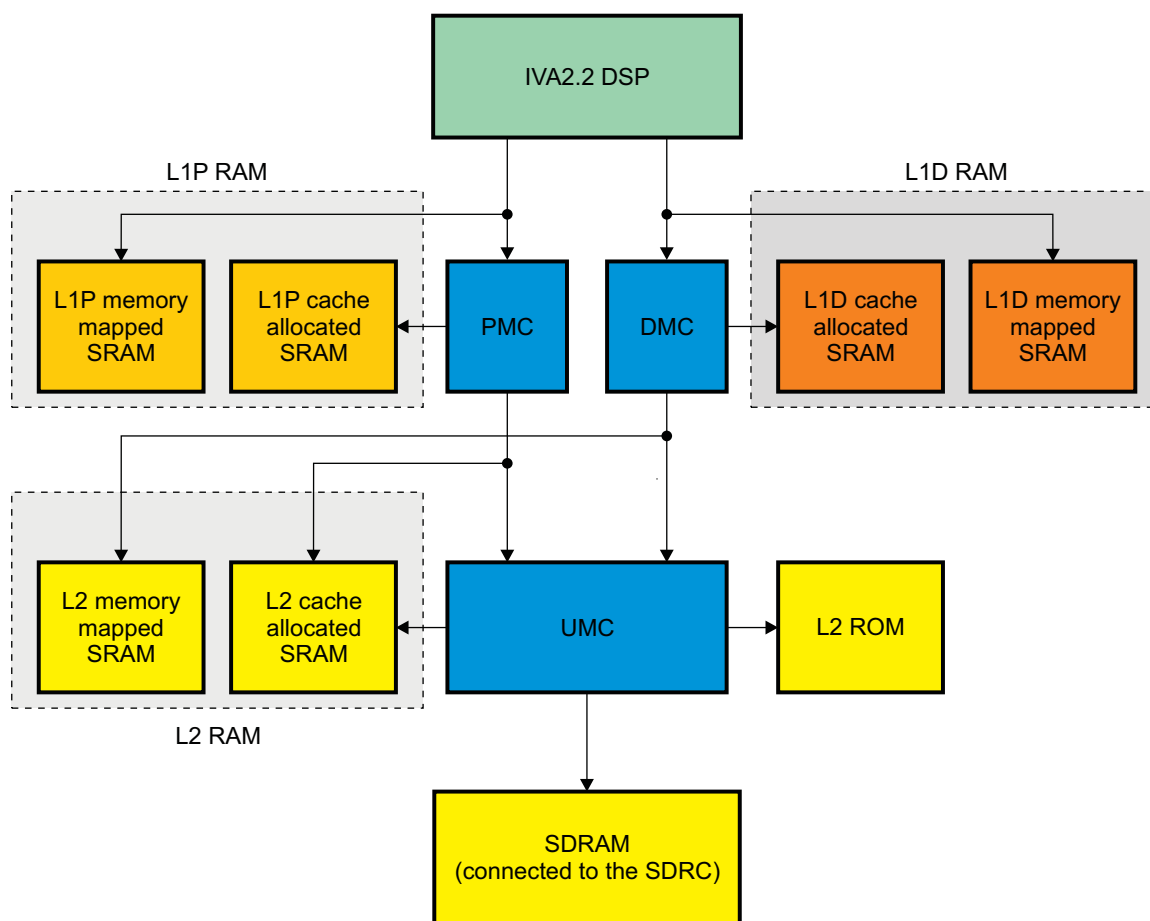

14.3.6 Local Memories

The IVA2.2 subsystem integrates three memory controllers under the control of the C64x + Megamodule:

- DMC
- PMC
- UMC

Depending on the software configuration of these memory controllers, the IVA2.2 subsystem local memories (ROM and RAMs) can be used as cache or memory-mapped memories.

[Figure 14-23](#) shows the memory hierarchy of the IVA2.2 subsystem.

Figure 14-23. IVA2.2 Local Memories Hierarchy

iva22-035

Table 14-6 lists the IVA2.2 C64x + Megamodule cache controller features.

Table 14-6. IVA2.2 C64x + Megamodule Cache Controller Features

Cache	L1 Program Cache	L1 Data Cache	L2 Unified Cache
SIZE	Programmable to 0KB, 4KB, 8KB, 16KB, or 32KB	Programmable to 0KB, 4KB, 8KB, 16KB, or 32KB	Programmable to 0KB, 32KB, or 64KB
ASSOCIATIVITY	Direct-mapped	Two-way set associative	Four-way set associative
SRAM MODE [memory-mapped SRAM]	Programmable to 0KB, 16KB, 24KB, 28KB, 32KB [32KB - cache size]	Programmable to 48KB, 64KB, 72KB, 76KB, 80KB [80KB - cache size]	Programmable to 32KB, 64KB, or 96KB [96KB - cache size]
WRITE BUFFER	NR	Yes	Yes
HIT UNDER MISS	Yes	Yes	No
MISS PIPELINING	Yes	Yes	No
REPLACEMENT POLICY	NR	True LRU	True LRU (pseudo-LRU)
CACHEABILITY	Always cached	Programmable	Programmable
BUFFERABILITY	NR	Always buffered	Always buffered
WRITE POLICY	NR	Always write-back	Always write-back
ALLOCATION POLICY	Read-allocate	Read-allocate	Read-write-allocate
CRITICAL WORD FIRST	No	No	No
CRITICAL LINE FIRST	NR	NR	Yes
ADVANCE FETCH	Yes, because of DSP advanced fetch-and-miss pipelining	NR	NR

14.3.6.1 ROM Overview

The IVA2.2 subsystem contains 16KB L2 ROM. The content of this ROM includes boot code.

For information about boot code and the IVA2.2 boot mechanism, see [Section 14.4.1, IVA2.2 Boot](#).

When the L1P SRAM is configured to be inactive (that is, fully memory-mapped SRAM), DSP program fetch accesses to the L2 ROM are realized directly, and thus suffer the L2 latency.

14.3.6.2 RAM Overview

- 32KB L1 program RAM (L1P)
- 80KB L1 data RAM (L1D)
- 96KB L2 unified RAM (L2)

Note: The maximum cache size for the PMC is 32KB. L1P memory-mapped RAM can be programmed to allocate 0KB (full-cache), 16KB, 24KB, 28KB, or 32KB (no cache, default) using the PMC registers. The remaining memory is allocated to the cache controller.

The maximum cache size for the DMC is the default 32K bytes. L1D memory-mapped RAM can be programmed to allocate 48KB (full-cache), 64KB, 72KB, 76KB, or 80KB (no cache, default). The remaining memory is allocated to the cache controller (DMC).

L1P and L1D RAM operate at the DSP frequency (CD0 clock domain).

L2 RAM operates at half the DSP frequency (CD1 clock domain).

In the IVA2.2 subsystem, L2 can be configured so that the memory-mapped RAM allocates 32KB, 64KB, or 96KB (no cache) of L2 memory. The remaining memory is allocated to the cache controller.

By default, L2 memory is used as 96-KB local memory-mapped RAM. However, L2 RAM is typically used as 64KB allocated to the cache RAM. This is programmable in the C64x + Megamodule UMC.

The L2 memory-mapped SRAM is shared by the C64x + Megamodule and the SL2 interface. An arbitration mechanism is implemented for concurrent access, with the C64x + Megamodule having priority. These last 32KB cannot be used as cache RAM, but only as memory-mapped RAM.

For information about the software programming model for cache management of the local RAM memories of the IVA2.2 subsystem, see [Section 14.4.2, Cache Management](#).

14.3.7 Local Interconnect Network

The local interconnect network is the IVA2.2 internal logic that allows internal communication between the modules of the subsystem (for example, the C64x + Megamodule can communicate with the EDMA or with the WUGEN module). Communication with the rest of the system is through the MMU as master port (accesses from the IVA2.2 subsystem to the L3 interconnect), and through a slave port for accesses from the L3 interconnect (accesses from the L3 interconnect to the IVA2.2 subsystem).

For information about global memory mapping of the IVA2.2 subsystem (DSP CPU view or MPU view through the L3 interconnect), see the *Memory Mapping* chapter.

14.3.7.1 Endianness

The IVA2.2 local interconnect network does not support the big-endian convention or any type of endianness conversion. Only little-endian is supported by the local interconnect network.

14.3.8 Error Reporting

Several mechanisms are available in the IVA2.2 subsystem to report errors at different levels.

The INTC of the C64x + Megamodule allows reporting of dropped interrupts, through the INTERR signal.

L3 out-of-band errors are also reported through the external L3 interrupt signal. For details about interrupt mapping, see [Table 14-3](#). For information about L3 interconnect error reporting, see the *Interconnect* chapter.

The IDMA and EDMA have their own error-reporting mechanism. Error-status registers and error interrupts inform the user of problems during IVA2.2 internal operation (data error, bus activity error, etc.).

For information about error management and the register set that allows error tracing, see [Section 14.4.7](#), *Error Identification Process*.

14.4 IVA2.2 Subsystem Basic Programming Model

14.4.1 IVA2.2 Boot

The boot-time configuration registers are IVA_SYSC.SYSC_BOOTADDR and IVA_SYSC.SYSC_BOOTMOD. These read-only registers are accessible only by the DSP CPU, and their values are determined when the IVA2.2 is released from reset, using the CONTROL.CONTROL_IVA2_BOOTADDR and CONTROL.CONTROL_IVA2_BOOTMOD registers of the system control module. For more information, see the *System Control Module* chapter. A change to those registers is not seen (not sampled) by the IVA2.2 until the next reset.

The IVA2.2 boots two ways:

- Boot under MPU control, described in [Section 14.4.1.2.1, Boot Under MPU Control](#).
- Autonomous boot, described in [Section 14.4.1.2.2, Autonomous Boot](#).

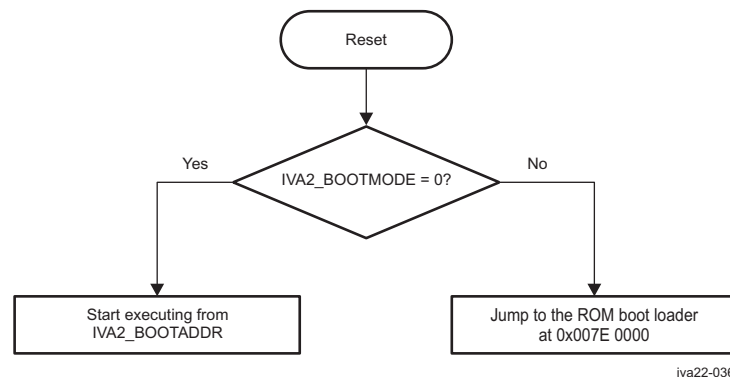

A boot under MPU control is typically used after the device cold reset as a first-time configuration of the IVA2.2 subsystem. Subsequent boots of the IVA2.2, resulting from a wake-up transition from OFF state, for example, use the autonomous boot.

For more information about booting the IVA2.2, see the *IVA2.2 Boot Loader Specification*.

14.4.1.1 IVA2.2 Boot Configuration

[Figure 14-24](#) shows the boot sequence followed by IVA2 on release from reset.

Figure 14-24. IVA2 Boot Mode Configuration

When the IVA2.2 subsystem is released from reset and CONTROL.CONTROL_IVA2_BOOTMOD[3:0] BootMode equals 0x0, the first fetch address of the C64x equals the address defined in the CONTROL.CONTROL_IVA2_BOOTADDR[31:10] BOOTLOADADDR bit field. This address can be aligned on any 1-K byte boundary, in ROM, in IVA2.2 local RAM, in on-chip memory (OCM-RAM), or directly in external memory (for example, SDRAM through the SDRC).

When the IVA2.2 subsystem is released from reset and CONTROL.CONTROL_IVA2_BOOTMOD[3:0] BootMode is different from 0x0, the first fetch address of the C64x is fixed to 0x007E0000 (in IVA2.2 local ROM). ROM code (boot-loader) can jump to the address defined in IVA_SYSC.SYSC_BOOTADDR[31:12] BOOTLOADADDR, which is a read-only copy (at reset time) of the CONTROL.CONTROL_IVA2_BOOTADDR[31:12] BOOTLOADADDR bit field. This address can be aligned on any 4-K byte boundary, in ROM, in local RAM, in on-chip memory, or directly in external memory (for example, SDRAM).

Bits 10 and 11 of the CONTROL_IVA2_BOOTADDR BOOTLOADADDR system control module register are ignored in this address alignment.

[Table 14-7](#) lists the boot modes for the boot loader.

Table 14-7. Boot Loader Configuration

Value of SYSC_IVA2_BOOTMOD	Description
0x01	IDLE boot: Boot loader executes the IDLE instruction.
0x02	Wait In self-loop boot: Boot loader puts IVA2 in a self-loop.
0x03	Wait In self-loop boot: Boot loader puts IVA2 in a self-loop.
0x04	Boot loader executes the default context restore code, which is part of the ROM boot loader.

For information about the IVA2.2 boot, see the *IVA2.2 Boot Loader Specification*.

14.4.1.2 Example of IVA2.2 Boot

14.4.1.2.1 Boot Under MPU Control

Before waking up the IVA2.2 subsystem, the MPU performs the following sequence (also shown in [Figure 14-25](#)):

1. The MPU prepares a translation table hierarchy (TTH) in SDRAM at address <TTH Physical Address>. This TTH must contain at least an address translation for the IVA2.2 MMU physical address range.

Note: The DSP CPU does not require an address translation for the TTH, as the TTH is under MPU control only. The IVA2.2 DSP CPU is responsible only for saving and restoring an IVA2.2 MMU context that has been programmed by the MPU.

2. The MPU writes a bootstrap sequence in SDRAM at address <BootLoader Physical Address>. This sequence is executable by the DSP CPU and contains only relative address references, so that it is relocatable without code modification. This sequence must contain at least (in order):
 - a. Set the size of the bootstrap code.
 - b. Program the IVA2.2 MMU using physical addresses, as described in the following steps.

Note: The device has two instances of MMU: camera MMU or MMU1 (used for the camera subsystem) and IVA2.2 MMU or MMU2 (used for the IVA2.2 subsystem). These two instances are programmed by two identical sets of configuration registers. For more information, see the *Memory Management Units* chapter.

3. Programming of the MMU2 is functionally restricted to setting the MMU2.MMU_CNTL[1] MMUENABLE bit, and the TLB misses are served by the MPU-dedicated interrupt service routine (ISR). However, MMU table-walking logic is preferred because the IVA2.2 must be autonomous after the preliminary settings.

Moreover, it is critical that the duration of the MMU save-and-restore process use a minimum number of cycles, so that address translation for the MMU configuration registers uses a TLB locked entry. For those reasons, it is recommended that the bootstrap follow the MMU initialization sequence:

- a. Write <TTH physical address>[31:7] to the MMU2.MMU_TTB[31:17] TTBADDRESS bit field.
- b. Lock the address translation for the MMU configuration registers.
 - i. Write 0x0 to the MMU2.MMU_LOCK[8:4] CURRENTVICTIM bit field.
 - ii. Write <MMU virtual address>[31:12] to the MMU2.MMU_CAM[31:12] VATAG bit field.
 - iii. Write 1 to the MMU2.MMU_CAM[2] V bit.
 - iv. Write 0x2 to the MMU2.MMU_CAM[1:0] PAGESIZE bit field.
 - v. Write <MMU physical address>[31:12] to the MMU2.MMU_RAM[31:12] PHYSICALADDRESS bit field.
 - vi. Write 1 to the MMU2.MMU_LD_TLB[0] LDTLBITEM bit.
 - vii. Write 0x1 to the MMU2.MMU_LOCK[8:4] CURRENTVICTIM bit field.
 - viii. Write 0x1 to the MMU2.MMU_LOCK[14:10] BASEVALUE bit field.
- c. Write 1 to the MMU2.MMU_CNTL[2] TWLENABLE bit.
- d. Write 1 to the MMU2.MMU_CNTL[1] MMUENABLE bit.
- e. Read back the MMU2.MMU_CNTL register to ensure write completion.

Note: This read does not generate a TLB miss, because the address translation for MMU configuration registers is locked in the TLB.

4. The MPU can lock some other TLB entries, define some power-management MMU settings, and/or enable some interrupts.
5. The MPU correctly programs the associated L3 firewall, ensuring that the DSP CPU has read access to the memory area containing the IVA2.2 bootstrap sequence.
6. The MPU programs the associated L3 firewall, ensuring that the DSP CPU has read and write access to the configuration registers of the MMU2.
7. The MPU writes <bootloader physical address> to the CONTROL.CONTROL_IVA2_BOOTADDR[31:10] BOOTADDR bit field and configures the correct CONTROL.CONTROL_IVA2_BOOTMOD[3:0] BOOTMOD bit field nonzero value.

Note: For a detailed description of the system boot registers, see the *System Control Module* chapter.

8. The MPU configures the IVA2.2 clock rate and IVA2.2-related power-management settings in the PRCM.

After initialization completes, the MPU allows the IVA2.2 to boot:

- a. The MPU releases the IVA2.2 from the OFF state by programming the PRCM.
- b. The MPU sets the clocks back to the IVA2.2.
- c. The MPU releases the IVA2.2 from reset.

Note: Following Steps 1 through 8, the IVA2.2 boot sequence is identical to the autonomous boot sequence. For information about the IVA2.2 boot sequence, see [Section 14.4.1, IVA2.2 Boot](#).

Figure 14-25. IVA2 Boot Basic Programming Model

iva22-037

14.4.1.2.2 Autonomous Boot

On an OFF-to-ACTIVE transition (under MPU control or upon interrupt wakeup), the IVA2.2 subsystem is released from reset.

After hardware configuration of values for C64x + Megamodule generic parameters, the IVA2.2 starts fetching from the address 0x00000000 in ROM. The IVA2.2 must follow the (nonexhaustive) boot process:

1. Configure memory protection:
 - a. Specify cache RAMs versus IDMA and DMA accesses.
 - b. Define accessible L2 space (static shared L2 with the MPU/LCD).
2. Load the bootstrap code:
 - a. Read the IVA_SYSC.SYSC_BOOTADDR[31:12] BOOTLOADADDR bit field.
 - b. Read the number of bootstrap words <NbOfWords> to transfer in the first word at the address pointed to by BOOTLOADADDR.
 - c. Transfer as many words as defined in <NbOfWords>.
3. Execute the bootstrap code.

Note: This prepares the MMU for address translation of external accesses. In the case of a boot upon interrupt wakeup, the MMU is restored to its exact context before the IVA2.2 is shut off, if this context was saved correctly.

Only from this point can the IVA2.2 subsystem work with virtual addresses.

14.4.2 Cache Management

The IVA2.2 subsystem has a 2-level cache-based architecture. Level 1 data memory/cache (L1D) consists of an 80-KB memory space dedicated to data. L1D memory can be configured as mapped memory, cache, or a combination of the two. The level 1 program memory/cache (L1P) consists of a 32-KB memory space dedicated to program instructions. L1P memory can be configured as mapped memory, cache, or a combination of the two. Level 2 memory/cache (L2) consists of a 96-KB memory space shared by program and data space. L2 memory can be configured as mapped memory, cache, or a combination of the two.

Configuration of the allocation of the L1D, L1P, and L2 memories to mapped memory and/or cache is described in [Section 14.4.2.1, Cache-Size Configuration](#).

The virtual address space is split into contiguous chunks to configure which parts of the memory are cacheable and not cacheable. Configuration of cacheability is described in [Section 14.4.2.3, Cacheability Settings](#).

14.4.2.1 Cache-Size Configuration

Cache-size configuration is controlled by a set of registers: IVA_XMC.L1PCFG, IVA_XMC.L1DCFG, and IVA_XMC.L2CFG, that correspond to the L1P, L1D, and L2 memories, respectively.

The IVA_XMC.L1PCFG register allows the selection of the size of the L1P cache. The user selects the size of the L1P cache by writing the requested mode to the L1PCFG[2:0] L1PMODE bit field.

[Table 14-8](#) lists the valid settings of L1PMODE.

Table 14-8. Cache Size Specified by L1PMODE

L1PCFG[2:0] L1PMODE	Amount of L1P
Setting	Cache
000b	0 KB (default)
001b	4KB
010b	8KB
011b	16KB

Table 14-8. Cache Size Specified by L1PMODE (continued)

L1PCFG[2:0] L1PMODE	Amount of L1P
100b	32KB
101b	Not used
110b	Not used
111b	Maximum cache (maps to 32KB)

The IVA_XMC.L1DCFG register allows the selection of the size of the L1D cache. The user selects the size of the L1D cache by writing the requested mode to the L1DCFG[2:0] L1DMODE bit field.

Table 14-9 lists the valid settings of L1DMODE.

Table 14-9. Cache Size Specified by L1DMODE

L1DCFG[2:0] L1DMODE	Amount of L1D
Setting	Cache
000b	0KB (default)
001b	4KB
010b	8KB
011b	16KB
100b	32KB
101b	Not used
110b	Not used
111b	Maximum cache (maps to 32KB)

In the same way, the L2CFG[2:0] L2MODE bit field controls the size of the L2 cache. The user sets the amount of L2 memory mapped as L2 cache by writing the desired cache mode to this bit field.

Table 14-10 shows the valid settings for L2MODE.

Table 14-10. Cache Size Specified by L2MODE

L2CFG[2:0] L2MODE	Amount of L2
Setting	Cache
000b	0KB (default)
001b	32KB
010b	64KB

When programs initiate a cache mode change, the L1D cache must write back and invalidate its current contents without losing data. This ensures that all updated data held in cache is written back, and that no false hits occur because of a change in the interpretation of cache tags. It also ensures that the L1D snoop tag RAM in the UMC stays in sync with L1D.

While the write-back-invalidate is required to ensure correct cache behavior and to ensure that no cached data is lost, it is not sufficient to prevent data loss as a result of portions of L1D RAM becoming cache. To safely change L1D cache modes, applications must adhere to the procedure described in Table 14-11.

Table 14-11. Switching Cache Modes

To switch from	To	The program must perform the following steps:
A mode with no or some cache	A mode with more cache	1: EDMA, IDMA, or copy necessary data out of the affected range of RAM. 2: Write the desired cache mode to the bit field in the configuration cache register (L1DCFG, L1PCFG, and L2CFG). 3: Read back the register to stall the DSP CPU until the mode change completes.
A mode with some cache	A mode with less or no cache	1: Write the desired cache mode to the bit field in the cache configuration register concerned.

Table 14-11. Switching Cache Modes (continued)

To switch from	To	The program must perform the following steps:
		2. Read back the register to stall the DSP CPU until the mode change completes.

L1P RAM is typically used as cache RAM, with no local flat RAM (not the default; must be configured by the user).

L1D RAM is typically used as 32KB allocated to the cache RAM and 48KB has local memory-mapped RAM. By default, L2 memory is configured as 0KB allocated to the cache RAM and 96KB as local memory-mapped RAM (see [Table 14-12](#)).

Table 14-12. Default Cache Configuration

Memory Type	Memory Size	Default Cache Setting
L1P RAM	32KB	0KB cache
L1D RAM	80KB	0KB cache
L2 RAM	96KB	0KB cache

14.4.2.2 Cache Mode Configuration

The memory cache controllers of the C64x + Megamodule (L1D, L1P, and L2) offer two additional operating modes: freeze and/or bypass. These modes are set by the [L1DCC\[2:0\]](#) OPER bit field for L1D, the [L1PCC\[2:0\]](#) OPER bit field for L1P, and the [L2CFG\[4:3\]](#) L2CC bit field for L2.

The freeze and bypass modes affect the operation of only the cache section (no impact on the memory-mapped section of the memory) of each memory controller.

This feature allows real-time applications to limit the amount of data evicted from cache controllers, such as interrupt handlers, during various sections of code.

[Table 14-13](#) summarizes the freeze and bypass modes for each cache controller (set through the OPER field in the [L1PCC](#) register for the L1P cache controller, the OPER field in the [L1DCC](#) register, and the L2CC field of the [L2CFG](#) register for the L2 cache controller).

Table 14-13. Cache Mode Configuration

Cache Controller	Operation Mode		
	Normal	Freeze	Bypass
L1P	Cache operates normally. Read hits return data from the cache. Write hits update the cached data for the cache line.	<p>The L1P cache does not allocate new cache lines on read misses, nor does it cause existing cache contents to be marked invalid. Write misses are dropped.</p> <p>The L1P cache responds normally to program-initiated cache controls (invalidate, mode change).</p>	N/A
L1D	Cache operates normally.	<p>The L1D cache does not allocate new cache lines on read misses, nor does it evict existing cache contents.</p> <p>The L1D cache responds normally to program-initiated cache commands (invalidate, write-back-invalidate mode change).</p>	N/A

Table 14-13. Cache Mode Configuration (continued)

Cache Controller	Operation Mode		
	Normal	Freeze	Bypass
L2	Cache operates normally.	Cache frozen. Hits proceed normally. L2 sends read and write misses directly to external memory, as if the L2 cache is not present. The L2 does not allocate a new cache line while frozen. Lines can be evicted from L2 only during freeze mode by program-initiated cache coherence operations.	Cache disabled, although internal cache state is retained. When in bypass mode, the L2 cache responds to neither reads nor writes. All requests for external addresses are sent externally. L2 does not update its contents in this mode. As with freeze mode, L2 evicts lines from L2 only during bypass mode as a result of program-initiated cache coherence operations.

14.4.2.3 Cacheability Settings

The address space of the IVA2.2 subsystem is split into contiguous regions of 16M bytes each. Each region has a cacheable attribute that defines whether a reference to a location belonging to the associated memory region must be sent directly to the memory (with exact size and occurrence as requested by the CPU) or must induce a cache line refill and potentially an eviction of another cache line.

The UMC contains registers that control whether certain ranges of memory are cacheable, and whether one or more requestors is allowed access to these ranges.

14.4.2.4 Coherence Maintenance

14.4.2.4.1 Memory-Mapped L1P and L1D Coherence

L1D and L1P are never cached, so there is no coherence maintenance for those memories.

14.4.2.4.2 Memory-Mapped L2 Coherence

Coherence is maintained by hardware between L1D cache content and the L2 memory-mapped memory region.

An L2 reference from the DSP CPU updating an L1D cache location is automatically made visible to the DMA and any master processor on the device with access to the C64x + Megamodule memory-mapped L2 through the IVA2.2 slave port.

An L2 reference from the DMA and any other master processor on the device with access to the C64x + Megamodule memory-mapped L2 through the IVA2.2 subsystem slave port is automatically made visible to the DSP CPU through the L1D cache, if it is holding the associated cache line.

Note: To reduce the complexity of the L1P cache controller to the L2 controller interface, the L1P cache coherency protocol is removed. This means that coherency between L2 cache and L1P cache is not maintained. On the C64x+ CPU, writes to L2 do not invalidate the corresponding region in L1P. This must be done manually.

14.4.2.4.3 Device Memory Coherence

Coherence is not maintained by hardware between the L2 cache (and L1D cache/L1P cache) and device memories (on-chip memories external to the IVA2.2 subsystem and off-chip memories connected to the SDRAM controller and/or general-purpose memory controller [GPMC]). Coherence in this case must be handled by software. The C64x + Megamodule offers two sets of registers for user-initiated coherence maintenance between DSP local memories and device memories.

Software coherence maintenance must be synchronized in the system (for example, through message passing; for information, see the *Interprocessor Communication* chapter). In the producer/consumer

model, the producer sends a completion message to the consumer only after the write is complete in end memory. If the producer has a cache-based architecture, the producer must initiate a write-back and track for the completion of the write-back sequence in end memory. For a description of how the write-back sequence occurs in the IVA2.2 subsystem, see [Section 14.4.2.4.6, Write-Back Completion](#). When the consumer receives the message, if the consumer has a cache-based architecture, updates by the producer must be effectively seen (not a local nonupdated copy). For a description of how the invalidate sequence occurs in the IVA2.2 subsystem, see [Section 14.4.2.4.4, Global Cache Management](#).

Two types of cache coherence management are possible:

- Global cache coherence allows the DSP CPU to ensure coherence of the entire cache at once. See [Section 14.4.2.4.4, Global Cache Management](#).
- Block cache coherence allows the DSP CPU to ensure coherence of a contiguous region of the virtual address map, restricted in size to only what is needed. See [Section 14.4.2.4.5, Block Cache Management](#).

Each management type provides three sets of actions:

- Invalidate ensures that all required lines are made invalid in the cache. After that operation, any update (before invalidate operation) in end memory by an alternate processor/DMA is seen by the DSP CPU, forcing a cache line refill.
- Write-back ensures that all required cache lines modified by the DSP CPU (also called dirty lines) are written back to end memory, so that any local update by the DSP CPU is made visible by an alternate processor/DMA. This applies only to L1D cache and L2 cache, not to L1P cache.
- Write-back and invalidate ensure that all required cache lines modified by the DSP CPU (also called dirty lines) are written back to end memory so that any local update by the DSP CPU is made visible by an alternate processor/DMA, and they ensure that all required lines are made invalid in the cache. After that operation, any update in end memory by an alternate processor/DMA is seen by the DSP CPU, forcing a cache line refill. This applies only to L1D cache and L2 cache, not to L1P cache.

14.4.2.4.4 Global Cache Management

This section describes how to invalidate and write back the cache memory

- Global invalidate
Global invalidate is controlled by the following registers: IVA_XMC.L2INV, IVA_XMC.L1DINV, and IVA_XMC.L1PINV.

Example of global invalidate:

```
/* -----
   */
/* Invalidate anything held in cache. */
/* -----
   */

L2INV = 1;
/* -----
   */
/* Now, spin waiting for operation to complete. */
/* -----
   */

while ((L2INV & 1) != 0)
;
```

[L2INV](#) = 0 ensures that L1D cache and L1P cache are also globally invalidated before the L2 cache invalidate process.

- Global write-back
Global write-back is controlled by the following registers: IVA_XMC.L2WB and IVA_XMC.L1DWB.

Example of global write-back:

```
/* -----
   */
/* Write back anything held in cache. */
/* -----
```

```

        */
L2WB = 1;
/* -----
        */
/* Now, spin waiting for operation to complete. */
/* -----
        */
while ((L2WB & 1) != 0)
;

```

To ensure write-back completion of a specific buffer (contiguous address range), see [Section 14.4.2.4.6, Write-Back Completion](#), for additional programming steps and an example.

- Global write-back and block invalidate

Global write-back and block invalidate is controlled by the following registers: IVA_XMC.L2WBINV and IVA_XMC.L1DWBINV.

Example of global write-back and block invalidate:

```

/* -----
        */
/* Write back and invalidate anything held in cache.
        */
/* -----
        */
L2WBINV = 1;
/* -----
        */
/* Now, spin waiting for operation to complete. */
/* -----
        */
while ((L2WBINV & 1) != 0)
;

```

To ensure write-back completion of a specific buffer (contiguous address range), see [Section 14.4.2.4.6, Write-Back Completion](#), for additional programming steps and an example.

14.4.2.4.5 Block Cache Management

- Block invalidate

Block invalidate is controlled by the following registers: IVA_XMC.L2BAR, IVA_XMC.L2IWC, IVA_XMC.L1DIBAR, IVA_XMC.L1DIWC, IVA_XMC.L1PIBAR, and IVA_XMC.L1PIWC.

Example of block invalidate:

```

/* -----
        */
/* Write base address of array to Base Address Register.
        /
/* Then write length of the array, in words, to the
        Word*/
/* Count register. */
/* -----
        */
L2IBAR = &array[0];
L2IWC = = sizeof(array) / sizeof(int);
/* . . . */
/* -----
        */
/* The CPU can execute other code here. Block cache
        operations proceed in parallel with CPU execution, stalling the
        CPU minimally. */
/* -----
        */
/* . . . */

```

```
/* -----
    */
/* Now, spin waiting for operation to complete. */
/* -----
    */
```

```
while (L2IWC != 0)
;
```

L2IWC = 0 ensures that L1D cache and L1P cache are also block invalidated before the L2 cache invalidate process.

- **Block write-back**

Block write-back is controlled by the following registers: IVA_XMC.L2WBAR, IVA_XMC.L2WWC, IVA_XMC.L1DWBAR, and IVA_XMC.L1DWWC.

Example of block write-back:

```
/* -----
    */
/* Write base address of array to Base Address
   Register.*/
/* Then write length of array, in words, to the Word
   */
/* Count register. */
/* -----
    */
L2WBAR = &array[0];
L2WWC = sizeof(array) / sizeof(int);
/* . . . */
/* -----
    */
/* CPU can execute other code here. Block cache operations
   proceed in parallel with CPU execution, stalling CPU minimally.
   */
/* -----
    */
/* . . . */
/* -----
    */
/* Now, spin waiting for operation to complete. */
/* -----
    */
while (L2WWC != 0)
;
```

To ensure write-back completion of a specific buffer (contiguous address range), see [Section 14.4.2.4.6, Write-Back Completion](#), for additional programming steps and an example.

- **Block write-back and invalidate**

Block write-back and invalidate is controlled by the following registers: IVA_XMC.L2WIBAR, IVA_XMC.L2WIWC, IVA_XMC.L1DWIBAR, and IVA_XMC.L1DWIWC.

Example of block write-back and invalidate:

```
/* -----
    */
/* Write base address of array to Base Address
   Register.*/
/* Then write length of array, in words, to the Word
   */
/* Count register. */
/* -----
    */
L2WIBAR = &array[0];
L2WIWC = (array) / sizeof(int);
```

```

/* . . . */
/* -----
    */

/*The CPU can execute other code here. Block cache
   operations proceed in parallel with CPU execution, stalling the
   CPU minimally. */

/* -----
    */

/* . . . */
/* -----
    */

/* Now, spin waiting for operation to complete. */
/* -----
    */

while (L2WIWC != 0)
;

```

To ensure write-back completion of a specific buffer (contiguous address range), see [Section 14.4.2.4.6](#) for additional programming steps and an example.

14.4.2.4.6 Write-Back Completion

The [SYSC_LICFG0](#)[15] GEMTRUECOMPEN bit must be set to 1 before any DSP CPU C64x+ write for which completion must be ensured. This applies to writes to noncacheable regions and to cache-line write-back completions. By default, [SYSC_LICFG0](#)[15] GEMTRUECOMPEN = 0. This default is recommended, to statically set that bit (unless the user wants to locally send a large number of writes to a noncacheable memory region):

- [SYSC_LICFG0](#).GEMTRUECOMPEN = 1;

Polling on the L*WWC (resp. L*WIWC) ensures that the block write-back operation (and associated invalidate, when applicable) was completely issued by the associated cache controller, but does not ensure that the write-back is effective in end memory.

To get completion of the write-back of a specific buffer after block or global cache write-back, the user must read back from a noncacheable region of the same L3 or L4 target as the buffer (if data is written in external DDR memory, the read access can be on an SDRC register). The C64x+ is uninstalled only after the read following the write-back is complete.

In the producer/consumer model, the cache-based producer typically ensures that the produced buffer is visible to the consumer of that buffer by writing back the address range of that buffer and checking for completion of the write-back sequence before sending a completion message to the consumer.

Example:

```

/* -----
    */

/* nonCachedArea to be linked to noncached SDRAM
   region*/
/* -----
    */

#pragma DATA_SECTION(nonCachedDummyVar, ".nonCachedArea")
volatile int nonCachedDummyVar;
/* -----
    */

/* outBuffer is produced buffer in SDRAM to be visible to
   the consumer */
/* -----
    */

L2WBAR = &outBuffer[0];
L2WWC = sizeof(outBuffer) / sizeof(int);
/* -----
    */

/* L2WWC ensures the sequence is completed by the cache
   controller but not completed in end memory */

```

```

/* -----
    */
while (L2WWC != 0)
;
/* -----
    */
/*C64x+ is stalled until dummy memory read has completed
  which the hardware ensures happens after write-back of outBuffer
  completed in SDRAM. */
/* -----
    */
int dummyRead = nonCachedDummyVar;
/* -----
    */
/* Then C64x SW (producer) can send message to consumer
    */
/* -----
    */

```

- sendCompletionMsgToConsumer();

Note: To ensure completion, the nonCachedDummyVar must be in the same target as the written-back buffer.

In the case of the C64x writing in the noncache area: To ensure the completion of the C64x write in physical end memory, set the [SYSC_LICFG0](#) [15] GEMTRUECOMPEN bit to 1 and also read back after the last C64x write.

1. DSP write and DMA read

The user writes to some noncache region with DSP and then reads from the same area with DMA. To ensure completion of the DSP write in physical end memory, set the SYSC.LICFG0[15] GEMTRUECOMPEN bit to 1 and also read back after the last DSP write. The sequence is:

- Set the [SYSC_LICFG0](#)[15] GEMTRUECOMPEN bit to 1.
- DSP writes data in external memory, noncache area.
- DSP reads data in external memory, noncache area: last write data for instance.
- DMA reads data from external memory.

2. DMA write and DSP read

The opposite of 1. To ensure the completion of DMA write in physical end memory, set the [SYSC_LICFG0](#) DMATRUECOMPEN bit to 1 and PARAM [LCHi].OPT.TCCMODE to 0 (no early completion). The sequence is:

- Set the [SYSC_LICFG0](#).DMATRUECOMPEN bit to 1.
- Set PARAM[LCHi].OPT.TCCMODE to 0.
- Set PARAM[LCHi].OPT.TCCMODE to 0.
- DSP waits for end of DMA transferred:
 - IPR/IPRH bit update (for polling-scheme)
 - Interrupt generation (for interrupt-scheme)
 - CER/CERH bit update (for chaining)
 - DSP reads data from external memory.

14.4.2.4.7 Performance Consideration Timing

Long burst is key to improving the efficiency of the SDRAM and reducing cache-line refill and cache-line write-back latencies. The IVA2.2 subsystem allows for improving the burst generation over the device interconnect. This is configurable with the [SYSC_LICFG0](#)[16].GEMBURSTOPTEN bit. By default, [SYSC_LICFG0](#)[16] GEMBURSTOPTEN = 0, and the burst optimization is disabled. This default is recommended to statically set the bit:

[SYSC_LICFG0](#).GEMBURSTOPTEN = 1

14.4.3 DMA Management

14.4.3.1 Transfers From/to Device Memories/Peripherals (EDMA)

The EDMA optimizes transfers from/to the C64x + Megamodule (memory-mapped) memories to/from device on-chip and off-chip memories.

The EDMA can perform transfers from IVA2.2 internal memories to IVA2.2 internal memories, but it is not designed for that purpose. The IDMA is recommended in that case (unless a 2-dimensional transfer is required).

The EDMA can perform transfers from device memories/peripherals to device memories/peripherals, but it is not designed for that purpose. The sDMA is recommended in that case. For more information, see the *DMA* chapter.

14.4.3.2 Internal Memory-to-Memory Transfer (IDMA)

The user can quickly page memory regions or fill a memory region of the C64x + Megamodule memories by using channel 1 of the IDMA module (internal to the C64x + Megamodule).

The IDMA.IDMA1_COUNT[16] FILL bit defines whether this is a transfer from memory to memory or if this is a solid-color fill.

An IDMA1 transfer where IDMA.IDMA1_COUNT[16] FILL = 0 copies IDMA.IDMA1_COUNT[15:2] COUNT bytes from the address defined in the IDMA.IDMA1_SOURCE register to the address defined in the IDMA.IDMA1_DEST register. The addresses must be aligned on word (4-byte) boundaries. The byte count must be a multiple of 4 bytes.

The IDMA.IDMA1_COUNT[28] INT register bit enables the IDMA_INT1 interrupt (Evt 14; for information about generation on completion of the IDMA1 transfer, see [Table 14-3](#)). By default, no interrupt is generated.

When conflicts occur, the IDMA.IDMA1_COUNT[31:29] PRI bit field defines the priority of the IDMA transfer with respect to DSP and DMA/HOST accesses.

The memory paging programming example follows:

- IDMA1_SOURCE = &mySrcTable[0]; // mySrcTable aligned on word boundary
- IDMA1_DEST = &myDstTable[0]; // myDstTable aligned on word boundary
- IDMA1_COUNT = (IDMA1_COUNT & ~(0xFFFC)) | size of (mySrcTable);
- IDMA1_COUNT = (IDMA1_COUNT & ~(116)) | 016; // copy mode
- IDMA1_COUNT = (IDMA1_COUNT & ~(128)) | 028; // no interrupt
- IDMA1_COUNT = (IDMA1_COUNT & ~(0x729)) | 0x729; // low priority

An IDMA1 transfer where IDMA.IDMA1_COUNT[16] FILL = 1 replicates the IDMA.IDMA1_SOURCE word as many times as defined in IDMA. An IDMA1_COUNT.COUNT (count divided by 4) to the address defined in the IDMA.IDMA1_DEST destination address must be aligned on word (4-byte) boundaries. The byte count must be a multiple of 4 bytes.

The solid-color copy (SSC) programming example follows:

- IDMA1_SOURCE = my32bPattern; // 32b pattern to be replicated
- IDMA1_DEST = &myDstTable[0]; // myDstTable aligned on word boundary
- IDMA1_COUNT = (IDMA1_COUNT & ~(0xFFFC)) | size of (mySrcTable);
- IDMA1_COUNT = (IDMA1_COUNT & ~(116)) | 116; // SCC mode
- IDMA1_COUNT = (IDMA1_COUNT & ~(128)) | 028; // no interrupt
- IDMA1_COUNT = (IDMA1_COUNT & ~(0x729)) | 0x729; // low priority

Note: Because the IVA2.2 subsystem is typically configured (recommended for video applications) so that L1D has memory-mapped SRAM, IDMA1 is normally used only for L1D>L1D fast copy.

14.4.3.3 Programming an EDMA Transfer

Programming a complete EDMA transfer requires the following steps:

1. Define the logical channel(s).
2. Prioritize the defined transfer (with respect to other defined transfers).
3. Start the transfer.
4. Review the progression and completion of the transfer.

14.4.3.4 Defining a Logical Channel

14.4.3.4.1 Single Logical Channel Definition

A complete EDMA transfer can be defined by one or several chained and/or linked logical channels.

Up to 128 independent contexts, each fully defining a logical channel, can be defined. These 128 contexts correspond to the 128 PaRAM entries available in the IVA2.2 subsystem. For more information about these PaRAM entries, see [Section 14.3.2.1.1.3, DMA/QDMA Channel Mapping and PaRAM Entry](#), and the corresponding [Figure 14-13](#).

Logical channel definition relies on the following:

- Base addresses:
 - PARAM[LCH#].SRCi: 32-bit source address
 - PARAM[LCH#].DSTi: 32-bit destination address
- Transfer sizes:

Transfer size is common to source and destination. A transfer can be constituted on a 3-dimensional array; C is an array of CCNT arrays, each composed of BCNT arrays, each composed of ACNT bytes:

 - PARAM[LCH#].ACNT: Number of bytes in the A array (from 0 to 65,535)
 - PARAM[LCH#].BCNT: Number of A arrays in the B array (from 0 to 65,535)
 - PARAM[LCH#].CCNT: Number of B arrays in the C array (from 0 to 65,535)

Note: Setting one of the ACNT, BCNT, or CCNT arrays to 0x0 prevents a transfer from being submitted to one of the physical channels (assuming that the compatibility mode is not set; see Kelvin DMA compatibility mode).

- PARAM[LCH#].BCNTRLD: BCNT reload value when BCNT reaches 0 (from 0 to 65,535)
-

Note: When programming CCNT>1, programming PARAM[LCH#].BCNTRLD to be equal to PARAM[LCH#].BCNT is recommended.

- Indexes between dimensions:
 - PARAM[LCH#].SRCBIDX: Index between A arrays at source (from -32,768 to 32,767)
 - PARAM[LCH#].SRCIDIX: Index between B arrays at source (from -32,768 to 32,767)
 - PARAM[LCH#].DSTBIDX: Index between A arrays at destination (from -32,768 to 32,767)
 - PARAM[LCH#].DSTCIDIX: Index between B arrays at destination (from -32,768 to 32,767)
-

Note: Programming the logical channel does not automatically start it. See [Section 14.4.3.6.1, Assigning a Logical Channel to a Trigger Event](#).

- Addressing modes:
 - PARAM[LCH#].OPT[0] SAM: source addressing mode (0: post-incremented; 1: constant)
 - PARAM[LCH#].OPT[1] DAM: destination addressing mode (0: post-incremented; 1: constant)

Note: Constant addressing mode is supported only from/to IVA2.2 C64x + Megamodule memories, not from/to device memories and peripherals. This can be replaced by using a post-increment addressing mode and an index equal to 0.

Example:

```

/* -----
   */
/*fills dstArray with cstValue values (w/o constant AM)
   */
/* -----
   */

PARAM[LCH#].SRC = &cstValue;
PARAM[LCH#].DST = &dstArray[0];
PARAM[LCH#].ACNT = sizeof(int);
PARAM[LCH#].BCNT = sizeof(dstArray) / sizeof(int);
PARAM[LCH#].CCNT = 1;
PARAM[LCH#].SRCBIDX = 0;
PARAM[LCH#].DSTBIDX = sizeof(int);
PARAM[LCH#].OPT.SAM = 0;
PARAM[LCH#].OPT.DAM = 0;

```

14.4.3.4.2 Controlling Submission Granularity

The logical channel (when triggered) can split a transfer into several requests submitted to one of the physical channels. The physical channel supports submitted requests of up to two dimensions, meaning that a 3-dimensional transfer is always split into (at least) 2-dimensional transfers. The user can also program the logical channel so that submitted requests are 1-dimensional transfers; for example:

- PARAM[LCH#].SYNCDIM = 0; // submitted transfers are maximum 1D.
- PARAM[LCH#].SYNCDIM = 1; // submitted transfers are maximum 2D.

14.4.3.4.3 Linking to Another Logical Channel

A logical channel can be programmed so that on its completion another context is copied from another logical channel. This is useful because the logical channel is used as a working set during the DMA transfer, meaning that initial context configuration is lost after the associated transfer completes.

- PARAM[LCH#].LINK = linkLCH# << 5

The LINK value is the base address of the linked logical channel context.

When the LINK value is set to 0xFFFF, no context is loaded for that logical channel:

- PARAM[LCH#].LINK = -1

Note: Only the context is copied, and the logical channel is not automatically restarted on link. Restarting a logical channel that just received its new context occurs only after a trigger event associated with that logical channel is detected. See [Section 14.4.3.6.1, Assigning a Logical Channel to a Trigger Event](#).

14.4.3.4.4 Chaining Logical Channel

A logical channel can be programmed so that on its total or partial completion, another logical channel is started. This is useful for defining a series of transfers with different contexts as a complete DMA transfer. The main advantage is that the overhead to program all the chained transfers is shared among all channels.

- Partial completion chaining
After the submitted section (see [Section 14.4.3.4.2, Controlling Submission Granularity](#)) of a logical channel is complete, a programmable completion code is returned. If partial completion chaining is enabled in the context of the logical channel, this completion code defines which trigger event is set. The logical channel associated with that trigger event is automatically submitted. See [Section 14.4.3.6.1, Assigning a Logical Channel to a Trigger Event](#).
To chain a logical channel LCHi to LCHj, so that LCHj is automatically started after each LCHi submission to a physical channel has completed:
 - PARAM[LCHi].OPT.TCC = trigEvtx; // trigEvtx: trigger event number
 - PARAM[LCHi].OPT.ITCCHEN = 1
 - DCHMAP[trigEvtx] = LCHj
- Total completion chaining
After all submitted parts of a logical channel are complete, programmable completion code is returned. If total completion chaining is enabled in the context of the logical channel, this completion code defines which trigger event is set. The logical channel associated with that trigger event is automatically submitted. See [Section 14.4.3.6.1, Assigning a Logical Channel to a Trigger Event](#).
For example, to chain a logical channel LCHi to LCHj so that LCHj is automatically started after LCHi has completed:
 - PARAM[LCHi].OPT.TCC = trigEvtx; // trigEvtx: trigger event number
 - PARAM[LCHi].OPT.TCCHEN = 1
 - DCHMAP[trigEvtx] = LCHj

14.4.3.5 Prioritizing Defined Transfers

14.4.3.5.1 Mapping Between DMA/QDMA Events and Event Queues

The assignment of 64 DMA and 8 QDMA channels to two event queues of the channel controller is achieved by configuring the DMA queue number registers (TPCC_DMAQNUM0 and TPCC_DMAQNUM1) and the QDMA queue number register (IVA_TPCC.QDMAQNUM). When an event is selected for submission, it is queued in the user-defined event queue. This typically defines a 2-level priority preemption scheme, as queues are usually mapped to different transfer controllers.

14.4.3.5.2 Mapping a Queue to a Transfer Controller

Events at the head of an event queue define which logical channel (Param Entry) is selected for submission to the associated physical channel (transfer controller). The association between an event queue and a physical channel can be defined in the TPCC_QUETCMAP register. By default, TPTC0 is associated with event queue 0, and TPTC1 is associated with event queue 1. This mapping is a static decision; it does not change during DMA operation.

Note: TPTC0 and TPTC1 are not symmetrical; their numbers are just inverted, compared to the Davinci device. To improve compatibility with Davinci devices, invert the mapping of the event queue to the transfer controller, as shown below:

QUETCMAP = (QUETCMAP & ~0xFF) | 0x10;

Typically, this is used to allow submission-time preemption, so that by example:

- Event queue 0 is used for background, potentially long, not very latency-sensitive, not very critical DMA transfers.
 - Event queue 1 is used for short, latency-sensitive, or critical (for example, hardware synchronized) DMA transfers.
-

14.4.3.5.3 Handling Priority

In IVA2.2 local interconnect arbitration, priority of individual bus requests for a DMA transfer over other DMA- or CPU-initiated bus requests is defined by the event queue to which the event associated with the transfer is submitted. This can be configured per event queue in the [TPCC_QUEPRI](#)[2:0] PRIQ0 and [TPCC_QUEPRI](#)[6:4] PRIQ1 bit fields. By default, event queues 0 and 1 have the same priority (highest possible priority is 0x0).

CPU bus-requests priority is defined in the IDMA.[MDMAARBE](#)[18:16] PRI bit field. By default, the CPU has the lowest possible priority (0x7).

Typically, this is used to allow transfer-time preemption, so that, for example, bus requests associated with event queue 1 are served ahead of event queue 1 or CPU requests.

Example:

- // DMA#0->0x7 (lowest), DMA#1->0x0 (highest), CPU->0x4 (mid)
- [QUEPRI](#) = ([QUEPRI](#) & ~0xFF) | 0x07;
- [MDMAARBE](#) = ([QUEPRI](#) & ~(0xF16)) | 0x4 16;

14.4.3.5.4 Aged Priority

To prevent having a DMA request stalled for a very long time, the IVA2.2 implements an aged priority scheme (also referred to as an inversion priority scheme) on the DMA ports to change the priority defined in the [TPCC_QUEPRI](#) register. This is done by regularly decreasing the priority level (increasing priority in arbitration) of a stalled request. The interval between two consecutive updates of the priority level is defined in the [SYSC_LICFG1](#) register. By default, the aged priority scheme is disabled ([SYSC_LICFG1](#)=0x0), and arbitration priority is dictated by programmed values in [QUEPRI](#) and [MDMAARBE](#).

14.4.3.5.5 Optimizing 2D Transfers

IVA2.2 EDMA can be configured so that DMA 2D transfers are optimized, allowing for large bursts to be generated to the SDRAM. This optimization has no effect on transfers issued as 1D transfers to the physical channels. This is recommended to enable that feature when the sources or destinations of the 2D transfers are the VRFB (SDRAM tiling structure).

To fully benefit from the optimization and disable MMU page-crossing checks:

- Large MMU page(s) are defined for the VRFB view(s) (typically 16MB super-section).
- The user software ensures that a 2D transfer does not span MMU large pages.

With the preceding conditions, use the following settings to use the IVA2.2 2D burst optimization:

- IVA_SYSC.[SYSC_LICFG0](#).DMA2DOPTEN = 1
- IVA_SYSC.[SYSC_LICFG0](#).PAGEXINGEN = 1

Note: The user software must ensure that a 2D transfer never spans MMU page boundaries. The reason for IVA_SYSC.[SYSC_LICFG0](#).PAGEXINGEN = 1 is to remove the hardware check mechanism of 2D bursts crossing MMU pages. A 2D burst that spans these boundaries can lead to undefined behavior. PAGEXINGEN = 0 prevents such situations through hardware.

14.4.3.6 Starting the Transfer

Before starting the transfer, a trigger event must be associated with the logical channel. Three modes trigger a DMA transfer:

- Manual trigger (software-synchronized transfers)
- Hardware trigger (hardware-synchronized transfers)
- Automatic trigger (automatic on-submission transfer start)

14.4.3.6.1 Assigning a Logical Channel to a Trigger Event

The 64 DMA channels and the 8 QDMA channels can be flexibly mapped to any of the 128 available PaRAM entries (see [Figure 14-13](#)).

Any of the 64 DMA channels can be mapped to any of the 128 PaRAM entries through DMA channel-mapping registers [TPCC_DCHMAP_i](#) (i = 0 to 63).

Any of the 8 QDMA channels can be mapped to any of the 128 PaRAM entries through QDMA channel-mapping registers [TPCC_QCHMAP_j](#) (i = 0 to 7).

14.4.3.6.2 Manual Trigger (Software-Synchronized Transfers)

When a logical channel is defined and prioritized, the user can assign the logical channel (or the first in the chained list) to a trigger event (from 0 to 63) by writing the number of the logical channel (PaRAMEntry #) to one of the DMA channel-mapping registers [TPCC_DCHMAP_i](#) (i = 0 to 63). Then, the user can manually start the transfer (one logical channel or a chained list of logical channels) by writing 1 to the bit in the [TPCC_ESR](#) or [TPCC_ESRH](#) register associated with the trigger event of the logical channel (or the first logical channel in the chained list).

Note: The event does not need to be enabled in the [TPCC_EER](#) register to be manually triggered.

Example:

```
/* -----
    */

/*To manually start defined logical channel #0x3, uses event
   #20 */

/* -----
    */

DCHMAP[20] = (DCHMAP[20] & ~(0x1FF<<5)) |
              0x3<<5;

ESR = 1 << 20;
```

14.4.3.6.3 Hardware Trigger (Hardware-Synchronized Transfers)

When a logical channel is defined and prioritized, the user can assign the logical channel (or the first in the chained list) to a trigger event (from 0 to 19) by writing the number of the logical channel (PaRAMEntry #) to one of the DMA channel-mapping registers [TPCC_DCHMAP_i](#) (i = 0 to 19). The user can allow this logical channel to be triggered by an associated hardware DMA request by writing 1 in the associated bit of the EER register. The mapping of a hardware DMA request to DMA events is fixed. The mapping of DMA requests to device peripheral sources is listed in [Table 14-2](#).

Example:

```
/* -----
    */

/* Associate defined logical channel #0x5 to
   UART3_DMA_TX*/

/* UART3_DMA_TX is DMA request #10 and associated to evt #10
    */

/* -----
    */

DCHMAP[10] = (DCHMAP[10] & ~(0x1FF<<5)) | 0x5<<5;
```

14.4.3.6.4 Automatic Trigger (QDMA)

The user can specify a trigger word from among any of the eight 32-bit words of the logical channel context (PaRAM entry) for QDMA. Writing to the trigger word triggers the channel controller of QDMA to issue a transfer request. The trigger word field of the QDMA channel mapping register [TPCC_QCHMAP_j](#) (where i = {0 to 3}) defines the trigger word for a particular QDMA channel, as shown in [Figure 14-13](#).

This flexibility enables the CPU to selectively modify only the PaRAM entry that requires modification, and thereby trigger the transfer. For example, after a transfer, if only count must change, QCHMAP can be configured so that count is the trigger word, and a write to it automatically triggers the transfer.

Example:

```
/* -----
   */
/* Associate defined logical channel #0x5 to QDMA #1
   */
/* -----
   */

QCHMAP[1] = (QCHMAP[1] & ~(0x1FF<<5)) | 0x5<<5;
/* -----
   */
/* Define DST parameter (0x3) to be trigger word of LCH
   */
/* -----
   */

QCHMAP[1] = (QCHMAP[1] & ~(0x7<<2)) | 0x3<<2;
```

In addition, the IDMA can be used to offload the CPU of the DMA configuration. See [Section 14.4.3.6.5, Offloaded Configuration \(Using IDMA\)](#).

14.4.3.6.5 Offloaded Configuration (Using IDMA)

The IVA2.2 allows quick programming of DMA transfers by offloading the CPU of most of the DMA transfer issue time. To do so, the user typically maintains a copy of the logical channel contexts (PaRAM entries) in L1D SRAM. A CPU update of a logical channel context is very fast in L1D SRAM. After completing a logical channel context update, the CPU can page the context from L1D to DMA PaRAM entries using another simple DMA, internal-to-C64x + Megamodule (IDMA). For example:

```
disable_interrupts();
while(IDMA0_STATUS & 0x3);// previous IDMA completion/*
-----
   */
/* Update of logical channels definition table in L1D
   */
/* -----
   */

LCTable->OPT = opt;
LCTable->SRC = src;
LCTable->ACNT = num_bytes;
LCTable->BCNT = num_arrays;
LCTable->DST = dst;
LCTable->DSTBIDX = dbidx;
LCTable->SRCBIDX = sbidx;
LCTable->LINK = 0xFFFF;
LCTable->BCNTRLD = bcntrld;
LCTable->DSTCIDX = dcidx;
LCTable->SRCCIDX = scidx;
LCTable->CCNT = num_frames;
/* -----
   */
```

```

/* initiate IDMA transfer */
/* -----
   */

IDMA0_SOURCE = &LCTable[0];
IDMA0_DEST = &PaRAM[0];
IDMA0_MASK = 0xFFFFF00;
IDMA0_COUNT = 0x0;
enable_interrupts();

```

14.4.3.6.6 Direct Configuration to Transfer Channel (Not Recommended)

The registers of the physical channels are memory-mapped, primarily to enable, clear, and read status for error interrupts generated by the physical channel. For more information, see [Section 14.4.7, Error Identification Process](#).

It is possible to write directly to other control registers of the physical channels and issue a transfer; however, this is not recommended and therefore is not described here.

Note: This can work safely only if the DMA controller is not used.

14.4.3.6.7 DMA Completion Mode

The IVA2.2 EDMA defines when a DMA transfer is complete:

- Early completion: All associated transfers were submitted to the physical channel. Early completion does not ensure that transfer is complete in end memory.
 - PARAM[LCHi].OPT.TCCMODE = 1
- True completion: All associated transfers were submitted to the physical channel, and all those transfers are complete, from the physical channel standpoint. True completion ensures that transfer is complete in end memory.
 - SYSC.SYSC_LICFG0.DMATRUECOMPEN = 1; // is statically set.
 - PARAM[LCHi].OPT.TCCMODE = 0

Note: TCCMODE = 0 does not ensure that transfer is complete in end memory if DMATRUECOMPEN = 0.

By default, DMATRUECOMPEN = 0. This is recommended to statically set DMATRUECOMPEN.

True completion is typically used when the IVA2.2 DMA is the producer of a buffer shared with another master processor or a DMA (consumer). A completion message is sent to the consumer only after the DMA transfer is complete.

Completion mode affects timing for the following actions:

- IPR/IPRH bit update (for polling scheme)
- Interrupt generation (for interrupt scheme)
- CER/CERH bit update (for chaining)

14.4.3.6.8 Partial Versus Total Completion

DMA can be programmed so that IPR bit update and interrupt generation occur:

- After each submission to the physical channel is complete
- After the last submission to the physical channel is complete

Partial completion interrupt

After the submitted section (see [Section 14.4.3.4.2, Controlling Submission Granularity](#)) of a logical channel is complete, a programmable completion code is returned. If a partial completion interrupt is enabled in the context of the logical channel, this completion code defines which IPR bit is set.

For example, to allow IPR to be updated (and possibly an interrupt to be generated) after each LCHi submission to a physical channel is complete:

- PARAM[LCHi].OPT.TCC = intEvtx; // intEvtx: IPR bit to be updated
- PARAM[LCHi].OPT.ITCINTEN = 1

Total completion interrupt

After all submitted parts of a logical channel are complete, a programmable completion code is returned. If a total completion interrupt is enabled in the context of the logical channel, this completion code defines which IPR bit is to be set.

For example, to allow IPR to be updated (and possibly an interrupt to be generated) after all LCHi submissions to a physical channel are complete:

- PARAM[LCHi].OPT.TCC = intEvtx; // intEvtx: IPR bit to be updated
- PARAM[LCHi].OPT.TCINTEN = 1
 - By polling
 - By interrupt

14.4.3.6.9 Tracking DMA Completion

There are two ways to track DMA completion:

- Polling the completion register when the estimated completion time has elapsed
- Enabling completion interrupts

Polling example (total completion)

- PARAM[myLCH].OPT.TCINTEN = 1; // total interrupt completion bit update
- PARAM[myLCH].OPT.ITCINTEN = 0; // no partial interrupt completion bit update
- PARAM[myLCH].OPT.TCC = myTCC
- // myTCC does not contribute to interrupt generation (polling mode)
- IER = (IER & ~(1<<myTCC)) | 0<<myTCC
- // start transfer
- DCHMAP[myEvt] = (DCHMAP[myEvt] & ~(0x1FF<<5)) | myLCH<<5
- ESR = 1 << myEvt
- // do something useful (that does not depend on DMA completion)
- // poll IPR bit
- while(!(IPR & (1<<myTCC))); // polls for completion

Interrupt example (total completion)

- disable_interrupts()
- PARAM[myLCH].OPT.TCINTEN = 1; // total interrupt completion bit update
- PARAM[myLCH].OPT.ITCINTEN = 0; // no partial interrupt completion bit update
- PARAM[myLCH].OPT.TCC = myTCC
- // myTCC does contribute to interrupt generation (polling mode)
- IER = (IER & ~(1<<myTCC)) | 1<<myTCC
- INTMUX[0] = (INTMUX[0] & ~(0x7F)) | 0x1D; // map CPU it #4
- CPU.IER = (CPU.IER & (1<<4)) | 1<<4; // unmask CPU it #4
- enable_interrupts()
- // start transfer
- DCHMAP[myEvt] = (DCHMAP[myEvt] & ~(0x1FF<<5)) | myLCH<<5
- ESR = 1 << myEvt
- // do something useful (that does not depend on DMA completion)

- // this code is interrupted when DMA completes

14.4.3.6.10 DMA Interrupt Service Routine

The channel controller does not generate a new interrupt signal for new pending interrupts if the user did not clear previous pending interrupts. There are two options for constructing an ISR for DMA. The first is to poll all the bits during execution of the ISR, and to clear all enabled bits in an interrupt-pending register by writing to the interrupt-pending clear (ICR/ICRH) register before exiting any ISR. Pseudo-code for this option follows:

1. Enter ISR.
2. Read [TPCC_IPR](#).
3. For the condition set in [TPCC_IPR](#),
 - a. Perform operation as needed.
 - b. Clear bit for serviced INT.
4. Read IPR.
 - a. If [TPCC_IPR](#) = 0, exit ISR.
 - b. If [TPCC_IPR](#) = 1, go to Step 3.

The second option is to service the ISR and then, before exiting the ISR, to write to the EVAL bit of the IEVAL register. This forces the EDMA channel controller to generate a new interrupt signal if there are still pending interrupts in the interrupt-pending register (IPR/IPRH). Pseudo-code for this ISR option follows:

1. Enter ISR.
2. Read [TPCC_IPR](#).
3. For the condition set in [TPCC_IPR](#),
 - a. Perform operation as needed.
 - b. Clear bit for serviced INT.
4. Read IPR.
 - a. If [TPCC_IPR](#)=0, exit ISR.
 - b. If [TPCC_IPR](#)=1, set the [TPCC_IEVAL](#).EVAL bit to force triggering a new interrupt.

14.4.3.6.11 Benchmarking

The DMA channel controller monitors the number of event entries in an event queue to determine whether they exceed the user-programmed threshold. The queue threshold for each event queue can be programmed in the [TPCC_QWMTHRA](#) and [TPCC_QWMTHRB](#) registers. When the number of event entries in an event queue exceeds the user-programmed threshold, a queue threshold error occurs. This error is captured in the THRXCD field of event-queue status register [TPCC_QSTATi](#) (i = 0 or 1) and in the QTHRXCDn field in the [TPCC_CCERR](#) register.

14.4.3.6.12 Kelvin DMA Compatibility Mode

Any channel can be configured to keep compatibility with Kelvin DMA settings. To achieve this, the user must set the [TPCC_OPTm](#)[19] WIMODE register bit. It is recommended to always clear this bit, except when reusing existing Kelvin code.

- [PARAM](#)[LCH#].OPT.WIMODE = 0

Note: If reusing existing Kelvin code, see the *EDMA Migration Guide for DM420*.

14.4.4 Interrupt Management

14.4.4.1 Interrupt Flow in IVA2.2 Subsystem

The C64x + Megamodule interrupt controller (IC) detects, combines, and routes up to 128 system events (internal and external) to the 12 DSP CPU interrupt lines. For more information about interrupt mapping of the IVA2.2 subsystem (internal and external interrupts), see [Table 14-3](#).

In addition to performing handshaking for chip-level wake-up sequencing for waking from static power-down, the C64x + Megamodule WUGEN module internally routes the interrupt request to the IC module. This occurs because the WUGEN module is the only C64x + Megamodule module in the CORE power domain to enable the powered-off DSP subsystem to be awakened after the DSP receives an interrupt from any device peripherals.

[Figure 14-26](#) shows the IVA2.2 subsystem interrupt flow with the main WUGEN and IC registers used for event generation.

The diagram illustrates the interrupt system architecture, showing the flow of interrupts from device peripherals through various registers and logic to the DSP CPU registers.

Interrupt Sources and MUXes:

- INTMUX3:** INT15, INT14, INT13, INT12, INT11, INT10, INT9, INT8, INT7, INT6, INT5, INT4.
- INTMUX2:** INT15, INT14, INT13, INT12, INT11, INT10, INT9, INT8, INT7, INT6, INT5, INT4.
- INTMUX1:** INT15, INT14, INT13, INT12, INT11, INT10, INT9, INT8, INT7, INT6, INT5, INT4.

Interrupt Selector (128->12): A central block that selects the interrupt source based on the INTMUX signals.

Registers and Fields:

- CSR/TSR:** Contains "Not interrupt-related fields" and "GIE" (Global Interrupt Enable).
- IER (Interrupt Enable Register):** Contains 12 bits, each corresponding to an interrupt source (INT0-INT11).
- IFR (Interrupt Flag Register):** Contains 12 bits, each corresponding to an interrupt source (INT0-INT11).
- ICR (Interrupt Clear Register):** Contains 12 bits, each corresponding to an interrupt source (INT0-INT11).

Event Flags and Clear Registers:

- EVT0-31:** Event flags for various interrupt sources.
- EVTCLR0-31:** Event clear registers for various interrupt sources.

Device Peripherals and Interrupts:

- Device peripherals:** Generate interrupts (IRQ47-0) which are mapped to WUGEN_PENDEVT1 and WUGEN_PENDEVT0 registers.
- WUGEN_PENDEVT1 and WUGEN_PENDEVT0:** Registers that store the interrupt status for device peripherals.
- WUGEN_MEVT1 and WUGEN_MEVT0:** Registers that store the interrupt status for device peripherals.

EDMA (External Data Memory Access): A block that generates interrupts (EVT27-40) which are mapped to the EVTCLR0-31 registers.

14.4.4.2 Event Combined Programming Sequence

In addition to generating a combined interrupt based on programmable event combinations, the event combiner provides a masked view of the event flag registers. By reading the masked event flag (IVA_IC.MEVTFLAG_i where $i = \{0 \text{ to } 3\}$) registers, the DSP CPU sees only the event flags pertaining to the corresponding combined event (EVT_x with $x = \{0, 1, 2, 3\}$).

When servicing a combined interrupt, perform the following steps:

1. Read the IVA_IC.MEVTFLAG_i register corresponding to the combined event EVT_x (where $i = \{0 \text{ to } 3\}$).
2. Check the pending events.
3. Write the value of the IVA_IC.MEVTFLAG_i register into the IVA_IC.EVTCLR_x register (where $i = \{0 \text{ to } 3\}$).
4. Service the received interrupts.
5. Repeat steps 1 through 4 until IVA_IC.MEVTFLAG_i = 0x0 (where $i = \{0 \text{ to } 3\}$).

This clears only those events combined on EVT_x. Any events masked in the IVA_IC.EVTMASK_i register (where $i = \{0 \text{ to } 3\}$) do not need to be cleared if set in the IVA_IC.EVTFLAG_i register (where $i = \{0 \text{ to } 3\}$) (they can generate an exception or are used as event outputs).

Before returning, the DSP CPU should repeat steps 1 through 4 until no pending events are found. This ensures that any events received during the ISR are captured. If an event EVT_x is received at the same time that its flag is being cleared in the IVA_IC.EVTCLR_i register (where $i = \{0 \text{ to } 3\}$), it does not clear. Repeating steps 1 through 4 ensures that no events are missed.

14.4.4.3 Event <-> Interrupt Mapping Programming Sequence

The INTC allows programming independently which of the 128 inputs events is mapped to each DSP CPU interrupt by writing the event number in the bit field corresponding to the CPU interrupt in the IC.INTMUX_i registers (where $i = \{1 \text{ to } 3\}$).

Example:

```
/* -----
    */

/*evtTable has the 12 evt &lt;-&gt; CPU interrupt
   mapping */

/* -----
    */

evtTable[0] = 55; // Mailbox event highest priority
evtTable[1] = 61; // McBSP1TX event
[...]
evtTable[11] = 29; // EDMA3 gbl completion event lowest
                priority
for(I=0; i<12; I++) { // for each CPU maskeable
    interrupt
    INTMUX(I >> 2 + 1) |= (evtTable[i] & 0x7F) <<
        ((I & 0x3) << 3);
}
```

14.4.4.4 Interrupt Exception Programming Sequence

The INTC can generate a system event (INTERR) that is internally routed to system event input EVT96. This event is generated when a DSP CPU interrupt is dropped (that is, when a DSP CPU interrupt is received while the interrupt flag is already set in the DSP CPU).

This can inform the user of possible problems in the software code, such as whether interrupts were disabled for an extended period of time, or whether pipelined (noninterruptible) code sections were too long.

Note: Because the interrupt drop detection logic is in the CPU, only interrupts sourced from a single system event can be detected. The dropping of individual combined events is not possible, although dropping the output of an event combiner is possible. Only the first dropped interrupt detected is reported by the INTERR event.

The IVA_IC.INTXSTAT register holds the ID of the CPU interrupt and the system event number of the dropped event. By setting the IVA_IC.INTXCLR[0] CLEAR bit to 1, the software user resets the IVA_IC.INTXSTAT register to 0.

When servicing the interrupt exception, the CPU performs three steps:

1. Reads the IVA_IC.INTXSTAT register
2. Checks the error condition
3. Clears the error through the IVA_IC.INTXCLR register

The dropped events that generate the INTERR event (EVT96) can be qualified by a mask register. CPU interrupts that are to be ignored by the drop detection hardware can be masked in the IVA_IC.INTDMASK register.

14.4.4.5 Interrupt Controller Basic Programming Model for Power Down of IVA2.2 Subsystem

When going to a low-power state not involving IVA2.2 logic power off, there are no special software settings to perform. In particular, the noncombined interrupts can be used without any specific handling for that power transition. To run the procedure for a correct transition to power-down state not involving logic-off, the user must perform the following sequence:

1. Ensure that all wake-up events are correctly mapped to enabled DSP CPU interrupts, and are unmasked in combined event registers (if combined events are used).
2. Clear associated bits in the WUGEN_MEVT0 and WUGEN_MEVT1 register to unmask wake-up interrupts.

Note: Software must not unmask in the WUGEN module an event that is not correctly mapped to an enabled DSP CPU interrupt. If that event is triggered, the IVA2.2 subsystem exits the power-down state but does not wake up.

The user must program the following procedure when transitioning to the (logic) power-off state (OFF state for device):

1. Ensure that all wake-up events are correctly mapped to enabled DSP CPU interrupts, and are unmasked in combined event registers (if combined events are used).
2. Clear correct bits in the WUGEN_MEVT0 and WUGEN_MEVT1 registers to unmask wake-up interrupts.
3. Save necessary context (all except interrupt-related registers).

Note: Steps 3 through 5 are automatic, but interruptible. If a wake-up interrupt occurs at this stage, the transition to power down is canceled and the next transition restarts from the beginning. Software tip: A software variable (semaphore) can be set in Step 3, modified in all calls of the wake-up interrupt ISR routine, and checked before executing the IDLE instruction in Step 5. For a complete description of the DSP CPU ISR register, see the C64x+ documentation.

4. Save the interrupt configuration in:
 - a. IVA_IC.INTMUXi register (where i = {1 to 3})
 - b. IVA_IC.EVTMASKi register (optional, where i = {0 to 3})
 - c. IVA_IC.INTDMASK register (optional)
 - d. DSP CPU IER register. See the C64x+ documentation for IER register description.
5. Execute the DSP IDLE instruction.

Note: Software must not unmask in the WUGEN module an event that is not correctly mapped to an enabled DSP CPU interrupt. If that event is triggered, the IVA2.2 subsystem exits the power-down state but does not wake up.

14.4.4.6 Interrupt Controller Basic Programming Model for Power On of IVA2.2 Subsystem

noncombined events can be lost after power on wakeup of the C64x + Megamodule module. To avoid this, one solution is to replay the DSP CPU interrupt after restoring the interrupt selector and event combiner context.

- Programming model at boot time

There is no specific software setting needed to use combined/noncombined events during normal operation. However, at boot time, the event can be captured in the event-combiner event flag and not propagated to DSP. For this purpose, the following sequence must be performed:

1. The IVA2.2 logic ensures that interrupts are only presented to C64x + Megamodule after:
 - a. The C64x + Megamodule module has its clock.
 - b. The C64x + Megamodule module is correctly reset.

Note: Steps a and b ensure that the C64x + Megamodule module cannot miss a dropped event.

2. From the time the pre-idle sequence is started to the time when the IVA2.2 context is fully restored and operational after wakeup, it is assumed that only external (from device peripherals) interrupts can occur. C64x + Megamodule internal interrupts can result only from an application software side-effect; the application is stopped when entering the pre-idle sequence and is restarted only after IVA2.2 context is fully restored and operational (with special attention to memory protection). EDMA interrupts are inactive at this stage, as the EDMA module is completely reset after power up, and a software action is required to make the EDMA interrupts active again.
3. All device peripheral interrupts are level and are kept asserted until the software acknowledges the interrupt by writing 1 to the interrupt status register (DSP CPU ISR) bit corresponding to the enabled asserted event(s). The device peripheral must keep an event flag to track missed interrupts. For a complete description of the DSP CPU ISR register, see the C64x+ documentation.
4. There is no specific requirement to configure or restore interrupt mapping, except having the interrupts globally disabled during the sequence:
 - a. Set the DSP CPU TSR[0] or CSR[0] GIE bit to 0 to disable all interrupts except the reset interrupt and NMI (nonmaskable interrupt). The GIE bit is the same physical bit in the TSR and CSR registers. For a complete description of these registers, see the C64x + documentation.
 - b. Remap interrupts by configuring the IVA_IC.INTMUXi registers (where i = {1 to 3}).
 - c. Set the DSP CPU TSR[0] or CSR[0] GIE bit to 1 to enable all DSP CPU interrupts.

The DSP CPU software recognizes which degree of power state the C64x reaches when executing the IDLE instruction, because the PRCM module is under C64x software control. Therefore, the DSP CPU software can correctly skip some unnecessary parts of the pre-idle routines.

- State after reset for DSP CPU and IVA2.2 IC registers:
 - The DSP CPU IER register value is 0x0.
 - The DSP CPU IFR register value is 0x0 because the interrupt selector default mapping is routing only emulation and unmapped events.
 - The IVA_IC.INTMUXi registers (where i = {1 to 3}): The default mapping is to route EVT_x (with x = {0 to 3}) on INT_y (with y = {4 .. 15}), that is, emulation and nonmapped events.
 - The IVA_IC.EVTMASKi registers (where i = {0 to 3}) value is 0x0 (all events are unmasked). These registers values are don't care values because of the default interrupt selector mapping (where IVA_IC.INTMUXi registers where i = {1 to 3}).
 - The IVA_IC.EVTFLAGi registers (where i = {0, 1, 2, 3}): These registers log the possible wake-up interrupt(s) (if more than one). At this stage, a new wake-up interrupt from device peripherals cannot be missed, because interrupts are level in the device, waiting for a software acknowledge (the user must clear the interrupt in the module to de-assert the interrupt line).

For a complete description of the DSP CPU IER and IFR registers, see the C64x+ documentation.

- State after reset for WUGEN registers: two cases depending on the reset type:
 - In case of cold power-on reset (the CORE power domain was in OFF state), the IVA_WUGEN.WUGEN_MEVT0 register value is 0xFFFFFFFF and the IVA_WUGEN.WUGEN_MEVT1 register value is 0xFFFF, meaning that all interrupts are masked.
 - In case of warm power-on reset (the CORE power domain was in ACTIVE state), the WUGEN_MEVT0 and WUGEN_MEVT1 registers value is the previous programmed one, enabling only wake-up interrupts.
- Programming model for a correct warm-reset:

The software user must replay the noncombined events required for wakeup (if any):

1. Globally mask interrupts by setting the DSP CPU TSR[0] or CSR[0] GIE bit to 0 (already done at boot time).
2. Restore the interrupt selector configuration:
 - a. IVA_IC.INTMUXi register (where i = {1 to 3})
 - b. IVA_IC.EVTMASKi register (optional, where i = {0 to 3})
 - c. IVA_IC.INTDMASK register (optional)
3. Replay the noncombined event captured in IVA_IC.EVTFLAGi (where i = {0 to 3}):

For each DSP CPU interrupt I = (4 to 15)

```

{
  a. Grab mapped event by setting the IVA_IC.INTMUXi INTSELi[6:0] field (where i = {1 to 3}).
  b. Check if the event is combined (EVT0...3) or not combined (EVT4...127).
  c. If combined, exit the loop and go to next loop iteration.
  d. If noncombined:
      i. Check whether the event is pending in the IVA_IC.EVTFLAGi EFy bit (where i = {0 to 3} and y = {0 to 127}).
      ii. If not pending, exit the loop and go to the next loop iteration.
      iii. If pending, set the associated IFi bit in the DSP CPU IFR register.
}
      
```

Note: Software must ensure that an event is enabled only once in the C64x + Megamodule interrupt selector/combiner: If a noncombined event is mapped to an enabled DSP CPU interrupt, the associated combined event is masked in the associated IVA_IC.EVTMASKi (where i = {0 to 3}) register (and/or the combined event is not mapped to the DSP CPU interrupt). Reciprocally, if a combined event is mapped to a DSP CPU interrupt, all the unmasked events in the associated IVA_IC.EVTMASKi (with i = {0, 1 to 3}) register are not mapped as noncombined events to an enabled DSP CPU interrupt (through the DSP CPU IER register).

Software program example for Step 3:

```

/* -----
   */

/* Replays IFR bits associated to noncombined events
   */

/* Assumes interrupts globally disabled (GIE bit set to
   0)*/

/* Assumes IVA_IC.INTMUXi() and IVA_IC.EVTFLAGi() are access
   macros to C64x + Megamodule IC registers */

/* -----
   */

myIPR = IPR; // save IPR
for(I=0; i<12; I++) { // for each CPU maskable
    interrupt

    myEvt = ( INTMUX( I >> 2 + 1 ) >> ( ( I & 0x3 )
        << 3 ) ) & 0x7F;

```

```

if(myEvt >= 4) { // noncombined event
if( (EVTFLAG(myEvt >> 5) >> (myEvt & 0x1F) )
    & 0x1 ) {

myIPR |= (1<<(I+4));
}
}
}

IPR=myIPR; // update IPR register
/* -----
    */

/* Interrupts can be globally re-enabled from that
    point*/
/* -----
    */

```

4. Restore the CPU interrupt configuration by setting the DSP CPU IER register accordingly.
5. Restore the IVA2.2 context (except saved return-PC).
6. Globally enable the interrupts by setting the DSP CPU TSR[0] or CSR[0] GIE bit to 1.
7. Branch to saved return-PC.

For a complete description of the DSP CPU TSR, CSR, IER, or IFR registers, see the C64x+ documentation.

- Procedure for a correct cold reset
 1. Globally mask interrupts by setting the DSP CPU TSR[0] or CSR[0] GIE bit to 0 (already done at boot time).
 2. Restore the interrupt selector configuration:
 - a. IVA_IC.INTMUX_i register (where i = {1 to 3})
 - b. IVA_IC.EVTMASK_i register (optional, with i = {0 to 3})
 - c. IVA_IC.INTDMASK register (optional)
 3. It is unnecessary to replay events, because they are masked in WUGEN_MEVT0 and WUGEN_MEVT1 registers (default WUGEN module configuration). This can be done to simplify the boot sequence without discriminating between cold and warm reset.
 4. Restore the CPU interrupt configuration by setting the DSP CPU IER REGISTER accordingly.
 5. Restore the WUGEN module context. This can be forced even in warm reset to simplify the boot sequence without discriminating between cold and warm reset.

Note: If Steps 3 and 5 are performed systematically, the boot code can be shared between warm and cold reset boot without programming two distinct software boot codes.

6. Restore the rest of the IVA2.2 subsystem context (except saved return-PC).
7. Globally enable the interrupts by setting the DSP CPU TSR[0] or CSR[0] GIE bit to 1.
8. Branch to saved return-PC.

14.4.5 Memory Management

14.4.5.1 External Memory

14.4.5.1.1 Cacheability

The L1P, L1D, and L2 cache sizes are all 0K byte after reset.

- The user enables the L2 cache by writing 0x2 (maximum cache is 64K bytes) to the IVA_XMC.L2CFG register.
- However, this is not sufficient, because the region external to the IVA2.2 is configured as a noncached area after reset. The user must configure the external area to be cached by setting the IVA_XMC.MAR_i[0] PC bit to 1, i referring to the index of the related 16-MB page (starting from i = 16 for the first external page at address 0x1000 0000).

The MAR settings only control the L2 and L1D cache's response to CPU data and program fetches. L1P caches the memory range regardless of the values of the MAR bits.

14.4.5.1.2 Virtual Addressing

The device embeds two instances of MMU: one instance is camera MMU (also named MMU1) dedicated to the camera subsystem; the other instance is IVA2.2 MMU (also named MMU2) used by the IVA2.2 subsystem. For more information about MMU2 software settings at IVA2.2 boot, see [Section 14.4.1.2, Example of IVA2.2 Boot](#).

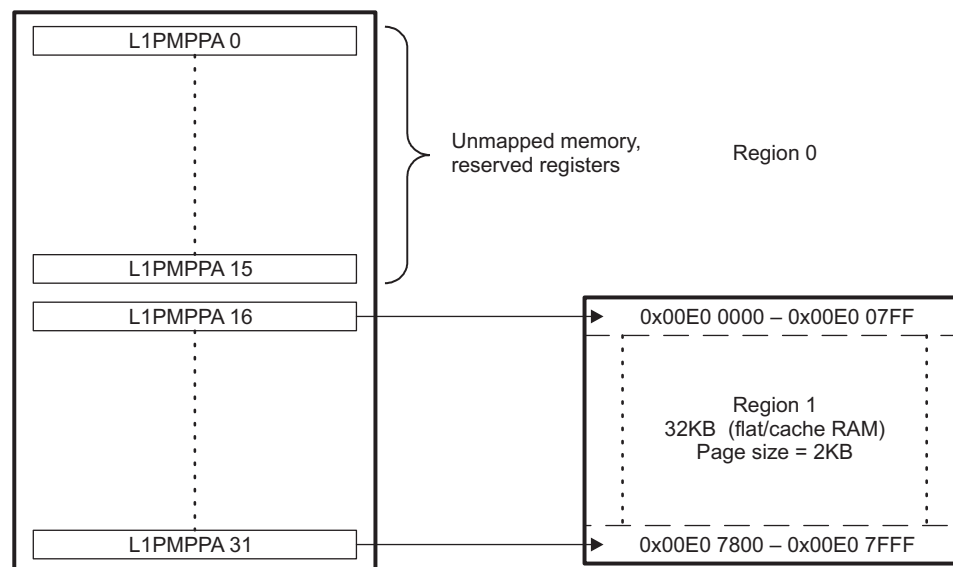

For a complete programming guide of IVA2.2 MMU, see the *Memory Management Units* chapter.

14.4.5.2 Internal Memory

14.4.5.2.1 Memory Protection

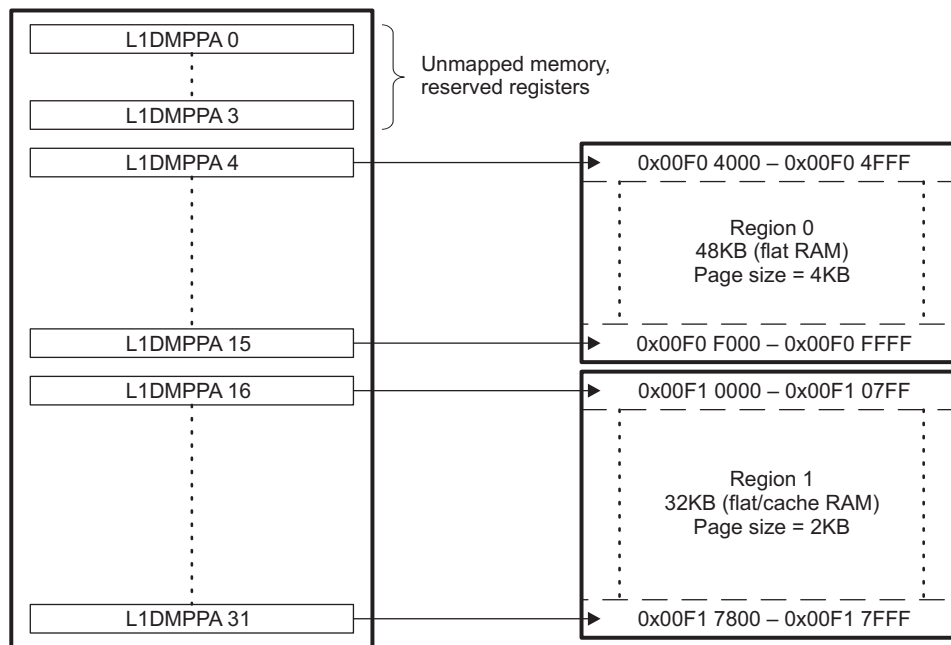

The C64x + Megamodule memory protection divides the memory map into pages and defines a per-page permission structure. This permission structure is in the MPPA registers: IVA_XMC.L1PMPPAk, IVA_XMC.L1DMPPAk, IVA_XMC.L1PMPPAk for L1P, L1D, L2 memory protection, and TPCC_MPPAG, TPCC_MPPAj for EDMA memory protection. [Figure 14-27](#), [Figure 14-28](#), and [Figure 14-29](#) show which register corresponds to each page permission structure.

Figure 14-27. L1P Memory Protection Registers

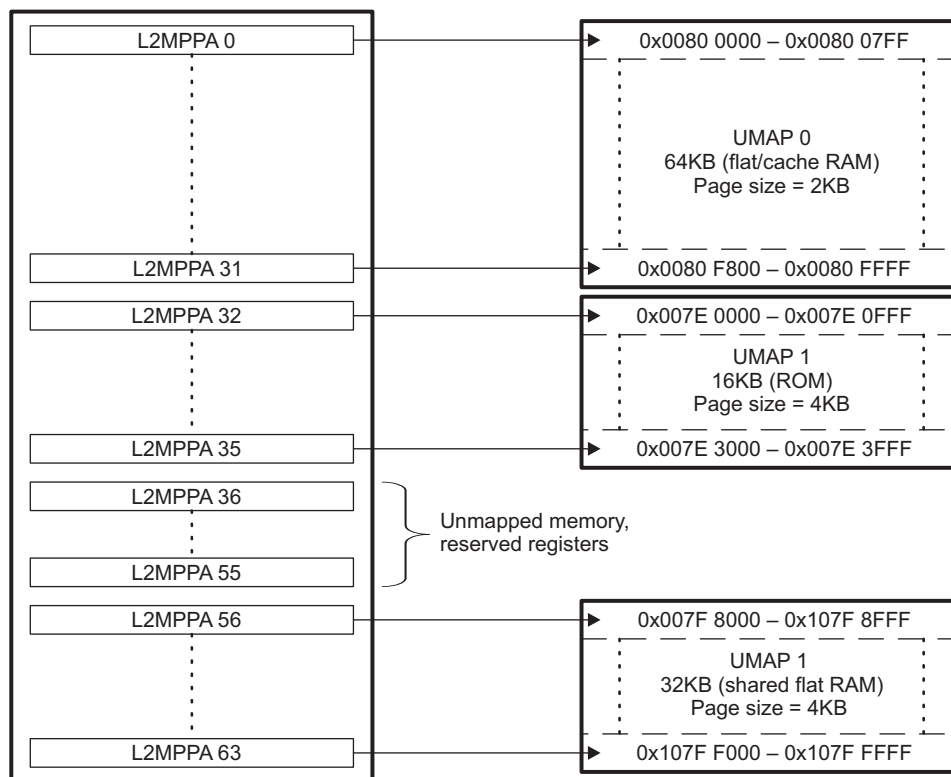

iva22-042

Figure 14-28. L1D Memory Protection Registers

iva22-043

Figure 14-29. L2 Memory Protection Registers

iva22-044

Note: When memory is used as cache, all its corresponding MPPA registers should be set to 0x0000.

Table 14-14 shows which register corresponds to each memory address for megacell internal memory.

Table 14-14. IVA2.2 Megacell Memory Protection Page Registers

Register Number	L1PMPPAk, Address Range	L1DMPPAk, Address Range	L2MPPAj, Address Range
0	N/A ⁽¹⁾	N/A	0x0080 0000 - 0x0080 07FF
1	N/A	N/A	0x0080 0800 - 0x0080 0FFF
2	N/A	N/A	0x0080 1000 - 0x0080 17FF

⁽¹⁾ N/A = nonmapped memory. All corresponding registers should be considered reserved.

All these registers include three permission fields in a 16-bit permission entry in the memory protection page attribute MPPA register:

- Allowed ID field:

Each requestor on the device has an N-bit code associated where it that identifies it for privilege purposes. This code, referred to as the VBUS PrivID, accompanies all memory accesses and DMAs/IDMAs on behalf of that requestor. That is, when a requestor triggers a DMA/IDMA transfer directly, either by writing to IDMA registers or by triggering the execution of a set of EDMA parameters, the corresponding DMA engine captures the PrivID of the requestor and provides that PrivID with the transfer.

Each memory protection entry is associated with an 8-bit allowed-IDs field that indicates which requestors can access the given page. The memory protection hardware maps the PrivIDs of all possible requestors to bits in the allowed-IDs field in the memory protection entries. The allowed-IDs field discriminates among the various CPUs, nonCPU requestors, and the accesses of a given CPU to its own local memories:

- AID0 through AID5 map small-numbered VBUS PrivIDs to allowed ID bits.
- An additional allowed-ID bit, AIDX, captures accesses by higher-numbered PrivIDs.
- The LOCAL bit treats CPU accesses to its local L1s and L2 specially. Only the L1 and L2 memory controllers implement the LOCAL bit.

When set to 1, the AID bit grants access to the corresponding PrivID. When set to 0, the AID bit denies access to the corresponding requestor.

PrivID assignments for bits AID0 through AIDX apply to:

- CPU memory and IDMA memory: IVA_XMC.L1PMPPAk[15:9] for L1P memory, IVA_XMC.L1DMPPAk[15:9] for L1D memory, and IVA_XMC.j[15:9] for L2 memory
- EDMA memory: TPCC_MPPAG[15:9] and TPCC_MPPAj[15:9] for EDMA block

The AIDX bit maps to PrivIDs that do not have dedicated AID bits associated with them. This bit refers to external mastering peripherals, especially on devices with a large number of CPUs. If a given device must discriminate among external mastering peripherals, it can assign lower-numbered PrivIDs to these peripherals.

For the EDMA module, the AIDX bit is the TPCC_MPPAj[9] and TPCC_MPPAj[9] EXT bits.

The LOCAL bit governs DSP CPU accesses to its own local L1 and L2 memories. It is defined in IVA_XMC.L1PMPPAk[8] for L1P memory, in IVA_XMC.L1DMPPAk[8] for L1D memory, and in IVA_XMC.L2MPPAj[8] for L2 memory. It is not defined for EDMA.

With respect to the allowed ID field, the C64x + Megamodule treats all remote CPU accesses to C64x + Megamodule memories identically to DMA accesses from that remote CPU. Therefore, C64x + Megamodule uses the PrivID to consult the corresponding AID bit when considering remote accesses.

However, the DPS megacell module never compares local accesses to L1 and L2 memory against the AID bits in the allowed ID field. Instead, it consults the LOCAL bit to determine whether the CPU can access its local memory.

With this scheme, a software program can designate a page as direct CPU access only by setting the LOCAL bit to 1 and setting all other allowed IDs to 0. Conversely, a software program can designate a page as DMAs issued from this CPU only by setting its AID bit and clearing the LOCAL bit. Such a setting is limited, but it can be useful in a high-secure environment such as a secure device, or in the context of a device driver.

- Request-Type Based Permissions field:

The DPS megacell memory protection model defines three fundamental functional access types: read, write, and execute. Read and write refer to data accesses originating through the load/store units on the DSP CPU or through the DMA/IDMA engines. Execute refers to accesses associated with program fetch.

The C64x + Megamodule memory protection model allows control of read, write, and execute permissions independently for both user and supervisor mode. This results in the 6-bit permission field shown in [Table 14-15](#).

Table 14-15. Request-Type Access Controls

Bit Name	Description
SR	Supervisor can read
SW	Supervisor can write
SX	Supervisor can execute ⁽¹⁾
UR	User can read
UW	User can write
UX	User can execute ⁽¹⁾

⁽¹⁾ IVA_XMC.L1DMPPAXX do not implement these bits.

For each bit, writing 1 permits the access type, and writing 0 denies it. For instance, setting the UX bit to 1 means that user mode can execute from the given page. The C64x + Megamodule allows specifying all six of these bits separately. For L1P, L1D, and L2 memories, and for EDMA, these bits are defined in IVA_XMC.L1PMPPAK[5:0], IVA_XMC.L1DMPPAK[5:0], IVA_XMC.L2MPPAJ[5:0], and TPCC_MPPAG[5:0] and TPCC_MPPAJ[5:0], respectively.

Note: IVA_XMC.L1DMPPAK do not implement the SX and UX bit, because execution is not possible from L1D memory. Therefore, these bits are reserved and should not be used in these registers.

- Other registers

The memory protection block records the address of the fault in the peripheral memory protection fault address register (MPFAR). It records the rest of the information about the fault in the peripheral memory protection fault status register (MPFSR); this register is formatted similarly to the MPPA. Software can write to the memory protection fault command register (MPFCR).

The MPFAR corresponds to the following registers: IVA_XMC.L1PMPPAR for L1P memory, IVA_XMC.L1DMPPAR for L1D memory, IVA_XMC.L2MPPAR for L2 memory, IVA_IDMA.ICFGMPFAR for IDMA, and TPCC_MPPAR for EDMA.

The MPFSR corresponds to the following registers: IVA_XMC.L1PMPPSR for L1P memory, IVA_XMC.L1DMPPSR for L1D memory, IVA_XMC.L2MPPSR for L2 memory, IVA_IDMA.ICFGMPFSR for IDMA, and TPCC_MPPSR for EDMA.

Using the MPFSR register, a memory protection fault can be decoded as follows by software:

- If the LOCAL status bit is set to 1, the request was a local DSP CPU request to its own memories. Otherwise (if the LOCAL status bit is set to 0), the VBUS ID of the faulting requestor is in the MPFSR[15:9] field.
- If the NS status bit is set to 1, the fault occurred in secure code. Otherwise (if the NS status bit is set to 0), it occurred in regular code.
- The value of the access type field (SR, SW, SX, UR, UW, UX) indicates the type of access that was at fault.

The MPFAR and MPFSR store information for only one fault. The hardware block holds the fault information until the software clears it by writing to MPFCR.

The user clears the recorded fault by setting the MPFCR[0] MPFCLR bit to 1. Writing 1 to this bit clears both MPFAR and MPFSR registers. The MPFAR and MPFSR read-only registers do not respond to writes. Once the user clears the fault, the hardware records the next protection violation, and signals an exception when it occurs. Writing 1 to any other bit of the MPFCR has no effect on the memory protection registers. Writing 0 to the MPFCR[0] MPFCLR bit also has no effect.

The MPFCR corresponds to the following registers: IVA_XMC.L1PMPPCR for L1P memory, IVA_XMC.L1DMPPCR for L1D memory, IVA_XMC.L2MPPCR for L2 memory, IVA_IDMA.ICFGMPFCR for IDMA, and TPCC_MPPCR for EDMA.

- Events generated to C64x + Megamodule IC block

Internal events are generated to inform the C64x + Megamodule module for memory protection:

- CCMPINT (EVT28) is generated for a TPCC memory protection interrupt.
- SYS_CMPA (EVT 119) is generated in case of a SYS CPU memory protection fault.
- PMC_CMPA (EVT120) and PMC_DMPA (EVT121) are generated in case of CPU and DMA memory protection faults, respectively, on PMC.

- DMC_CMPA (EVT122) and DMC_DMPA (EVT123) are generated in case of CPU and DMA memory protection faults, respectively, on DMC.
- UMC_CMPA (EVT124) and UMC_DMPA (EVT125) are generated in case of CPU and DMA memory protection faults, respectively, on UMC.
- PMC_CMPA (EVT126) is generated in case of a CPU memory protection fault on EMC.

The AID of the DSP appears in the DNUM control register in the CPU. DNUM is the DSP core number register; it is used to identify which DSP subsystem accessed the shared resources. Because there is only one C64x+:

- GEM_DNUM[7:4] always equals 0x0.
- GEM_DNUM[3:0] equals 0x0 because C64x + Megamodule is labeled as CPU0 in the single core system.

Thus, the possible requestors are:

- C64x
- IDMA
- EDMA
- Any device L3 initiator (through the IVA2.2 slave port)

The PrivID (relative to the DNUM register) equals 0. The ID of IVA DMA accesses is always 0x0, because the IVA DMA inherits ID from C64x + Megamodule. All accesses on the IVA2 slave port to local memories are seen by C64x + Megamodule as accesses from an external (non-C64x + Megamodule) initiator.

Thus, the hard-mapped memory protection IDs are:

- AID0, used for IVA DMA
- AID1 to AID5 (not used)
- AIDX, used by the slave port (L3 initiators)
- LOCAL bit, used by DSP loads, stores, and program fetches to memory attached directly to C64x + Megamodule

14.4.5.2.2 Bandwidth Management

The bandwidth management scheme can be summarized as weighted-priority-driven bandwidth allocation. Each requestor (EDMA, IDMA, CPU, etc.) is assigned a priority level on a per-transfer basis. The programmable priority level has a single meaning throughout the system: there is a total of nine priority levels, where priority 0 is highest and priority 8 is lowest priority. When requests for a single resource contend, access is granted to the highest priority requestor. When contention occurs for multiple successive cycles, a contention counter ensures that the lower priority requestor gets access to the resource every one out of n arbitration cycles, where n is programmable through the MAXWAIT field. For each identified requestor, a corresponding MAXWAIT field controls the maximum number of cycles that a request can be blocked.

- CPUARB registers: CPU priority and MAXWAIT programming model

The DSP CPU-initiated transfers consist of two components:

1. Program fetch transfers are issued by the CPU to the PMC, and the resulting L1P cache coherency operations (such as alloc/evict) are then issued to the UMC.
2. Data load/store transfers are issued by the CPU to the DMC, and the resulting L1D cache coherency operations (such as alloc/evict/long distance accesses) are then issued to the UMC.

Both program and data requests use the CPUARB values to define the maximum wait time (CPUARB[5:0] MAXWAIT) and priority (CPUARB[18:16] PRI). The effect of the CPUARB values is not just local to PMC or DMC. Priority/maxwait time applies to DMC/PMC cache transactions throughout the C64x + Megamodule and controls arbitration at each relevant sub-block within C64x + Megamodule. The priority (PRI) and MAXWAIT field is programmed locally in the UMC, DMC, and EMC blocks, through the IVA_UMC.CPUARBU, IVA_DMC.CPUARBD, and IVA_IDMA.CPUARBE PRI and MAXWAIT fields, respectively.

The default value of the CPUARB[18:16] PRI field is set so that CPU transactions are second to highest in the system. This should be a relatively typical value used in most systems, which results in the DSP CPU being granted highest priority most of the time, but a McBSP-type peripheral (typically programmed as the highest priority transfer for sDMA requests) can interrupt the DSP CPU transfers on a nearly immediate basis.

Note: CPU priority is software-programmable, but it is considered static (1-time-programmable) for bandwidth management. That is, during normal operation, all DSP CPU transactions are of the same priority. There is no concept of priority inheritance for CPU-initiated transfers as a result of CPU transfer A set at priority X and CPU transfer B set at priority Y. Because CPUARB must be programmed by the CPU, and is therefore a run-time program, the effect of the new CPUARB value must take effect for future CPU transfers.

- UCARB registers - User coherence operations

User coherence operations are broken into two types, block-oriented coherence and global coherence operations. The priority of these requests relative to other requests in the system varies as follows:

- Global user coherence: Always highest priority
- Block-oriented coherence: Always lowest priority

Because user coherence priority is fixed, the UCARB registers do not include a priority field. And because global user coherence operations are inherently highest priority, the MAXWAIT field programming applies only to block-oriented user coherence operations, not to global cache operations.

The UCARB[5:0] MAXWAIT field affects only the UMC (IVA_UMC.UCARBU register) and the DMC (IVA_DMC.UCARBD register). The priority values (being fixed) are assumed to be known at both the UMC and the DMC.

Note: The UCARB[5:0] MAXWAIT field (and the implied priorities) does not control the priority of coherence operations that result from DMA transactions or CPU transactions.

- IDMAARB registers - IDMA priority programming model

IDMA supports two active transfers at any time through IDMA channel 0 (used for memory to/from configuration bus transfers) and IDMA channel 1 (used for memory-to-memory transfers). The IDMAARB[5:0] MAXWAIT field is used to determine the maximum wait time for IDMA transactions. The priority level is not programmed through the IDMAARB register. Instead, the priority level is programmed directly through the IDMA control registers. In summary, IDMA transfer priority is:

- IDMA channel 0: Always highest priority
- IDMA channel 1: Programmable priority: the IVA_IDMA.IDMA1_COUNT[31:29] PRI field

For this reason, the IDMAARB registers do not include a priority field. The IDMAARB[5:0] MAXWAIT field affects not only the EMC (IVA_IDMA.IDMAARBE register) but also the UMC (IVA_UMC.IDMAARBU register) and the DMC (IVA_DMC.IDMAARBD register).

Note: IDMA channel 0 has no need for priority inheritance, because it is always the highest priority transfer in the system.

However, if an IDMA channel 1 transfer and an IDMA channel 0 transfer are pending at the same instant, but the IDMA channel 1 queue is blocked because of contention with another requestor, the IDMA channel 1 transfer should briefly inherit the priority of the IDMA channel 0 transfer (which is always 0x0) so that the pending datapath on IDMA channel 1 can complete and the normal priority mechanism can take control.

- SDMAARB registers - Slave DMA priority programming model

The C64x + Megamodule slave DMA (SDMA) interface can support multiple active transfers at a time. The SDMAARB[5:0] MAXWAIT field controls the maximum wait time for all slave DMA transactions. The priority level is not programmed by the SDMAARB register. Instead, the priority level is dictated by the priority fields of the IVA_TPCC.QUEPRI register.

The SDMAARB[5:0] MAXWAIT field does not affect only the EMC (IVA_IDMA.SDMAARBE register), but also the UMC (IVA_UMC.SDMAARBU register) and the DMC (IVA_DMC.SDMAARBD register).

Note: Because of the pipelined nature of the VBUS interface, the C64x + Megamodule module can have multiple DMA transfers in flight at a time. To avoid priority inversion, the C64x + Megamodule must not only evaluate the priority of the transfer at the head of the EMC queue(s), but the priority of all transfers that have been accepted/queued on the VBUS interface(s), and of higher priority transfers that are queued in the device-level DMA infrastructure.

- **MDMAARBE** register - Master DMA priority programming model

The IVA_IDMA.MDMAARBE[18:16] PRI field controls the submission priority for master DMA transactions (which are a result of cache misses or long-distance accesses to nonconfiguration space) and configuration bus transactions (long-distance accesses to configuration space or IDMA transfers to configuration space).

The IVA_IDMA.MDMAARBE priority is different from other programmable priorities in the system, in that the priority value does not affect internal arbitration for resources. This PRI[3:0] value is simply used as the VBUS priority value for all transactions initiated by the DMA master interface or memory-mapped register configuration interface.

Arbitration for the internal half of the transfer depends on the initiator (which could be DSP CPU, PMC, or DMC) or user coherence (UMC), or IDMA, etc. Arbitration for the external half of the transfer is DMA-dependent, and should rely on the Vbus priority, which is copied from the IVA_IDMA.MDMAARBE[18:16] PRI field.

Note: Because no internal arbitration results from the IVA_IDMA.MDMAARBE register, there is no need for the MAXWAIT field in this register.

14.4.6 IWA2.2 Power Management

14.4.6.1 Clock Management

14.4.6.1.1 Clock Configuration

The IWA2.2 subsystem receives one single-clock signal from the PRCM, the DPLL2_ALWON.FCLK.

From the DPLL2_ALWON.FCLK functional clock provided by the PRCM, three internal clocks (CD0_CLK, CD1_CLK, and CD2_CLK) are generated by the IWA2.2 DPLL and SYSC modules:

- The frequency of the CD0_CLK clock can be software-tuned with a PRCM register by setting the PRCM.CM_CLKSEL1_PLL_IWA2 and PRCM.CM_CLKSEL2_PLL_IWA2 registers.
- The CD1_CLK clock is always a divide-by-two of the CD0_CLK clock and its frequency cannot be changed by software.
- The CD2_CLK clock is always a divide-by-two of the CD0_CLK clock and its frequency cannot be changed by software.

For a complete description of the PRCM registers discussed in this section, see the *Power, Reset, and Clock Management* chapter.

14.4.6.1.2 Clock Gating

- IWA2.2 subsystem

The IWA2.2 internal clocks can be hardware-disabled by the PRCM when the MSTANDBY/WAIT handshake protocol occurs. To configure the PRCM so that IWA2.2 internal clocks are hardware-supervised, set the PRCM.CM_AUTOIDLE_PLL_IWA2[2:0] AUTO_IWA2_DPLL field to 0x1. When the IWA2.2 subsystem does not require its internal clocks, they can be disabled at the PRCM level by setting the PRCM.CM_FCLKEN_IWA2[0] EN_IWA2 bit to 0.

For a complete description of these PRCM registers, see the *Power, Reset, and Clock Management* chapter.

- SYSC module

The IWA2.2 SYSC module implements automatic clock gating on internal hardware detection of the absence of activity. The transition from clock-gated to clock-nongated state is operated with no cycle latency penalty.

The automatic clock-gating feature is enabled by setting the IVA_SYSC.SYSC_SYSCONFIG[0] AUTOIDLE bit to 1 (default value). This feature can be disabled by setting the IVA_SYSC.SYSC_SYSCONFIG[0] AUTOIDLE bit to 0 and making the clock free-running.

- WUGEN module

The IWA2.2 WUGEN module implements automatic clock gating on internal hardware detection of the absence of activity. The transition from clock-gated to clock-nongated state operates with no cycle latency penalty.

Automatic clock gating is enabled by setting the IVA_WUGEN.WUGEN_SYSCONFIG[0] AUTOIDLE bit to 1 (default mode). The clock can be made free-running by setting the IVA_WUGEN.WUGEN_SYSCONFIG[0] AUTOIDLE bit to 0.

- TPCC from EDMA module

The EDMA (or TPCC) module implements automatic clock gating on internal hardware detection of the absence of activity. The transition from clock-nongated to clock-gated state operates with no cycle latency penalty.

Automatic clock gating is enabled by default. The software user can disable auto-clock gating by setting the TPCC_CLKGDIS[0] CLKGDIS bit to 1. In this case, all TPCC internal clocks are free-running.

Note: To save power, it is recommended to not disable TPCC clock gating and to leave the TPCC_CLKGDIS register at its reset value.

14.4.6.2 Reset Management

In addition to hardware reset signals generated by the PRCM, the IVA2.2 subsystem can be reset by software control.

The three DSP power domain software resets (DSP_RST1, DSP_RST2, and DSP_RST3) are partial warm-reset sources. These software resets map to the PRCM.RM_RSTCTL_IVA2[0] RST1_IVA2 bit, the RM_RSTCTL_IVA2[1] RST2_IVA2 bit, and the PRCM.RM_RSTCTL_IVA2[2] RST3_IVA2 bit, respectively, in the PRCM register RM_RSTCTL_IVA2.

Setting these 3 bits to 1 performs a software reset to the IVA2.2 subsystem.

The reset status is logged in the PRCM.RM_RSTST_IVA2[8] IVA2_SW_RST1 read-only bit for IVA2_RST1 software reset, the PRCM.RM_RSTST_IVA2[9] IVA2_SW_RST2 read-only bit for IVA2_RST2 software reset, and the PRCM.RM_RSTST_IVA2[10] IVA2_SW_RST3 read-only bit for IVA2_RST3 software reset.

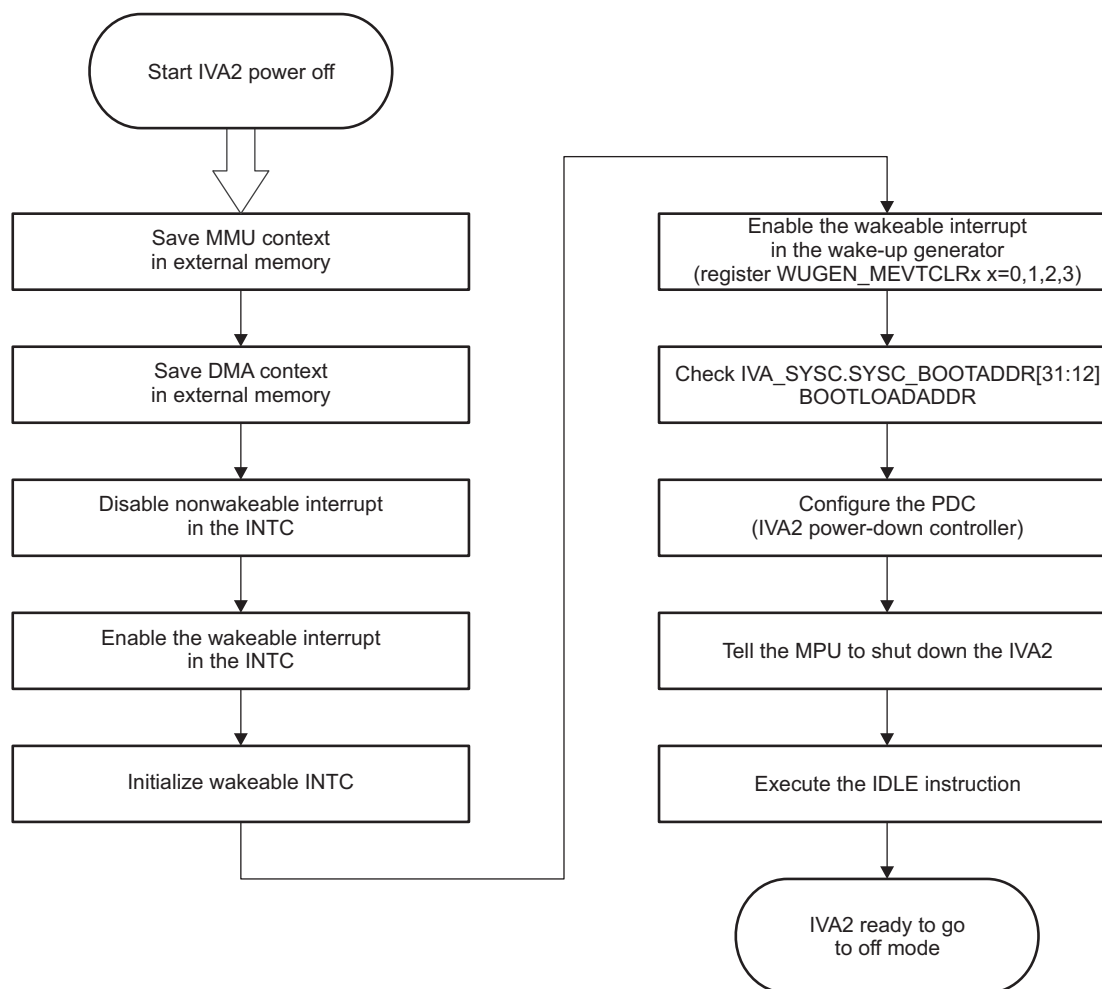

For a complete description of these PRCM registers, see the *Power, Reset, and Clock Management* chapter.

Note: Software reset can be applied only while the IVA2.2 subsystem is in clock-off mode.

14.4.6.3 Power-Down and Wake-Up Management

- C64x + Megamodule power-down controller (PDC)
The C64x + Megamodule embeds a PDC block that allows power-down management by software. Individual C64x + Megamodule blocks such as C64x + Megamodule CPU, PMC, DMC, EMC, and UMC can be powered off by the PDC.
- This software control is ensured by the IVA_SYS.PDCCMD register:
 - By setting the IVA_SYS.PDCCMD[16] GEMPD bit to 1, the user enables power-down management during idle mode.
 - By setting the IVA_SYS.PDCCMD xMCLOG[1:0] and IVA_SYS.PDCCMD xMCMEM[1:0] fields (x = {P, D, U}), the user controls the XMC clock-gating and standby memory modes. For example, DMC is controlled with the IVA_SYS.PDCCMD[5:4] DMCLOG and IVA_SYS.PDCCMD[7:6] xMCMEM fields.
 - The programming sequence for transition to clock-off state is as follows:
Before executing the IDLE instruction, the user must perform the following sequence:
 1. Write 1 to the IVA_SYS.PDCCMD[16] GEMPD bit (standby state); by default, the IVA_SYS.PDCCMD xMCLOG[1:0] and IVA_SYS.PDCCMD xMCMEM[1:0] (x = {P, D, U}) field values are all 0x1, so that module clock gating is enabled and standby mode of memories is statically activated after the IDLE instruction executes.
 2. Mask all interrupts not intended to wake up the IVA2.2 subsystem.
 3. Program the PRCM so that IVA2.2 clocks are cut on IVA2.2 standby. For more information, see the *Power, Reset, and Clock Management* chapter.
 4. Read back all the written registers to ensure write completion.
 5. No user-initiated cache coherence operations are in progress.
 6. IDLE code sequence is in L1P SRAM or L2 SRAM.

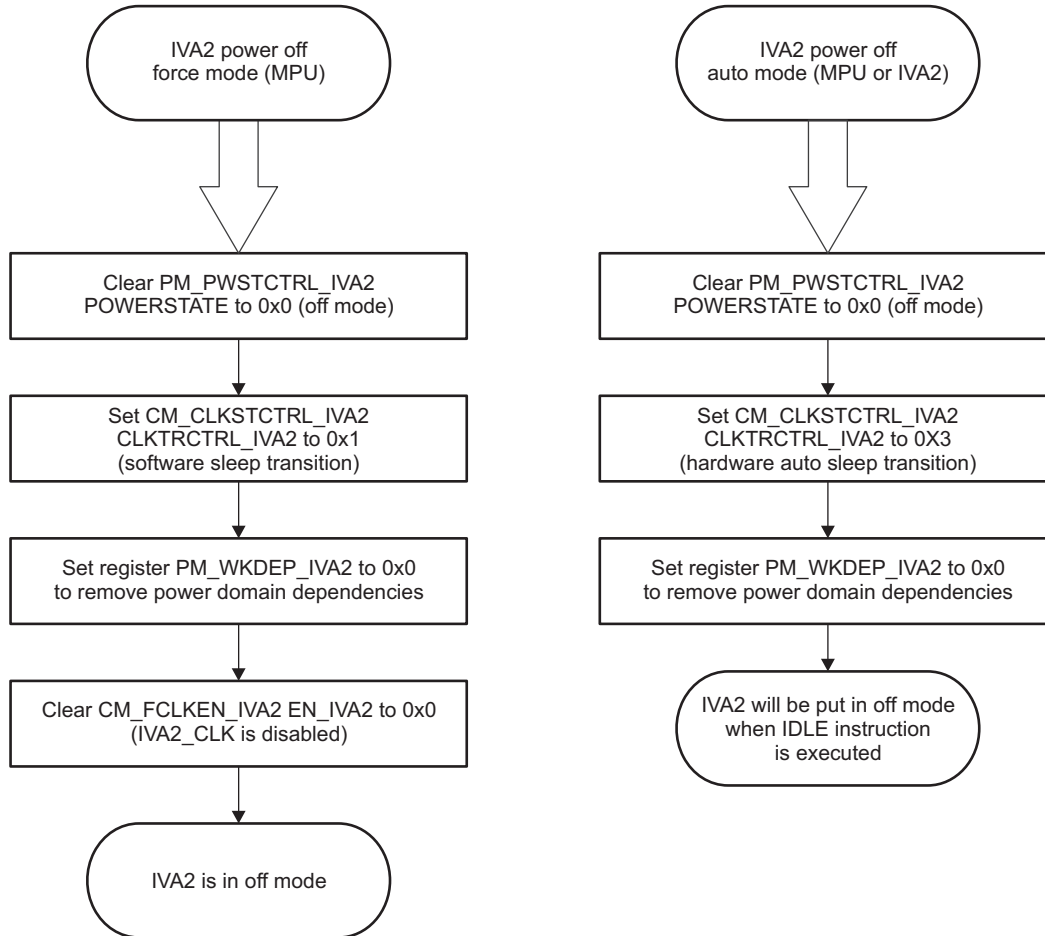

The user must also ensure that no other instruction is executed parallel to the IDLE instruction. When a clock stop request is asserted, the PDC_INT event (EVT118, see [Table 14-3](#)) is generated to the C64x + Megamodule IC module to inform the DSP CPU to initiate a power-down sequence. For more information about interrupt management, see [Section 14.4.4, Interrupt Management](#).
- Programming sequence for transition to power-off state:
Before executing the IDLE instruction, the user must perform the sequence shown in [Figure 14-30](#).

Figure 14-30. IVA2 Power Off

iva22-045

The user must also ensure that no other instruction is executed parallel to the IDLE instruction. When IVA2 is ready to go to off mode, there are two ways to completely shut down IVA2 subsystem (see [Figure 14-31](#)):

Figure 14-31. IVA2 Power Down

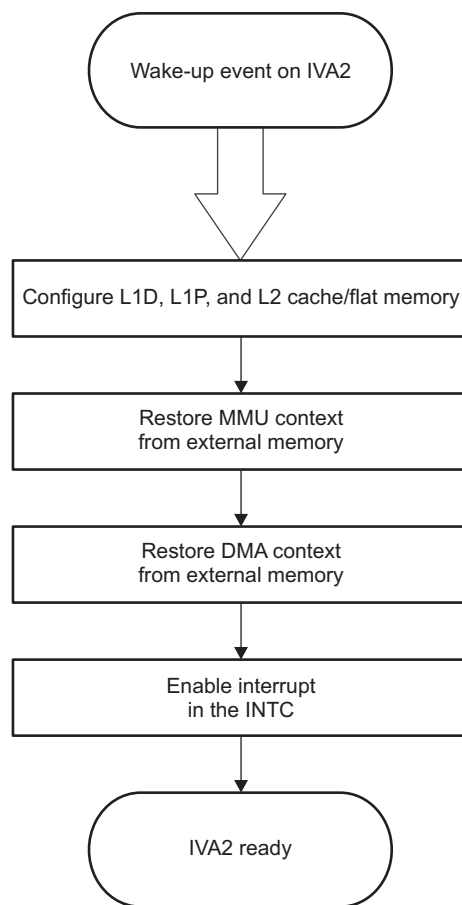

iva22-046

CAUTION

The IVA2 clock must not be stopped manually; otherwise, the WUGEN module inside the IVA2 has no functional clock and cannot wake up the IVA subsystem.

When the IVA2 is shut down, it can be waked up by an external event. The boot code executed after wakeup must include at least the following steps (see [Figure 14-32](#)):

Figure 14-32. IVA2 Wake Up

iva22-047

14.4.6.4 Powering Down L2\$ Memory While IVA2 is Active

If the L2\$ is unused while the DSP is active, the IVA2.2 can completely switch off the 96-KB SRAM attached to the L2\$ controller. This typically happens when the DSP is running at a low frequency (for instance, at the same frequency as the SDRAM) where L2\$ is not justified. The alternative is to switch off L2\$ SRAM completely, losing all L2-cache content and memory-mapped SRAM (from 0x10800000 to 0x1080FFFF). It is impossible to put the SRAM in low-leakage mode and retain data/program while the DSP is active. Also, L2 cache SRAM is the only memory/cache that supports this off mode while DSP is active. L1D and L1P cache SRAM off modes are not supported while DSP is active.

The sequence to enter L2\$ off mode while DSP is active follows:

1. Save [L2CFG](#) and disable the L2\$ by converting L2-cache SRAM to memory-mapped SRAM only (96KB): [L2CFG.L2MODE](#) = 0x0.
2. Read back [L2CFG](#) to ensure that Step 1 is complete.
3. Save [L2MPPAj](#) (i = 0 to 31) and write 0x0 to the [L2MPPAj](#) (i = 0 to 31) registers to report access to L2 memory (for debug) and enable associated permission check interrupt and/or exception.
4. Configure the PRCM to switch off L2:
[PRCM.PM_PWSTCTRL_IVA2.SHAREDL2CACHEFLATONSTATE](#) = 0x0.
5. Read back [PRCM.PM_PWSTCTRL_IVA2](#) to ensure that Step 4 is complete.

After this sequence, the user must not access the L2 memory. If this happens (typically in code under debug), a memory-protection interrupt and/or exception is taken.

The sequence to exit L2\$ off mode (while DSP is active) follows:

1. Configure the PRCM to switch on L2:
PRCM.PM_PWSTCTRL_IVA2.SHARED_L2CACHEFLATONSTATE = 0x3.
2. Read back PRCM.PM_PWSTCTRL_IVA2 to ensure that Step 1 is complete.
3. Restore [L2MPPAj](#) (i = 0 to 31).
4. Restore [L2CFG](#).
5. Read back PRCM.PM_PWSTCTRL_IVA2 to ensure that Step 4 is complete.

Note: After this sequence, L2\$ is empty and content in L2\$-SRAM configured as memory-mapped is lost.

Note: This mode does not provide large power savings, but is provided in IVA2.2 as an enabler for power-management software development, anticipating that leakage is a major contributor to power consumption, even in active mode.

14.4.7 Error Identification Process

Several mechanisms are available in the IVA2.2 subsystem to report errors at different levels.

14.4.7.1 Error Reporting for IDMA Module

The IDMA has its own error-reporting mechanism. The C64x + Megamodule implements an error register in EMC (IVA_IDMA.[IBUSERR](#)) that latches errors for external invalid transactions on either the DMA (MDMA) bus or the configuration (CFG) bus. Errors are detected on the CFG and MDMA write status or read status interfaces. If an error is received and the corresponding command is an invalid transaction, the IVA_IDMA.[IBUSERR](#)[31:29] ERR, IVA_IDMA.[IBUSERR](#)[10:8] XID, and IVA_IDMA.[IBUSERR](#)[2:0] STAT fields are updated accordingly. An error signaled through a non-0 read status is detected on the read data/status interface or a non-0 write status on the write status interface. Alternately, the EMC records an error if a read or write status response is detected for an unrecognized write ID.

Note: The user must ensure that the EMC detects/stores error information only for the first detected error on either the MDMA or CFG bus, regardless of whether it is a read or write status. In other words, a single error register (IVA_IDMA.[IBUSERR](#)) is shared by read and write errors and by the MDMA bus and the CFG bus, and only the first error is stored. If a read error and a write error are detected at the same time, the write status error is given higher priority and is latched into the IVA_IDMA.[IBUSERR](#) register.

When an error is detected and stored in the IVA_IDMA.[IBUSERR](#) register, the EMC_BUSERR event (EVT127, see [Table 14-3](#)) is available as a system event that can be selected as either a DSP CPU interrupt or an exception event.

The user can clear latched errors by writing 1 to the IVA_IDMA.[IBUSERRCLR](#)[0] CLR bit.

14.4.7.2 Error Reporting for EDMA Module

The TPTC and TPCC blocks of the EDMA module also contain registers to inform the user of a problem during IVA2.2 external DMA communication.

TPCC Block

The TPCC provides a single error interrupt output CCERRINT (EVT38, see [Table 14-3](#)) that consolidates the error conditions:

- QDMA missed events (stored in the [TPCC_QEMR](#) register)
- DMA missed events (stored in the [TPCC_EMR](#) register)
- Transfer completion code error (stored in the [TPCC_CCERR](#)[16] TCCERR bit)
- Queue threshold error events (stored in the [TPCC_CCERR](#)[n] QTHRXCDn bit, n = {0,1})

When an error is detected, the CCERRINT event is asserted, because error events do not have enables.

Note: The CCERRINT event follows the same conventions as other TPCC interrupt outputs. When the error interrupt condition transitions from a no-errors-are-set state to at least one error set, the error output (CCERRINT) pulses high for one TPCC clock cycle. If additional errors are latched before the original error is cleared by the user, the TPCC does not generate additional interrupt pulses. The software must poll all bits during execution of the ISR, and clear all error conditions, so that subsequent error pulses can be generated by the TPCC block.

Error interrupts can be set and/or reevaluated by writes to the [TPCC_EEVAL](#) register.

TPTC Block

The TPTC can also detect several error conditions:

- Read status or write status errors in the [TPTCj_ERRSTAT\[0\]](#) BUSERR status bit
- TR error in the [TPTCj_ERRSTAT\[2\]](#) TRERR status bit
- MMR address error in the [TPTCj_ERRSTAT\[3\]](#) MMRAERR status bit

Errors are recorded in the [TPTCj_ERRSTAT](#) register, regardless of whether they are enabled. They can be cleared from the [TPTCj_ERRSTAT](#) register only by writing 1 to the corresponding bit of the [IVA_TPTCj_ERRCLR](#) register.

The error details register ([IVA_TPTCj_ERRDET](#)) contains additional information about the first read status error or write status error detected. Future errors are bit-recorded until the [TPTCj_ERRDET](#) register is cleared.

If read status and write status are returned to the TPTC in the same cycle, the read or write status value that has an error (nonzero) is latched in the [TPTCj_ERRDET](#) register and the [TPTCj_ERRSTAT\[0\]](#) BUSERR bit is set. If both read and write status are nonzero, the write status is given priority for setting the [TPTCj_ERRDET](#) register. The [TPTCj_ERRDET](#) register is cleared by writing 1 to the [TPTCj_ERRCLR\[0\]](#) BUSERR bit.

If an error is enabled (by the [TPTCj_ERREN](#) register bits), the first occurrence of an enabled error generates a pulsed interrupt to the CPU by the TCERRINT event output (TCERRINT0 with EVT39 for TPTG0 and TCERRINT1 with EVT40 for TPTG1, respectively; see [Table 14-3](#)). Subsequent errors do not generate a new pulse until all accumulated errors are cleared by the CPU. The CPU clears bits in the [TPTCj_INTSTAT](#) register by writing 1 to the corresponding bit(s) of the [TPTCj_NTCLR](#) register.

14.4.7.3 Error Reporting for the L3 Interconnect

L3 interconnect out-of-band errors are also reported by the external L3 interrupt signal ([I3_ia_iva2_initSErr_o](#)). This signal corresponds to the EVT84 event and is directly connected to the [IVA2.2_nIRQ\[39\]](#) DSP CPU interrupt line. For more information about L3 interconnect error reporting, see the *Interconnect* chapter.

14.4.8 Recommendations for Static Settings

The following static settings are recommended:

- [SYSC.SYSC_LICFG0.DMATRUECOMPEN](#) = 1; // DMA last write is nonposted.
- [SYSC.SYSC_LICFG0.GEMTRUECOMPEN](#) = 1; // C64x + Megamodule last write is nonposted.
- [SYSC.SYSC_LICFG0.GEMBURSTOPTEN](#) = 1; // C64x + Megamodule burst optimization

Ensure that the following setting is carefully set:

- All 2D DMA transfers source and/or destination are to a VRFB view (tiling structure):
 - // DMA 2D burst optimization
 - [SYSC.SYSC_LICFG0.DMA2DOPTEN](#) = 1

Note: If the preceding condition is not set accurately, setting the DMA2DOPTEN optimization can degrade performance.

Notes:

1. A super-section type MMU page (16MB) must be defined for that VRFB view.
2. When the SYSC.SYSC_LICFG0.PAGEXINGEN is set to 1, a 2D DMA should not cross a MMU page boundary. When this bit is set, it disables the hardware check mechanism for better performance (but the user should ensure that 2D DMA does not cross MMU pages).

Therefore, ensure that the following setting is carefully set:

SYSC.SYSC_LICFG0.PAGEXINGEN = 1.

Note: If the preceding condition is not set accurately, setting the PAGEXINGEN optimization can cause undefined results, including deadlock situations.

14.5 IVA2.2 Subsystem Registers

IVA hardware accelerators are not available on all devices. See Chapter 1, *OMAP35x Family* section, to check availability of this feature.

Table 14-16 lists the IVA2.2 memory space mapping as seen by the IVA2.2 C64x + Megamodule.

Table 14-16. Instance Summary

Module Name	Base Address	Size
IC	0x0180 0000	64K bytes
SYS	0x0181 0000	64K bytes
IDMA	0x0182 0000	64K bytes
XMC	0x0184 0000	64K bytes
TPCC	0x01C0 0000	64K bytes
TPTC0	0x01C1 0000	1K byte
TPTC1	0x01C1 0400	1K byte
SYSC	0x01C2 0000	4K bytes
WUGEN	0x01C2 1000	4K bytes
Video Hardware Accelerator	0x0008 0000	22K bytes
IA_GEM	0x000F 8800	1K bytes
IA_EDMA	0x000F 8C00	1K bytes

For more information on the IVA2.2 memory mapping, see the *Memory Mapping* chapter.

Note: The MMU2 (IVA2.2 MMU) registers are described in Chapter 8, *Memory Management Units*. (The MMU base address is 0x5D00 0000 on the L3 interconnect).

CAUTION

The IVA2.2 registers are limited to 32-bit data accesses. 16-bit and 8-bit are not allowed and can corrupt register content.

14.5.1 Register Mapping Summary

Table 14-17. IC Register Mapping Summary

14.5.3 SYS Register Descriptions

This section provides information about the SYS Module. Each register in the module is described separately below.

14.5.3.1 PDCCMD

Table 14-51. PDCCMD

Address Offset	0x0000 0000																															
Physical address	0x0181 0000															Instance	IVA2.2 GEMSYS															
Description	Power-Down Command Register																															
Type	RW																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reserved																GEMPD	EMCMEM	EMCLOG	UMCMEM	UMCLOG	DMCMEM	DMCLOG	PMCMEM	PMCLOG								
Bits		Field Name		Description																		Type		Reset								
31:17		Reserved		Write 0s for future compatibility. Read returns 0.																		RW		0x0000								
16		GEMPD		Power-down during IDLE: GEMPD = 0: Normal operation. Do not power-down CPU or C64x + Megamodule when CPU is IDLE. GEMPD = 1: Sleep mode. Power-down CPU and C64x + Megamodule when CPU enters IDLE state																		RW		0								
15:14		EMCMEM		SRAM Sleep Modes Determines the RAM sleep modes used by the EMC for powering-down internal memories. 0x0: No sleep mode supported 0x1: Sleep mode 1 Write 0x2: Sleep mode 2 - equivalent to sleep mode 1 Write 0x3: Sleep mode 3 - equivalent to sleep mode 1																		RW		0x1								
13:12		EMCLOG		Logic Clock Gating Modes. Determines to what degree the EMC gates its clock internally. 0x0: No clock gating supported beyond leaf clock gating. 0x1: Static clock gating of unused modules regions when C64x + Megamodule is active (pmc_pd_pdstat[1:0] = 00) and Static clock gating when C64x + Megamodule is in standby (pmc_pd_pdstat[1:0] = 11)																		RW		0x1								
11:10		UMCMEM		SRAM Sleep Modes Determines the RAM sleep modes used by the UMC for powering-down L2 pages. 0x0: No sleep mode supported 0x1: Sleep mode 1 Write 0x2: Sleep mode 2 - equivalent to sleep mode 1 Write 0x3: Sleep mode 3 - equivalent to sleep mode 1																		RW		0x1								
9:8		UMCLOG		Logic Clock Gating Modes. Determines to what degree the UMC gates its clock internally. 0x0: No clock gating supported beyond leaf clock gating. 0x1: Static clock gating of unused modules regions when C64x + Megamodule is active (pmc_pd_pdstat[1:0] = 00) and Static clock gating when C64x + Megamodule is in standby (pmc_pd_pdstat[1:0] = 11)																		RW		0x1								

Bits	Field Name	Description	Type	Reset
7:6	DMCMEM	SRAM Sleep Modes Determines the RAM sleep modes used by the DMC for powering-down L1D pages. 0x0: No sleep mode supported 0x1: Sleep mode 1 Write 0x2: Sleep mode 2 - equivalent to sleep mode 1 Write 0x3: Sleep mode 3 - equivalent to sleep mode 1	RW	0x1
5:4	DMCLOG	Logic Clock Gating Modes. Determines to what degree the DMC gates its clock internally. 0x0: No clock gating supported beyond leaf clock gating. 0x1: Static clock gating of unused modules regions when C64x + Megamodule is active (pmc_pd_pdstat[1:0] = 00) and Static clock gating when C64x + Megamodule is in standby (pmc_pd_pdstat[1:0] = 11)	RW	0x1
3:2	PMCMEM	SRAM Sleep Modes Determines the RAM sleep modes used by the PMC for powering-down L1P pages. 0x0: No sleep mode supported 0x1: Sleep mode 1 Write 0x2: Sleep mode 2 - equivalent to sleep mode 1 Write 0x3: Sleep mode 3 - equivalent to sleep mode 1	RW	0x1
1:0	PMCLOG	Logic Clock Gating Modes. Determines to what degree the PMC gates its clock internally. 0x0: No clock gating supported beyond leaf clock gating. 0x1: Static clock gating of unused modules regions when C64x + Megamodule is active (pmc_pd_pdstat[1:0] = 00) and Static clock gating when C64x + Megamodule is in standby (pmc_pd_pdstat[1:0] = 11)	RW	0x1

14.5.5 XMC Register Descriptions

This section provides information about the XMC module, which contains the registers related to the three memory controllers of MidGEM: UMC, PMC, and DMC. Each register in the module is described separately below.

14.5.5.1 L2CFG

Table 14-91. L2CFG

Address Offset		0x0000 0000																															
Physical address		0x0184 0000								Instance		IVA2.2 GEMXMC																					
Description		L2 cache configuration register																															
Type		RW																															

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				NUM_MM				Reserved				MMID				Reserved				NOINIT	IP	ID	Reserved			L2CC		L2MODE			

Bits	Field Name	Description	Type	Reset
31:28	Reserved	Write 0s for future compatibility. Read returns 0.	R	0x0
27:24	NUM_MM	Number of megamodules -1 (always 0 for IVA2)	R	0x0
23:20	Reserved	Write 0s for future compatibility. Read returns 0.	R	0x0
19:16	MMID	Megamodule ID (always 0x0 for IVA2)	R	0x0
15:11	Reserved	Write 0s for future compatibility. Read returns 0.	W	0x00
10	NOINIT	No init upon cache config: when written '1', cache config is restored without reinitializing cache context (tags, validity bits) (this is assumed here that the restored cache settings are the same as prior to the execution of the IDLE instruction) when written '0', cache context is reinitialized (cache content is indirectly lost) this bit is always read as 0	W	0
9	IP	Global L1P invalidate (for backward compatibility, deprecated)	W	0
8	ID	Global L1D invalidate (for backward compatibility, deprecated)	W	0
7:5	Reserved	Write 0s for future compatibility. Read returns 0.	W	0x0
4:3	L2CC	L2 cache control 0x0: L2 cache operates normally 0x1: L2 Cache is frozen 0x2: L2 cache is bypassed	RW	0x0
2:0	L2MODE	L2 Configuration Register 0x0: 0KB of L2 Cache 0x1: 32KB of L2 Cache 0x2: 64KB of L2 Cache	RW	0x0

Table 14-261. TPCC_ER

Address Offset	0x1000	Instance	IVA2.2 TPCC																																																																																												
Physical address	0x01C0 1000																																																																																														
Description	Event Register: If ER.En bit is set and the EER.En bit is also set, then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. ER.En bit is set when the input event #n transitions from inactive (low) to active (high), regardless of the state of EER.En bit. ER.En bit is cleared when the corresponding event is prioritized and serviced. If the ER.En bit is already set and a new inactive to active transition is detected on the input event #n input AND the corresponding bit in the EER register is set, then the corresponding bit in the Event Missed Register is set. Event N can be cleared through sw by writing 1 to the ECR pseudo-register.

14.5.6.44 TPCC_CER

Table 14-271. TPCC_CER

Address Offset	0x1018	Instance	IVA2.2 TPCC
Physical address	0x01C0 1018		
Description	Chained Event Register: If CER.En bit is set (regardless of state of EER.En), then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. CER.En bit is set when a chaining completion code is returned from one of the TPTCs through the completion interface, or is generated internally through Early Completion path. CER.En bit is cleared when the corresponding event is prioritized and serviced. If the CER.En bit is already set and the corresponding chaining completion code is returned from the TC, then the corresponding bit in the Event Missed Register is set. CER.En cannot be set or cleared through software.

Table 14-273. TPCC_CERH

Address Offset	0x101C	Instance	IVA2.2 TPCC
Physical address	0x01C0 101C		
Description	Chained Event Register (High Part): If CERH.En bit is set (regardless of state of EERH.En), then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. CERH.En bit is set when a chaining completion code is returned from one of the TPTCs through the completion interface, or is generated internally through Early Completion path. CERH.En bit is cleared when the corresponding event is prioritized and serviced. If the CERH.En bit is already set and the corresponding chaining completion code is returned from the TC, then the corresponding bit in the Event Missed Register is set. CERH.En cannot be set or cleared through software.

Table 14-275. TPCC_EER

Address Offset	0x1020																																																																																														
Physical address	0x01C0 1020								Instance										IVA2.2 TPCC																																																																												
Description	<p>Event Enable Register: Enables DMA transfers for ER.En pending events. ER.En is set based on externally asserted events (through tpcc_eventN_pi). This register has no effect on Chained Event Register (CER) or Event Set Register (ESR). Note that if a bit is set in ER.En while EER.En is disabled, no action is taken. If EER.En is enabled at a later point (and ER.En has not been cleared through SW) then the event will be recognized as a valid TR Sync EER.En is not directly writeable. Events can be enabled through writes to EESR and can be disabled through writes to EECR register. EER.En = 0: ER.En is not enabled to trigger DMA transfers. EER.En = 1: ER.En is enabled to trigger DMA transfers.</p>

14.5.6.64 TPCC_QER

Table 14-311. TPCC_QER

Address Offset	0x1080	Instance	IVA2.2 TPCC
Physical address	0x01C0 1080		
Description	QDMA Event Register: If QER.En bit is set, then the corresponding QDMA channel is prioritized vs. other qdma events for submission to the TC. QER.En bit is set when a vbus write byte matches the address defined in the QCHMAPn register. QER.En bit is cleared when the corresponding event is prioritized and serviced. QER.En is also cleared when user writes a 1 to the QSECR.En bit. If the QER.En bit is already set and a new QDMA event is detected due to user write to QDMA trigger location and QEER register is set, then the corresponding bit in the QDMA Event Missed Register is set.

14.5.6.75 TPCC_CER_Rn

Table 14-333. TPCC_CER_Rn

Address Offset	0x2018-0x2E18 in 0x200 byte increments		
Physical address	0x01C0 2018-0x01C0 2E18	Instance	IVA2.2 TPCC
Description	Chained Event Register: If CER.En bit is set (regardless of state of EER.En), then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. CER.En bit is set when a chaining completion code is returned from one of the TPTCs through the completion interface, or is generated internally through Early Completion path. CER.En bit is cleared when the corresponding event is prioritized and serviced. If the CER.En bit is already set and the corresponding chaining completion code is returned from the TC, then the corresponding bit in the Event Missed Register is set. CER.En cannot be set or cleared through software.

Physical address	0x01C0 2020-0x01C0 2E20																Instance	IVA2.2 TPCC																																																																														
Description	<p>Event Enable Register:</p> <p>Enables DMA transfers for ER.En pending events. ER.En is set based on externally asserted events (through tpcc_eventN_pi). This register has no effect on Chained Event Register (CER) or Event Set Register (ESR). Note that if a bit is set in ER.En while EER.En is disabled, no action is taken. If EER.En is enabled at a later point (and ER.En has not been cleared through SW) then the event will be recognized as a valid TR Sync EER.En is not directly writeable. Events can be enabled through writes to EESR and can be disabled through writes to EECR register.</p> <p>EER.En = 0: ER.En is not enabled to trigger DMA transfers.</p> <p>EER.En = 1: ER.En is enabled to trigger DMA transfers.</p>

Table 14-373. TPCC_QER_Rn

Address Offset	0x2080-0x2E80 in 0x200 byte increments		
Physical address	0x01C0 2080-0x01C0 2E80	Instance	IVA2.2 TPCC
Description	QDMA Event Register: If QER.En bit is set, then the corresponding QDMA channel is prioritized vs. other qdma events for submission to the TC. QER.En bit is set when a vbus write byte matches the address defined in the QCHMAPn register. QER.En bit is cleared when the corresponding event is prioritized and serviced. QER.En is also cleared when user writes a 1 to the QSECR.En bit. If the QER.En bit is already set and a new QDMA event is detected due to user write to QDMA trigger location and QEER register is set, then the corresponding bit in the QDMA Event Missed Register is set.

Physical address	0x01C0 4008 + (0x20*i)		
Description	A and B byte count		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BCNT																ACNT															

Bits	Field Name	Description	Type	Reset
31:16	BCNT	<p>BCNT : Count for 2nd Dimension: BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT can be anywhere between 1 and 65535. Therefore, the maximum number of arrays in a frame is 65535 (64K-1 arrays). BCNT=1 means 1 array in the frame, and BCNT=0 means 0 arrays in the frame.</p> <p>In normal mode, a BCNT of 0 is considered as either a Null or Dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field.</p> <p>If the OPTi.WIMODE bit is set, then the programmed BCNT value will be incremented by 1 before submission to TC. I.e., 0 means 1, 1 means 2, 2 means 3, ..., 0xFFFFE means 0xFFFF. A value of 0xFFFF is an illegal value that will be treated as a Null TR.</p>	RW	0x----
15:0	ACNT	<p>ACNT : number of bytes in 1st dimension: ACNT represents the number of bytes within the first dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65535. Therefore, the maximum number of bytes in an array is 65535 bytes (64K-1 bytes). ACNT must be greater than or equal to 1 for a TR to be submitted to TC. An ACNT of 0 is considered as either a null or dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field.</p> <p>If the OPTi.WIMODE bit is set then the ACNT field represents a word count. The CC must internally multiply by 4 to translate the word count to a byte count prior to submission to the TC. The 2 MSBs of the 16-bit ACNT are Reserved and should always be written as b00 by the user. If user writes a value other than 0, it will still be treated as 0 since the multiply-by-4 operation (to translate between a word count and a byte count) will drop the 2 msbits. For dummy and null transfer definition, the ACNT definition will disregard the 2 msbits. I.e., a programmed ACNT value of 0x8000 in WI-mode will be treated as 0 byte transfer, resulting in null or dummy operation dependent on the state of BCNT and CCNT.</p>	RW	0x----

Physical address	0x01C0 4014 + (0x20*i)																																
Description	Link and Reload parameters																																
Type	RW																																

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BCNTRLD																LINK															

Bits	Field Name	Description	Type	Reset
31:16	BCNTRLD	BCNT Reload: BCNTRLD is a 16-bit unsigned value used to reload the BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-Synced transfers. In this case, the CC decrements the BCNT value by one on each TR submission. When BCNT (conceptually) reaches zero, then the CC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value. For AB-synchronized transfers, the CC submits the BCNT in the TR and therefore the TC is responsible to keep track of BCNT, not CC-thus BCNTRLD is a don't care field.	RW	0x----
15:0	LINK	Link Address: The CC provides a mechanism to reload the current PaRAM Entry upon its natural termination (i.e., after count fields are decremented to 0) with a new PaRAM Entry. This is called linking. The 16-bit parameter LINK specifies the byte address offset in the PaRAM from which the CC loads/reloads the next PaRAM entry in the link. The CC should disregard the value in the upper 2 bits of the LINK field as well as the lower 5-bits of the LINK field. The upper two bits are ignored such that the user can program either the literal byte address of the LINK parameter or the PaRAM base-relative address of the link field. Therefore, if the user uses the literal address with a range from 0x4000 to 0x7FFF, it will be treated as a PaRAM-base-relative value of 0x0000 to 0x3FFF. The lower-5 bits are ignored and treated as b00000, thereby guaranteeing that all Link pointers point to a 32-byte aligned PaRAM entry. In the latter case (5-lsbs), behavior is undefined for the user (i.e., don't have to test it). In the former case (2 msbs), user should be able to take advantage of this feature (i.e., do have to test it). If a Link Update is requested to a PaRAM address that is beyond the actual range of implemented PaRAM, then the Link will be treated as a Null Link and all 0s plus 0xFFFF will be written to the current entry location. A LINK value of 0xFFFF is referred to as a NULL link which should cause the CC to write 0x0 to all entries of the current PaRAM Entry except for the LINK field which is set to 0xFFFF. The Priv/Privid/Secure state is overwritten to 0x0 when linking. MSBs and LSBS should not be masked when comparing against the 0xFFFF value. I.e., a value of 0x3FFE is a non-NULL PaRAM link field. 7	Reserved	Read returns 0.	R	0

Bits	Field Name	Description	Type	Reset
6:4	DSTACTV	Destination Active State Specifies the number of TRs that are resident in the Dst Register FIFO at a given instant. Legal values are constrained by the DSTREGDEPTH parameter. Read 0x0: FIFO set is empty. Read 0x1: Dst FIFO contains 1 TR Read 0x2: Dst FIFO contains 2 TR Read 0x3: Dst FIFO contains 3 TR Read 0x4: Dst FIFO contains 4 TR	R	0x0
3	Reserved	Read returns 0.	R	0
2	WSACTV	Write Status Active WSACTV = 0: Write status is not pending. Write status has been received for all previously issued write commands. WSACTV = 1: Write Status is pending. Write status has not been received for all previously issued write commands.	R	0
1	SRCACTV	Source Active State SRCACTV = 0: Source Active set is idle. Any TR written to Prog Set will immediately transition to Source Active set as long as the Dst FIFO Set is not full (DSTFULL == 1). SRCACTV = 1: Source Active set is busy either performing read transfers or waiting to perform read transfers for current Transfer Request.	R	0
0	PROGBUSY	Program Register Set Busy PROGBUSY = 0: Prog set idle and is available for programming. PROGBUSY = 1: Prog set busy. User should poll for PROGBUSY equal to 0 prior to reprogramming the Program Register set.	R	0

14.5.7.11 TPTCj_ERRDET

Table 14-421. TPTCj_ERRDET

Address Offset	0x12C																
Physical address	0x01C1 012C								Instance	IVA2.2 TPTC0							
Physical address	0x01C1 052C								Instance	IVA2.2 TPTC1							
Description	Error Details Register																
Type	R																

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														TCCHEN	TCINTEN	Reserved	TCC				Reserved				STAT						

Bits	Field Name	Description	Type	Reset
31:18	Reserved	Read returns 0.	R	0x0000
17	TCCHEN	Contains the OPT.TCCHEN value programmed by the user for the Read or Write transaction that resulted in an error.	R	0
16	TCINTEN	Contains the OPT.TCINTEN value programmed by the user for the Read or Write transaction that resulted in an error.	R	0
15:14	Reserved	Read returns 0.	R	0x0
13:8	TCC	Transfer Complete Code: Contains the OPT.TCC value programmed by the user for the Read or Write transaction that resulted in an error.	R	0x00
7:4	Reserved	Read returns 0.	R	0x0
3:0	STAT	Transaction Status: Stores the non-zero status/error code that was detected on the read status or write status bus. MS-bit effectively serves as the read vs. write error code. If read status and write status are returned on the same cycle, then the TC chooses non-zero version. If both are non-zero then write status is treated as higher priority. Encoding of errors matches the CBA spec and is summarized here: 0xF = Read 0x0: No Error (should not cause error to be latched) Read 0x1: Read Addressing error Read 0x2: Read Privilege error Read 0x3: Read Timeout error Read 0x4: Read Data error Read 0x7: Read Exclusive-operation failure Read 0x8: No Error (should not cause error to be latched) Read 0x9: Write Addressing error Read 0xA: Write Privilege error Read 0xB: Write Timeout error Read 0xC: Write Data error Read 0xF: Write Exclusive-operation failure	R	0x0

Bits	Field Name	Description	Type	Reset
31:10	Reserved	Read returns 0.	R	0x000000
9	SECURE	Secure Level: SECURE = 0: nonsecure access SECURE = 1: Secure access PMPPRXY.SECURE is always updated with the value from the configuration bus secure field on any/every write to Program Set BIDX Register (trigger register). The SECURE value for the SA Set and DF Set are copied from the value in the Program set along with the remainder of the parameter values. The secure attribute is issued on the VBusM read and write command bus such that the target endpoints can perform memory protection and security checks based on the SECURE level of the external host that sets up the DMA transaction.	R	0
8	PRIV	Privilege Level: PRIV = 0: User level privilege PRIV = 1: Supervisor level privilege PMPPRXY.PRIV is always updated with the value from the configuration bus Privilege field on any/every write to Program Set BIDX Register (trigger register). The PRIV value for the SA Set and DF Set are copied from the value in the Program set along with the remainder of the parameter values. The privilege ID is issued on the VBusM read and write command bus such that the target endpoints can perform memory protection checks based on the PRIV of the external host that sets up the DMA transaction.	R	0
7:4	Reserved	Read returns 0.	R	0x0
3:0	PRIVID	Privilege ID: PMPPRXY.PRIVID is always updated with the value from configuration bus Privilege ID field on any/every write to Program Set BIDX Register (trigger register). The PRIVID value for the SA Set and DF Set are copied from the value in the Program set along with the remainder of the parameter values. The privilege ID is issued on the VBusM read and write command bus such that the target endpoints can perform memory protection checks based on the privid of the external host that sets up the DMA transaction.	R	0x0
