

OMAP™

OMAP35x Applications Processor

Texas Instruments OMAP™ Family of Products

Technical Reference Manual

Literature Number: SPRUF98B
September 2008

1	Introduction	181
1.1	Overview	182
1.2	Environment	184
1.3	Description	185
1.3.1	MPU Subsystem	185
1.3.2	IVA2.2 Subsystem	186
1.3.3	On-Chip Memory	187
1.3.4	External Memory Interfaces	187
1.3.5	DMA Controllers	188
1.3.6	Multimedia Accelerators	188
1.3.7	Security (HS Devices Only)	189
1.3.8	Comprehensive Power Management	189
1.3.9	Peripherals	189
1.4	Package-On-Package Concept	191
1.5	OMAP35x Family	193
1.5.1	Device Features	193
1.5.2	Device Identification	195
1.5.3	General Recommendations Relative to Unavailable Features/Modules	197
1.6	Revision History	199
2	Memory Mapping	201
2.1	Introduction	202
2.2	Global Memory Space Mapping	204
2.3	L3 and L4 Memory Space Mapping	207
2.3.1	L3 Memory Space Mapping	207
2.3.2	L4 Memory Space Mapping	208
2.3.2.1	L4-Core Memory Space Mapping	208
2.3.2.2	L4-Wakeup Memory Space Mapping	211
2.3.2.3	L4-Peripheral Memory Space Mapping	212
2.3.2.4	L4-Emulation Memory Space Mapping	213
2.3.3	Register Access Restrictions	215
2.4	IVA2.2 Subsystem Memory Space Mapping	216
2.4.1	IVA2.2 Subsystem Internal Memories and Cache Allocation	216
2.4.1.1	IVA2.2 Subsystem Memory Hierarchy	216
2.4.1.2	IVA2.2 Cache Allocation	217
2.4.2	DSP Access to L2 Memories	218
2.4.2.1	DSP Access to L2 ROM	218
2.4.2.2	DSP Access to L2 RAM	218
2.4.3	DSP and EDMA Access to Memories and Peripherals	218
2.4.4	L3 Interconnect View of the IVA2.2 Subsystem Memory Space	219
2.4.5	DSP View of the IVA2.2 Subsystem Memory Space	219
2.4.6	EDMA View of the IVA2.2 Subsystem Memory Space	221

2.5	Revision History	222
3	MPU Subsystem	223
3.1	MPU Subsystem Overview	224
3.1.1	Introduction	224
3.1.2	Features	225
3.2	MPU Subsystem Integration	226
3.2.1	MPU Subsystem Clock and Reset Distribution	228
3.2.1.1	Clock Distribution	228
3.2.1.2	Reset Distribution	229
3.2.2	ARM Subchip	230
3.2.2.1	ARM Overview	230
3.2.2.2	ARM Description	231
3.2.2.2.1	ARM®Cortex™-A8 Instruction, Data, and Private Peripheral Port	231
3.2.2.2.2	MPU Subsystem Features	231
3.2.2.3	Clock, Reset, and Power Management	232
3.2.2.3.1	Clocks	232
3.2.2.3.2	Reset	232
3.2.2.3.3	Power Management	232
3.2.3	AXI2OCP and I2Async Bridges	232
3.2.3.1	Bridges Overview	232
3.2.3.2	AXI2OCP Description	233
3.2.3.3	AXI Tag to OCP Thread Remapping	234
3.2.3.4	Clocks, Reset, and Power Management	234
3.2.3.4.1	Clocks	235
3.2.3.4.2	Reset	235
3.2.3.4.3	Power Management	235
3.2.4	Interrupt Controller	235
3.2.4.1	Clocks	235
3.2.4.2	Reset	235
3.2.4.3	Power Management	235
3.3	MPU Subsystem Functional Description	236
3.3.1	Interrupts	236
3.3.2	Power Management	236
3.3.2.1	Power Domains	236
3.3.2.2	Power States	237
3.3.2.3	Power Modes	237
3.3.2.4	Transitions	241
3.4	MPU Subsystem Basic Programming Model	242
3.4.1	Clock Control	242
3.4.2	MPU Power Mode Transitions	242
3.4.2.1	Basic Power-On Reset	242
3.4.2.2	MPU Into Standby Mode	242
3.4.2.3	MPU Out of Standby Mode	242
3.4.2.4	MPU Power-On from a Powered-Off State	242
3.4.3	NEON Power Mode Transition	243
3.4.4	ARM Programming Model	243
3.5	Revision History	244
4	Power, Reset, and Clock Management	245

4.1	PRCM Introduction to Power Management	246
4.1.1	Goal of Power Management.....	246
4.1.2	Power-Management Techniques	246
4.1.2.1	Dynamic Voltage and Frequency Scaling	246
4.1.2.2	SmartReflex Adaptive Voltage Control	247
4.1.2.3	Dynamic Power Switching.....	248
4.1.2.4	Standby Leakage Management	249
4.1.2.5	DPS Versus SLM	249
4.1.2.6	Combining Power-Management Techniques	250
4.1.3	Architectural Blocks for Power Management.....	251
4.1.3.1	Clock Domain	251
4.1.3.2	Power Domain	252
4.1.3.3	Voltage Domain.....	253
4.1.4	Device Power-Management Architecture.....	253
4.1.4.1	Module Interface and Functional Clocks	255
4.1.4.2	Autoidle Clock Control	255
4.1.5	SmartReflex Voltage-Control Overview	256
4.1.5.1	Manual SmartReflex Voltage Control	257
4.1.5.2	Automatic SmartReflex Voltage Control	258
4.2	PRCM Overview	259
4.2.1	Introduction	259
4.2.2	PRCM Features	261
4.3	PRCM Environment	262
4.3.1	External Clock Signals	263
4.3.2	External Reset Signals	264
4.3.3	External Power Signals	265
4.4	PRCM Integration.....	266
4.4.1	Power-Management Scheme, Reset, and Interrupt Requests.....	269
4.4.1.1	Power Domain	269
4.4.1.2	Resets.....	269
4.4.1.3	Interrupt Requests.....	270
4.5	PRCM Reset Manager Functional Description	271
4.5.1	Overview	271
4.5.2	General Characteristics of Reset Signals	271
4.5.2.1	Scope	272
4.5.2.2	Occurrence	272
4.5.2.3	Source Type.....	272
4.5.3	Reset Sources.....	273
4.5.3.1	Global Reset Sources.....	273
4.5.3.2	Local Reset Sources	274
4.5.4	Reset Distribution	275
4.5.5	Power Domain Reset Descriptions	276
4.5.5.1	MPU Power Domain	276
4.5.5.2	NEON Power Domain.....	277
4.5.5.3	IVA2 Power Domain.....	277
4.5.5.4	CORE Power Domain.....	277
4.5.5.5	DSS Power Domain	278
4.5.5.6	CAM Power Domain	278
4.5.5.7	USBHOST Power Domain	278

4.5.5.8	SGX Power Domain	278
4.5.5.9	WKUP Power Domain	279
4.5.5.10	PER Power Domain	279
4.5.5.11	SmartReflex Power Domain.....	279
4.5.5.12	DPLL Power Domains	279
4.5.5.13	EFUSE Power Domain	280
4.5.5.14	BANDGAP Logic.....	280
4.5.5.15	External Warm Reset Assertion	280
4.5.6	Reset Logging	281
4.5.6.1	PRCM Reset Logging Mechanism	281
4.5.6.2	SCM Reset Logging.....	281
4.5.7	Reset Management Overview	281
4.5.8	Reset Summary	286
4.5.9	Reset Sequences	290
4.5.9.1	Power-Up Sequence	290
4.5.9.2	Global Warm Reset Sequence	292
4.5.9.3	IVA2.2 Subsystem Power-Up Sequence	294
4.5.9.4	IVA2 Software Reset Sequence	296
4.5.9.5	IVA2 Global Warm Reset Sequence.....	298
4.5.9.6	IVA2 Power Domain Wake-Up Cold Reset Sequence	300
4.5.9.7	CPEFUSE Reset Sequence	302
4.6	PRCM Power Manager Functional Description	303
4.6.1	Overview	303
4.6.1.1	Introduction	303
4.6.1.2	Device Partitioning	304
4.6.1.3	Memory and Logic Power Management.....	306
4.6.1.4	Power Domain States	307
4.6.1.5	Power State Transitions	307
4.6.1.6	Device Power Modes	308
4.6.1.7	Isolation Between Power Domains.....	308
4.6.2	Power Domain Implementation	308
4.6.2.1	Device Power Domains.....	308
4.6.2.2	Power Domain Memory Status	310
4.6.2.3	Power Domain State Transition Rules.....	310
4.6.2.4	Power Domain Dependencies	310
4.6.2.5	Power Domain Controls	311
4.6.2.5.1	Power Domain Hardware Control	311
4.6.2.5.2	Power Domain Software Controls	311
4.7	PRCM Clock Manager Functional Description.....	312
4.7.1	Overview	312
4.7.1.1	Interface and Functional Clocks	313
4.7.2	External Clock I/Os	313
4.7.2.1	External Clock Inputs	313
4.7.2.1.1	32-kHz Always-On Clock	313
4.7.2.1.2	High-Frequency System Clock.....	313
4.7.2.1.3	Alternate Clock.....	314
4.7.2.2	External Clock Outputs	314
4.7.2.3	Summary	314

4.7.3	Internal Clock Generation.....	315
4.7.3.1	PRM	317
4.7.3.2	CM	319
4.7.3.3	DPLLs	321
4.7.3.3.1	DPLL1 (MPU) and DPLL2 (IVA2)	322
4.7.3.3.2	DPLL3 (CORE)	323
4.7.3.3.3	DPLL4 (Peripherals).....	324
4.7.3.3.4	DPLL5 (Peripherals).....	325
4.7.3.3.5	DPLL Clock Summary	326
4.7.3.4	32-kHz Oscillator	326
4.7.3.5	Summary	326
4.7.4	Clock Distribution	327
4.7.4.1	Power Domain Clock Distribution	327
4.7.4.1.1	MPU Power Domain.....	327
4.7.4.1.2	IVA2 Power Domain	327
4.7.4.1.3	SGX Power Domain	328
4.7.4.1.4	CORE Power Domain.....	329
4.7.4.1.5	EFUSE Power Domain.....	333
4.7.4.1.6	DSS Power Domain	333
4.7.4.1.7	CAM Power Domain.....	334
4.7.4.1.8	USBHOST Power Domain.....	336
4.7.4.1.9	WKUP Power Domain	337
4.7.4.1.10	PER Power Domain	338
4.7.4.1.11	SMARTREFLEX Power Domain	339
4.7.4.1.12	DPLL Domains.....	340
4.7.4.2	Clock Distribution Summary.....	341
4.7.4.2.1	Power Domain Source Clocks	341
4.7.4.2.2	Peripheral Module Clocks	343
4.7.5	External Clock Controls	344
4.7.5.1	Clock Request (sys_clkreq) Control.....	344
4.7.5.2	System Clock Oscillator Control	345
4.7.5.3	External Output Clock1 (sys_clkout1) Control	347
4.7.5.4	External Output Clock2 (sys_clkout2) Control	348
4.7.6	DPLL Control	348
4.7.6.1	DPLL Multiplier and Divider Factors	348
4.7.6.2	DPLL Jitter Correction	348
4.7.6.3	DPLL Frequency Ramp-Up Delay.....	349
4.7.6.4	DPLL Modes	349
4.7.6.5	DPLL Low-Power Mode	351
4.7.6.6	DPLL Clock Path Power Down	351
4.7.6.7	Latencies	352
4.7.6.8	Recalibration	352
4.7.6.9	DPLL Programming Sequence	354
4.7.7	Internal Clock Controls	354
4.7.7.1	PRM Source-Clock Controls	355
4.7.7.2	CM Source-Clock Controls	357
4.7.7.3	Common Interface Clock Controls	358
4.7.7.4	DPLL Source-Clock Controls	359
4.7.7.5	SGX Power Domain Clock Controls	360

4.7.7.6	CORE Power Domain Clock Controls	361
4.7.7.7	EFUSE Power Domain Clock Controls	364
4.7.7.8	DSS Power Domain Clock Controls	364
4.7.7.9	CAM Power Domain Clock Controls	365
4.7.7.10	USBHOST Power Domain Clock Controls	366
4.7.7.11	WKUP Power Domain Clock Controls	367
4.7.7.12	PER Power Domain Clock Controls	368
4.7.7.13	SMARTREFLEX Power Domain Clock Controls	370
4.7.8	Clock Configurations	371
4.7.8.1	Processor Clock Configurations	371
4.7.8.2	Interface and Peripheral Functional Clock Configurations	372
4.8	PRCM Idle and Wake-Up Management	374
4.8.1	Overview	374
4.8.2	Sleep Transition	376
4.8.3	Wakeup	376
4.8.4	Device Wake-Up Events	377
4.8.5	Sleep and Wake-Up Dependencies	382
4.8.5.1	Sleep Dependencies	382
4.8.5.2	Wake-Up Dependencies	384
4.8.6	USBHOST/USBTLL Save-and-Restore Management	386
4.8.6.1	USBHOST SAR Sequences	388
4.8.6.1.1	Save Sequence on Sleep Transition	388
4.8.6.1.2	Restore Sequence on Wake-Up Transition	388
4.8.6.2	USB TLL SAR Sequences	388
4.8.6.2.1	Save Sequence on Sleep Transition	388
4.8.6.2.2	Restore Sequence on Wake-Up Transition	388
4.9	PRCM Interrupts	389
4.10	PRCM Voltage Management Functional Description	391
4.10.1	Overview	391
4.10.2	Voltage Domains	394
4.10.3	Voltage Domains Dependencies	395
4.10.4	Voltage-Control Architecture	396
4.10.5	VDD1 and VDD2 Control	398
4.10.5.1	Direct Control with VMODE Signals	398
4.10.5.2	Direct Voltage Control with I ² C Interface	399
4.10.5.3	Voltage Controller and Dedicated SmartReflex I ² C Interface	399
4.10.5.4	SmartReflex Voltage Control	399
4.10.5.4.1	SmartReflex in the Device	400
4.10.6	Analog Cells, LDOs, and Level Shifter Controls	400
4.10.6.1	SRAM Voltage Control	400
4.10.6.2	Wake-Up and Emulation Voltage Control	401
4.11	PRCM Off-Mode Management	402
4.11.1	Overview	402
4.11.2	Device Off-Mode Configuration	402
4.11.3	CORE Power Domain OFF-Mode Sequences	403
4.11.3.1	Sleep Sequences (Transition From ON to RETENTION/OFF)	403
4.11.3.2	Wake-Up Sequences (Transition from RETENTION/OFF to ON)	404
4.11.4	Device Off-Mode Sequences	404

4.11.4.1	Sleep Sequences	405
4.11.4.1.1	Device Off-Mode Transition without Using the OFF_MODE Signal	405
4.11.4.1.2	Device Off-Mode Transition Using Only the OFF_MODE Signal	405
4.11.4.2	Wake-Up Sequences	406
4.11.4.2.1	Device Wakeup from Off Mode without Using the OFF_MODE Signal	406
4.11.4.2.2	Device Wakeup from Off Mode Using Only the OFF_MODE Signal	406
4.12	PRCM Basic Programming Model	407
4.12.1	Global Registers	407
4.12.1.1	Revision Information Registers	407
4.12.1.2	PRCM Configuration Registers	407
4.12.1.3	Interrupt Configuration Registers	407
4.12.1.3.1	MPU Interrupt Event Sources	407
4.12.1.3.2	MPU Interrupt Registers	408
4.12.1.3.3	IVA2.2 Interrupt Event Sources	409
4.12.1.3.4	IVA2 Interrupt Registers	409
4.12.1.4	Event Generator Control Registers	409
4.12.1.5	Output Signal Polarity Control Registers	409
4.12.1.5.1	CM_POLCTRL (CM Polarity Control Register)	409
4.12.1.5.2	PRM_POLCTRL (PRM Polarity Control Register)	411
4.12.1.6	SRAM Precharge Time Control Register	411
4.12.1.6.1	PRM_SRAM_PCHARGE (Voltage SRAM Precharge Counter Register)	411
4.12.2	Clock Management Registers	411
4.12.2.1	System Clock Control Registers	411
4.12.2.1.1	PRM_CLKSRC_CTRL (Clock Source Control Register)	411
4.12.2.1.2	PRM_CLKSETUP (Source-Clock Setup Register)	411
4.12.2.1.3	PRM_CLKSEL (Source-Clock Selection Register)	411
4.12.2.2	External Clock Output Control Registers	412
4.12.2.2.1	PRM_CLKOUT_CTRL (Clock Out Control Register)	412
4.12.2.2.2	CM_CLKOUT_CTRL (Clock Out Control Register)	412
4.12.2.3	DPLL Clock Control Registers	412
4.12.2.3.1	CM_CLKSELn_PLL_<processor_name> (Processor DPLL Clock Selection Register)	412
4.12.2.3.2	CM_CLKSELn_PLL (DPLL Clock Selection Register)	412
4.12.2.3.3	CM_CLKEN_PLL_<processor_name> (Processor DPLL Clock Enable Register)	413
4.12.2.3.4	CM_CLKEN_PLL (DPLL Enable Register)	413
4.12.2.3.5	CM_AUTOIDLE_PLL_<processor_name> (Processor DPLL Autoidle Register)	414
4.12.2.3.6	CM_AUTOIDLE_PLL (DPLL Autoidle Register)	414
4.12.2.3.7	CM_AUTOIDLE1_PLL (DPLL5 Autoidle Register)	414
4.12.2.3.8	CM_IDLEST_CKGEN (Source-Clock Idle-Status Register)	414
4.12.2.3.9	CM_IDLEST2_CKGEN (DPLL5 Source-Clock Idle-Status Register)	415
4.12.2.3.10	CM_IDLEST_PLL_<processor_name> (Processor DPLL Idle-Status Register)	415
4.12.2.4	Power-Domain Clock Control Registers	415
4.12.2.4.1	CM_CLKSEL_<domain_name> (Clock Select Register)	415
4.12.2.4.2	CM_FCLKEN_<domain_name> (Functional Clock Enable Register)	416
4.12.2.4.3	CM_ICLKEN_<domain_name> (Interface Clock Enable Register)	416
4.12.2.4.4	CM_AUTOIDLE_<domain_name> (Autoidle Register)	417
4.12.2.4.5	CM_IDLEST_<domain_name> (Idle-Status Register)	417
4.12.2.4.6	CM_CLKSTCTRL_<domain_name> (Clock State Control Register)	418
4.12.2.4.7	CM_CLKSTST_<domain_name> (Clock State Status Register)	419
4.12.2.4.8	CM_SLEEPDEP_<domain_name> (Sleep Dependency Control Register)	420

4.12.2.5	Domain Wake-Up Control Registers	420
4.12.2.5.1	PM_WKEN_<domain_name> (Wake-Up Enable Register)	421
4.12.2.5.2	PM_WKST_<domain_name> (Wake-Up Status Register)	421
4.12.2.5.3	PM_WKDEP_<domain_name> (Wake-Up Dependency Register)	421
4.12.2.5.4	PM_<processor_name>GRPSEL_<domain_name> (Processor Group Selection Register)	423
4.12.3	Reset Management Registers	423
4.12.3.1	Reset Control	423
4.12.3.1.1	PRM_RSTTIME (Reset Time Register)	423
4.12.3.1.2	RM_RSTCTRL_<domain_name> (Reset Control Register)	423
4.12.3.1.3	RM_RSTST_<domain_name> (Reset Status Register)	424
4.12.4	Power Management Registers	425
4.12.4.1	PM_PWSTCTRL_<domain_name> (Power State Control Register)	425
4.12.4.2	PM_PWSTST_<domain_name> (Power State Status Register)	427
4.12.4.3	PM_PREPWSTST_<domain_name> (Previous Power State Status Register)	428
4.12.5	Voltage Management Registers	428
4.12.5.1	External Voltage Control Register Descriptions	428
4.12.5.1.1	PRM_VOLTSETUP (Voltage Setup Time Register)	429
4.12.5.1.3	PRM_VOLTOFFSET (Voltage Offset Register)	429
4.12.5.1.4	PRM_VOLTCTRL (Voltage Source Control Register)	430
4.12.5.2	Voltage Controller Registers	430
4.12.5.2.1	PRM_VC_SMPS_SA (Voltage Controller SMPS Slave Address Register)	431
4.12.5.2.2	PRM_VC_SMPS_VOL_RA (Voltage Controller SMPS Voltage Register Address Register)	431
4.12.5.2.3	PRM_VC_SMPS_CMD_RA (Voltage Controller SMPS Command Register Address Register)	431
4.12.5.2.4	PRM_VC_CMD_VAL_0 and PRM_VC_CMD_VAL_1 (Voltage Controller Command and Voltage Value Register 0 and 1)	431
4.12.5.2.5	PRM_VC_CH_CONF (Voltage Controller Channel Configuration Register)	431
4.12.5.2.6	PRM_VC_I2C_CFG (Voltage Controller I ² C Interface Configuration Register)	431
4.12.5.2.7	PRM_VC_BYPASS_VAL (Voltage Controller Bypass Command Register)	431
4.12.6	Generic Programming Examples	432
4.12.6.1	Clock Control	432
4.12.6.1.1	Enabling and Disabling the Functional Clocks	432
4.12.6.1.2	Enabling and Disabling the Interface Clocks	434
4.12.6.1.3	Enabling and Disabling the INACTIVE State	435
4.12.6.1.4	Processor Clock Control	436
4.12.6.2	Reset Management	439
4.12.6.3	Wake-Up Control	439
4.12.6.4	Voltage Controller Initialization Basic Programming Model	441
4.12.6.5	Event Generator Programming Examples	443
4.13	PRCM Use Cases and Tips	444
4.13.1	Voltage Control Using VMODE	444
4.13.1.1	Introduction	444
4.13.1.2	Programming Sequence	444
4.13.1.2.1	Initialization Procedure	444
4.13.1.2.2	VMODE Signals Toggling	445
4.13.1.2.3	Summary Flow Chart	446
4.14	PRCM Registers	447
4.14.1	CM Module Registers	447

4.14.1.1	CM Module Registers Mapping Summary	447
4.14.1.2	IVA2_CM Register Descriptions	451
4.14.1.2.1	CM_FCLKEN_IVA2	451
4.14.1.2.2	CM_CLKEN_PLL_IVA2.....	451
4.14.1.2.3	CM_IDLEST_IVA2	453
4.14.1.2.4	CM_IDLEST_PLL_IVA2	453

16-35 Register Call Summary for Register TWPS.....	2473
16-36 TMAR	2473
16-37 Register Call Summary for Register TMAR.....	2474
16-38 TCAR1	2474
16-39 Register Call Summary for Register TCAR1	2474
16-40 TSICR.....	2475
16-41 Register Call Summary for Register TSICR	2475
16-42 TCAR2.....	2476
16-43 Register Call Summary for Register TCAR2	2476

16-44	TPIR.....	2476
16-45	Register Call Summary for Register TPIR	2477
16-46	TNIR	2477
16-47	Register Call Summary for Register TNIR	2477
16-48	TCVR	2478
16-49	Register Call Summary for Register TCVR	2478
16-50	TOCR	2478
16-51	Register Call Summary for Register TOCR.....	2478
16-52	TOWR.....	2479
16-53	Register Call Summary for Register TOWR	2479
16-54	WD Timers Default State for GP, EMU and HS Device.....	2480
16-55	Clock, Power, and Reset Domains for WDTs	2482
16-56	WDT PRCM Clock Control Bits.....	2482
16-57	IDLEMODE Settings	2483
16-58	CLOCKACTIVITY Settings.....	2484
16-59	WDT Interrupt Names and Processor IRQ Mapping	2485
16-60	Count and Prescaler Default Reset Values.....	2485
16-61	Prescaler Clock Ratios	2486
16-62	Reset Period Examples	2487
16-63	Default WDT Time Periods.....	2487
16-64	WDT Instance Summary	2490
16-65	WDT1 Register Summary	2490
16-66	WDT2 Register Summary	2490
16-67	WDT3 Register Summary	2491
16-68	WD_SYSCONFIG	2491
16-69	Register Call Summary for Register WD_SYSCONFIG	2492
16-70	WD_SYSSTATUS.....	2492
16-71	Register Call Summary for Register WD_SYSSTATUS	2493
16-72	WISR.....	2493
16-73	Register Call Summary for Register WISR	2493
16-74	WIER.....	2494
16-75	Register Call Summary for Register WIER	2494
16-76	WCLR.....	2494
16-77	Register Call Summary for Register WCLR	2495
16-78	WCRR	2495
16-79	Register Call Summary for Register WCRR	2495
16-80	WLDR.....	2496
16-81	Register Call Summary for Register WLDR	2496
16-82	WTGR.....	2496
16-83	Register Call Summary for Register WTGR	2496
16-84	WWPS	2497
16-85	WSPR.....	2497
16-86	Register Call Summary for Register WSPR	2498
16-87	Clock, Power, and Reset Domains for 32-kHz Sync Timer.....	2500
16-88	32-kHz Sync Timer Instance Summary	2501
16-89	Sync Timer Register Summary.....	2501
16-90	REG_32KSYNCNT_SYSCONFIG	2501
16-91	Register Call Summary for Register REG_32KSYNCNT_SYSCONFIG.....	2502
16-92	REG_32KSYNCNT_CR	2502
16-93	Register Call Summary for Register REG_32KSYNCNT_CR.....	2502
16-94	Document Revision History	2503

17-1	UART Mode Baud Rates, Divisor Values, and Error Rates	2507
17-2	UART IrDA Mode Baud Rates, Divisor Values, and Error Rates	2508
17-3	UART I/O Pin Description	2510
17-4	UART3 I/O Description	2511
17-5	EFR_REG[0-1] IR Address Checking Options	2514
17-6	FIR Transmit Frame Format	2517
17-7	4-PPM Format	2517
17-8	FIR Preamble, Start Flag, and Stop Flag	2517
17-9	FIR Data Byte Transmission Order Example	2517
17-10	CIR I/O Description	2518
17-11	UART Clocks.....	2522
17-12	Reset Domain.....	2523
17-13	Power Domain	2523
17-14	Interrupt Mapping to MPU Subsystem.....	2524
17-15	Interrupt Mapping to IVA2.2 Subsystem	2524
17-16	UART DMA Requests to System DMA.....	2524
17-17	UART DMA Requests to IVA2.2 Subsystem DMA	2524
17-18	Wake-Up Requests from PRCM	2524
17-19	TX FIFO Trigger Level Setting Summary	2528
17-20	RX FIFO Trigger Level Setting Summary	2528
17-21	UART/IrDA/CIR Register Access Mode Programming (Using LCR_REG)	2535
17-22	Sub-Configuration_Mode_A Mode Summary.....	2535
17-23	Sub-Configuration_Mode_B Mode Summary.....	2535
17-24	Sub-Operational_Mode Mode Summary	2535
17-25	UART/IrDA/CIR Register Access Mode Overview	2536
17-26	UART Mode Selection	2537
17-27	UART Mode Register Overview	2537
17-28	IrDA Mode Register Overview	2538
17-29	CIR Mode Register Overview.....	2539
17-30	UART Baud Rate Settings (48-MHz Clock).....	2540
17-31	UART Parity Bit Encoding.....	2541
17-32	EFR_REG[0-3] Software Flow Control Options	2542
17-33	UART Mode Interrupts.....	2545
17-34	IrDA Baud Rates Settings.....	2547
17-35	IrDA Mode Interrupts.....	2551
17-36	Duty Cycle.....	2553
17-37	CIR Mode Interrupts	2554
17-38	Instance Summary	2563
17-39	UART Mode Overview	2563
17-40	UART1/2/3 Mode Summary.....	2564
17-41	UART1/2/3 Register Summary for Configuration_Mode_A Mode Active	2564
17-42	UART1/2/3 Subconfiguration_Mode_A Mode Summary	2564
17-43	UART1/2/3 Register Summary for Sub-Configuration_Mode_A Mode: MSR_SPR Mode Active	2565
17-44	UART1/2/3 Register Summary for Sub-Configuration_Mode_A Mode: TCR_TLR Mode Active	2565
17-45	UART1/2/3 Register Summary for Configuration_Mode_B Mode Active	2565
17-46	UART1/2/3 Sub-Configuration_Mode_B Mode Summary	2566
17-47	UART1/2/3 Register Summary for Sub-Configuration_Mode_B Mode: TCR_TLR Mode Active	2566
17-48	UART1/2/3 Register Summary for Sub-Configuration_Mode_B Mode: XOFF Mode Active	2566
17-49	UART1/2/3 Register Summary for Operational_Mode Mode Active.....	2566
17-50	UART1/2/3 Sub-Operational_Mode Mode Summary	2567
17-51	UART1/2/3 Register Summary for Sub-Operational_Mode Mode: MSR_SPR Mode Active.....	2567

17-52	UART1/2/3 Register Summary for Suboperational_Mode Mode: TCR_TLR Mode Active	2567
17-53	DLL_REG	2568
17-54	Register Call Summary for Register DLL_REG	2568
17-55	RHR_REG.....	2569
17-56	Register Call Summary for Register RHR_REG	2569
17-57	THR_REG	2570
17-58	Register Call Summary for Register THR_REG	2570
17-59	IER_REG	2570
17-60	Register Call Summary for Register IER_REG	2571
17-61	DLH_REG	2573
17-62	Register Call Summary for Register DLH_REG.....	2574
17-63	FCR_REG	2574
17-64	Register Call Summary for Register FCR_REG	2575
17-65	IIR_REG	2576
17-66	Register Call Summary for Register IIR_REG.....	2577
17-67	EFR_REG	2578
17-68	Register Call Summary for Register EFR_REG.....	2579
17-69	LCR_REG	2580
17-70	Register Call Summary for Register LCR_REG.....	2581
17-71	MCR_REG	2581
17-72	Register Call Summary for Register MCR_REG	2582
17-73	XON1_ADDR1_REG	2583
17-74	Register Call Summary for Register XON1_ADDR1_REG	2583
17-75	LSR_REG	2583
17-76	Register Call Summary for Register LSR_REG.....	2584
17-77	XON2_ADDR2_REG	2586
17-78	Register Call Summary for Register XON2_ADDR2_REG	2586
17-79	XOFF1_REG.....	2587
17-80	Register Call Summary for Register XOFF1_REG	2587
17-81	TCR_REG	2587
17-82	Register Call Summary for Register TCR_REG	2588
17-83	MSR_REG	2588

21-122	MCBSP_LP_XCCR_REG.....	2961
21-123	Register Call Summary for Register MCBSP_LP_XCCR_REG	2962
21-124	MCBSP_LP_RCCR_REG.....	2963
21-125	Register Call Summary for Register MCBSP_LP_RCCR_REG	2964
21-126	MCBSP_LP_XBUFFSTAT_REG.....	2964
21-127	Register Call Summary for Register MCBSP_LP_XBUFFSTAT_REG	2964
21-128	MCBSP_LP_RBUFFSTAT_REG.....	2965
21-129	Register Call Summary for Register MCBSP_LP_RBUFFSTAT_REG	2965
21-130	MCBSP_LP_SSELCR_REG.....	2965
21-131	Register Call Summary for Register MCBSP_LP_SSELCR_REG	2966
21-132	MCBSP_LP_STATUS_REG.....	2966
21-133	Register Call Summary for Register MCBSP_LP_STATUS_REG	2967
21-134	ST_SYSCONFIG_REG	2967
21-135	Register Call Summary for Register ST_SYSCONFIG_REG	2967
21-136	ST_IRQSTATUS_REG	2967
21-137	Register Call Summary for Register ST_IRQSTATUS_REG	2968

21-138 ST_IRQENABLE_REG	2968
21-139 Register Call Summary for Register ST_IRQENABLE_REG	2968
21-140 ST_SGAINCR_REG.....	2969
21-141 Register Call Summary for Register ST_SGAINCR_REG	2969
21-142 ST_SFIRCR_REG	2969
21-143 Register Call Summary for Register ST_SFIRCR_REG	2970
21-144 ST_SSELCR_REG	2970
21-145 Register Call Summary for Register ST_SSELCR_REG.....	2970
21-146 Document Revision History	2972
22-1 MMC/SD/SDIOi I/O Description	2979
22-2 MMC/SD/SDIO2 I/O Description	2980
22-3 Relation Between Configuration and Name of Response Type.....	2984
22-4 SmartIdle Mode and Wakeup Capabilities	2988
22-5 MMC, SD, SDIO responses in the MMCHS_RSPxx registers	3000
22-6 CC and TC Values Upon Error Detected	3000
22-7 MMC/SD/SDIOi Controller Transfer Stop Command Summary.....	3002
22-8 Register Print for the MMCHS1 controller's clocks Initialization	3022
22-9 MMCHS Controller Voltage Capabilities Initialization	3022
22-10 MMC Controller Default Initialization Values.....	3023
22-11 MMCHS Controller INIT Procedure Start	3023
22-12 MMCHS Controller Pre-Card Identification Configuration.....	3024
22-13 Sending CMD0	3024
22-14 Sending CMD5	3024
22-15 Sending CMD8	3025
22-16 Sending CMD55.....	3025
22-17 Sending CMD1	3025
22-18 Sending CMD2	3026
22-19 Sending CMD3	3026
22-20 MMC Bus Setting Change Table.....	3027
22-21 Sending CMD9	3027
22-22 MMCHS_SYSCTL Value.....	3028
22-23 Sending CMD7	3028
22-24 Setting Data Bus Width with CMD6.....	3028
22-25 MMCHS_CON Value	3029
22-26 Enabling High Speed with CMD6	3029
22-27 MMCHS_SYSCTL Value	3029
22-28 Setting Block Length	3030
22-29 Setting Number of Blocks	3030
22-30 CMD25 Issuing	3030
22-31 CMD18 Issuing	3031
22-32 Instance Summary	3033
22-33 MMC/SD/SDIO1 Register Offset Addresses.....	3033
22-34 MMC/SD/SDIO2 Register Offset Addresses.....	3034
22-35 MMC/SD/SDIO3 Register Offset Addresses.....	3034
22-36 MMCHS_SYSCONFIG	3035
22-37 Register Call Summary for Register MMCHS_SYSCONFIG.....	3036
22-38 MMCHS_SYSSTATUS	3036
22-39 Register Call Summary for Register MMCHS_SYSSTATUS.....	3037
22-40 MMCHS_CSRE.....	3037
22-41 Register Call Summary for Register MMCHS_CSRE	3037
22-42 MMCHS_SYSTEST.....	3038

22-43	Register Call Summary for Register MMCHS_SYSTEST	3038
22-44	MMCHS_CON	3038
22-45	Register Call Summary for Register MMCHS_CON.....	3041
22-46	MMCHS_PWCNT	3041
22-47	Register Call Summary for Register MMCHS_PWCNT	3041
22-48	MMCHS_BLK	3042
22-49	Register Call Summary for Register MMCHS_BLK.....	3042
22-50	MMCHS_ARG	3043
22-51	Register Call Summary for Register MMCHS_ARG.....	3043
22-52	MMCHS_CMD	3044
22-53	Register Call Summary for Register MMCHS_CMD	3045
22-54	MMCHS_RSP10.....	3046
22-55	Register Call Summary for Register MMCHS_RSP10	3046
22-56	MMCHS_RSP32.....	3047
22-57	Register Call Summary for Register MMCHS_RSP32	3047
22-58	MMCHS_RSP54.....	3047
22-59	Register Call Summary for Register MMCHS_RSP54	3047
22-60	MMCHS_RSP76.....	3048
22-61	Register Call Summary for Register MMCHS_RSP76	3048
22-62	MMCHS_DATA	3049
22-63	Register Call Summary for Register MMCHS_DATA	3049
22-64	MMCHS_PSTATE.....	3050
22-65	Register Call Summary for Register MMCHS_PSTATE	3051
22-66	MMCHS_HCTL	3052
22-67	Register Call Summary for Register MMCHS_HCTL.....	3054
22-68	MMCHS_SYSCTL.....	3054
22-69	Register Call Summary for Register MMCHS_SYSCTL	3056
22-70	MMCHS_STAT	3056
22-71	Register Call Summary for Register MMCHS_STAT.....	3060
22-72	MMCHS_IE.....	3060
22-73	Register Call Summary for Register MMCHS_IE	3062
22-74	MMCHS_ISE.....	3062
22-75	Register Call Summary for Register MMCHS_ISE	3063
22-76	MMCHS_AC12	3064
22-77	Register Call Summary for Register MMCHS_AC12.....	3065
22-78	MMCHS_CAPA.....	3065
22-79	Register Call Summary for Register MMCHS_CAPA	3066
22-80	MMCHS_CUR_CAPA	3067
22-81	Register Call Summary for Register MMCHS_CUR_CAPA.....	3067
22-82	MMCHS_REV.....	3069
22-83	Register Call Summary for Register MMCHS_REV	3069
22-84	Document Revision History	3070
23-1	USB Clocks	3075
23-2	High-Speed USB Interface Clock	3075
23-3	Input/Output Description.....	3076
23-4	PERI_TXCSR Register Bit Configuration for Bulk IN Transactions	3090
23-5	PERI_RXCSR Register Bit Configuration for Bulk OUT Transactions	3092
23-6	PERI_TXCSR Register Bit Configuration for Isochronous IN Transactions	3094
23-7	PERI_RXCSR Register Bit Configuration for Isochronous OUT Transactions.....	3095
23-8	High-Speed USB Master Interface Power Management Modes	3116
23-9	High-Speed USB Slave Interface Power Management Modes	3117

23-10	Universal Serial Bus (USB) Registers	3121
23-11	Function Address Register (FADDR) Field Descriptions.....	3132
23-12	Power Management Register (POWER) Field Descriptions.....	3133
23-13	Interrupt Register for Endpoint 0 Plus Transmit Endpoints 1 to 15 (INTRTX) Field Descriptions	3133
23-14	Interrupt Register for Receive Endpoints 1 to 15 (INTRRX) Field Descriptions	3134
23-15	Interrupt Enable Register for INTRTX (INTRTXE) Field Descriptions.....	3135
23-16	Interrupt Enable Register for INTRRX (INTRRXE) Field Descriptions	3136
23-17	Interrupt Register for Common USB Interrupts (INTRUSB) Field Descriptions	3137
23-18	Interrupt Enable Register for INTRUSB (INTRUSB) Field Descriptions	3138
23-19	Frame Number Register (FRAME) Field Descriptions	3139
23-20	Index Register for Selecting the Endpoint Status and Control Registers (INDEX) Field Descriptions.....	3139
23-21	Register to Enable the USB 2.0 Test Modes (TESTMODE) Field Descriptions	3140
23-22	Maximum Packet Size for Peripheral/Host Transmit Endpoint (TXMAXP) Field Descriptions	3141
23-23	Control Status Register for Endpoint 0 in Peripheral Mode (PERI_CSR0) Field Descriptions.....	3142
23-24	Control Status Register for Endpoint 0 in Host Mode (HOST_CSR0) Field Descriptions	3143
23-25	Control Status Register for Peripheral Transmit Endpoint (PERI_TXCSR) Field Descriptions	3144
23-26	Control Status Register for Host Transmit Endpoint (HOST_TXCSR) Field Descriptions.....	3145
23-27	Maximum Packet Size for Peripheral Host Receive Endpoint (RXMAXP) Field Descriptions	3146
23-28	Control Status Register for Peripheral Receive Endpoint (PERI_RXCSR) Field Descriptions.....	3147
23-29	Control Status Register for Host Receive Endpoint (HOST_RXCSR) Field Descriptions	3148
23-30	Count 0 Register (COUNT0) Field Descriptions	3150
23-31	Receive Count Register (RXCOUNT) Field Descriptions	3150
23-32	Type Register (Host mode only) (HOST_TYPE0) Field Descriptions	3151
23-33	Transmit Type Register (Host mode only) (HOST_TXTYPE) Field Descriptions.....	3151
23-34	NAKLimit0 Register (Host mode only) (HOST_NAKLIMIT0) Field Descriptions	3153
23-35	Transmit Interval Register (Host mode only) (HOST_TXINTERVAL) Field Descriptions.....	3153
23-36	Receive Type Register (Host mode only) (HOST_RXTYPE) Field Descriptions	3154
23-37	Receive Interval Register (Host mode only) (HOST_RXINTERVAL) Field Descriptions	3155
23-38	Configuration Data Register (CONFIGDATA) Field Descriptions.....	3155
23-39	Transmit and Receive FIFO Register for Endpoints _n (FIFO _n) Field Descriptions	3157
23-40	OTG Device Control Register (DEVCTL) Field Descriptions	3158
23-41	Transmit Endpoint FIFO Size (TXFIFOSZ) Field Descriptions	3159
23-42	Receive Endpoint FIFO Size (RXFIFOSZ) Field Descriptions	3159
23-43	Transmit Endpoint FIFO Address (TXFIFOADDR) Field Descriptions	3160
23-44	Receive Endpoint FIFO Address (RXFIFOADDR) Field Descriptions	3160
23-45	ULPI VBUS Control Register (ULPIVBUSCONTROL) Field Descriptions	3161
23-46	ULPI UTMI Control Register (ULPIUTMICONTROL) Field Descriptions	3161
23-47	ULPI Interrupt Mask Register (ULPIINTMASK) Field Descriptions	3162
23-48	ULPI Interrupt Source Register (ULPIINTSRC) Field Descriptions.....	3162
23-49	ULPI Data Register (ULPIREGDATA) Field Descriptions	3162
23-50	ULPI Address Register (ULPIREGADDR) Field Descriptions.....	3163
23-51	ULPI Control Register (ULPIREGCONTROL) Field Descriptions	3163
23-52	Asynchronous Modes (ULPIRAWDATA) Field Descriptions	3164
23-53	Synchronous Modes (ULPIRAWDATA) Field Descriptions.....	3164
23-54	Transmit Function Address (TXFUNCADDR) Field Descriptions	3165
23-55	Transmit Hub Address (TXHUBADDR) Field Descriptions	3165
23-56	Transmit Hub Port (TXHUBPORT) Field Descriptions	3165
23-57	Receive Function Address (RXFUNCADDR) Field Descriptions	3166
23-58	Receive Hub Address (RXHUBADDR) Field Descriptions.....	3166
23-59	Receive Hub Port (RXHUBPORT) Field Descriptions.....	3166
23-60	DMA Interrupts (DMA_INTR)	3167

23-61	DMA Control Register for Channel <i>n</i> (CNTL_CH <i>n</i>).....	3167
23-62	DMA Address Register for DMA Channel <i>n</i> (ADDR_CH <i>n</i>)	3168
23-63	DMA Count Register for DMA Channel <i>n</i> (COUNT_CH <i>n</i>).....	3169
23-64	Number of Requested Packets for Receive Endpoint <i>n</i> (RqPktCount <i>n</i>)	3169
23-65	OTG High-Speed Core Revision Register (OTG_REVISION) Field Descriptions	3170
23-66	OTG High-Speed System Configuration Register (OTG_SYSCONFIG) Field Descriptions	3171
23-67	OTG High-Speed System Status Register (OTG_SYSSTATUS) Field Descriptions	3172
23-68	OTG High-Speed Interface Selection Register (OTG_INTERFSEL) Field Descriptions.....	3173
23-69	OTG High-Speed Forced Stand By Register (OTG_FORCESTDBY) Field Descriptions	3174
23-70	USB Connectivity Modes	3178
23-71	I/O Description	3186
23-72	Signaling Between High-Speed USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DAT/SE0 Signaling)	3189
23-73	Signaling Between High-Speed USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DP/DM Signaling).....	3189
23-74	Signaling Between High-Speed USB Host Subsystem and 3-Pin Bidirectional USB Transceiver Using DAT/SE0 Signaling.....	3190
23-75	Signaling Between High-Speed USB Host Subsystem and 4-Pin Bidirectional USB Transceiver Using DP/DM Signaling	3191
23-76	Pullup/Pulldown Configuration for DP/DM Encoding	3198
23-77	Pullup/Pulldown Configuration for DAT/SE0 Encoding.....	3199
23-78	I/O Description	3199
23-79	High-Speed USB Host Subsystem Reset Description	3203
23-80	High-Speed USB Host Subsystem Clocks	3204
23-81	High-Speed USB Controller L3 Master Interface Clock	3205
23-82	USBTLL Module Interface Clock	3205
23-83	High-Speed USB Host Controller PRCM Clock Control Bits	3206
23-84	High-Speed USB Host Controller MIDDLEMODE Settings.....	3207
23-85	High-Speed USB Host Controller SIDLEMODE Settings	3207
23-86	High-Speed USB Host Controller CLOCKACTIVITY Settings.....	3208
23-87	USBTLL Module PRCM Clock Control Bits.....	3208
23-88	USBTLL Module SIDLEMODE Settings.....	3209
23-89	USBTLL Module CLOCKACTIVITY Settings	3209
23-90	High-Speed USB Host Subsystem Interrupts	3210
23-91	USBTLL Channel USB Ports	3215
23-92	USBTLL Channel Configuration	3216
23-93	VBUS Level Software Reporting for Serial Transceiver Configuration.....	3218
23-94	Emulation of VBUS Levels for UTMI-to-ULPI TLL Mode.....	3219
23-95	Serial Mode Description, Signal Functionality	3220
23-96	Pullup Enable Emulation in Serial TLL Modes	3221
23-97	USBTLL Registers Impacted by the SAR Context.....	3222
23-98	USB Connectivity Mode Description	3225
23-99	ULPI Register Mapping Summary (For a Single ULPI Port).....	3226
23-100	Instance Summary.....	3227
23-101	USBTLL Register Mapping Summary (L4-Core Interconnect Register Space)	3228
23-102	UHH_config Register Mapping Summary	3229
23-103	OHCI Register Mapping Summary	3229
23-104	EHCI Register Mapping Summary	3230
23-105	USBTLL_REVISION.....	3232

Introduction

This chapter introduces the features, supporting subsystems, and architecture of the OMAP35x high-performance applications processors.

Topic		Page
1.1	Overview	182
1.2	Environment	184
1.3	Description	185
1.4	Package-On-Package Concept	191
1.5	OMAP35x Family	193
1.6	Revision History	199

1.1 Overview

The OMAP35x family of high-performance, applications processors are based on the enhanced OMAP™ 3 architecture and are integrated on TI's advanced 65-nm process technology.

Note: The OMAP 3 architecture is configured with different sets of features in different devices. This technical reference manual details all of the features available in current and future OMAP35x devices. Some features may not be available or supported in your particular device. For more information, see [Section 1.5, OMAP35x Family](#) and your device-specific data manual.

The architecture is designed to provide best-in-class video, image, and graphics processing sufficient to support the following:

- Streaming video
- 2D/3D mobile gaming
- Video conferencing
- High-resolution still image
- Video capture in 2.5G wireless terminals, 3G wireless terminals, and rich multimedia-featured handsets, and high-performance personal digital assistants (PDAs).

This OMAP device also features the M-Shield™ mobile security technology to enable more secure e-commerce applications and the replay of copyright-protected digital media content.

Security features integrated on the devices support applications designed for:

- Protection against malicious attacks
- M-commerce
- Content protection for recordable media (CPRM)
- Digital rights management (DRM)

High-security (HS) devices rely on a security scheme based on hardware mechanisms and a secure read-only memory (ROM) code, ensuring that only trusted code can access the secure resources. These resources are in specific regions of memories as well as in peripherals, hardware cryptographic accelerators, and eFuse keys. General-purpose (GP) devices do not include a security feature.

Note: This technical reference manual focuses only on general-purpose (GP) devices. To determine if a high-security (HS) version of your device is available and for more information on HS devices, see [Section 1.5, OMAP35x Family](#), and your device-specific data manual.

The device supports high-level operating systems (OSs), such as:

- Windows CE
- Linux

This OMAP device includes state-of-the-art power-management techniques required for high-performance mobile products.

The following subsystems are part of the device:

- Microprocessor unit (MPU) subsystem based on the ARM® Cortex™-A8 microprocessor
- IVA2.2 subsystem with a C64x+ digital signal processor (DSP) core
- SGX subsystem for 2D and 3D graphics acceleration to support display and gaming effects

Note: IVA2.2 and SGX are not available on all devices. See [Section 1.5, OMAP35x Family](#), for more information on available features.

- Camera image signal processor (ISP) that supports multiple formats and interfacing options connected

to a wide variety of image sensors

- Display subsystem with a wide variety of features for multiple concurrent image manipulation, and a programmable interface supporting a wide variety of displays. The display subsystem also supports NTSC/PAL video out.
- Level 3 (L3) and level 4 (L4) interconnects that provide high-bandwidth data transfers for multiple initiators to the internal and external memory controllers and to on-chip peripherals

The device also offers:

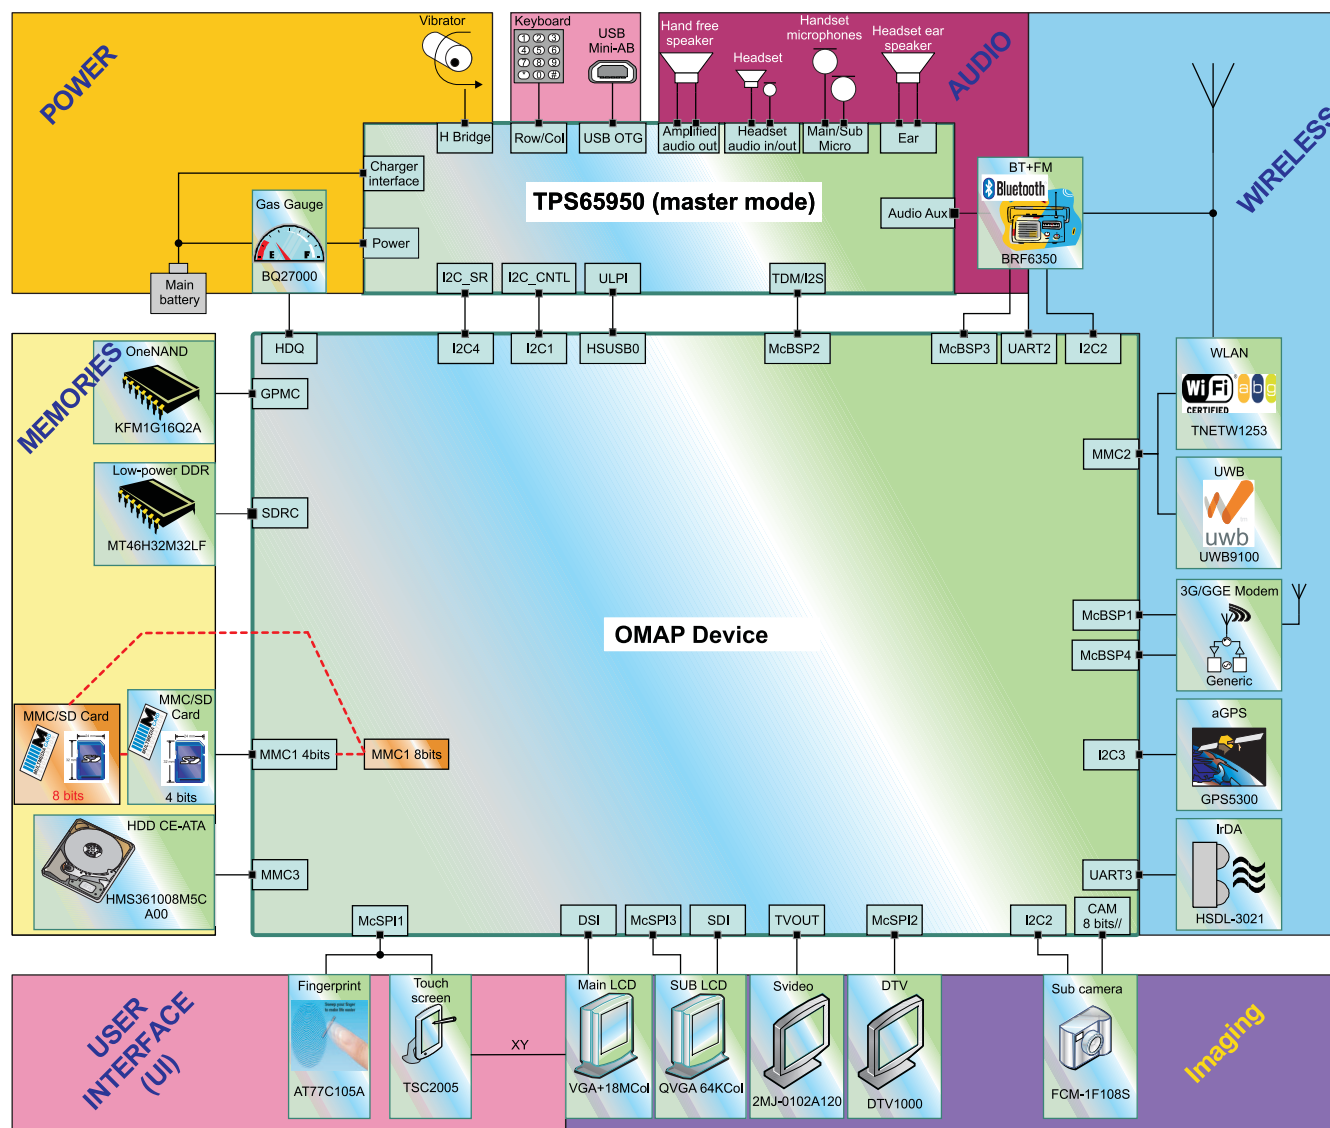

- A comprehensive power and clock-management scheme that enables high-performance, low-power operation, and ultralow-power standby features. The device also supports SmartReflex™ adaptative voltage control. This power management technique for automatic control of the operating voltage of a module reduces the active power consumption.
- A memory stacking feature using the package-on-package (POP) implementation (see [Section 1.4](#), *Package-on-Package Concept*)

1.2 Environment

This section provides an overview of the OMAP environment. The device is associated with a power integrated circuit (IC). Texas Instruments provides a global solution with the TPS65950 device. For more information on the TPS65950 device, contact your TI representative.

Figure 1-1 provides an overview of a nonexhaustive environment for the high-tier OMAP35x device.

Figure 1-1. OMAP35x Environment Using TPS65950

108-001

Note: Some features are not available on all devices. See [Section 1.5, OMAP35x Family](#), for more information on available features.

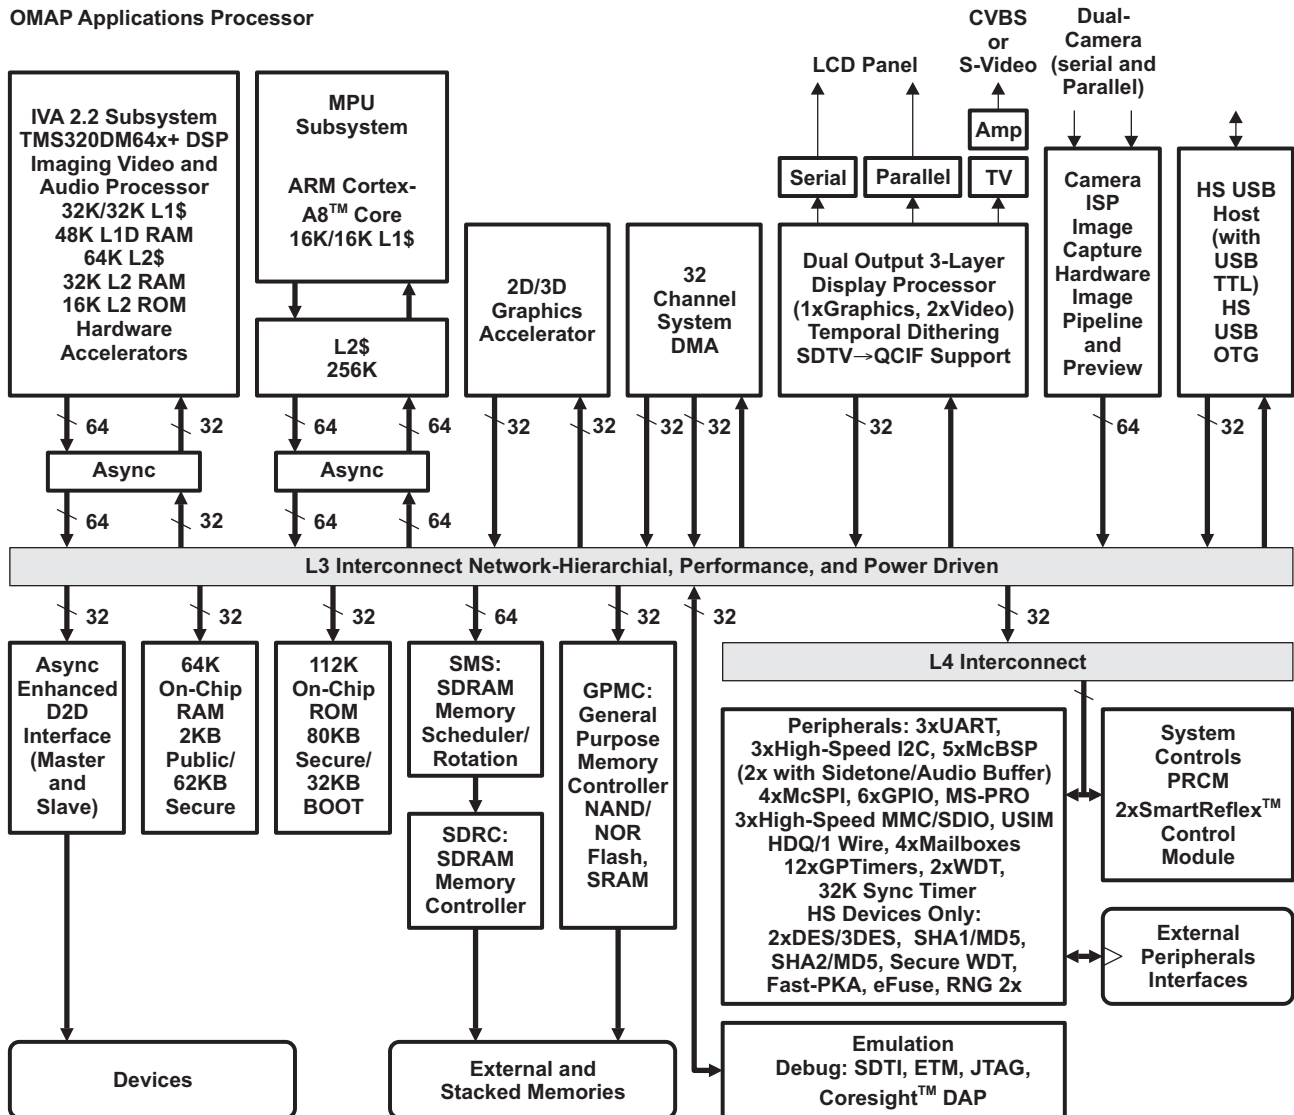

1.3 Description

The device is offered in two packages:

- CBB package: 515-ball, 12 x 12 mm, package-on-package (POP) 0.5-mm (top) and 0.4-mm (bottom) ball pitch package. Some balls are available at the top of the device to allow memory stacking. For more information, see [Section 1.4, Package-on-Package Concept](#).
- CUS package: 423-ball, 16 x 16mm, 0.65-mm (bottom) ball pitch package

Figure 1-2 shows the block diagram.

Figure 1-2. Block Diagram

Note: Some features are not available on all devices. See [Section 1.5, OMAP35x Family](#), for more information on available features.

1.3.1 MPU Subsystem

The MPU subsystem integrates the following modules

- ARM subchip

- ARM® Cortex™-A8 core
- ARM Version 7™ ISA: Standard ARM instruction set + Thumb®-2, Jazelle® RCT Java accelerator, and media extensions
- NEON™ SIMD coprocessor (VFP lite + media streaming instructions)
- Cache memories
 - Level 1: 16KB instruction and 16KB data—4-way set associative cache, 64 bytes/line
 - Level 2: see [Section 1.5](#), *OMAP35x Family*.
- Interrupt controller (MPU IN TC) of 96 synchronous interrupt lines
- Asynchronous interface with core logic
- Debug, trace, and emulation features: ICE-Crusher, ETM, ETB modules.

1.3.2 IVA2.2 Subsystem

The device includes a high-performance imaging video and audio (IVA2.2) accelerator based on the Texas Instruments TMS320DMC64x+ VLIW DSP core.

The IVA2.2 subsystem includes the following main features:

- 32-bit fixed-point media processor
- Very long instruction word (VLIW) architecture based on the programmable enhanced version of C64x DSP core
- Eight instructions/cycle, eight execution units
 - Optimized instruction set for video and imaging processing
 - Eight 8 x 8 or 16 x 16 multiply accumulate (MAC) per cycle
 - Eight slave asynchronous die (SAD) per cycle
 - Eight interpolations ($a + b + 1$) $\gg 1$ per cycle
 - Two (32-bit x 32-bit > 64-bit) multiply operations per cycle
- Low-power processor and megacell
 - Dynamically mixed 32-bit and 16-bit instruction sets
 - Software pipelined loop (SPLOOP) instruction buffer
 - Separate power domain
 - Supported multiple power-down states
- Two-level memory subsystem hierarchy
 - L1P (program)
 - 32KB direct-mapped cache—32-byte cache line, configurable as cache or memory mapped (Possible values are: 0KB cache/32KB memory, 4KB/28KB, 8KB/24KB, 16KB/16KB, or 32KB/0KB)
 - L1D (data)
 - 32KB 2-way set associative cache—4-byte cache line, configurable as cache or memory mapped (Possible values are: 0KB cache/32KB memory, 4KB/28KB, 8KB/24KB, 16KB/16KB, or 32KB/0KB)
 - 48KB memory-mapped SRAM
 - L2 (program and data)
 - 64KB 4-way set associative cache—128-byte cache line, configurable as cache or memory mapped (Possible values are: 0KB cache/64KB memory, 32KB/32KB, or 64KB/0KB)
 - 32KB memory-mapped SRAM
 - 16KB ROM
- Video hardware accelerators
 - Improved motion estimation (iME) dedicated hardware
 - Improved loop filtering (iLF) dedicated hardware
 - Improved variable length coder/decoder (iVLC) with quantizing capabilities dedicated hardware
 - Video dedicated sequencer
 - Video local interconnect

- Local level 2 (L2) memory interface/arbiter
- Private direct memory access (DMA) controller:
 - 128 logical channels
 - 1D/2D addressing
 - Chaining capability
 - Fully pipelined, two 64-bit read ports, two 64-bit write ports
 - Single access 32-byte or 64-byte incrementing bursts
- Level 1 (L1) interrupt controller (INTC)
- Local IVA2.2 digital phase-locked loop (DPLL) supplying the IVA2.2 subsystem clocking
- 32-entry memory management unit (MMU) for seamless integration in high-level OS environment
- IVA2.2 system interfaces
 - 64-bit L3 port shared for external memory accesses
 - Multithreaded link shared by DSP core and DMA accesses
 - Interface with the L3 interconnect that can be synchronous or asynchronous for clock decoupling between IVA2.2 and L3 interconnect
 - Incrementing burst support
 - Critical line first to reduce line fetch latency to the processor
 - Host port interface (HPI) for MMU programming and access to the IVA2.2 internal memories. Can be synchronous or asynchronous
 - System interfaces: clocking, power management
- C-friendly environment (state-of-the-art C compiler for VLIW architecture)
- Texas Instruments low-overhead DSP-BIOS operating system

Note: IVA2.2 is not available on all devices. See [Section 1.5](#), *OMAP35x Family*, for more information on available features.

1.3.3 On-Chip Memory

On-chip memory configuration offers memory resources for program and data storage:

- 112KB ROM
- 64KB single-access static random access memory (SRAM)

1.3.4 External Memory Interfaces

The device includes two external memory interfaces supporting the stacking of a multichip memory package using the generic POP interface:

- General-purpose memory controller (GPMC)
 - NOR flash, NAND flash (with ECC Hamming code calculation), SRAM and Pseudo-SRAM asynchronous and synchronous protocols
 - Flexible asynchronous protocol control for external ASIC or peripheral interfacing
 - 16-bit data, up to 8 chip-selects (CSs)
 - 128M-byte addressable per chip-select, 1G-byte total address space
 - Nonmultiplexed device with limited address (2K bytes)
- SDRAM controller (SDRC)
 - Mobile single data rate (M-SDR) SDRAM and low-power double data rate (LPDDR) SDRAM
 - 16-bit or 32-bit data, 2 chip-selects, configurations for a maximum of 1 G-byte address space per chip-select
 - Work in conjunction with the SDRAM memory scheduler (SMS) companion module

1.3.5 DMA Controllers

The device embeds one generic DMA controller, the system DMA (sDMA) controller, used for memory-to-memory, memory-to-peripheral, and peripheral-to-memory transfers:

- One read port, one write port
- 32 prioritizable logical channels
- 96 hardware requests
- 256 x 32-bit FIFO dynamically allocable between active channels

The device also embeds three dedicated DMA controllers: enhanced DMA (EDMA), which is embedded in the IVA2.2 subsystem, display DMA, and USB HS DMA.

1.3.6 Multimedia Accelerators

The device uses the following multimedia accelerators for display and gaming effects as well as high-end imaging and video applications:

- 2D and 3D graphics accelerator (SGX)
 - 2D and 3D graphics and video codecs supported on common hardware
 - Tile-based architecture
 - Universal scalable shader engine (USSE™) multithreaded engine incorporating pixel and vertex shader functionality reducing die area
 - Advanced shader feature set in excess of Microsoft VS3.0, PS3.0, and OGL2.0
 - Industry standard API support Direct3D mobile, OGL-ES 1.1 and 2.0, OpenVG 1.0, OpenMax
 - Fine-grained task switching, load balancing, and power management
 - Programmable high-quality image anti-aliasing
 - Advanced geometry DMA driven operation for minimum CPU interaction
 - Fully virtualized memory addressing for OS operation in a unified memory architecture
 - Advanced and standard 2D operations (that is, vector graphics, BLTs, ROPs, etc.)
 - Programmable video encode and decode support for H.264, H.263, MPEG4 (SP), WMV9, and JPEG

Note: Multimedia accelerators are not available on all devices. See [Section 1.5](#), *OMAP35x Family*, for more information on available features.

- Camera interface
 - Supports most of the raw image sensors available in the market
 - Includes video processing hardware
 - 12-bit parallel interface supported
 - Pixel clock up to 83 MHz

CAUTION

Clock configurations depend on the core voltage and maximum clock frequencies. Values in this document might not apply to production devices. Refer to your device-specific data manual for supported values for production devices.

- Display interface
 - Display controller
 - Color and monochrome displays up to 2048 x 2048 x 24-bpp resolution
 - 256 x 24-bit entries palette in red, green, blue (RGB)
 - 3,375 colors, 15 grayscales
 - Picture-in-picture (overlay), color-space conversion, rotation, color-phase rotation, and resizing support

- Remote frame buffer interface
- Liquid-crystal display (LCD) pixel interfaces (MIPI DPI 1.0) and LCD bus interfaces (MIPI DBI 1.0) supported
- NTSC/PAL video encoder outputs with integrated digital-to-analog converters (DACs) output are supported on CVBS and S-video TV analog output signals
- Serial display interface implements high-speed differential output buffers to support FlatLink3G™, Mobile CMADS and MIPI DSI 1.0 formats
- Embedded DMA controller

1.3.7 Security (HS Devices Only)

The secure firmware resides in a secure version of the ROM and includes hardware security features that enable HS devices and the following encryption/decryption accelerators:

- RNG
- 2 x DES/3DES
- SHA1/MD5
- SHA2/MD5
- 2 x AES with counter mode
- Fast PKA

The customer programmable fuse ROM (CPFROM) module is only available on high-security (HS) devices.

The universal subscriber identity module (USIM) that supports 3GPP extended features and EMV specific feature is available only on HS devices. This interface includes two modules: the fast-deactivate (FD) module and the USIM.

Note: This technical reference manual focuses only on general-purpose (GP) devices. To determine if a high-security (HS) version of your device is available and for more information on HS devices, see [Section 1.5](#), *OMAP35x Family*, and your device-specific data manual.

1.3.8 Comprehensive Power Management

OMAP35x devices include the following power management features:

- Clock and reset generation and distribution
- Wake-up event management
- SmartReflex™ technology
- Dynamic voltage frequency shifting
- Dynamic power shifting
- Static leakage management

1.3.9 Peripherals

The device supports a comprehensive set of peripherals to provide flexible and high-speed interfacing and on-chip programming resources. [Table 1-1](#) provides a list and description of the peripherals available on OMAP35x devices.

Table 1-1. OMAP35x Peripherals

Type	Name	Number	Description
Serial Communication	Multi-channel Buffered Serial Ports (McBSPs)	5	The McBSPs provide a full-duplex direct serial interface between the device and other devices in a system such as audio and voice codecs and other application chips. McBSP1, McBSP2, and McBSP3 serve as general purpose serial ports while McBSP2 and McBSP3 include additional audio-loopback capability.
	Multi-channel Serial Port Interface (McSPI)	4	The McSPIs provide a master/slave interface to SPI devices.
	High-speed Multi-port USB Host Controller	1	High-speed USB2.0 host controller with three host ports each offering high-speed data transactions (up to 480 Mbps) or full-speed/low-speed data transactions (12 and 1.5 Mbps, respectively). In high-speed mode, the USB host controller ports interface to external USB PHYs using a 12-pin or 8-pin UTMI low pin interface (ULPI). In full-speed and low-speed mode, the ports interface to external USB PHYs using a 6-/4-/3-pin serial interface. Additionally each port can be directly connected to a USB device (bypassing the need for USB PHY) by using an the on-chip transceiver-less link logic (TLL) adapter.
	High-speed USB OTG Controller	1	High-speed USB2.0 OTG controller that offers high-speed data transactions (up to 480 Mbps) on a USB port with embedded DMA controller. The high-speed USB OTG controller interfaces to an external USB PHY using a 12-pin UTMI low pin interface (ULPI).
	HDQ/1-Wire	1	The HDQ/1-Wire interface supports the Benchmark HDQ protocol and the Dallas Semiconductor 1-Wire protocol.
	Universal Asynchronous Receiver/Transmitter (UART)	3	Serial communication interfaces compatible to the industry standard TL16C550 asynchronous communications element. UART1 and UART 2 are general serial communication interfaces. UART3 provides additional support for infrared data association (IrDA) and consumer infrared (CIR) communications.
	High-speed (HS) Inter-integrated Circuit (I2C) Controllers	3 ⁽¹⁾	Master/slave I2C high-speed standard interfaces with support for standard mode (up to 100K bits/s), fast mode (up to 400K bits/s), and high-speed mode (up to 3.4M bits/s).
Removable Media	Multimedia Card/Secure Digital/Secure Digital I/O (MMC/SDIO) Card Interface	1	MMC memory card, SD memory card, or SDIO cards interface.
Miscellaneous	GP timers	12	Twelve general-purpose timers
	Watchdog timers (WDTs)	2	Three watchdog timers
	32-kHz synchronization timer	1	32-kHz clock timer
	General-purpose input/output (GPIO)	Package-specific	General-purpose input/output pins controlled by six GPIO controllers.
	Mailbox	6	MPU/IVA2.2 inter-processor communications mailboxes. All six mailboxes are available in chassis mode, however, only two mailboxes are available in stand-alone mode.
	Control module	1	I/O multiplexing and chip-configuration control.
Security Modules (High-security Devices Only)			RNG, Fast PKA, 2xDES/3DES, SHA1/MD5, SHA2/MD5, 2xAES, Secure Watchdog Timer, and universal subscriber identity module (USIM).

⁽¹⁾ A fourth master/transmitter high-speed I2C interface (I2C4) is included in the power, reset, and clock management (PRCM) module to perform dynamic voltage control and power sequencing.

1.4 Package-On-Package Concept

The OMAP35x CBB package provides a package-on-package (POP) memory interface to support multiple stacked package configurations, including a flash multi-chip package, depending on customer needs. Note that use of standalone memory devices is also possible on the CBB package; use of POP technology is not required.

The stacked memory package is directly connected to the two memory interfaces (GPMC and SDR3) of the OMAP35x CBB package through the POP interface present at the top. For more information on the interconnect between the stacked memory package and the OMAP35x CBB package, see Chapter 11, Memory Subsystem, and your device-specific OMAP35x data manual.

Note: Before using the POP memory interface, a compatible memory device supply must first be secured directly from specific memory vendors.

Figure 1-3 shows the concept of the POP solution, and Figure 1-4 shows stacked memory package on the POP device.

Figure 1-3. POP Concept (CBB Package)

108-003

Figure 1-4. Stacked Memory Package on the POP Device (CBB Package)

108-004

The memory interfaces should be correctly configured based on the memory package used with the POP device.

Table 1-2 summarizes the supported configurations with the generic POP interface.

Note: Use of standalone memory devices is also possible on the CBB package; use of POP technology is not required.

Table 1-2. Summary of Memories Supported by the POP Interface

Generic POP Interface Features Set	SDRC Interface	GPMC Interface
Type of memory supported	MDDR	NOR flash asynchronous and synchronous burst flash NAND flash "CE don't care" One NAND on CS0 and CS1 NOR flash address/data nonmultiplexed is not supported.
Number of chip-selects	2	2
Maximum density per chip-select	1G bit	512M bits (NOR flash) or 4G bits NAND flash
Maximum size per interface	2G bits	1G bit (NOR flash) or 8G bits NAND flash
Interface width	X 32 bits	X 16 bits
I/O voltage	1.8 V LVCMOS	1.8 V LVCMOS

For more information on the memory interface configuration, see the *Memory Subsystem* chapter.

The POP device includes feedthroughs in addition to the GPMC and SDRC interfaces positioned at the top of the package. Up to 47 feedthroughs are defined from the bottom ball-grid array (BGA) to the top (or POP) interface to support different memory combinations.

The feedthroughs either provide power to a top memory device or provide specific memory signals (for example, control and/or address signals) from the bottom BGA to the POP interface.

Note: It is possible to monitor the DDR SDRAM temperature if the memory multichip package allows the temperature sensing option. A feedthrough is used to lower the temperature sensing dedicated signal to make a connection with a GPIO. For more information on DDR SDRAM temperature sensing management, see the *Memory Subsystem* and the *General-Purpose Interface* chapters.

Figure 1-5 shows the implementation of feedthroughs on the POP and the different paths between the bottom and the top of the package.

Figure 1-5. Stacked Memory Package on the POP Device (CBB Package)

108-005

- (1) Path 1: feedthrough only; Path 2: all but feedthrough; Path 3: POP interface (SDRC + subset GPMC)
- (2) Any signal available on the POP interface to a top-side ball is also available to a bottom-side ball.

1.5 OMAP35x Family

1.5.1 Device Features

The OMAP 3 architecture is configured with different sets of features in different devices. This technical reference manual details all of the features available in current and future OMAP35x devices. Some features may not be available or supported in your particular device. The features supported across different OMAP35x devices are shown on [Table 1-3](#) (CBB and CBC packages) and [Table 1-4](#) (CUS package). For more information on the CBB, CBC, and CUS packages, refer to your device-specific data manual.

1.5.2 Device Identification

The identification registers include the CONTROL_IDCODE and CONTROL_DIE_ID data registers. These registers are accessible through the L4 interconnect port starting at physical address 0x4830 A204 and 0x4830 A218, respectively. See the Memory Mapping chapter for more information about the L4 memory space mapping. [Table 1-5](#) describes the identification registers.

The silicon type can be read in the HAWKEYE bit field value of the CONTROL.CONTROL_IDCODE register. The silicon revision can be read in the VERSION bit field value of the CONTROL.CONTROL_IDCODE register.

Table 1-5. Device Identification Registers

Register Name	Address	Size
CONTROL.CONTROL_IDCODE[31:0]	0x4830 A204	32
CONTROL.CONTROL_DIE_ID[127:0]	0x4830 A218	128

To retrieve OMAP35x chip identification, see [Table 1-6](#). This register helps software identify chip derivative.

Table 1-6. Chip Identification

Table 1-7. CONTROL_IDCODE Register Definition

Field	Bits	Value	Comment
CONTROL.CONTROL_IDCODE [31:28]	VERSION	See Table 1-9 .	Revision number
CONTROL.CONTROL_IDCODE [27:12]	HAWKEYE	See Table 1-8 .	Hawkeye number
CONTROL.CONTROL_IDCODE [11:1]	TI_IDM	0x13	Manufacturer identity (TI)
CONTROL.CONTROL_IDCODE [0]	--	0x1	Always set to 1.

The Hawkeye number is hardcoded in the design. [Table 1-8](#) lists the Hawkeye number values, and [Table 1-9](#) lists the revision number values.

Table 1-8. Hawkeye Number Value

Silicon Type	Field	Value
OMAP35x ES1.0	CONTROL.CONTROL_IDCODE[27:12]	0xB6D6
OMAP35x ES2.0	CONTROL.CONTROL_IDCODE[27:12]	0xB7AE
OMAP35x ES2.1	CONTROL.CONTROL_IDCODE[27:12]	0xB7AE
OMAP35x ES3.0	CONTROL.CONTROL_IDCODE[27:12]	0xB7AE

Table 1-9. Revision Number Value

Silicon Type	Field	Value
ES2.0	CONTROL.CONTROL_IDCODE[31:28]	0001
ES2.1	CONTROL.CONTROL_IDCODE[31:28]	0010
ES3.0	CONTROL.CONTROL_IDCODE[31:28]	0011

- The CONTROL.CONTROL_IDCODE value is 0x1B7A E02F for OMAP35x ES2.0.
- The CONTROL.CONTROL_IDCODE value is 0x2B7A E02F for OMAP35x ES2.1.
- The CONTROL.CONTROL_IDCODE value is 0x3B7A E02F for OMAP35x ES3.0.
- The CONTROL.CONTROL_DIE_ID register is the 128 bits single identifier of the device.

Table 1-10. CONTROL_DIE_ID

Field	Bits	Value
DIE_ID[127:0]	RESERVED	Single identifier

1.5.3 General Recommendations Relative to Unavailable Features/Modules

As explained in the previous section, some features are not available in all OMAP35x devices. For unavailable features, use the following recommendations:

- Memory mapping: Memory area of unavailable modules and features are RESERVED, read is undefined, and write can lead to unpredictable behavior.
- Interrupt controllers: Ensure that interrupts of unavailable modules and features are masked in MPU/IVA subsystems.
- DMA: Ensure that DMA requests of unavailable modules and features are masked in DMA subsystems.
- System Control Module (SCM): Unavailable modules and feature pins are not functional and should not be used.
- Power, Reset, and Clock Management Module (PRCM): For power management and power-saving consideration, ensure that power domains of unavailable features/modules are switched off and clocks are cut off.
- Interconnect: To flag potential interconnect outstanding commands, the time-out of target agents attached to unavailable modules can be enabled with the lowest setting.

1.6 Revision History

[Table 1-11](#) lists the changes made since the previous version of this document.

Table 1-11. Document Revision History

Reference	Additions/Modifications/Deletions
Global	Changed TWL4030 to TPS65950.
Table 1-3	Changed table title and added table note.
Table 1-6	Added table.
Table 1-8	Changed all table values and added last row.
Table 1-9	Added last row.
Section 1.5.2	Added 3rd bullet.

Memory Mapping

This chapter describes the memory mapping in the OMAP35x Applications Processor.

Note: This chapter gives information about all modules and features in the high-tier device. See Chapter 1, the *OMAP35x Family* section, to check availability of modules and features. The memory area of unavailable modules and features is RESERVED, read is undefined, and write can lead to unpredictable behavior.

Topic	Page
2.1 Introduction	202
2.2 Global Memory Space Mapping	204
2.3 L3 and L4 Memory Space Mapping	207
2.4 IVA2.2 Subsystem Memory Space Mapping	216
2.5 Revision History	222

2.1 Introduction

The microprocessor unit (MPU) has a 32-bit address port, allowing it to handle a 4Gbytes space divided into several regions, depending on the target type.

The memory map is composed of a memory space (general-purpose memory controller [GPMC], SDRAM controller [SDRC], etc.), register space (L3 and L4 interconnects), and dedicated spaces (IVA2.2 subsystem, SGX, etc.), all of which are shared among the initiators (for example, the MPU subsystem or the IVA2.2 subsystem).

The GPMC and SDRC are dedicated to memory connection. The GPMC is used for NOR/NAND flash and SRAM memories. The SDRC is used for Low-Power DDR (LPDDR) SDRAM. For more information, see the *Memory Subsystem* chapter.

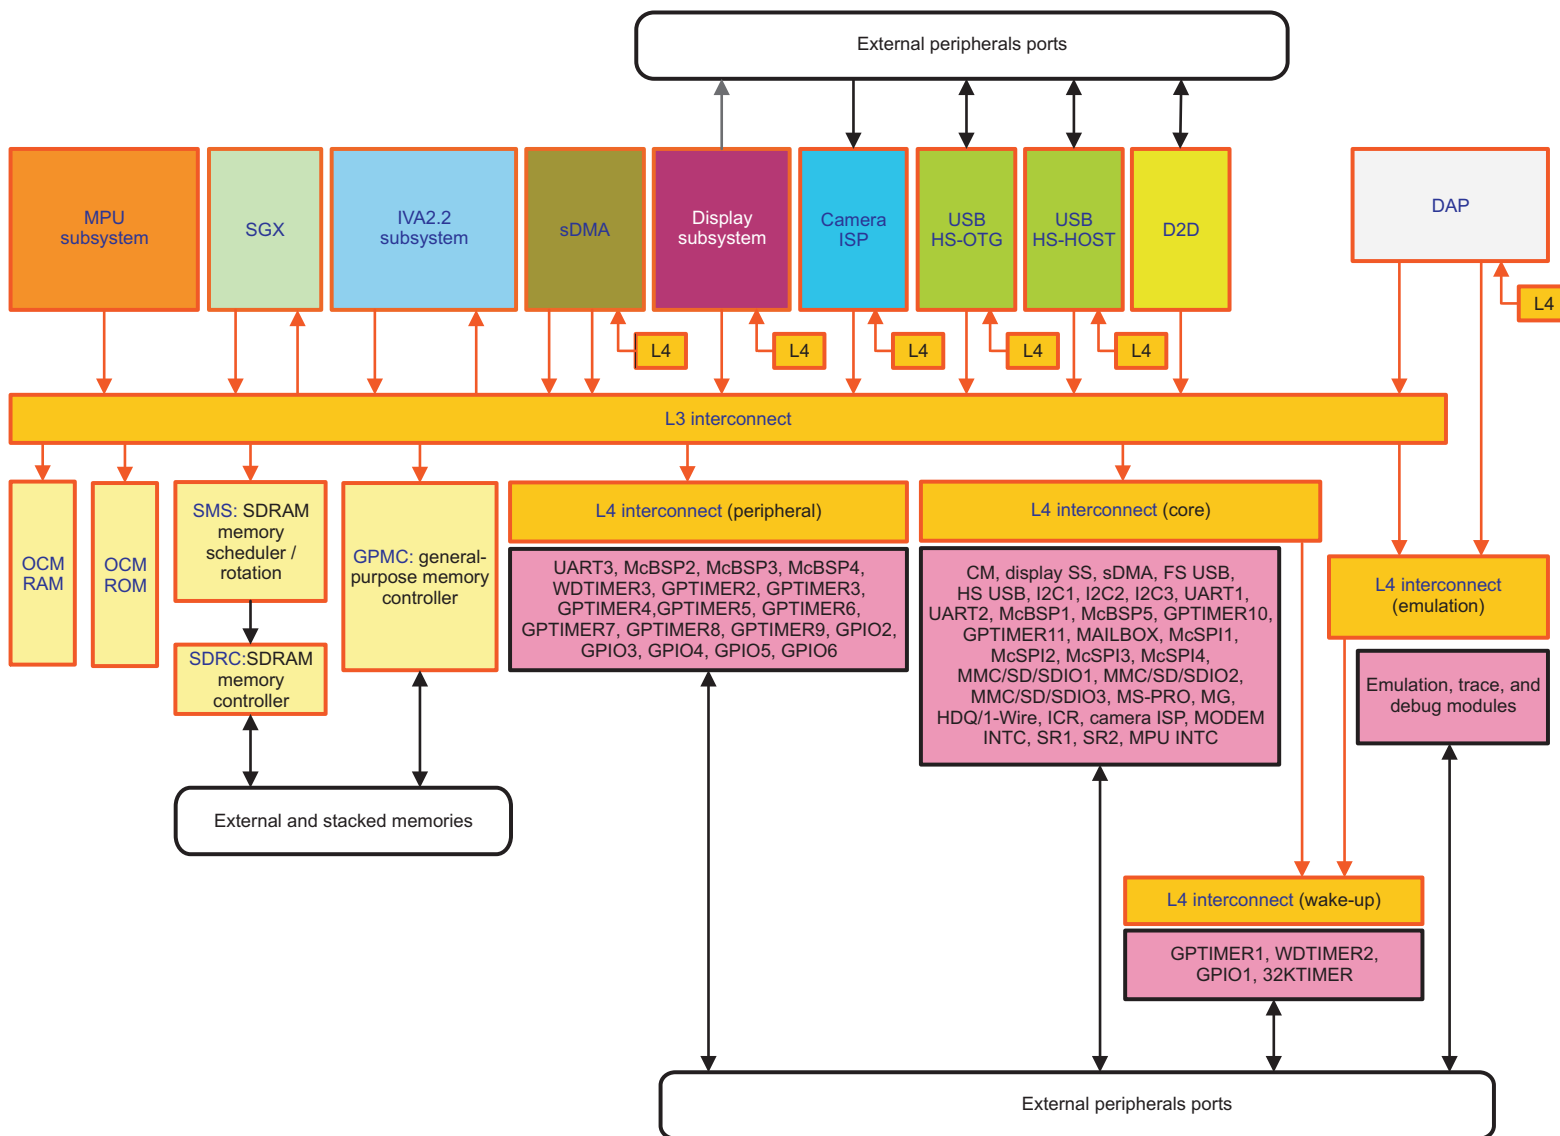

The L3 interconnect allows the sharing of resources, such as peripherals and external or on-chip memories, between all the initiators of the platform. The L4 interconnects control access to the peripherals.

Transfers between initiators and targets across the platform are physically conditioned by the chip interconnect and can be logically conditioned by firewalls. See the *Interconnect* chapter for more information about the intercommunication (L3 and L4 interconnects) and protection mechanisms implemented in the device.

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

[Figure 2-1](#) shows the interconnect of the device and the main modules and subsystems in the platform.

Figure 2-1. Interconnect Overview

memmap-001

2.2 Global Memory Space Mapping

This section provides a global view of the memory mapping and details the boot, GPMC, SDRC, and virtual rotated frame buffer (VRFB) memory spaces.

The system memory mapping is flexible, with two levels of granularity for target address space allocation:

- Level 1: Four quarters are labeled Q0, Q1, Q2, and Q3. Each quarter corresponds to a 1Gbyte address space (total address space is 4Gbytes).
- Level 2: Each quarter is divided into eight blocks of 128Mbytes, with target spaces mapped inside the blocks.

This organization allows all target spaces to be decoded based on the five most significant bits (MSBs) of the 32-bit address ([31:27]).

- **Boot space**

The system has a 1Mbyte boot space either in the on-chip boot ROM or on the GPMC memory space. When booting from the on-chip ROM with the appropriate external sys_boot5 pin configuration, the 1Mbyte memory space is redirected to the on-chip boot ROM memory address space [0x4000 0000 – 0x400F FFFF].

When booting from the GPMC with the appropriate external sys_boot5 pin configuration, the memory space is part of the GPMC memory space.

For more information on sys_boot5 pin configuration, see the *Memory Subsystem* and the *Initialization* chapters.

- **GPMC space**

Eight independent GPMC chip-selects (gpmc_ncs0 to gpmc_ncs7) are available in the first quarter (Q0) of the addressing space to access NOR/NAND flash and SRAM memories. The chip-selects have a programmable start address and programmable size (16Mbytes, 32Mbytes, 64Mbytes, or 128Mbytes) in a total memory space of 1Gbyte.

- **SDRC space**

Two SDRC chip-selects (sdrc_ncs0 and sdrc_ncs1) are available on the third quarter (Q2) of the addressing space to access SDRAM memories. The chip-selects have a programmable size (64Mbytes, 128Mbytes, 256Mbytes, or 512Mbytes) in a total memory space of 1Gbyte.

The base address of the chip-select 0 (sdrc_ncs0) memory space is always 0x8000 0000. The base address of the chip-select 1 (sdrc_ncs1) memory space is programmable. The default value after reset is 0xA000 0000.

- **VRFB space**

The SDRC-SMS virtual memory space is a different memory space used to access a subset of the SDRC memory space through the rotation engine. The virtual address space size is 768Mbytes split into two parts: The first 256M-byte part is in the second quarter (Q1) of the memory; the second 512Mbytes part is in the fourth quarter (Q3) of the memory.

For more information on boot, GPMC, SDRC, and VRFB, see the *Memory Subsystem* chapter.

This section gives information about all modules and features in the high-tier device. See Chapter 1, *OMAP35x Family* section, to check availability of modules and features. The memory area of unavailable modules and features is RESERVED, read is undefined, and write can lead to unpredictable behavior.

[Table 2-1](#) describes the global memory space mapping.

⁽¹⁾ Boot space location depends on the external sys_boot5 pin configuration.

⁽²⁾ Executable

⁽³⁾ Default public/secure settings after reset only

⁽⁴⁾ Peripherals connected to the L4-Wakeup interconnect are accessed through the L4-Core interconnect.

Table 2-1. Global Memory Space Mapping (continued)

QUARTER	Device Name	Start Address (HEX)	End Address (HEX)	Size	Description
Q2 (1GB)	SDRC/SMS			256MB	SDRC/SMS
	SDRC/SMS virtual Address space #0	0x7000 0000	0x7FFF FFFF	256MB	SDRC-SMS virtual address space 0
	SDRC / SMS			1GB	SDRAM main address space (SMS)
	CS0 – SDRAM ⁽⁵⁾	0x8000 0000	0x9FFF FFFF	512MB	SDRC / SMS
Q3 (1GB)	CS1 – SDRAM ⁽⁵⁾	0xA000 0000	0xBFFF FFFF	512MB	SDRC / SMS
	Reserved			512MB	Reserved
	Reserved	0xC000 0000	0xDFFF FFFF	512MB	Reserved for future use.
	SDRC/SMS			512MB	SDRC/SMS
	SDRC/SMS virtual Address space 1	0xE000 0000	0xFFFF FFFF	512MB	SDRC-SMS virtual address space 1

⁽⁵⁾ Chip-select 0 and chip-select 1 spaces are configurable within the 1GB SDRC / SMS space. However, the base address for chip-select 0 cannot be configured and is always 0x8000 0000.

2.3 L3 and L4 Memory Space Mapping

The memory space system is defined from a hierarchical view: L1, L2, L3, and L4.

L1 and L2 are memories included in the MPU and the imaging video and audio (IVA2.2) subsystems.

The chip-level interconnect, which is made of one L3 and four L4s, enables communication between all modules and subsystems.

L3 handles many types of data transfers and, in particular, the data exchange with system on-chip/external memories.

The four L4s handle transfers with peripherals but are in four distinct power domains: the L4-Core, L4-Wakeup, L4-Per, and L4-Emu interconnects, which are in the CORE, WAKEUP, PER, and EMU power domains, respectively.

For more information about the interconnect, see the *Interconnect* chapter.

The following sections describe the register mapping of the L3 and L4 interconnects. The software configures these registers.

2.3.1 L3 Memory Space Mapping

The L3 interconnect control registers are mapped in a 16Mbytes space and allow the configuration of the L3 interconnect parameters.

The L3 default settings are fully functional and enable all possible functional data paths. However, the interconnect parameters can be changed to accommodate expectations.

Accesses to the L3 interconnect can be configured on a per-module basis using the internal L3 registers, which are grouped into five register block types:

- IA: initiator agent configuration registers
- TA: target agent configuration registers
- RT: register target (global configuration registers)
- PM: protection mechanism (firewalls) configuration registers
- SI: global sideband signal configuration registers

For more information, see the *Interconnect* chapter.

This section gives information about all modules and features in the high-tier device. See Chapter 1, *OMAP35x Family* section, to check availability of modules and features. The memory area of unavailable modules and features is RESERVED, read is undefined, and write can lead to unpredictable behavior.

[Table 2-2](#) describes the mapping of the L3 interconnect control registers.

Table 2-2. L3 Control Register Mapping

Device Name	Start Address (HEX)	End Address (HEX)	Size	Description

2.3.2 L4 Memory Space Mapping

The device contains four L4 interconnects: the L4-Core, L4-Wakeup, L4-Per, and L4-Emu interconnects.

As with the L3 interconnect, the L4 interconnects can be configured to tune the access depending on the characteristics of each module.

For more information on the L4 interconnect, see the *Interconnect* chapter.

2.3.2.1 L4-Core Memory Space Mapping

The L4-Core interconnect is a 16Mbytes space composed of the L4-Core interconnect configuration registers and the module registers.

[Table 2-3](#) describes the mapping of the registers for the L4-Core interconnect.

Note: All memory spaces described as modules provide direct access to module registers outside the L4-Core interconnect. All other accesses are internal to the L4-Core interconnect.

This section gives information about all modules and features in the high-tier device. See Chapter 1, *OMAP35x Family* section, to check availability of modules and features. The memory area of unavailable modules and features is RESERVED, read is undefined, and write can lead to unpredictable behavior.

2.3.2.3 L4-Peripheral Memory Space Mapping

The L4-Per interconnect is a 1Mbyte space composed of the L4-Per interconnect configuration registers and the module registers.

Table 2-5 describes the mapping of the registers for the L4-Per interconnect.

Note: All memory spaces described as modules provide direct access to the module registers outside the L4-Per interconnect. All other accesses are internal to the L4-Per interconnect.

⁽¹⁾ These modules are accessed through the L4-Wakeup interconnect (for emulation purpose only).

⁽²⁾ The registers mapped in this range are shadow registers of the first 2Kbytes region A [0x5470 6000 - 0x5470 67FF]. Region A and region B share the same port.

2.3.3 Register Access Restrictions

This section gives information about all modules and features in the high-tier device. See Chapter 1, *OMAP35x Family* section, to check availability of modules and features. The memory area of unavailable modules and features is RESERVED, read is undefined, and write can lead to unpredictable behavior.

Table 2-7 gives the supported data access widths per module.

Table 2-7. Register Access Restrictions

Module	Allowed Access
MPU subsystem	8-bit/16-bit/32-bit
IVA2.2 subsystem	32-bit

2.4 IVA2.2 Subsystem Memory Space Mapping

This section gives information on hardware accelerators of IVA2.2. See Chapter 1, *OMAP35x Family* section, to check availability of modules. The memory area of unavailable modules and features is RESERVED, read is undefined, and write can lead to unpredictable behavior.

Some devices include the high-performance Texas Instruments IVA2.2. See the *IVA2.2 Subsystem* chapter for more information.

This section explains how the IVA2.2 internal memories and registers are accessed through the L3 interconnect and by the IVA2.2 internal initiators (that is, the digital signal processor [DSP] and the enhanced direct memory access [EDMA]).

Three views of the IVA2.2 subsystem memory space mapping are provided:

- L3 interconnect view: External view (subsystem memories and configuration registers) as seen by the MPU subsystem and most of the initiators of the platform through the L3 interconnect
- IVA2.2 DSP view: Internal view as seen by the DSP
- IVA2.2 EDMA view: Internal view as seen by the EDMA

Note: The IVA2.2 subsystem also contains a local interconnect with its own memory space mapping that can be accessed only by the DSP and the video accelerator and sequencer inside the IVA2.2 subsystem. For more information about this video accelerator/sequencer local interconnect and its memory space mapping, see the *IVA2.2 Subsystem* chapter.

2.4.1 IVA2.2 Subsystem Internal Memories and Cache Allocation

2.4.1.1 IVA2.2 Subsystem Memory Hierarchy

The IVA2.2 subsystem includes the following memory features:

- L1P (program)
 - 32Kbytes configurable: Memory-mapped (default after reset) or direct-mapped cache—32bytes cache line
- L1D (data)
 - 32Kbytes configurable: Memory-mapped (default after reset) or 2-way set associative cache—64bytes cache line
 - 48Kbytes memory-mapped
- L2 (program and data)
 - 64Kbytes configurable: Memory-mapped (default after reset) or 2-way set associative cache—128bytes cache line
 - 32Kbytes memory-mapped
 - 16Kbytes ROM

The local memories can be used as cache RAMs or memory-mapped RAMs, depending on the configuration of the different memory controllers in the IVA2.2 subsystem.

[Figure 2-2](#) shows the memory hierarchy of the IVA2.2 subsystem.

Figure 2-2. IVA2.2 Subsystem Memory Hierarchy

mmap-002

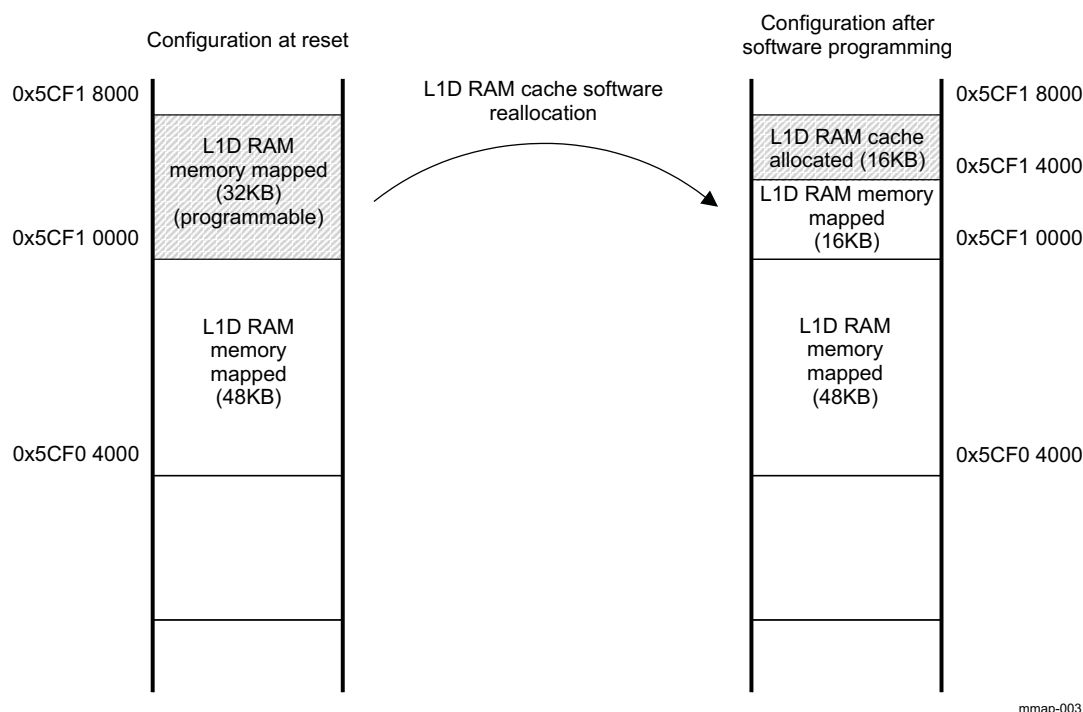

2.4.1.2 IVA2.2 Cache Allocation

After reset, the L1P RAM is used as a 32Kbytes memory-mapped RAM. The L1P RAM can be programmed in the GEM program memory controller to allocate 0Kbyte (default), 4Kbytes, 8Kbytes, 16Kbytes, or 32Kbytes to cache. When 32Kbytes are allocated to cache, there is no more memory-mapped L1P.

After reset, the L1D RAM is used as an 80Kbytes memory-mapped RAM. The L1D RAM can be programmed in the GEM data memory controller to allocate 0Kbyte (default), 4Kbytes, 8Kbytes, 16Kbytes, or 32Kbytes to cache. When 32Kbytes are allocated to cache, 48Kbytes are still allocated to the memory-mapped L1D.

After reset, the L2 is used as a 96Kbytes memory-mapped RAM. The L2 can be programmed to allocate 0Kbyte (default), 32Kbytes, or 64Kbytes to cache. When 64Kbytes are allocated to cache, 32Kbytes are still allocated to memory-mapped L2.

Figure 2-3 shows an example of the L1D RAM cache allocation, where 16Kbytes are allocated to cache.

Figure 2-3. L1D RAM Cache Allocation Example (L3 Interconnect View)

2.4.2 DSP Access to L2 Memories

2.4.2.1 DSP Access to L2 ROM

The IVA2.2 subsystem contains 16Kbytes of L2 ROM. The L2 ROM provides boot code.

When the L1P cache is configured to be inactive (default configuration), the DSP program fetch accesses to the L2 ROM are accomplished directly, and thus suffer the L2 latency.

When the L1P cache is configured to be active, the DSP program fetch accesses to L2 ROM are always serviced by the L1P cache controller, which partly hides the L2 latency.

2.4.2.2 DSP Access to L2 RAM

The IVA2.2 contains 96Kbytes of L2 RAM. The L2 RAM can be configured to allocate up to 64Kbytes to the L2 cache.

When the L1P and L1D caches are configured to be inactive (default configuration), the DSP accesses to the L2 RAM are accomplished directly and thus suffer the L2 latency.

When the L1P and L1D RAM are configured to be active, the DSP program accesses to L2 RAM are always serviced by the L1P cache controller (if code fetch) or the L1D cache controller (if data access), which partly hides the L2 latency.

2.4.3 DSP and EDMA Access to Memories and Peripherals

The IVA2.2 DSP and EDMA access the memories and peripherals using virtual addressing. This allows the DSP and EDMA to access memories and peripherals in the same contiguous view, even when the memory is physically segmented. [Table 2-9](#) and [Table 2-10](#) give the address range where the DSP and the EDMA can access the memories and peripherals, respectively.

The IVA2.2 memory management unit (IVA2.2 iMMU) handles the virtual to physical address translation based on the software configuration (typically under control of the MPU subsystem).

Virtual addresses are issued by the initiator to the IVA2.2 iMMU. Using the translation look-aside buffer (TLB), the MMU then translates the initiator virtual addresses into real physical addresses.

Figure 2-4 shows the relationship between physical addresses, virtual addresses, and the IVA2.2 iMMU.

Figure 2-4. IVA2.2 iMMU Address Translation

See the *Memory Management Units* chapter for more information on the MMU.

2.4.4 L3 Interconnect View of the IVA2.2 Subsystem Memory Space

Table 2-8 lists the IVA2.2 subsystem memory space mapping from the perspective of the MPU subsystem through the L3 interconnect.

Table 2-8. L3 Interconnect View of the IVA2.2 Subsystem Memory Space

MPU Subsystem

This chapter describes the microprocessor unit (MPU) subsystem in the OMAP35x Applications Processor.

Topic	Page
3.1 MPU Subsystem Overview.....	224
3.2 MPU Subsystem Integration	226
3.3 MPU Subsystem Functional Description	236
3.4 MPU Subsystem Basic Programming Model	242
3.5 Revision History	244

3.1 MPU Subsystem Overview

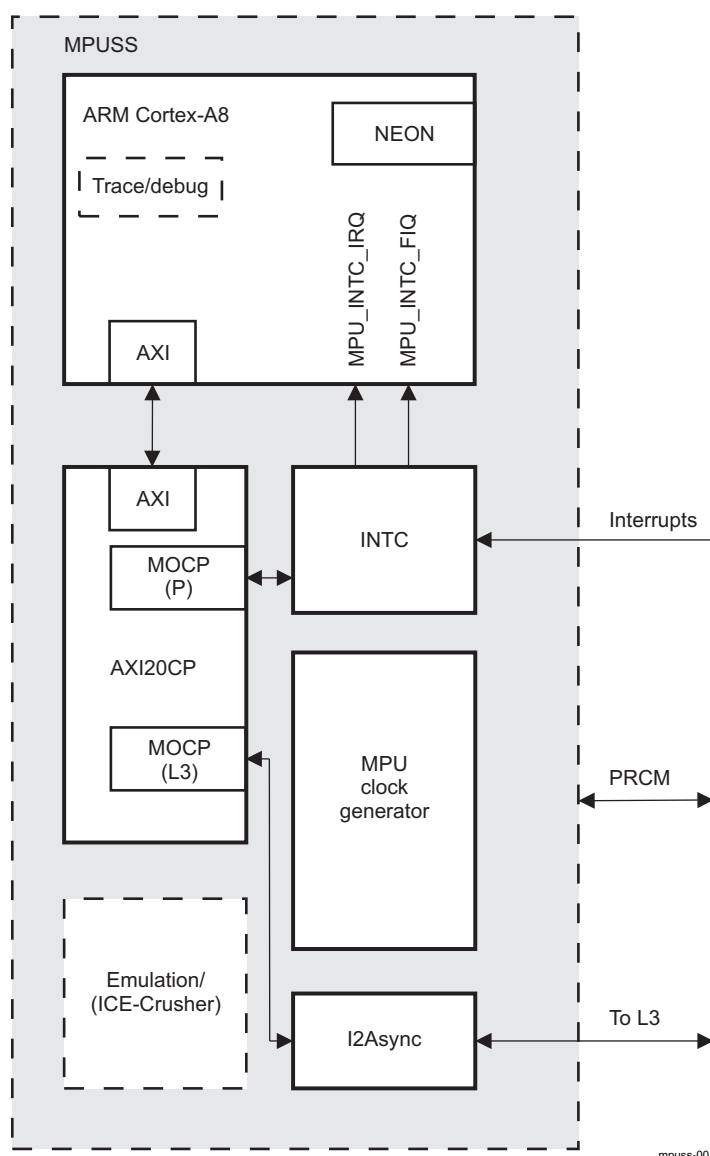

3.1.1 Introduction

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

The microprocessor unit (MPU) subsystem of the device handles transactions between the ARM core, the L3 interconnect, and the interrupt controller (INTC).

The MPU subsystem is a hard macro that integrates the ARM subchip with additional logic for protocol conversion, emulation, interrupt handling, and debug enhancements. Figure 3-1 shows the high-level block diagram of the MPU subsystem.

Figure 3-1. MPU Subsystem Overview

3.1.2 Features

The MPU subsystem integrates the following:

- ARM subchip
 - ARM® Cortex™-A8 core
 - ARM version 7 ISA: Standard ARM instruction set + Thumb®-2, Jazelle® RCT Java accelerator, and media extensions
 - NEON™ SIMD coprocessor (VFP light + media streaming instructions)
 - Cache memories
 - Level 1: 16KB instruction and 16KB data caches - 4 ways associative, 64 bytes/line
 - Level 2: See Chapter 1, *OMAP35x Family* section.
 - Emulation/debug
- Interrupt controller (INTC) of 96 synchronous interrupt lines (For details, see the *Interrupt Controller* chapter.)
- AXI2OCP bridge between ARM AXI bus, L3 master OCP bus, and interrupt controller master OCP bus
- MPU clock generator: Clock generation module that generate clocks, power modes, and idle and active acknowledge signals
- Debug, trace, and emulation features: ICE-Crusher, ETM, APB modules.
- I2Async bridge: An asynchronous bridge interface providing an asynchronous OCP to OCP interface.

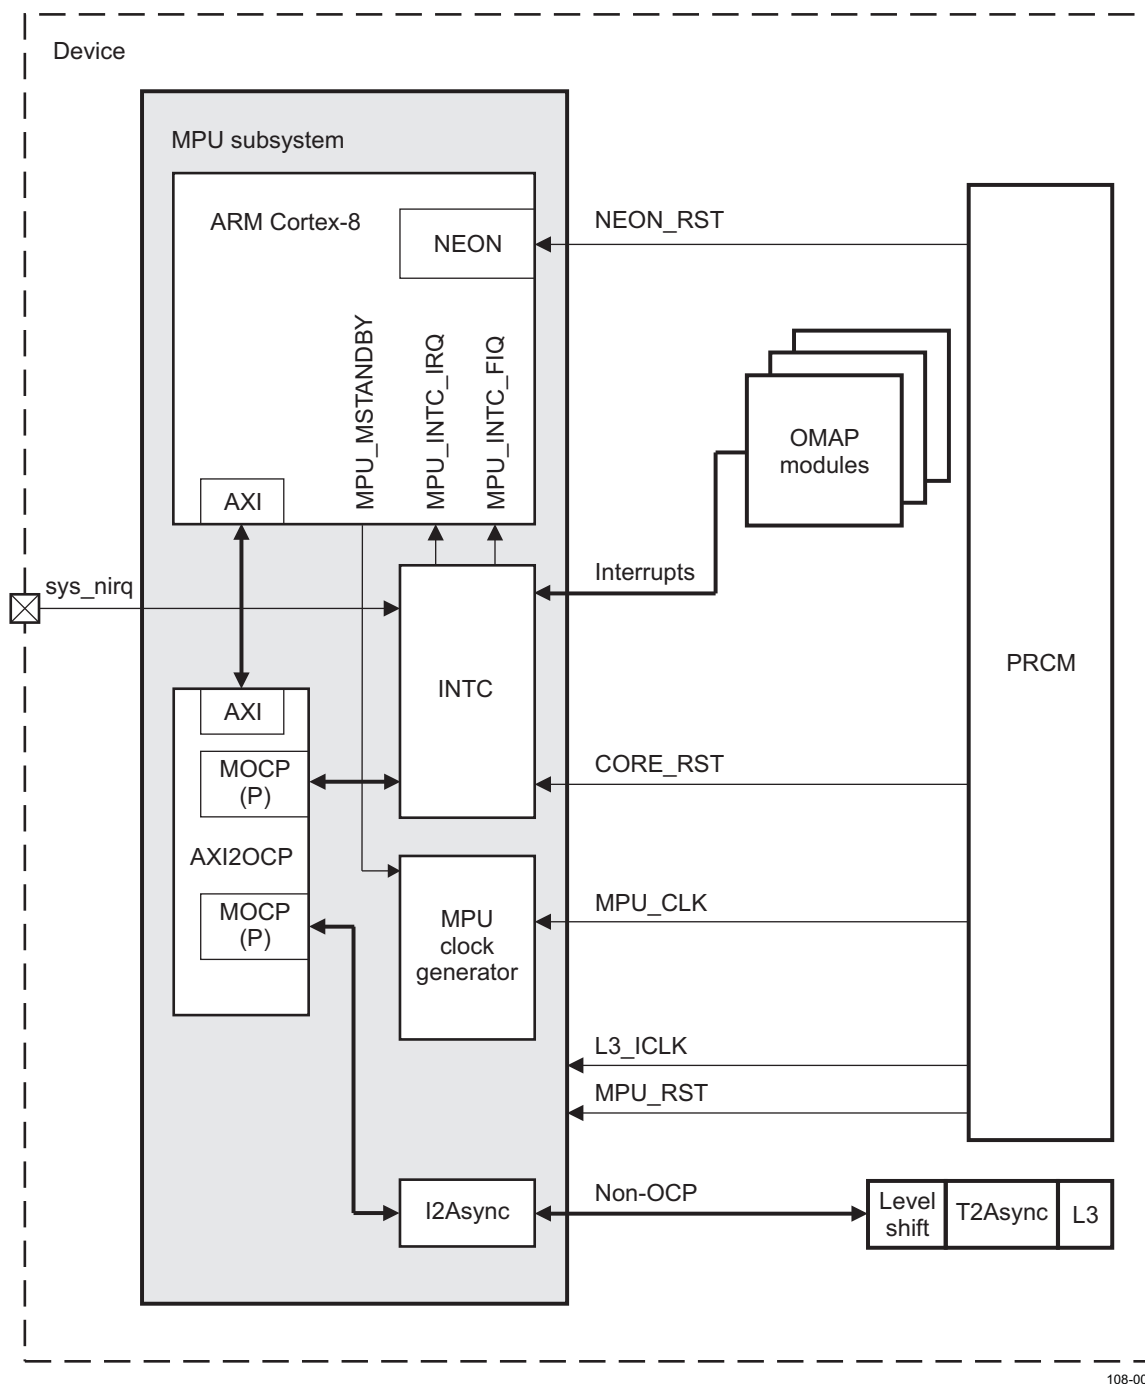

3.2 MPU Subsystem Integration

The MPU subsystem integrates the following group of submodules:

- ARM Cortex-A8 Revision: r1p1 MPU: Provides a high processing capability, including the NEON technology for mobile multimedia acceleration. The ARM communicates through an AXI bus with the AXI2OCP bridge and receives interrupts from the MPU subsystem interrupt controller (MPU INTC).
- Interrupt controller: Handles the module interrupts (for details, see the *Interrupt Controller* chapter).
- AXI2OCP bridge: Allows communication between the ARM (AXI), the INTC (OCP), and the modules (OCP L3).
- I2Async bridge: An asynchronous bridge interface providing an asynchronous OCP to OCP interface. This interface is between the AXI2OCP bridge within the MPU subsystem and the T2Async bridge external to the MPU subsystem. The T2Async bridge connects to OCP L3.
- MPU clock generator: Provides clocks to internal modules of the MPU subsystem and is fed by the MPU DPLL of the power, reset, and clock management (PRCM) module of the device.

[Figure 3-2](#) shows the signals that interface with the external modules.

Figure 3-2. MPU Subsystem Integration Overview

Note: Some debug, trace, and emulation features are implemented in the MPU subsystem. This chapter includes only clock/reset inputs and power management aspects for these features.

108-002

3.2.1 MPU Subsystem Clock and Reset Distribution

3.2.1.1 Clock Distribution

The MPU subsystem includes a clock generator block that supplies all the clocks for the modules inside the MPU subsystem. It is fed by the MPU_CLK clock from PRCM.

All major modules inside the MPU subsystem are clocked at half the frequency of the ARM core. The divider of the output clock can be programmed with the PRCM.CM_CLKSEL2_PLL_MPU[4:0]MPU_DPLL_CLKOUT_DIV register field, the frequency is relative to the ARM core. For details see the *Power, Reset, and Clock Management (PRCM)* chapter. The clock generator generates the following functional clocks:

- **ARM (ARM_FCLK):** This is the core clock. It is the base fast clock that is routed internally to the ARM logic and internal RAMs, including NEON, L2 cache, the ETM core (emulation), and the ARM core. It runs at one half the frequency of MPU_CLK when DPLL1 is locked, and runs at the same frequency of MPU_CLK when DPLL1 is bypassed.
- **AXI2OCP Clock (AXI_FCLK):** This clock is half the frequency of the ARM clock (ARM_FCLK). The OCP interface thus performs at one half the frequency of ARM.
- **Interrupt Controller Functional Clock (MPU_INTC_FCLK):** This clock, which is part of the INTC module, is half the frequency of the ARM clock (ARM_FCLK).
- **ICE-Crusher Functional Clock (ICECRUSHER_FCLK):** ICE-Crusher clocking operates on the APB interface, using the ARM core clocking. This clock is half the frequency of the ARM clock (ARM_FCLK).
- **I2Async Clock (I2ASYNC_FCLK):** This clock is half the frequency of the ARM clock (ARM_FCLK). It matches the OCP interface of the AXI2OCP bridge.

Note: The second half of the asynchronous bridge (T2ASYNC) is clocked directly by the PRCM with the core clock. T2ASYNC is not part of the MPU subsystem.

Emulation Clocking: Except for the ICE-Crusher functional clock, which is provided by the MPU DLL, the emulation modules inside the MPU subsystem are not generated by the MPU subsystem DPLL, but by an EMU DPLL. These clocks (EMU_CLOCKS) are distributed by the PRCM module, are asynchronous to the ARM core clock (ARM_FCLK) and can run at a maximum of 1/3 the ARM core clock.

Figure 3-3 shows the MPU subsystem clocking scheme.

Figure 3-3. MPU Subsystem Clocking Scheme

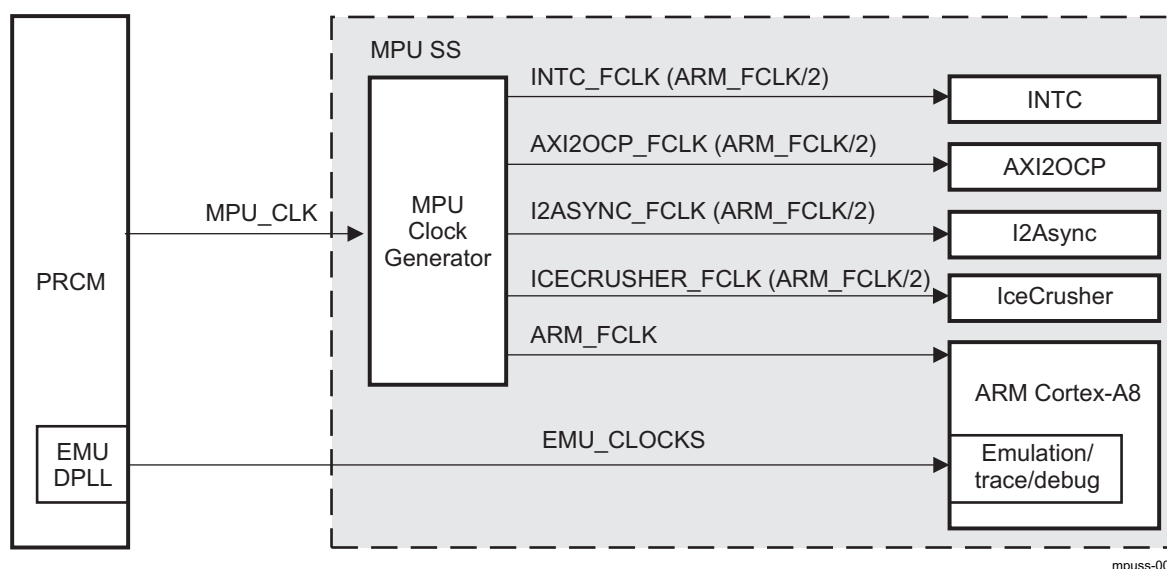

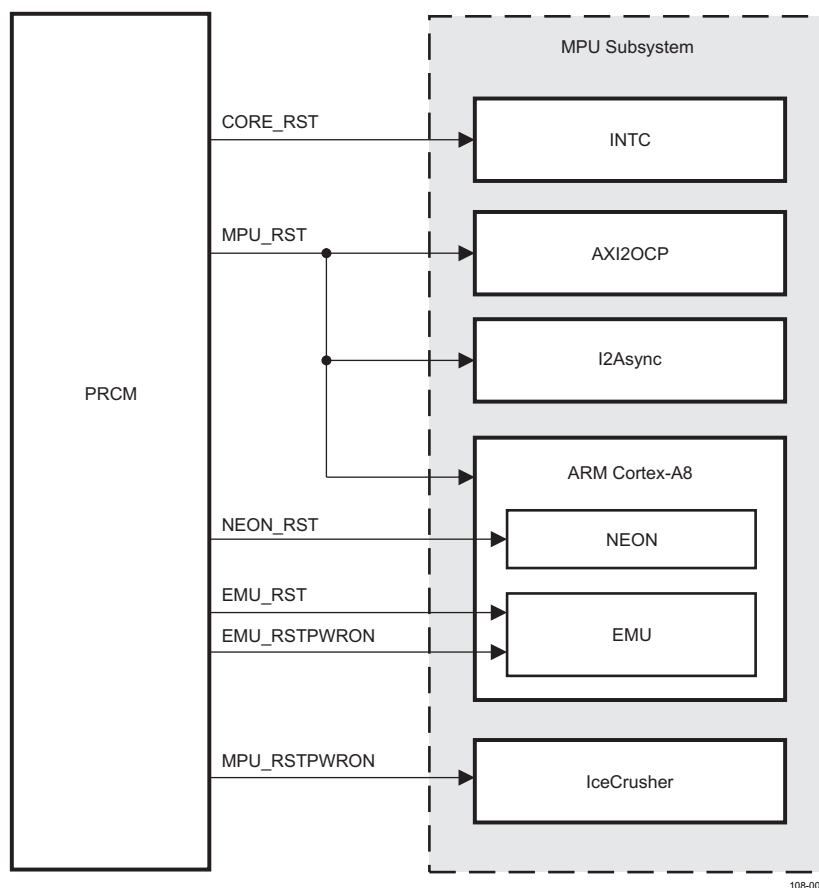

Table 3-1 summarizes the clocks generated in the MPU subsystem by the MPU clock generator.

Table 3-1. MPU Clock Generator Clock Signals

Signal Name	I/O	Interface	Comments
MPU_CLK	I	PRCM	MPU DPLL clock out
ARM_FCLK	O	ARM	ARM functional clock
MPU_INTC_FCLK	O	MPU INTC	MPU INTC functional clock
I2ASYNF_FCLK	O	I2Async	I2Async functional clock
AXI_FCLK	O	AXI2OCP	AXI2OCP functional clock
ICECRUSHER_FCLK	O	ICE-Crusher	ICE-Crusher functional clock

3.2.1.2 Reset Distribution

Resets to the MPU subsystem are provided by the PRCM and controlled by the clock generator module. There are as many reset signals as power domains. For details about power domains, see [Section 3.3.2.1](#). [Figure 3-4](#) shows the reset scheme of the MPU subsystem.

Figure 3-4. MPU Subsystem Reset Scheme

Table 3-2. MPU Subsystem Reset Signals

Signal Name	I/O	Interface	Comments
MPU_RST	I	PRCM	MPU power domain reset
NEON_RST	I	PRCM	NEON power domain reset
CORE_RST	I	PRCM	CORE power domain reset
MPU_RSTPWON	I	PRCM	ICE-Crusher reset. It is active upon a cold reset only
EMU_RST	I	PRCM	Emulation interconnect reset

Table 3-2. MPU Subsystem Reset Signals (continued)

EMU_RSTPWRON	I	PRCM	Emulation modules reset
--------------	---	------	-------------------------

For details about clocks, resets, and power domains, see the *Power, Reset, and Clock Management (PRCM)* chapter.

3.2.2 ARM Subchip

3.2.2.1 ARM Overview

The ARM Cortex-A8 Revision: r1p1 processor incorporates the technologies available in the ARM7™ architecture. These technologies include NEON™ for media and signal processing and Jazelle™ RCT for acceleration of realtime compilers, Thumb®-2 technology for code density and the VFPv3 floating point architecture.

For details, see the *ARM®Cortex™-A8 Technical Reference Manual*.

3.2.2.2 ARM Description

3.2.2.2.1 ARM®Cortex™-A8 Instruction, Data, and Private Peripheral Port

The AXI bus interface is the main interface to the ARM system bus. It performs L2 cache fills and non-cacheable accesses for both instructions and data. The AXI interface supports 64-bit wide input and output data buses. It supports multiple outstanding requests on the AXI bus and a wide range of bus clock to core clock ratios. The bus clock is synchronous with the core clock.

See the *ARM®Cortex™-A8 Technical Reference Manual* for a complete programming model of the transaction rules (ordering, posting, and pipeline synchronization) that are applied depending on the memory region attribute associated with the transaction destination address.

3.2.2.2.2 MPU Subsystem Features

Table 3-3 is a list of main functionalities of the ARM core supported inside the MPU subsystem for the device. The MPU subsystem implements the ARM7™ Instruction Set Architecture.

Table 3-3. ARM Core Key Features

Feature	Comment
ARM version 7 ISA	Standard ARM instruction set + Thumb-2, Jazelle RCT Java accelerator, and Media extensions. Backward-compatible with previous ARM ISA versions.
L1 Icache and Dcache	16KB, 4-way, 64 byte cache line, and 128 bit interface. Note: L1 memories cannot be put into retention mode.
L2 Cache	The L2 cache and cache controller are embedded in the ARM core.
TLB	Fully associative and separate ITLB with 32 entries and DTLB with 32 entries
CoreSight ETM	The CoreSight ETM is embedded in the ARM core. The 4KB buffer (ETB) exists at the device level.
Branch target address cache	512 entries
Enhanced Memory Management Unit	Mapping sizes are 4KB, 64KB, 1MB, and 16MB. ARM MMU adds extended physical address ranges.
NEON	Enhances throughput for media workloads and VFP-Lite support
Tightly coupled memory	Not present
AXI Bus	Separate 64-bit input and 64-bit output data buses. ARM Cortex™-A8 Revision: r1p1 has a single AXI bus interface. The AXI interface is shared among Instruction fetches, data accesses, peripheral accesses and PLE (onchip preload engine, previously known as DMA) accesses. DMA is available.
Low interrupt latency	The IRQ & FIQ are directly connected to ARM and INTC is before L3
Vectored Interrupt Controller Port	Not used
JTAG based debug	Supported through DAP.
Trace support	Supported through TPIU.
External coprocessor	Not supported

For more information, see the *ARM® Cortex™-A8 Technical Reference Manual*.

3.2.2.3 Clock, Reset, and Power Management

3.2.2.3.1 Clocks

Table 3-4 shows the ARM functional clock. For configuration, see the *Power, Reset, and Clock Management* chapter.

Table 3-4. MPU Subsystem Clock Signal

Signal Name	I/O	Interface	Comments
ARM_FCLK	I	MPU Clock Generator	Functional clock

3.2.2.3.2 Reset

Table 3-5 lists the resets for the ARM. They include the power domains reset; NEON_RST, which resets the neon module of the ARM subchip only; and MPU_RST, which resets the rest of the ARM subchip and also the AXI2OCP and I2Async bridges.

Table 3-5. ARM Reset Signals

Signal Name	I/O	Interface	Comments
MPU_RST	I	PRCM	MPU power domain reset
NEON_RST	I	PRCM	Reset NEON only
EMU_RST	I	PRCM	Emulation interconnect reset
EMU_RSTPWON	I	PRCM	Emulation modules reset

3.2.2.3.3 Power Management

For details, see [Section 3.3.2](#).

3.2.3 AXI2OCP and I2Async Bridges

3.2.3.1 Bridges Overview

The AXI2OCP bridge is used in the device design to connect the AXI bus on the ARM MPU to the OCP native L3 interconnect and interrupt controller. It converts between AXI and OCP protocols and maintains a mapping of AXI tags to the OCP thread ID. This bridge is responsible for some minimal address decoding to decide where to forward the requests between L3 and INTC.

Bridging to the L3 is accomplished through an asynchronous interface involving the I2Async and T2Async modules. The I2Async module inside the MPU subsystem has an OCP port that is asynchronously transferred to the T2Async module and routed to the L3. T2Async is outside the MPU subsystem.

Note: The interface between I2Async and T2Async is not an OCP protocol.

Figure 3-5 is an overview of the AXI2OCP and the L3 bridges.

3.2.3.3 AXI Tag to OCP Thread Remapping

The tables below show the number of outstanding request per OCP thread and the mapping:

Table 3-6. Maximum number of Outstanding Request per OCP Thread

OCP Thread	Maximum Outstanding Requests
Thread_DR	1
Thread_DW	8
Thread_IR	1
Thread_CR	6
Thread_CW	4

Table 3-7. AXI-Tag to OCP-Thread Remap Table

ARID (ARVALID=1)	APROT[2]	Mthreadid (Encoding)	Outstanding Transactions
4'b0000-4'b0001, 4'b0110	x	Thread_DR (3)	2
4'b0011	x	Peripheral (na)	1
4'b0100-4'b0101, 4'b1111	x	Thread_IR (0)	1
4'b1110	x	Thread_CR (1)	5
4'b1000-4'b1011	0	Thread_CR (1)	5
4'b1000-4'b1011	1	Thread_IR (0)	1
AWID (AWVALID=1)	APROT[2]	Mthreadid (Encoding)	Outstanding Transactions
4'b0000-4'b0001	x	Thread_DW (4)	8
4'b0011	x	Peripheral (na)	1
4'b0010, 4'b1000-4'b1011	x	Thread_CW (2)	12

The following tags are never used for read channel (ARID): 0x2, 0x7, 0xC, 0xD.

The following tags are not used for write channel (AWID): 0x4-0x7, 0xC-0xF.

Note: For the AXITag ID in the range of 0x8-0xf, the ARM core does not use the same tag again when a request with that same tag ID is outstanding. This is to prevent out of order responses on Thread_CR vs Thread_IR when using APROT[2] to map AXITag ID 4'b1000-4'b101. Thus a response for two requests cannot come out of order.

A 2KB memory region within a 1MB memory space is reserved for an INTC. See [Table 3-8](#) for the memory map.

Table 3-8. Memory Map for Interrupt Controller

	Start	End	Size	Comments
Interrupt controller	0x4820 0000	0x4820 03FF	2K bytes	non shared device mapping
Reserved (alias to INTC)	0x4820 0400	0x4827 FFFF		non shared device mapping
Reserved	0x4828 0000	0x482F FFFF		non shared device mapping

3.2.3.4 Clocks, Reset, and Power Management

3.2.3.4.1 Clocks

Table 3-9 lists the bridge functional clocks.

Table 3-9. Bridges Clock Signals

Signal Name	I/O	Interface	Comments
AXI2OCP_FCLK	I	MPU Clock Generator	AXI2OCP functional clock
I2ASYNCR_FCLK	I	MPU Clock Generator	I2Async functional clock

3.2.3.4.2 Reset

Table 3-10 lists the bridge reset. It is a power domain reset that also resets the ARM.

Table 3-10. MPU Subsystem Reset Signal

Signal Name	I/O	Interface	Comments
MPU_RST	I	PRCM	MPU power domain reset

3.2.3.4.3 Power Management

For details, see Section 3.3.2.

3.2.4 Interrupt Controller

For information, see the *Interrupt Controllers* chapter.

3.2.4.1 Clocks

Table 3-11 lists the INTC clocks.

Table 3-11. Bridge Clock Signals

Signal Name	I/O	Interface	Comments
MPU_INTC_FCLK	I	MPU Clock Generator	INTC functional clock
MPU_INTC_ICLK	I	OCP Clock	INTC interface clock

3.2.4.2 Reset

Table 3-12 lists the reset of the INTC. It is a power domain reset that also resets the whole core domain. For details, see the *Interrupt Controller* and the *Power, Reset, and Clock Management (PRCM)* chapters.

Table 3-12. MPU Subsystem Reset Signal

Signal Name	I/O	Interface	Comments
CORE_RST	I	PRCM	CORE power domain reset

3.2.4.3 Power Management

See the *Interrupt Controller* and the *PRCM* chapters.

3.3 MPU Subsystem Functional Description

3.3.1 Interrupts

The MPU INTC is connected to the MPU through the AXI2OCP bridge. It runs at half-processor speed. The INTC prioritizes all service requests from the system peripherals and generates either an IRQ or an FIQ to the MPU, depending on the INTC programming. The INTC handles only the interrupts directed to the MPU subsystem. A maximum of 96 requests can be steered/prioritized as MPU FIQ or IRQ interrupt requests. For details, see the *Interrupt Controller* chapter.

3.3.2 Power Management

3.3.2.1 Power Domains

The MPU subsystem is divided into 5 power domains controlled by the PRCM, as shown in [Figure 3-6](#). Note that the emulation domain and the core domain are not fully embedded in MPU subsystem.

Figure 3-6. MPU Subsystem Power Domain Overview

Power management requirements at the device level govern power domains for the MPU subsystem.

The device-level power domains are directly aligned with voltage domains and thus can be represented as a cross reference to the different voltage domains. [Table 3-13](#) shows the different power domains of the MPU subsystem and the modules inside.

Table 3-13. Overview of the MPU Subsystem Power Domain

Functional Power Domain	Physical Power Domain per System/Module
MPU subsystem domain	ARM, AXI2OCP, I2Asynch Bridge, ARM L1 and L2 periphery logic and array, ICE-Crusher, ETM, APB modules
MPU NEON domain	ARM NEON accelerator
CORE domain	MPU interrupt controller
EMU domain	EMU (ETB,DAP)

Note: L1 and L2 array memories have separate control signals into the in MPU Subsystem, thus directly controlled by PRCM

For details on the physical power domains and the voltage domains, see the *Power, Reset, and Clock Management (PRCM)* chapter.

3.3.2.2 Power States

Each power domain can be driven by the PRCM in 4 different states, depending on the functional mode required by the user.

Table 3-14. MPU Power States

Power State	Logic Power	Memory Power	Clocks	Memory State Retention
Active	On	On or Off	On (at least one clock)	All
Inactive	On	On or Off	Off	All
Retention	On or Off	On or Off	Off (all clocks)	All or part
Off	Off	Off	Off (all clocks)	None

For each power domain the PRCM manages all transitions by controlling domain clocks, domain resets, domain logic power switches, memory power switches, and memory retention. The MPU DPLL then internally synchronizes the internal clocks, resets, and switches.

3.3.2.3 Power Modes

MPU DPLL power modes:

The PRCM.CM_AUTOIDLE_PLL_MPU[2:0] AUTO_MPU_DPLL register field allows putting the MPU DPLL in an auto-idle mode when set to 0x1. In this mode, MPU DPLL is automatically put in low power stop mode when the MPU clock is not required anymore. It is also restarted automatically. The following table describes the different modes that the MPU DPLL can be used in auto-idle or manual mode. The manual modes (locked and low power bypass) can be configured by the PRCM.CM_CLKEN_PLL_MPU[2:0] EN_MPU_DPLL register field. The status of the MPU DPLL clock activity can be checked with the PRCM.CM_IDLEST_PLL_MPU[0] ST_MPU_CLK bit.

Table 3-15. MPU DPLL Power Modes

Mode	System Input Clock	Clock Output	DPLL Power State	Condition
Locked	ON	ON	ON	Software request (manual) or MPU wakes up (auto)
Low power bypass	ON	ON	ON	Software request (manual) or upon global reset release (auto)
Stop low power	OFF	OFF	ON	MPU is RET or OFF (auto)
OFF	OFF	OFF	OFF	Device is OFF (auto)

MPU DPLL power domain is switched off automatically by the PRCM only when the device enters OFF mode.

MPU Subsystem power modes:

The major part of the MPU subsystem belongs to the MPU power domain. The modules inside this power domain can be off at a time when the ARM processor is in an OFF or standby mode. IDLE/WAKEUP control is managed by the clock generator block but initiated by the PRCM module. The MPU Standby status can be checked with PRCM.CM_IDLEST_MPU[0] ST_MPU bit.

For the MPU to be on, the core (referred here as the device core) power must be on.

Device power management does not allow INTC to go to OFF state when MPU domain is on (active or one of retention modes).

The NEON core has independent power off mode when not in use. Enabling and disabling of NEON can be controlled by software.

CAUTION

The MPU L1 cache memory does not support retention mode, and its array switch is controlled together with the MPU logic. For compliance, the L1 retention control signals exist at the PRCM boundary, but are not used. The ARM L2 can be put into retention independently of the other domains.

MPU retention modes are:

- Open switch retention (OSwR)
- Closed switch retention (CSwR)

These modes are described in [Table 3-16](#).

Table 3-16. MPU Retention Modes

Name	Mode	ARM Logic	L1	L2
Dormant	OSwR	OFF	OFF	RET
RET	CSwR	ON	ON	RET

[Table 3-17](#) outlines the supported operational power modes. All other combinations are illegal. The ARM L2, NEON, and ETM/Debug can be powered up/down independently. The APB/ATB ETM/Debug column refers to all three features: ARM emulation, trace, and debug.

Table 3-17. MPU Subsystem Operation Power Modes

Mode	MPU and ARM Core Logic	AMR L2 RAM	NEON	OMAP Core INTC	APB/ATB Debug and ETM	Comments
1	Active	Active	Active	Active	Disabled or enabled	Functional active run mode (ETM enabled mode when emulation/debug required. Production devices should have ETM disabled).
2	Active	Active	OFF	Active	Disabled or enabled	Functional active run mode. NEON disabled via SW; NEON is internally clock gated.
3	Active	RET	Active	Active	Disabled or enabled	Do not use; see Note 1.
4	Active	RET	OFF	Active	Disabled or enabled	Do not use; see Note 1.

Table 3-17. MPU Subsystem Operation Power Modes (continued)

Mode	MPU and ARM Core Logic	AMR L2 RAM	NEON	OMAP Core INTC	APB/ATB Debug and ETM	Comments
5	Active	OFF	Active	Active	Disabled or enabled	Active mode, L2 is off. Controlled via SW to PRCM. L2 context save and restore required or L2 flush.
6	Active	OFF	OFF	Active	Disabled or enabled	Active mode, L2 is off. Controlled via SW to PRCM. L2 context save and restore required or L2 flush.
7	OFF	RET	OFF	OFF	Disabled or enabled	Lowest power sleep mode (dormant mode), L2 is in retention. Controlled via SW to PRCM. ARM core and L1 context save and restore required or L1 flush.
8	Standby	Active	Standby	Active	Disabled or enabled	Standby mode. StandbyWFI controlled to put into standby and wakeup via interrupt.
9	Standby	Active	OFF	Active	Disabled or enabled	Standby mode. StandbyWFI controlled to put into standby and wakeup via interrupt when NEON is off.
10	Standby	RET	Standby	Active	Disabled or enabled	Standby mode (retention mode). StandbyWFI controlled to put into standby and wakeup via interrupt when L2 is in retention.
11	Standby	RET	OFF	Active	Disabled or enabled	Standby mode (retention mode). StandbyWFI controlled to put into standby and wakeup via interrupt when L2 is in retention and NEON is off.
12	Standby	OFF	Standby	Active	Disabled or enabled	Standby mode. StandbyWFI controlled to put into standby and wakeup via interrupt when L2 is off.
13	Standby	OFF	OFF	Active	Disabled or enabled	Standby mode. StandbyWFI controlled to put into standby and wakeup via interrupt when both L2 and NEON are off.
14	OFF	OFF	OFF	OFF	Disabled or enabled	Power-down mode

In any mode where the MPU or NEON power domains are active, the MPU DPLL clocks must be active (modes 1, 3, and 5 require active clocks from the DPLL, while Modes 7 and 8 do not).

Thus, the MPU DPLL must be in one of these states:

- Locked State
- Low power bypass state: inclk=on, clkout=on, power=on

When the MPU DPLL is not providing clocks, the MPU subsystem must be in a power mode where the MPU power domain, NEON power domain, debug power domain, and INTC power domain are in standby, retention, or off state. The states of the MPU DPLL can be:

- Locked
- STOP low power
- OFF

CAUTION

The L2 can be put into retention mode regardless of other voltage domain states. The combination of ARM Logic active and L2 in retention mode (modes 3 and 4) is legal, but results in improper execution of instructions with referencing data from L2. This combination must not be used.

3.3.2.4 Transitions

[Table 3-18](#) describes allowable transitions from power modes described in [Table 3-17](#). For example, a transition from mode 13 to mode 4 is allowed, but the reverse is not true because the L2 RET to OFF is illegal.

Any mode change that requires state saving or flush must be serialized. For example, L2 RET does not require state saving, so it can happen at the same time as power-down NEON. L2 off and NEON off cannot happen at the same time, because L2 flush and NEON state saving must be serialized. Standby mode can enter from active mode only by executing the wait for interruption (WFI) instruction.

Table 3-18. Power Mode Allowable Transitions

From	To Power Mode													
	1	2	3	4	5	6	7	8	9	10	11	12	13	14
1	Y	Y	Y	Y	Y			Y						Y
2	Y	Y	Y	Y		Y			Y		Y			Y
3	Y	Y	Y	Y			Y			Y				
4	Y	Y	Y	Y			Y				Y			
5	Y		Y	Y	Y	Y	Y			Y		Y		Y
6		Y	Y	Y	Y	Y	Y				Y		Y	Y
7	Y	Y	Y	Y			Y							
8	Y		Y					Y		Y

For more information about clocks, reset, power management, and wake-up events for the MPU subsystem, see the *Power, Reset, and Clock Management (PRCM)* chapter.

3.4 MPU Subsystem Basic Programming Model

For detailed descriptions of registers used for MPU configuration, see the *Power, Reset, and Clock Management*, and the *Interrupt Controller* chapters.

3.4.1 Clock Control

For clock configuration settings, see the *Power, Reset, and Clock Management (PRCM)* chapter.

3.4.2 MPU Power Mode Transitions

The following subsections describe transitions of different power modes for MPU power domain:

- Basic power on reset
- MPU into standby mode
- MPU out of standby mode
- MPU power on from a powered off state

3.4.2.1 Basic Power-On Reset

The power on reset follows the following sequence of operation and is applicable to initial power-up and wakeup from device off mode.

1. Reset DPLL, supply reference clock, program the MPU DPLL in applicable DPLL mode to generate clocks for MPU subsystem modules. This is controlled solely by the PRCM module.
2. Reset the INTC (CORE_RST) and the MPU subsystem modules (MPU_RST). The clocks must be active during the MPU reset and CORE reset.

3.4.2.2 MPU Into Standby Mode

The MPU into standby mode follows the following sequence of operation and is applicable to initial power-up and wakeup from device Off mode.

1. The ARM core initiates entering into standby via software only (CP15 - WFI).
2. MPU modules requested internally of MPU subsystem to enter idle, after ARM core standby detected.
3. MPU is in standby output asserted for PRCM (all outputs guaranteed to be at reset values).
4. PRCM can now request INTC to enter into idle mode. Acknowledge from INTC goes to PRCM.
5. PRCM can start to shut down clocks through DPLL programming.

Note: The INTC SWAKEUP output is a pure hardware signal to PRCM for the status of its IDLE request and IDLE acknowledge handshake.

Note: In debug mode, ICE-Crusher could prevent MPU subsystem from entering into IDLE mode.

3.4.2.3 MPU Out of Standby Mode

The MPU out of standby mode follows the following sequence of operation and is applicable to initial power-up and wakeup from device Off mode.

1. PRCM must start clocks through DPLL programming.
2. Detect active clocking via status output of DPLL.
3. Initiate an interrupt through the INTC to wake up the ARM core from STANDBYWFI mode.

3.4.2.4 MPU Power-On from a Powered-Off State

1. DPLL Power On, MPU Power On, NEON Power On, Core Power On (INTC) should follow the ordered sequence per power switch daisy chain to minimize the peaking of current during power-up.

Note: The core domain must be on, and reset, with the clocks of the DPLL on, before the MPU can be reset.

2. Then follow the reset sequence as described in [Section 3.4.2.1](#), *Basic Power-On Reset*.

3.4.3 NEON Power Mode Transition

When NEON power domain transition is configured to Automatic Hardware-supervised mode (CM_CLKSTCTRL_NEON[1:0] CLKTRCTRL_NEON bits are set to 0x3), it can not transition into idle unless MPU goes into Standby, because of the Hardware Sleep dependency between NEON and the MPU domain. In that case, the MPU domain must also be configured in Automatic Hardware Supervised mode (CM_CLKSTCTRL_MPU[1:0] CLKTRCTRL_MPU bits must be set to 0x3) for the NEON power domain transition to happen.

3.4.4 ARM Programming Model

For the complete programming model, see the *ARM® Cortex™-A8 Technical Reference Manual*.

4.1 PRCM Introduction to Power Management

This introduction contains the following information:

- Requirement and goal of power management in mobile devices
- State-of-the-art power-management techniques for maximizing battery life for mobile devices
- Essential architectural building blocks for power management
- Overview of the device power-management architecture

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

4.1.1 Goal of Power Management

Power management (efficient use of the available limited battery resources of a mobile device) is one of the most important design aspects of any mobile system. It imposes strong control over limited available power resources to ensure they function for the longest possible amount of time.

The device architecture ensures maximum performance for user satisfaction (audio/video support) while offering versatile power-management techniques for maximum design flexibility, depending on application requirements.

4.1.2 Power-Management Techniques

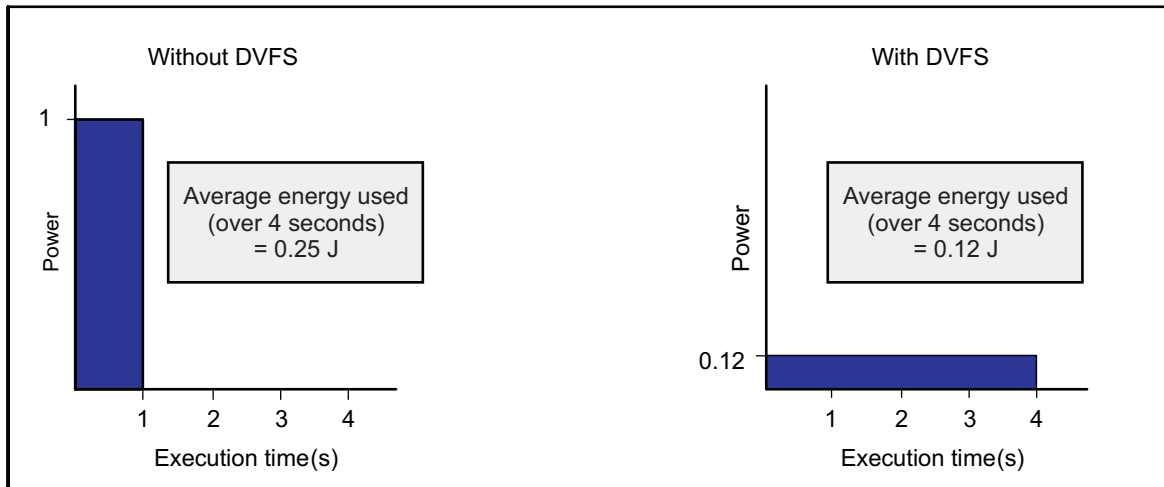

The following sections describe the state-of-the-art power-management techniques supported by the device.

Note: The values in [Figure 4-1](#) through [Figure 4-4](#), which show power-management techniques, are hypothetical only. They do not represent valid test results on the device.

4.1.2.1 Dynamic Voltage and Frequency Scaling

Dynamic voltage and frequency scaling (DVFS) consists of minimizing the idle time of the system. The DVFS technique uses dynamic selection of the optimal operating frequency and voltage to allow a task to be performed in the required amount of time. This reduces the active power consumption (power consumed while executing a task) of the device while still meeting task requirements.

Figure 4-1. Comparison of Energy Consumed With/Without DVFS

prcm-001

Figure 4-1 shows the DVFS technique by comparing a process executed at maximum frequency and operating voltage without applying DVFS to the same process executed at optimal frequency and voltage using DVFS, based on the task requirements. If a task that must terminate in 4 seconds is performed at maximum operating frequency (left side of the figure), it terminates in 1 second, and the remaining 3 seconds are spent in idle mode. With DVFS (right side of the figure), the operating frequency is reduced to an optimal level; the task takes the full 4 seconds to complete, but power consumption is reduced. In addition, the voltage can be reduced further to save power so both dynamic and leakage power consumption are reduced.

DVFS requires control over the clock frequency and the operating voltage of the device elements. By intelligently switching the individual elements of the device to their optimal operating points, it is possible to minimize the power consumption of the device for a given task.

For practical reasons related to device making (flow, tools), DVFS can be used only for a few discrete steps, not over a continuum of voltage and frequency values. Each step, or operating performance point (OPP), is composed of a voltage (V) and frequency (F) pair. For an OPP, the frequency corresponds to the maximum frequency allowed at a voltage, or reciprocally; the voltage corresponds to the minimum voltage allowed for a frequency.

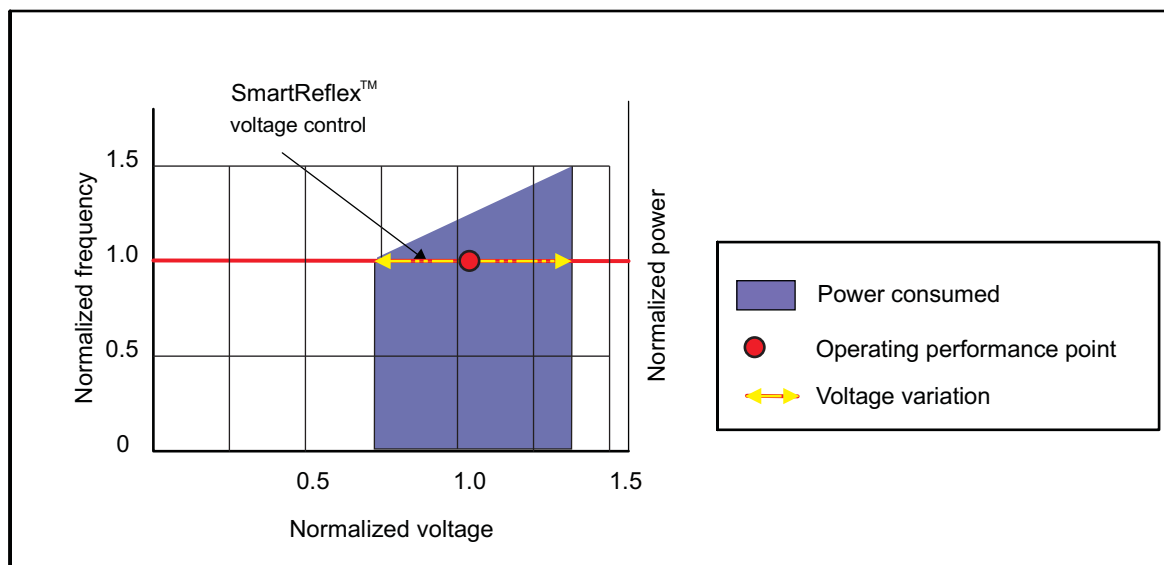

When applying DVFS, a processor or system always runs at the lowest OPP that meets the performance requirement at a given time. The user determines the optimal OPP for a given task and then switches to that OPP to save power.

4.1.2.2 SmartReflex Adaptive Voltage Control

SmartReflex is a power-management technique for automatic control of the operating voltage of a module to reduce active power consumption.

With SmartReflex, power-supply voltage is adapted to silicon performance, either statically (based on performance points predefined in the manufacturing process of a given device) or dynamically (based on the temperature-induced real-time performance of the device). A comparison of these predefined performance points to the real-time on-chip measured performance determines whether to raise or lower the power-supply voltage.

SmartReflex achieves the optimal performance/power trade-off for all devices across the technology process spectrum and across temperature variation.

Figure 4-2. SmartReflex Example

prcm-002

In [Figure 4-2](#), the self-adjusting voltage scaling with SmartReflex ensures the frequency performance of the current OPP. For a given device operating frequency, the device voltage is automatically adapted to maintain performance of the device. This ensures optimal power consumption for a given OPP.

With SmartReflex, the frequency steps are identified and the voltage is adapted according to the silicon performance of the device. In this case, instead of a voltage step for each frequency step, there is a corresponding range of voltages. The range depends on the fabrication process of the device and its real-time operating state (temperature) at a given frequency.

4.1.2.3 Dynamic Power Switching

Like DVFS, dynamic power switching (DPS) is a power-management technique aimed at reducing active power consumption of a device. However, whereas DVFS reduces both dynamic and leakage power consumption, DPS reduces only leakage power consumption, at the expense of a slight overhead in dynamic power consumption.

With DPS, the system switches dynamically between high- and low-consumption system power modes during system active time. When DPS is applied, a processor or system runs at the highest OPP (maximum frequency and voltage) to complete its tasks quickly, followed by an automatic switch to a low-power mode, for minimum power consumption. DPS is useful when a real-time application is waiting for an event. The system can switch into a low-power system mode if the wake-up latency conditions allow it.

This technique consists of maximizing the idle period of the system to reduce its power consumption.

Figure 4-3. Comparison of Energy Consumed With/Without DPS

prcm-003

Figure 4-3 compares the power consumption behavior for the same device operation without DPS (left side of the figure) and with DPS (right side of the figure). When operating without DPS, the device has a constant leakage current in idle mode. By using DPS, the system reduces the leakage current to zero. However, the transitions between system power modes may require storing the information before entering a low-power INACTIVE state and restoring the information after a wake-up event (see Figure 4-3). This results in additional dynamic power consumption, referred to as the transition overhead, (see Figure 4-3). Transition overhead must be considered for a DPS operation.

For efficient deployment of DPS techniques, it is necessary to predict dynamically the performance requirement of the applications running on the processor. The DPS controller must account for the overhead of wake-up latencies related to domain switching and ensure that they do not significantly affect the performance of the device. Even with transition overhead, however, the user can identify an optimal idle-time limit after which the DPS is useful for dynamic power-saving.

4.1.2.4 Standby Leakage Management

Standard leakage management (SLM) is a power-management technique that reduces standby power consumption by reducing power leakage.

With SLM, the device switches into low-power system modes automatically or in response to user requests during system standby (that is, in situations when no application is started and system activity is negligible or limited).

When applying SLM, the system remains in the lowest static power mode compatible with the system response time requirement.

This technique trades static power consumption for wake-up latency.

4.1.2.5 DPS Versus SLM

DPS and SLM are similar concepts: they consist of switching the system between high- and low-power consumption modes. However, their operating timescales differ, principally in the latency allowed for mode transitions.

DPS is generally used in an applicative context (tasks are started). Therefore, mode transitions are related to system performance requirements or the processor load. DPS transition latencies must be small (typically between 10 μ s and 100 μ s) compared to the time constraints or deadlines of the application so that they do not degrade application performance. DPS requires performance prediction to ensure that transition latencies do not deteriorate device performance to the point that real-time application deadlines are missed or the user experience degrades too much for an interactive application.

SLM is not used in an applicative context (no task started). Mode transitions are related more to system responsiveness, and the transition latencies must be small compared to user sensitivity so that they do not degrade the user experience. For SLM, transition latencies are typically 1 ms to 10 ms or more.

DPS and SLM also differ in the type of wake-up event used to exit low-power idle mode. For DPS, wake-up events are application-related (timer, DMA request, peripheral interrupt, etc.); for SLM, wake-up events are user-related (touch screen, key pressed, peripheral connections, etc.).

4.1.2.6 Combining Power-Management Techniques

The power-management techniques previously described have specific features and are most effective when used under the specific operating conditions of the device. Hence, the best active power saving is obtained by combining the DVFS, DPS, SLM, and SmartReflex techniques. For a given operating state, one or more of the power-saving techniques can be applied to ensure optimal operation with maximum power saving.

SmartReflex can be used at boot time to adapt the voltage to device process characteristics (strong/weak) and then used continuously to compensate temperature variations. It can also ensure maximum available application performance of the device at a given OPP.

When medium application performance is required, or when application performance requirements vary, DVFS can be applied. The voltage and frequency can be scaled to match the closest OPP that meets the performance requirement.

When application performance requirements fall between two OPPs, or when a low application performance is required that is below the lowest performance OPP, DPS can be applied to switch to low-power mode.

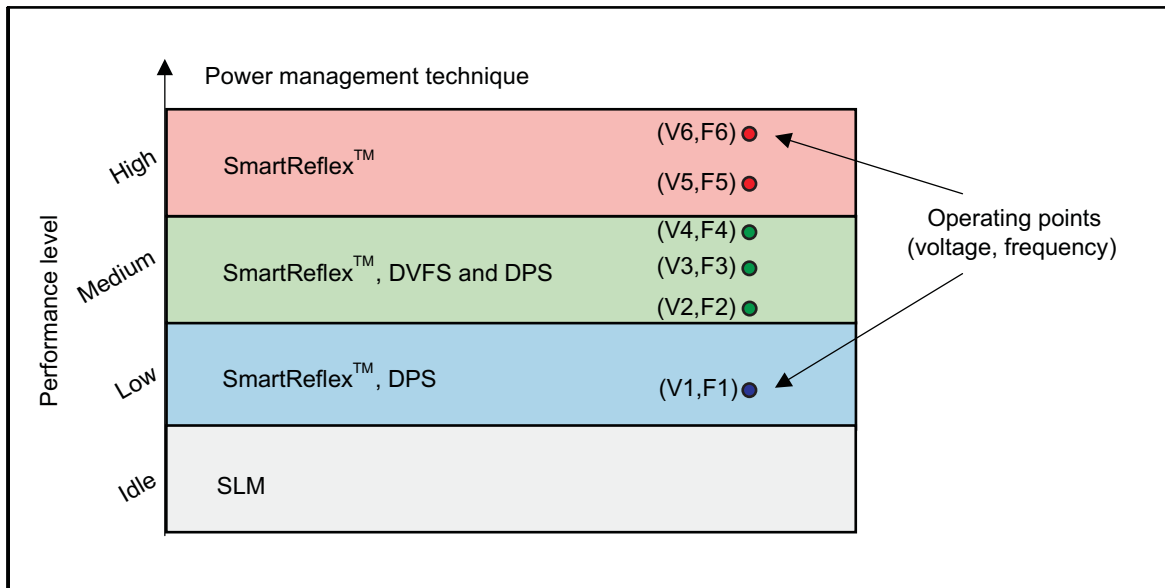

When combining DVFS and DPS, the operating frequency must not be scaled to match the performance requirement without scaling the voltage. Lower operating frequency increases task completion time and reduces idle time. This prevents DPS or reduces its efficiency (DPS becomes more effective as idle time increases). Unless DPS cannot be applied for other reasons, for a given operating point of DVFS the operating frequency must always be set to the maximum allowed at a given voltage. This ensures optimal process completion time and application of DPS.

If DPS cannot be applied in a given context, scaling the frequency while keeping the voltage constant does not save energy; it does, however, reduce peak power consumption. This can have a positive effect on temperature dissipation and battery life.

In situations where no applications are running and performance requirement drops to zero, SLM must be used.

Note: The OPPs shown in [Figure 4-4](#) are only for indication and clarity of text. They do not correspond to validated OPPs of the device.

Figure 4-4. Performance Level and Applied Power-Management Techniques

prcm-004

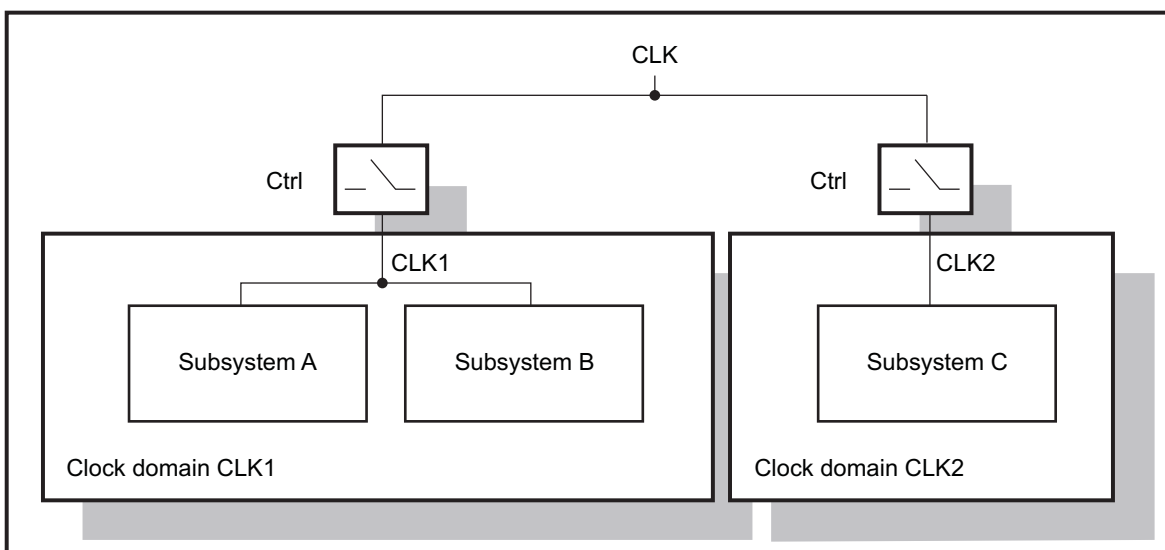

4.1.3 Architectural Blocks for Power Management

The device supports the previously described power-management techniques through three architectural blocks: the power, clock, and voltage domains. A domain is a group of modules or subsections of the device that share a common entity (clock, voltage, or power switching).

4.1.3.1 Clock Domain

A clock domain is a group of modules fed with the same gated clock signal (see Figure 4-5). By gating the clock to each domain, it is possible to cut a clock to a group of inactive modules to lower their active power consumption. Thus, a clock domain allows control of dynamic power consumption by the device.

Figure 4-5. Generic Clock Domain

prcm-005

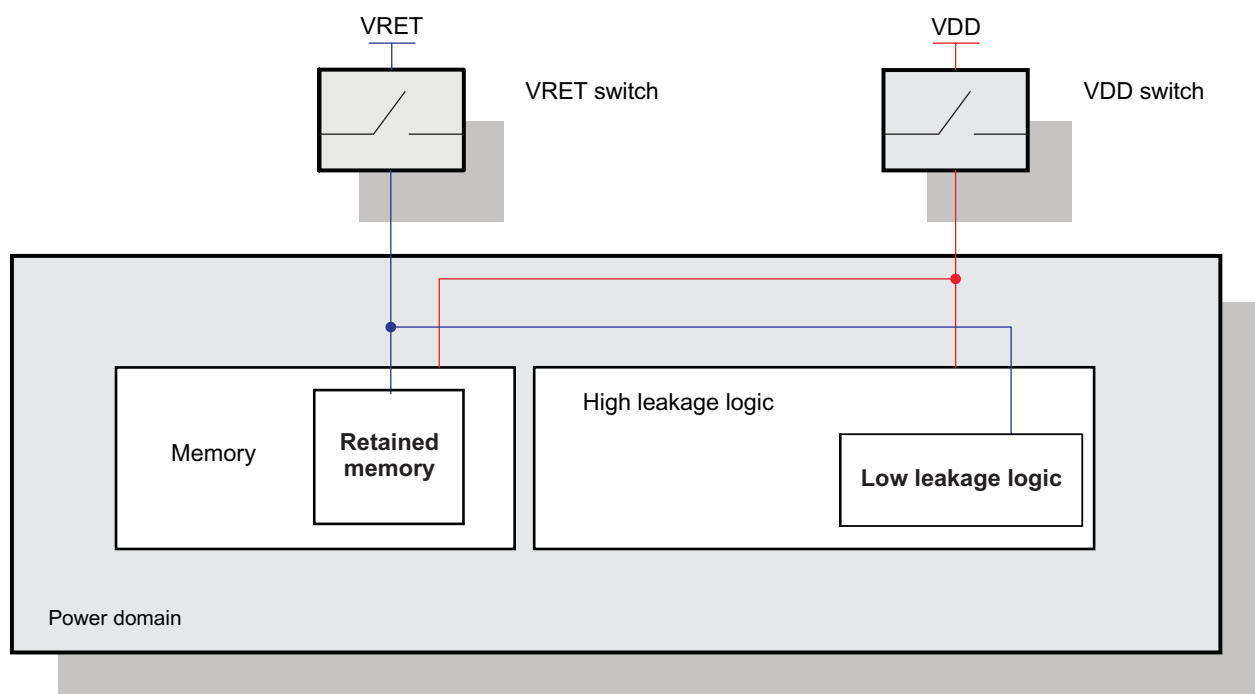

Table 4-1 lists the two possible states of the clock domain.

Table 4-1. States of a Clock Domain

State	Description
Active	The domain clock is running.
Idle	The domain clock is stopped or gated.

4.1.3.2 Power Domain

A power domain is a section of the device with independent and dedicated power rails (see [Figure 4-6](#)). A power domain can be turned on/off without affecting the other parts of the device.

Figure 4-6. Generic Power Domain

prcm-006

To minimize power consumption by the device, the modules are placed in power domains. A power domain is attached to two voltage sources: an active voltage source (VDD) and a retention voltage source (VRET). Active voltage is the normal operating voltage of logic and memory in the power domain. Retention voltage is less than active voltage. At retention voltage, logic and memory are not operational, but their content or state is retained. This RETENTION state is useful for quickly switching to low-power idle mode without losing the context, and then quickly switching back to ACTIVE state when necessary. In RETENTION state, power consumption is less than in normal operating mode. VRET and VDD are connected to the power domain by two switches. VRET is supplied to the parts of the logic whose context is to be retained (with retention flip-flops [RFFs]) and to the memory section, whose contents are to be maintained. Then, depending on the power state, the two switches can be opened or closed.

[Table 4-2](#) lists the possible states of the power domain with the corresponding status of the VDD and VRET switches.

Table 4-2. Power Domain States

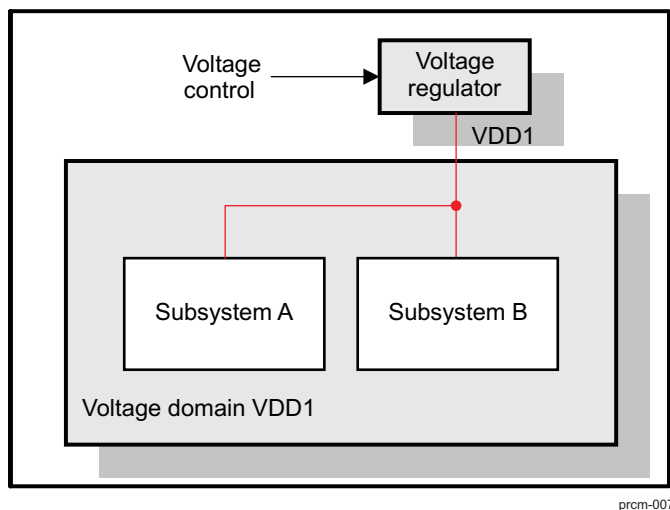

State	VDD Switch	VRET Switch
ACTIVE	Close	Open
RETENTION	Open	Close
OFF	Open	Open

4.1.3.3 Voltage Domain

A voltage domain is a group of modules supplied by the same voltage regulator (embedded or external). The power consumption of this group can be controlled by regulating its voltage independently.

Figure 4-7 shows the voltage domain.

Figure 4-7. Generic Voltage Domain

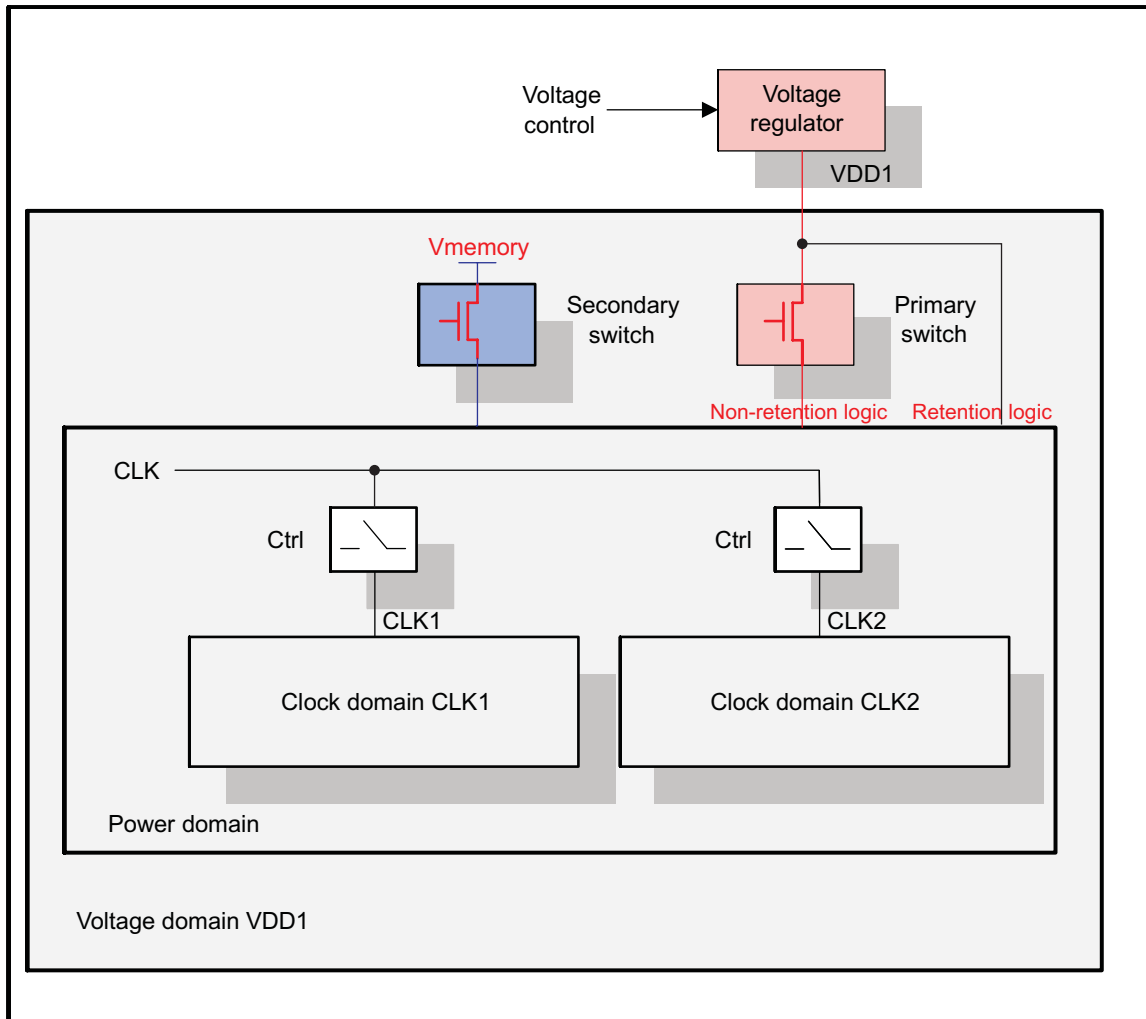

By partitioning the device into independent voltage domains it is possible to assign different operating voltages to the different modules. The independent voltage control allows voltage scaling of device subsections to ensure that each module operates at the optimized operating voltage level based on the application performance requirements. When all modules within a voltage domain are inactive, the domain voltage can be lowered to reduce power consumption and then be switched back to normal operating voltage when a wake-up event is received.

4.1.4 Device Power-Management Architecture

The device architecture integrates the power-management architectural blocks for power-management support. It is composed of scalable/switchable voltage domains (their voltage can be controlled) and switchable power domains. Figure 4-8 shows the general hierarchical architecture scheme of the voltage, power, and clock domains.

A clock domain is a subset of a power domain. This avoids unnecessary dependencies between power domains caused by clocks covering multiple power domains. Each clock within a power domain, with an independent gating control, is a separate clock domain.

Figure 4-8. Voltage, Power, and Clock Domain Hierarchical Architecture

108-008

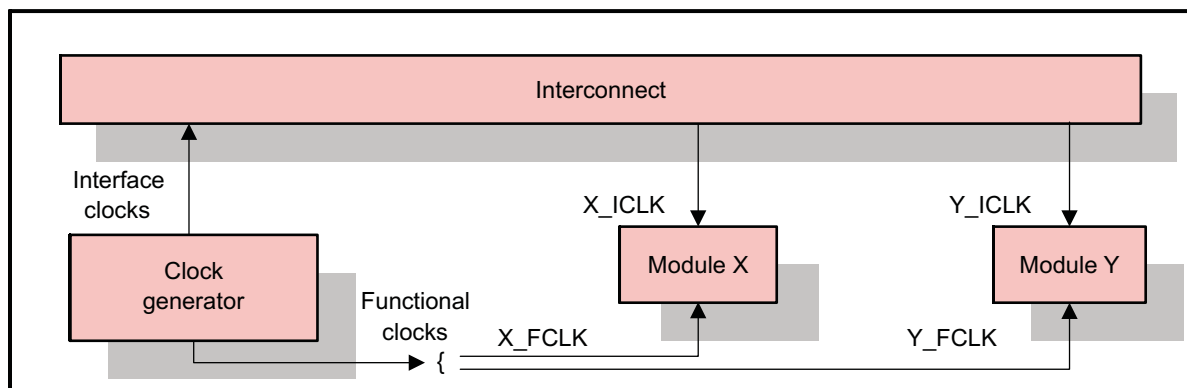

Each power domain is supplied by one or more voltage domains that can be scaled down or switched off to save power. Internal memory and logic can be put in standby (retention) mode independently. In this state, memory is not operational, but the content is retained with minimized leakage. This feature allows power consumption to be reduced when the device is in sleep mode while maintaining memory contents for fast context restore. The logic and memory standby feature is software-controllable.

The OMAP35x supports a clock distribution and control architecture, which is described in the following sections.

4.1.4.1 Module Interface and Functional Clocks

The clocks delivered to the modules in the device are divided into two categories: interface clocks and functional clocks (see [Figure 4-9](#)).

Figure 4-9. Functional and Interface Clocks

prcm-009

Interface clocks have the following characteristics:

- They ensure proper communication between any module/subsystem and the interconnect.
- In most cases, they supply the module interface and registers.
- A typical module has one interface clock, but it can have several.
- They are synchronous across the entire device, because the interconnect fabric is itself fully synchronous.
- Interface clock management is done at the device level.
- From the standpoint of the power, reset, and clock management (PRCM) module, an interface clock is distributed through the device interconnect and is identified with an _ICLK suffix.

Functional clocks have the following characteristics:

- They supply the functional part of a module or a subsystem.
- Each module can have several functional clocks, or none at all. A module may or may not require its functional clocks to be active (nonidle).
- Several modules can share the same functional clock signals, but the branches of the clock tree are not balanced between the modules.
- From the PRCM standpoint, a functional clock is directly distributed to the related modules through a dedicated clock tree. It is identified with an _FCLK suffix.

Note: At the module level, the interface clocks are always fed by the interface clock outputs of the PRCM. The functional clocks are fed either by a PRCM functional clock output or a PRCM interface clock output. In the latter case, the functional and interface clocks of the module inherit capabilities (autoidle features) from the PRCM interface clock (see [Section 4.7, Clock Manager Functional Description](#)).

4.1.4.2 Autoidle Clock Control

The device supports an autoidle clock control scheme for the module interface clocks. With this control scheme, PRCM can automatically activate and deactivate the interface clock of any device module, depending on its operating mode. This scheme executes under hardware control and is transparent to the software. This scheme identifies two module types in the device: the target and the initiator modules, or subsystems.

Note: The functional clocks do not have the autoidle clock scheme, and the software must gate the functional clock of each module when it is not needed.

Initiator

An initiator can generate bus transactions (read, write, etc.) toward targets. It is considered to be active when it generates transactions. If it enters standby mode, it stops generating transactions. Because most initiators also support a target port for configuration purposes, they are both targets and initiators. Some examples of initiators are processors, direct memory access (DMA), and memory management unit (MMU).

Target

A target is a passive module that can process bus transactions (that is, it reads/writes to memory-mapped registers). It is considered to be active when its interface clocks and some or all of its functional clocks are available so it can accept incoming transactions. A target can be put in idle mode by the PRCM, and in this mode its interface clock can be gated at any time. An idle module can still receive its functional clocks and generate interrupts and DMA requests. It can also generate asynchronous wake-up requests, if it is wakeup-capable.

Active, Idle, and Standby Modes

The PRCM module handles automatic clock control differently for initiator and target modules.

For the initiator module, the following hardware handshake scheme is employed:

1. The initiator, when switching from active to idle mode, signals its status to the PRCM.
2. The PRCM cuts off the interface clock to the initiator module.
3. When the initiator module must reactivate, it signals the PRCM, which reactivates its functional and interface clocks.

For the target module, the following hardware handshake scheme is employed:

1. When the PRCM confirms that the target module satisfies the idle conditions, it signals the target module.
2. The target module acknowledges the idle request of the PRCM, depending on its idle mode internal settings (for details about idle mode settings, see the chapter in the technical reference manual for the corresponding device module):
 - If the module is set to smart-idle mode, it terminates its current operations, and then acknowledges the idle request to the PRCM.
 - If the module is set to force-idle mode, it acknowledges immediately, regardless of its current state. Because pending transfers, interrupts, and DMA requests can potentially be lost, special software care must be taken.
 - If the module is set to no-idle mode, it does not acknowledge the idle request. This forces the PRCM to maintain the clock active.
3. The PRCM cuts off the module clocks.
4. The target module can be wakened by the PRCM when its wake-up conditions are satisfied (wake-up event). It activates the module clocks, and then signals the wakeup.
5. The target module acknowledges the wake-up request.
6. Some target modules can support wake-up capability. They can explicitly request the PRCM to activate their clock.

This automatic clock control ensures reduced dynamic power consumption of the device without any associated software overhead.

4.1.5 SmartReflex Voltage-Control Overview

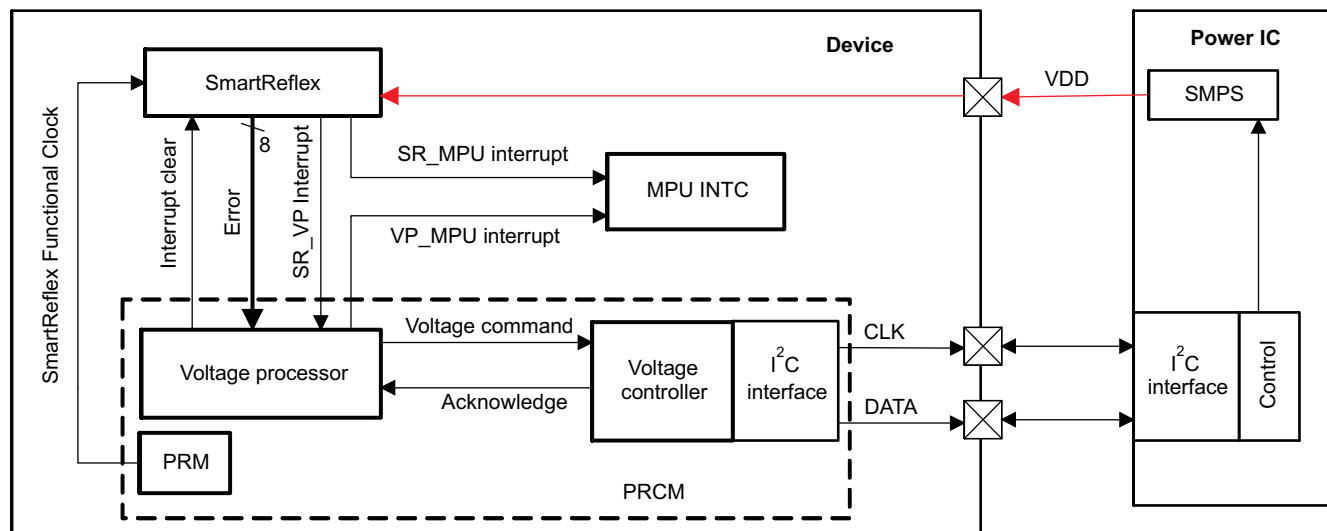

SmartReflex is a power-management technique for controlling the operating voltage of a device to reduce its active power consumption.

With SmartReflex, the power-supply voltage is adapted to the silicon performance either statically (adapted to the manufacturing process of a given device) or dynamically (adapted to the temperature-induced current performance of the device). A comparison of predefined performance points to real-time on-chip measured performance determines whether to raise or lower the power supply voltage.

SmartReflex achieves optimal performance/power trade-off for all devices across the technology process spectrum and across temperature variations.

Figure 4-10 is a functional overview of the SmartReflex voltage-control architecture of the device connected to an external power IC.

Figure 4-10. SmartReflex Voltage-Control Functional Overview

SmartReflex voltage control consists of the following modules:

- SmartReflex
- Microprocessor unit (MPU) interrupt controller (INTC)
- Voltage processor
- Voltage controller
- Inter-integrated circuit (I²C) interface
- Switch mode power supply (SMPS)

The SmartReflex module senses input voltage (VDD) and generates an error value that identifies the difference between the desired voltage and the actual value of the SMPS. This error value is set in an internal register (for software read, if necessary) and is also passed to the voltage processor.

The voltage processor converts the error value to a voltage command that defines the change in the output voltage of the SMPS required to bring it to the desired voltage level.

The voltage command is sent to the voltage controller, which passes it to the power IC through the dedicated I²C interface. The power IC then adjusts the output voltage of the SMPS according to the command.

In this way, the SmartReflex module dynamically adjusts the SMPS voltage to compensate for voltage variations.

The device supports two operational modes for SmartReflex voltage control:

- Manual (software-controlled)
- Automatic (hardware-controlled)

4.1.5.1 Manual SmartReflex Voltage Control

In manual voltage control, the SmartReflex module interrupts the MPU when the voltage level crosses the defined voltage limits (minimum/maximum). The MPU reads the error value and determines the new voltage command to be sent to the SMPS to return the voltage to within the limits. The new voltage command is sent to the voltage controller, which passes the command to the SMPS and acknowledges its reception.

In manual control, the voltage processor is bypassed.

4.1.5.2 Automatic SmartReflex Voltage Control

In automatic voltage control, the SmartReflex module interrupts the voltage processor module when the voltage level crosses the defined voltage limits (minimum/maximum). The voltage processor reads the error value and determines the new voltage command to be sent to the SMPS to return the voltage to within the limits. The new voltage command is sent to the voltage controller, which passes the command to the SMPS and acknowledges its reception.

In automatic mode, the software does not intervene in voltage control; the entire loop is handled by the hardware modules.

4.2 PRCM Overview

This section gives information about all modules and features in the high-tier device. See Chapter 1, *OMAP35x Family* section, to check availability of modules and features. For power-management saving consideration, ensure that power domains of unavailable features and modules are switched off and clocks are cut off.

4.2.1 Introduction

The power-management framework of the device significantly reduces dynamic power consumption and static leakage current to extend the life of the battery in the end-product. This framework incorporates support for state-of-the-art power-management techniques. It ensures optimal device operation with significantly reduced power consumption. The PRCM module, which is the enhanced power-management subsystem of the device, is the central control module for the clock, reset, and power-management signals in the device.

The device has the following features to support the different power-management techniques:

- Partitioning of the device into 9 voltage domains and 18 power domains
- Domain isolation that allows any combination of domain ON/OFF states
- Clock tree with selective clock-gating conditions
- Hardware-controlled reset sequencing management
- Power, reset, and clock control hardware mechanism to manage sleep and wake-up dependencies of power domains
- Support for hardware-controlled autogating of module clocks
- Memory retention capability for preserving memory contents in low-power sleep mode
- Scalable voltage and frequency support for the processors, CORE, and peripherals for DVFS
- SmartReflex adaptive voltage control for real-time performance adjustments
- Support for low-power device off mode input/output (I/O) pad configuration for minimum power consumption when in OFF power state

The PRCM module is the centralized management module for the power, reset, and clock control signals of the OMAP device. It interfaces with all the components on the device for power, clock, and reset management through power-control signals. It integrates enhanced features to allow the device to adapt energy consumption dynamically according to changing application and performance requirements. The innovative hardware architecture allows a substantial reduction in leakage current.

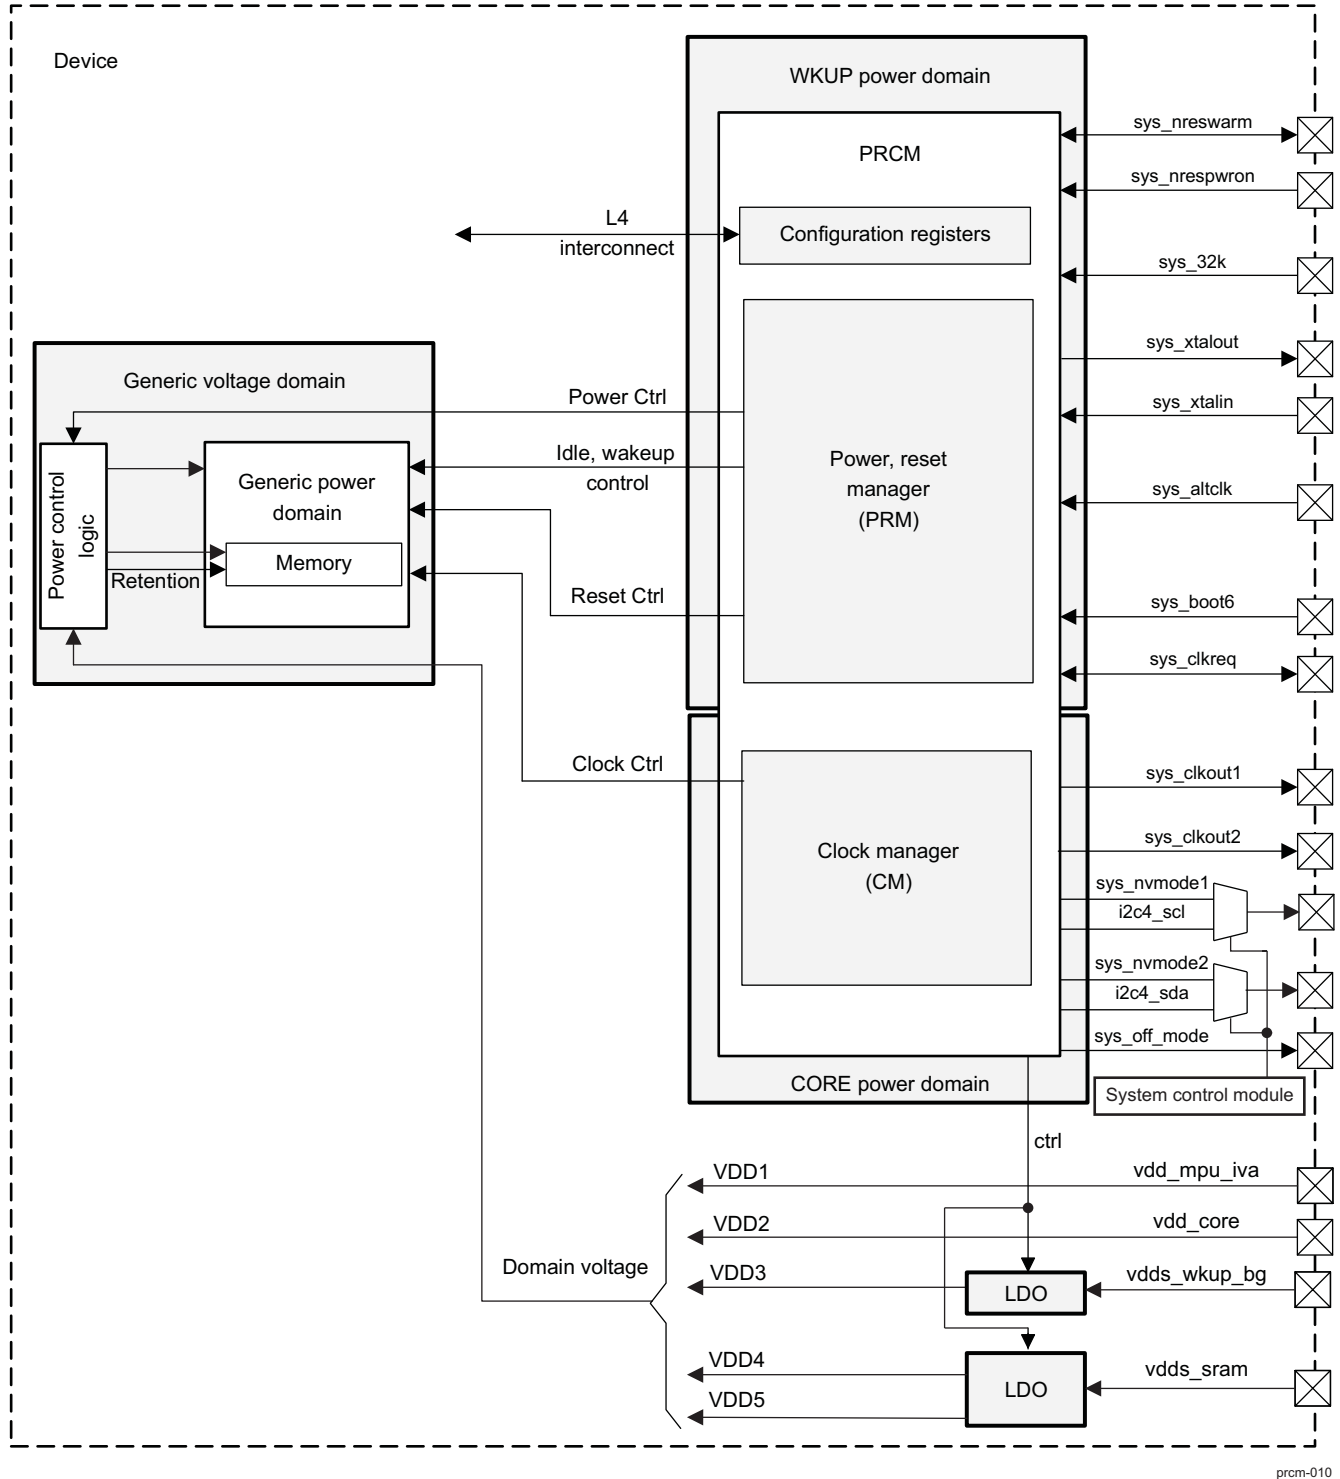

The PRCM module is composed of two main entities:

- Power reset manager (PRM): Handles the power, reset, wake-up management, and system clock source control (oscillator)
- Clock manager (CM): Handles the clock generation, distribution, and management

The PRCM is fully configurable through its L4 interface port.

[Figure 4-11](#) is an overview of the PRCM module and its internal connections with a generic power domain.

Figure 4-11. PRCM Overview

4.2.2 PRCM Features

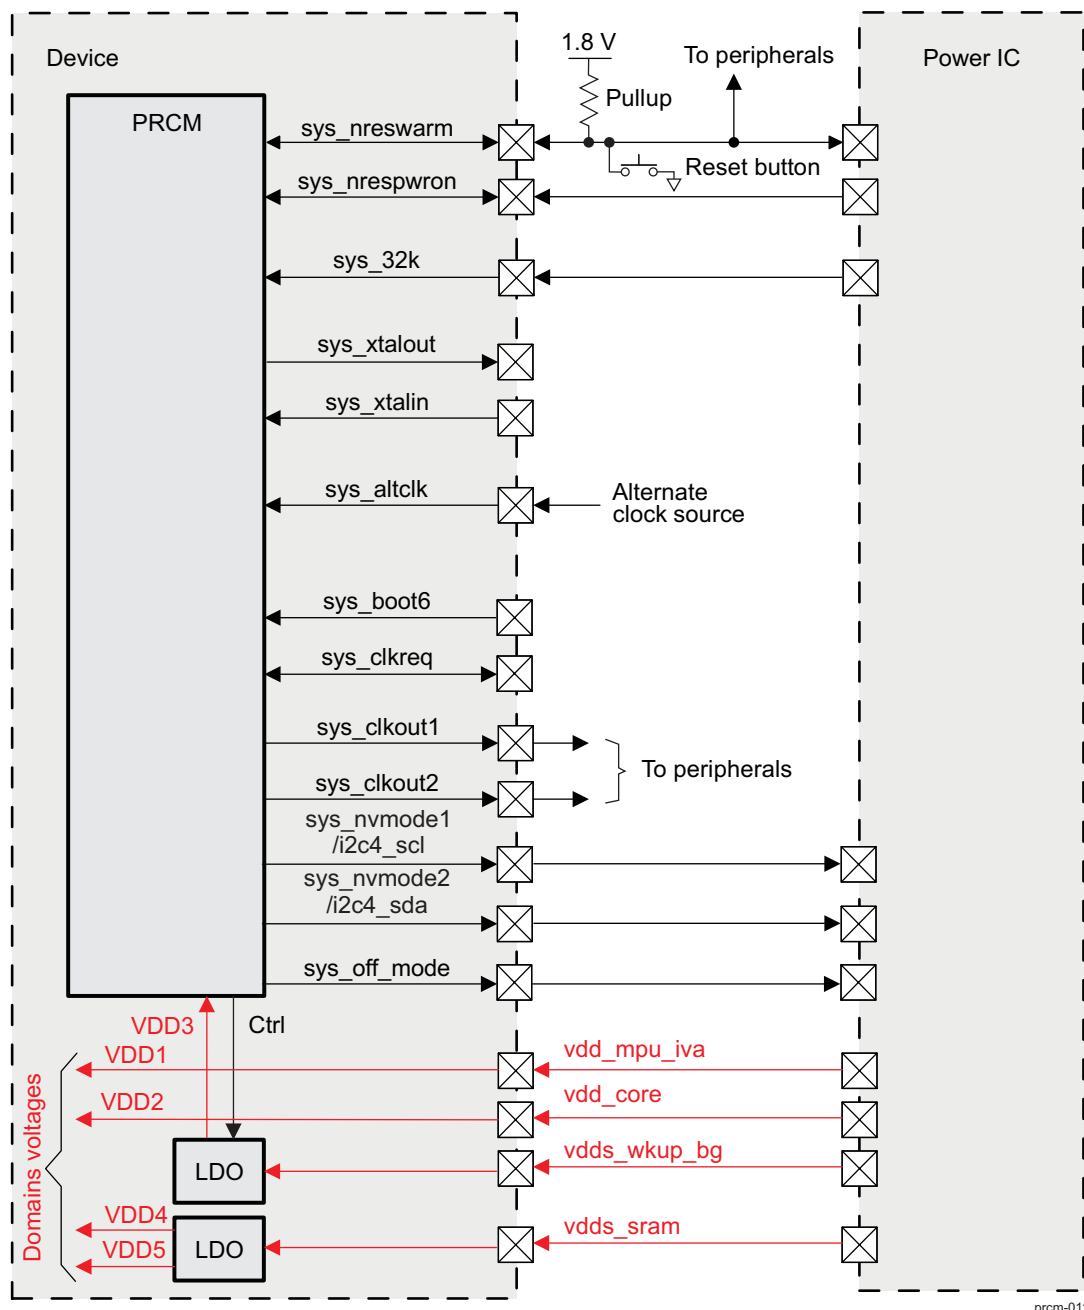

The PRCM module includes the following features:

- Management of 18 independent power domains
- Control of two scalable and three memory-selectable voltage modes
- Handling proper idle/wake-up procedures
- Allowing both software and partial hardware control
- Monitoring and handling wake-up events
- Controlling system clock/reset input sources
- Managing and distributing clocks and resets with high granularity
- Handling power-up sequences
- Debug and emulation features
- Control of external supply voltage regulation through dedicated high-speed (HS) I²C interface
- CM implementation of RFFs to support DPS

4.3 PRCM Environment

The PRCM module receives the external reset, clock, and power signals. Figure 4-12 shows the interface of the PRCM with external reset, clock, and power sources.

Figure 4-12. PRCM Functional External Interface (Detailed View)

Note: In the remainder of this chapter, the term "power IC" refers to a peripheral power source IC that is interfaced with the device. It receives power control commands (voltage scaling and power switching) from the device and provides the necessary voltages and reset signals.

Texas Instruments provides a global solution (for power supply and other support functions) with a device connected to the TPS65950 device. For more information about the TPS65950 device, contact your TI representative.

The following sections describe the interfaces for the external clock, reset, and power sources.

4.3.1 External Clock Signals

The device has three external clock inputs: low frequency (sys_32k), high frequency (sys_xtalin), and an optional clock (sys_altdclk). The device has two configurable clock outputs: sys_clkout1 and sys_clkout2. Figure 4-13 shows the external clock signals of the PRCM module. Table 4-3 lists the external clock signals, I/Os, and module reset values.

Figure 4-13. External Clock Interface

Table 4-3. External Clock Signal Descriptions

Signal Name	I/O ⁽¹⁾	Description	Module Reset Value
sys_boot6	I	Boot oscillator mode control	Unknown
sys_32k	I	32-kHz clock input	Unknown
sys_xtalout	O	Output of oscillator	0
sys_xtalin	I	Main input clock. Crystal oscillator clock (only at 12, 13, 16.8, or 19.2 MHz) or CMOS digital clock (at 12, 13, 16.8, 19.2, 26, or 38.4 MHz).	Unknown
sys_clkreq	I/O	Clock request to/ from device for system clock	1
sys_clkout1	O	Configurable output clock 1	0
sys_altdclk	I	Alternate clock source selectable for USB (48 MHz) or NTSC/PAL (54 MHz)	Unknown
sys_clkout2	O	Configurable output clock 2	0

⁽¹⁾ I = Input, O = Output

Figure 4-14 shows the PRCM external clock sources.

Figure 4-14. PRCM External Clock Sources

The system clock source can be either of the following:

- Internal oscillator with crystal connected between sys_xtalin and sys_xtalout
- A CMOS digital clock that arrives at the sys_xtalin pin

In the first option, the sys_clkreq signal is used in input mode to control sys_clkout1 and the internal clock oscillator. In the second option, the signal is used in output mode to request the external system clock.

An external pulldown or pullup tied on sys_boot6 determines whether the internal oscillator is used or an external clock source is supplied, respectively.

CAUTION

Only one clock source option can be used at a time.

An alternate clock input (sys_altclk) provides a precise clock source for 54 MHz, 48 MHz, or other frequencies (for example, 59 MHz or 49.04 MHz for VDAC).

For more information about external clock signals, see [Section 4.7.5](#), *External Clock Controls*.

4.3.2 External Reset Signals

The device supports two reset signals: power-on (sys_nrespwron) and warm reset (sys_nreswarm).

sys_nrespwron is asserted at power up to reset the full logic in the device. sys_nreswarm can be activated at any time by an external device or an external reset push-button action (see [Figure 4-12](#)) to cause a global warm reset event.

Because sys_nreswarm is bidirectional, it can also be used to drive a reset of external devices. Any global warm reset source (for example, a push-button) causes sys_nreswarm to be driven out and maintained for a limited length of time at the boundary of the device. In this way, the device and its related peripherals are properly reset together.

The sys_nrespwron assertion also causes the sys_nreswarm assertion.

[Figure 4-15](#) shows the external reset signals. [Table 4-4](#) lists the external reset signals, I/Os, and module reset values.

Figure 4-15. External Reset Signals

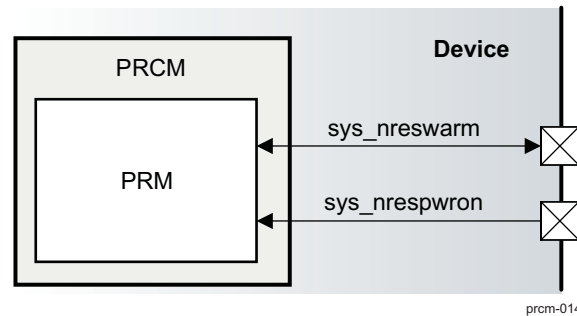

Table 4-4. External Reset Signals Description

Signal Name	I/O ⁽¹⁾	Description	Module Reset Value
sys_nreswarm	I/O	Warm-boot reset	1
sys_nrespwron	I	Power-on reset	Unknown

⁽¹⁾ I = Input, O = Output

4.3.3 External Power Signals

The power control signals allow the PRCM to control the device voltage levels. The voltage level of the scalable voltage sources in the external power IC can be scaled by sending commands to the power IC through this interface. The PRCM can also command the power IC to switch the device voltages off when the device is in off mode and activate them when it wakes up.

Figure 4-16 shows the power control interface for the external power IC. Table 4-5 lists the signals, I/Os, and module reset values for the external power IC.

Figure 4-16. Power Control Interface for External Power IC

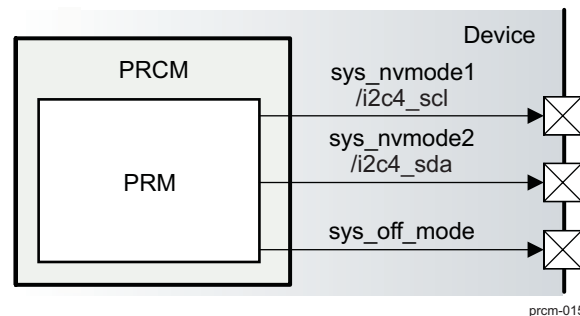

Table 4-5. Power Control Interface Description

Signal Name	I/O ⁽¹⁾	Description	Module Reset Value
sys_nvmode1	O	Commands the external power IC for control of VDD1 and VDD2 voltages. Shared by the VMODE interface and the SmartReflex dedicated I2C interface.	0x1
sys_nvmode2	O	Commands the external power IC for control of VDD1 and VDD2 voltages. Shared by the VMODE interface and the SmartReflex dedicated I2C interface.	0x1
sys_off_mode	O	Requests the external power IC to switch the device voltage level according to the device power status	0x0

⁽¹⁾ I = Input, O = Output

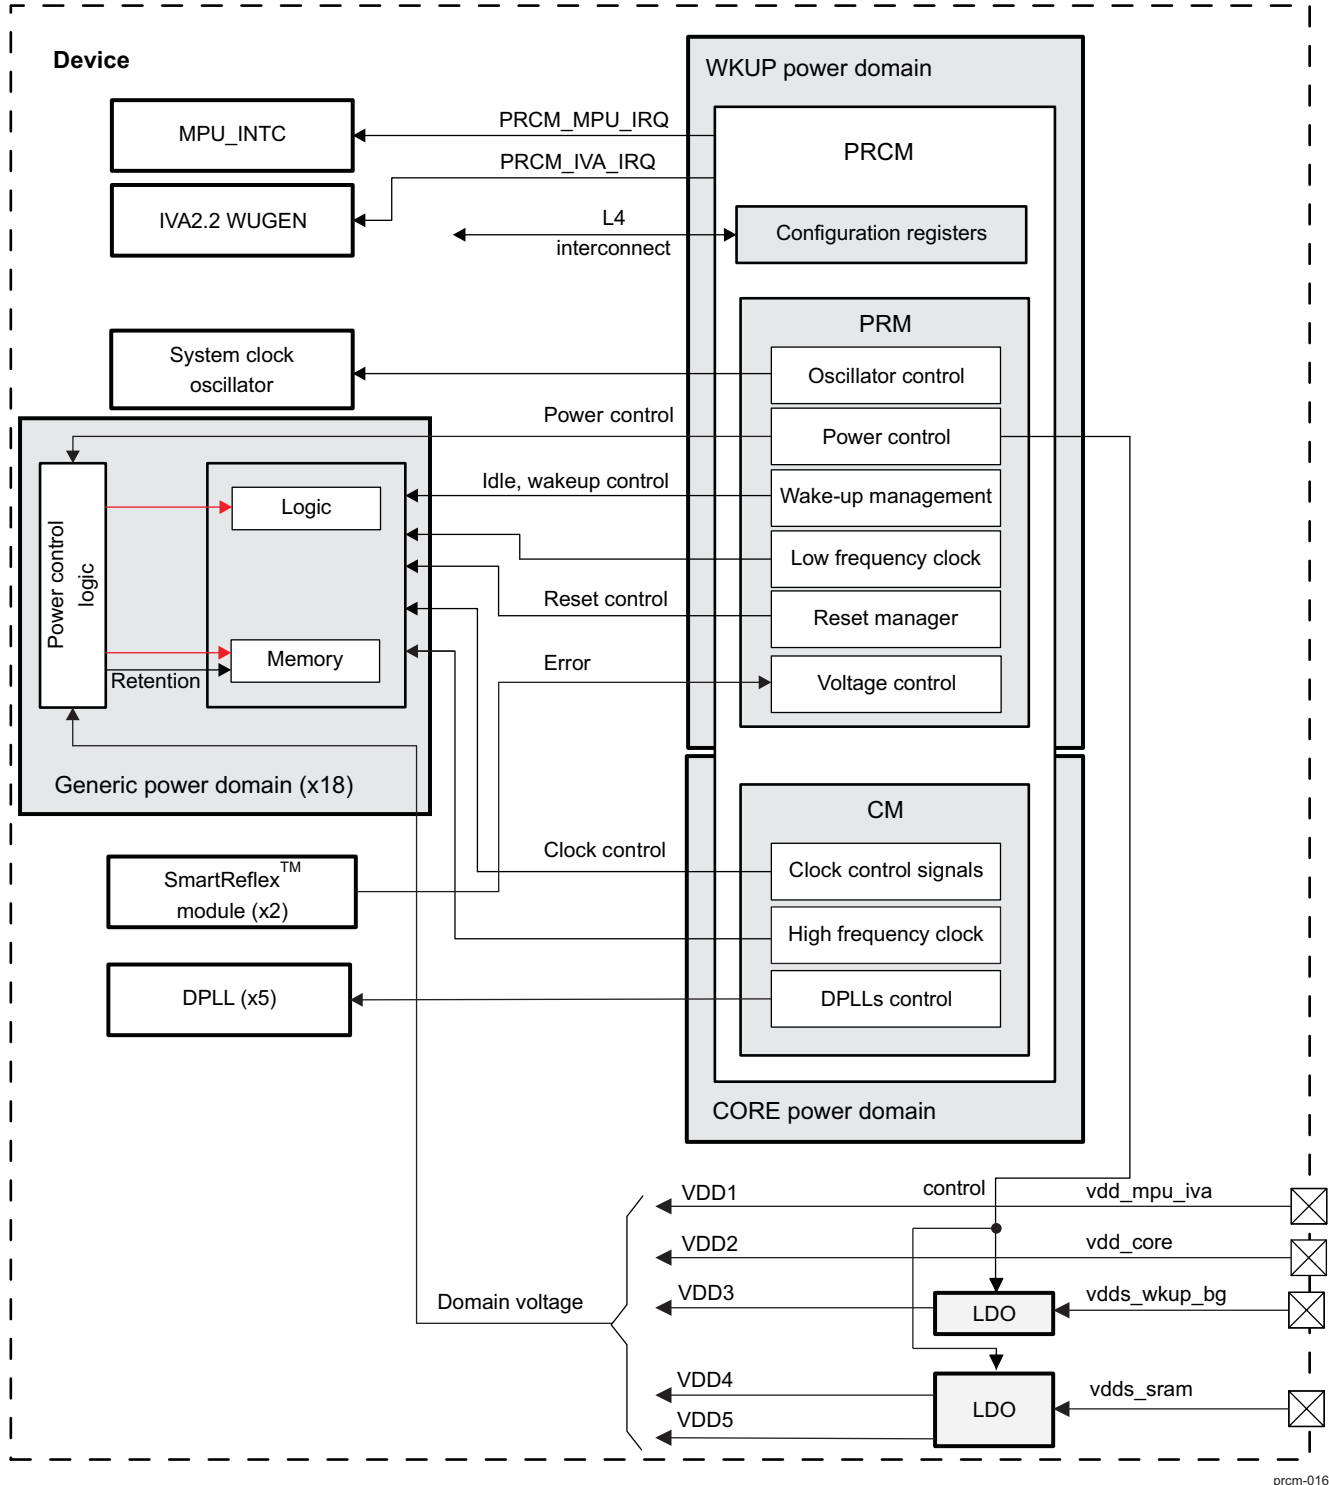

4.4 PRCM Integration

The PRCM internal registers can be accessed for configuration and controlled through the WKUP L4 interconnect. In addition to the L4 interconnect, the PRCM internal module interface contains the following:

- A set of signals for idle/wake-up control for each module
- Clocks and reset signals
- Power control signals (switches and memories) to the power domains
- Interrupts to the MPU subsystem and IVA2.2 subsystem interrupt controllers (INTCs)
- Voltage error commands from the SmartReflex modules
- Digital phase-locked loop (DPLL) control commands for recalibration and bypass
- System clock oscillator control for device-level sleep/wake-up transitions

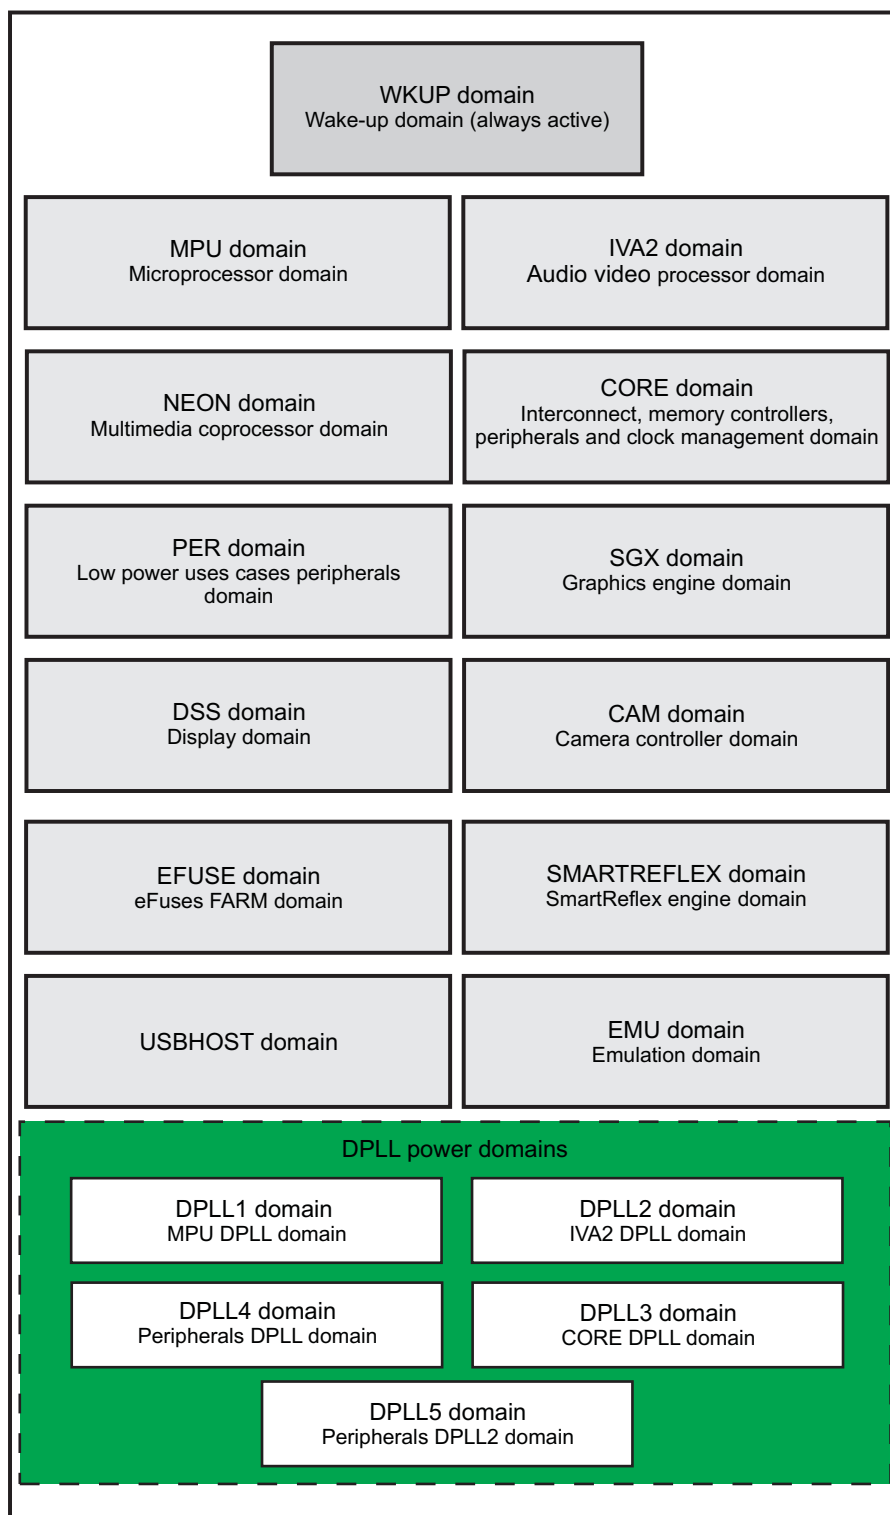

[Figure 4-17](#) shows details of the control interface to a generic power domain.

Figure 4-17. PRCM Integration

prcm-016

To significantly reduce leakage in sleep modes (SLM strategy) and to optimize active power consumption savings (DPS strategy), the device is segmented into 18 power domains (see [Figure 4-18](#)).

Figure 4-18. Device Power Domains

prcm-017

Each power domain is fed through an independent switch controlled by the PRM module. In this way, depending on the application scenario, unused parts (domains) can be switched off or put in RETENTION state while others remain active.

4.4.1 Power-Management Scheme, Reset, and Interrupt Requests

4.4.1.1 Power Domain

The PRCM module is in two power domains (see [Table 4-6](#)).

Table 4-6. PRCM Power Domains

PRCM Subsystem Modules	Power Domain
PRM	WKUP
CM	CORE

The PRM module is in the WKUP power domain, which is continuously active. It is composed of the logic that must be permanently supplied to manage domain power-state transitions and detect wake-up events.

The CM module is in the CORE power domain, which can be activated and deactivated according to the requirements of the executing applications.

4.4.1.2 Resets

The PRM and CM modules are reset by independent reset signals (see [Table 4-7](#)).

Table 4-7. PRCM Reset Signals

PRCM Subsystem	Reset Signal
PRM	PRM_RSTPWON
CM	CM_RSTPWON_RET

The PRM module is reset by the cold reset signal PRM_RSTPWON. The CM module is reset by assertion of the CM_RSTPWON_RET signal.

The CM logic is reset on:

- Any global cold reset
- A CORE power domain transition from OFF to ON

The PRM logic is reset on:

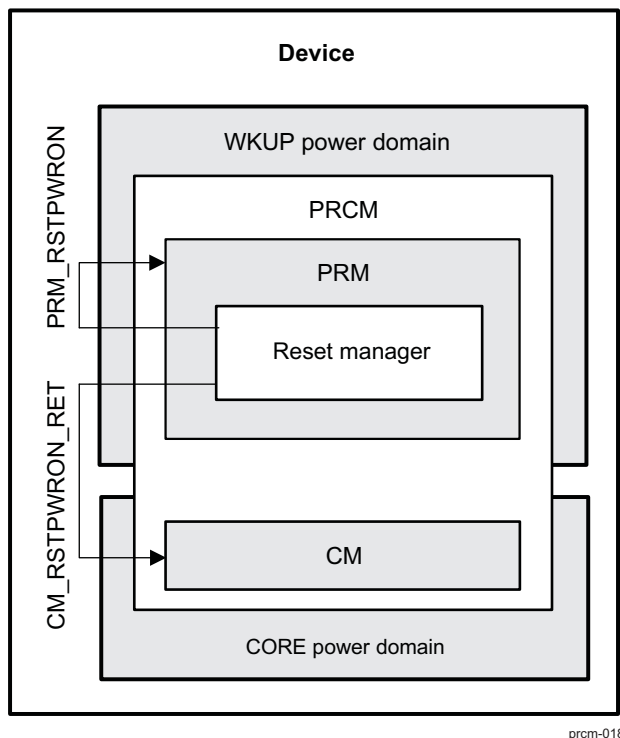

- Any global cold reset

CM and PRM registers that are sensitive to a warm reset are also reset when a global warm reset occurs. However, the CM and PRM logic is not reset.

Note: At global cold reset:

- Only the device finite state-machine (FSM) in the PRM is operating on the 32-kHz clock, and it is released from reset on the release of the global reset.
- PRM logic operates on the system clock and is released from reset on release of the reset PRM_RSTPWON.

[Figure 4-19](#) shows the PRCM reset signals.

Figure 4-19. PRCM Reset Signals

4.4.1.3 Interrupt Requests

The PRCM module can generate two interrupts:

- **PRCM_MPU_IRQ**: Mapped to the MPU INTC module (M_IRQ_11 interrupt line)
- **PRCM_IVA_IRQ**: Mapped to the IVA2.2 WUGEN module (IVA2_IRQ[12] interrupt line)

4.5 PRCM Reset Manager Functional Description

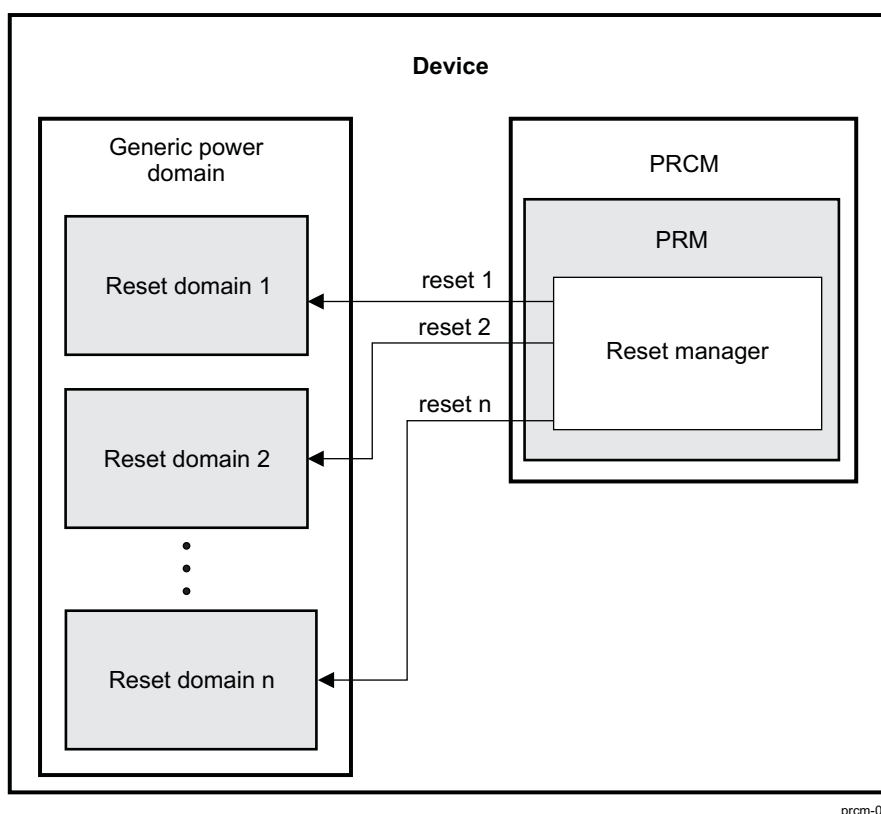

4.5.1 Overview

The PRCM manages the reset of all the modules in the device. Resets are distributed across the 18 independent power domains (including DPLLs and SmartReflex modules).

In each power domain, one or several reset domains are defined. A reset domain is defined by a unique reset signal that originates from the reset manager and is connected to one or multiple modules of the device. All the connected modules of the reset domain are reset simultaneously when the reset signal is asserted. Independent control of these reset domains allows sequencing the release of resets and ensures a safe reset on the entire power domain.

Figure 4-20 is an overview of the reset manager interface with a generic power domain in the device.

Figure 4-20. Reset Manager Interface with Generic Power Domain

prcm-019

Resets can be generated either by hardware sources or software control. For modules that can be reset by software control, a software-reset bit is implemented in their <module name>_SYSCONFIG configuration register. Software reset has the same effect on the module logic as a hardware reset.

Special reset control is available when the device operates under emulation control to reset specific reset domains.

Note: All reset assertion is asynchronous, and all reset signals are active low, except for the DPLL reset signals.

4.5.2 General Characteristics of Reset Signals

Reset signals can be categorized based on three criteria:

- Scope

- Occurrence
- Source type

4.5.2.1 Scope

A reset signal can be categorized according to its scope (the area of the device affected by that reset):

- Global reset: Affects the entire device; all modules are reset. Generally, when the device powers up or an abnormal operation is detected (secure watchdog timer overflows, the eFuse bad device is detected, etc.).
- Local reset: Affects one power or reset domain. Generally, when a power domain transitions from off mode to active mode, or when a software-reset control bit for a domain is set, only the group of modules within that domain is affected.

4.5.2.2 Occurrence

A reset signal can also be categorized depending on when the reset occurs:

- Cold reset: Occurs only on device power up or in certain emulation modes. The cold reset is a global reset that affects every module on the device. It usually corresponds to the initial power-on reset.
- Warm reset: Occurs when the device is in normal operating state. The warm reset is also a global reset, but it does not affect all the modules on the device. Usually, the device does not require a complete reboot on a warm reset. Several reset sources are types of warm resets, such as the global software reset and the watchdog reset.

Modules that behave differently in cold reset and warm reset have two reset signals: RST and PWRON_RST. These reset signals reconstruct warm reset and cold reset in modules that require them.

For a global warm reset, the PRCM performs the following sequence:

1. It applies a warm reset on all the modules, including modules built with RFFs.
2. It drives the sys_nreswarm reset output low and holds it for a specified length of time (programmed in the PRCM.PRM_RSTTIME[7:0] RSTTIME1 bit field).
3. All ongoing transactions on the voltage control I²C interface (I2C4 module) are aborted, and the external power IC is expected to return to nominal voltage values on receiving a sys_nreswarm reset.
4. All power domains that are in off power mode are switched back to on power mode.

A global warm reset does not apply to the following modules of the device:

- SDRC
- System control module (SCM) (I/O control)
- Part of PRM and CM registers (see note below)
- 32-kHz synchronization timer
- DPLL3 (refer to [Section 4.5.9.2](#))
- Emulation modules
- eFuse farm

Note: For information on the PRCM registers affected by the global warm reset see the Registers Mapping Summary tables in [Section 4.14](#), *PRCM Register Manual*.

4.5.2.3 Source Type

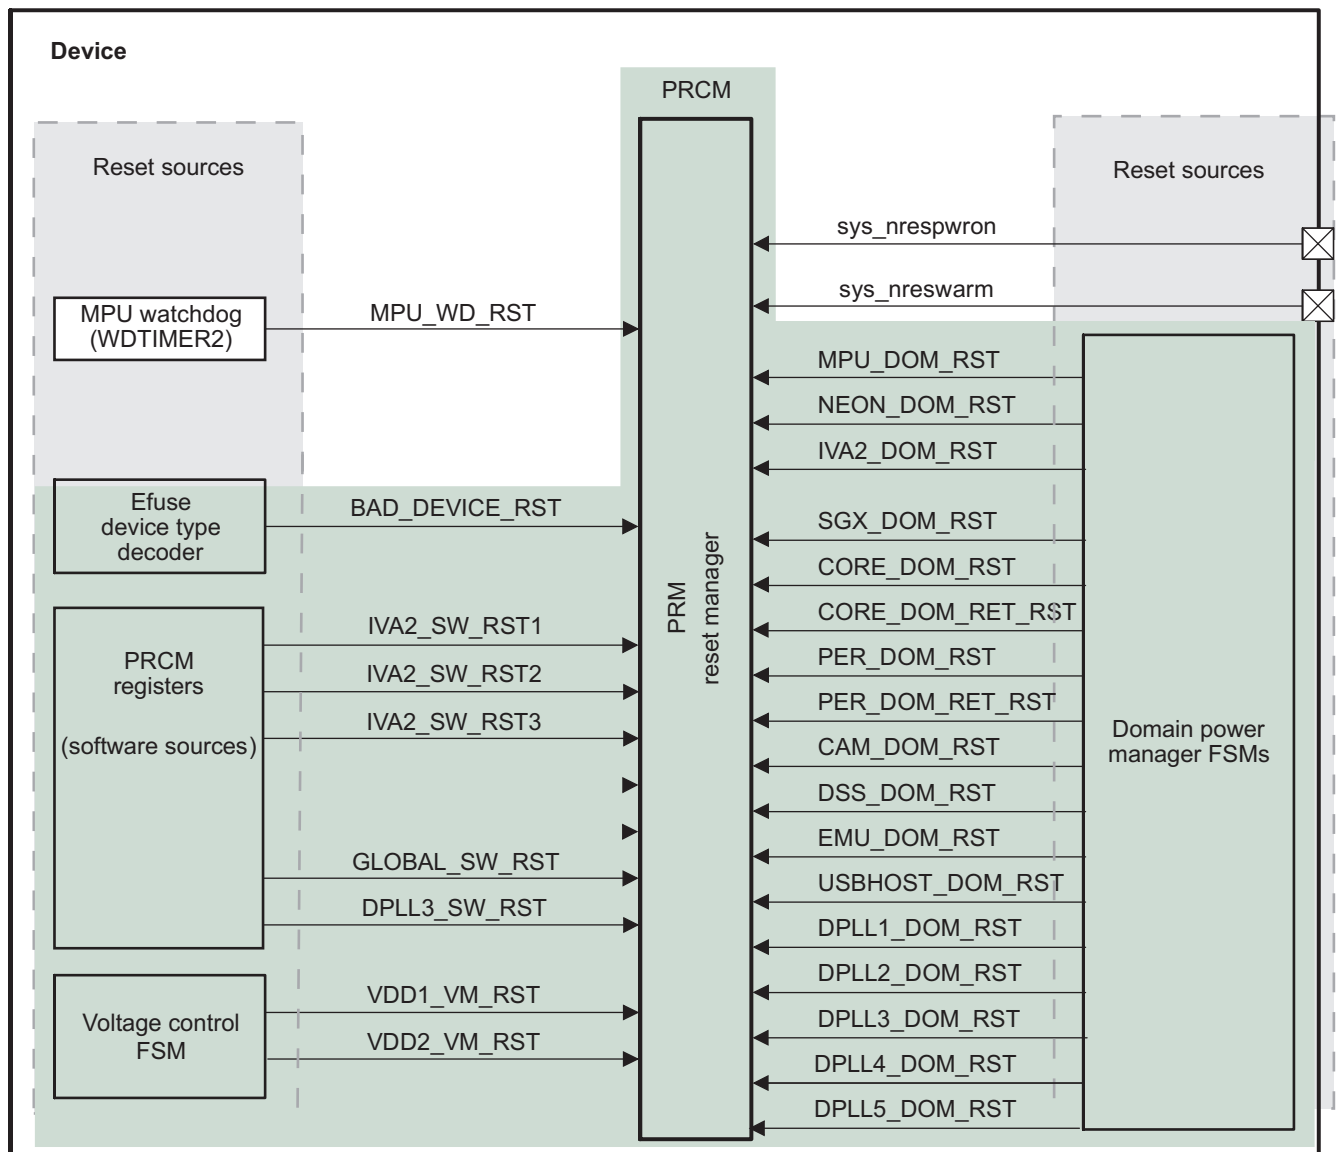

A reset can also be categorized depending on whether it is software-controlled or hardware-triggered:

- Software reset: Triggered by setting a bit in a configuration register of the PRCM module
- Hardware reset: Triggered by a signal from a hardware module inside or outside the PRCM module

4.5.3 Reset Sources

Figure 4-21 is an overview of the reset sources.

Figure 4-21. Reset Sources Overview

*The green region in the figure represents the boundary of the PRCM.

prcm-020

4.5.3.1 Global Reset Sources

Table 4-8 lists the global reset sources of the device. The global reset source signals received by the reset manager trigger the reset of all the device modules. For all hardware reset signals, the source of the reset is identified; for the software reset signals, the reset triggering bit is identified.

Table 4-8. Global Reset Sources

Type ⁽¹⁾	Name	Source/Control	Description
H/C	sys_nrespwron	Input pin	The entire device is reset on power up.

⁽¹⁾ H = Hardware reset, S = Software reset, C = Cold reset, W = Warm reset

Table 4-8. Global Reset Sources (continued)

Type ⁽¹⁾	Name	Source/Control	Description
H/C	BAD_DEVICE_RST	PRCM	Asserted when during the power-up sequence the device is identified as bad, after reading eFuses.
H/W	sys_nreswarm	Bidirectional pin	External hardware warm reset
H/W	SECURE_WD_RST	WDTIMER1	Security watchdog timer overflow reset
H/W	MPU_WD_RST	WDTIMER2	MPU watchdog timer overflow reset
H/W	MPU_SEC_VIOL_RST	OMAP security FSM	Security violation reset request by the OMAP security FSM
S/W	GLOBAL_SW_RST	PRCM.PRM_RSTCTRL[1] RST_GS	Global software reset
H/W	VDD1_VM_RST	PRCM	Asserted by the voltage manager FSMs when no response from the power IC is received during wake-up transition from retention or off mode.
H/W	VDD2_VM_RST	PRCM	
S/W	DPLL3_SW_RST	PRCM.PRM_RSTCTRL[2] RST_DPLL3	Local cold reset for DPLL3 and a global cold reset to the device.

4.5.3.2 Local Reset Sources

Table 4-9 lists the local reset sources of the device. A local reset source signal received by the reset manager resets only some of the device modules.

Table 4-9. Local Reset Sources

Type ⁽¹⁾	Name	Source/Control	Description
H/C	CORE_DOM_RET_RST	PRCM	Asserted only for a power domain state transition from OFF to ACTIVE state
H/C	USB_DOM_RET_RST	PRCM	
H/C	PER_DOM_RET_RST	PRCM	
H/C	MPU_DOM_RST	PRCM	Asserted for any power domain transition from OFF or RETENTION state to ACTIVE state.
H/C	IVA2_DOM_RST	PRCM	
H/C	NEON_DOM_RST	PRCM	
H/C	SGX_DOM_RST	PRCM	
H/C	CORE_DOM_RST	PRCM	
H/C	PER_DOM_RST	PRCM	
H/C	CAM_DOM_RST	PRCM	
H/C	DSS_DOM_RST	PRCM	
H/C	DPLL1_DOM_RST	PRCM	
H/C	DPLL2_DOM_RST	PRCM	
H/C	DPLL3_DOM_RST	PRCM	
H/C	DPLL4_DOM_RST	PRCM	
H/C	DPLL5_DOM_RST	PRCM	
S/W	IVA2_SW_RST1	PRCM.RM_RSTCTRL_IVA2[0] RST1_IVA2	IVA2.2: DSP reset control
S/W	IVA2_SW_RST2	PRCM.RM_RSTCTRL_IVA2[1] RST2_IVA2	IVA2.2: MMU reset control and video hardware accelerator reset control
S/W	IVA2_SW_RST3	PRCM.RM_RSTCTRL_IVA2[2] RST3_IVA2	Video hardware accelerator reset control

⁽¹⁾ H = Hardware reset, S = Software reset, C = Cold reset, W = Warm reset

Note: For power domains with <domain name>_DOM_RST and <domain name>_DOM_RET_RST, the reset sources are asserted together when the domain transitions from OFF to ON power state, whereas only <domain name>_DOM_RET_RST is asserted on a global or local warm reset.

4.5.4 Reset Distribution

Each power domain can contain one power-on reset (RSTPWRON) and one or more reset (RST) signals. These signals behave as follows:

- On any global or local cold reset, both RST and RSTPWRON are asserted.
- On any global or local warm reset, only RST is asserted.

The CORE power domain receives two additional retention logic reset signals: retention reset (RST_RET) and power-on retention reset (RSTPWRON_RET). These signals behave as follows:

- On any global cold reset or wakeup from OFF state to ACTIVE state, both RST_RET and RSTPWRON_RET are asserted.
- On any global warm reset, only RST_RET is asserted.
- On wakeup from RETENTION state, these signals are not asserted.

The IVA2 power domain outputs the IVA2_RST_DONE signal, which is used to properly handle the synchronous reset scheme of the IVA2.2 subsystem.

[Figure 4-22](#) shows the reset distribution among the 18 power domains.

Figure 4-22. Reset Destinations Overview

* The green region in the figure represents the boundary of the PRCM

prcm-021

4.5.5 Power Domain Reset Descriptions

4.5.5.1 MPU Power Domain

The MPU power domain has one input and one output reset signal (see Table 4-10).

Table 4-10. MPU Power Domain Reset Signals

Name	I/O ⁽¹⁾	Source/Destination ⁽²⁾	Reset Domain
MPU_RST	I	PRM	Resets the MPU processor core and the asynchronous bridge in the MPU power domain
MPU_SEC_VIOL_RST	O	PRM	Global cold reset source to reset manager. Generated by the security FSM in the MPU subsystem.

(1) I = Input, O = Output

(2) Source for an input signal and destination for an output signal

Note: The MPU_CLK is divided by 2 inside the MPU subsystem to generate the ARM_FCLK. This divider is only active when the DPLL is locked. (Refer to MPU Subsystem for information on ARM_FCLK).

4.5.5.2 NEON Power Domain

The NEON power domain has one reset input signal (see [Table 4-11](#)).

Table 4-11. NEON Power Domain Reset Signal

Name	I/O ⁽¹⁾	Source	Reset Domain
NEON_RST	I	PRM	Resets the NEON coprocessor

⁽¹⁾ I = Input, O = Output

4.5.5.3 IVA2 Power Domain

The IVA2 power domain has four inputs and one output reset signal (see [Table 4-12](#)).

Table 4-12. IVA2 Power Domain Reset Signals

Name	I/O ⁽¹⁾	Source/Destination ⁽²⁾	Reset Domain
IVA2_RST1	I	PRM	Resets the IVA2.2 DSP and part of the two asynchronous bridges in the IVA2 power domain
IVA2_RST2	I	PRM	Resets the IVA2.2 MMU
IVA2_RST3	I	PRM	Resets the video hardware accelerator module
IVA2_RSTPWON	I	PRM	Performs a power-on reset on the IVA2.2 subsystem. Active on a cold reset only.
IVA2_RSTDONE	O	PRM	Release condition of the IVA_RST1 and RST2. Generated by the IVA2.2 subsystem at the end of the initialization sequence.

⁽¹⁾ I = Input, O = Output

⁽²⁾ Source for an input signal and destination for an output signal

4.5.5.4 CORE Power Domain

The CORE power domain has eight input reset signals. (See [Table 4-13](#)).

Table 4-13. CORE Power Domain Reset Signals

Name	I/O ⁽¹⁾	Source/Destination ⁽²⁾	Reset Domain
CORE_RST	I	PRM	Resets parts of the three asynchronous bridges, MPU INTC, IVA2.2 WUGEN, interconnects, ICR, modem INTC, SAD2D, mailboxes, GPMC, OCM, UART[1,2], HDQ and HS USB, I2C[1..3], McBSP 1 and 5, McSPI [1..3], MMC[1..3], MS-PRO, GPTIMER[10,11], D3D[1,2], SHAM1, RNG, AES[1..2], PKA, SHAM2 and MAD2D2
CORE_RST_RET	I	PRM	Resets part of the SDRC, SDMA, SMS, MPU INTC, and IVA2 WUGEN
CORE_RSTPWON_RET	I	PRM	Resets part of the SDRC and SCM
CM_RSTPWON_RET	I	PRM	Resets the clock manager

⁽¹⁾ I = Input, O = Output

⁽²⁾ Source for an input signal and destination for an output signal

Table 4-13. CORE Power Domain Reset Signals (continued)

Name	I/O ⁽¹⁾	Source/Destination ⁽²⁾	Reset Domain
CPEFUSE_RST	I	PRM	Reset the Customer Programmable EFUSE controller. Asserted under the same condition as that of CORE_RST. The CPEFUSE functional clock must be active to release the reset. This clock is enabled by default following a power-on reset. (For the reset sequence, see Section 4.5.9.7.)
USBTLL_RST	I	PRM	Resets the USB TLL asynchronously

The CM logic is reset on:

- Any global cold reset
- A CORE power domain transition from OFF to ON

Because the CM logic is not reset in this case, the CM registers that are sensitive to a warm reset must also be reset synchronously with the L4 clock when a global warm reset occurs.

4.5.5.5 DSS Power Domain

The DSS power domain has one reset input signal (see [Table 4-14](#)).

Table 4-14. DSS Power Domain Reset Signal

Name	I/O ⁽¹⁾	Source	Reset Domain
DSS_RST	I	PRM	Resets the entire display subsystem

⁽¹⁾ I = Input, O = Output

4.5.5.6 CAM Power Domain

The CAM power domain has one reset input signal (see [Table 4-15](#)).

Table 4-15. CAM Power Domain Reset Signal

Name	I/O ⁽¹⁾	Source	Reset Domain
CAM_RST	I	PRM	Resets the entire camera subsystem

⁽¹⁾ I = Input, O = Output

4.5.5.7 USBHOST Power Domain

The USBHOST power domain has one reset input signal (see [Table 4-16](#)).

Table 4-16. USBHOST Power Domain Reset Signal

Name	I/O ⁽¹⁾	Source	Reset Domain
USBHOST_RST	I	PRM	Resets the entire HS USB Host subsystem

⁽¹⁾ I = Input, O = Output

4.5.5.8 SGX Power Domain

The SGX power domain has one reset input signal (see [Table 4-17](#)).

Table 4-17. SGX Power Domain Reset Signal

Name	I/O ⁽¹⁾	Source	Reset Domain
SGX_RST	I	PRM	Resets the entire SGX subsystem

⁽¹⁾ I = Input, O = Output

4.5.5.9 WKUP Power Domain

The WKUP power domain has three reset input signals and two reset output signals (see [Table 4-18](#)).

Table 4-18. WKUP Power Domain Reset Signals

Name	I/O ⁽¹⁾	Source/Destination ⁽²⁾	Reset Domain
WKUP_RST	I	PRM	Resets the GPTIMER[1,12], WDTIMER2, GPIO 1 and USIMOCP
WKUP_RSTPWON	I	PRM	Reset the wake-up control module and WDTIMER1
SYNCT_RST	I	PRM	Resets the 32-kHz sync timer. This reset is directly connected to the sys_nrespwron global reset source.
SECURE_WD_RST	O	PRM	Global warm reset for PRM. Generated by WDTIMER1.
MPU_WD_RST	O	PRM	Global warm reset for PRM. Generated by WDTIMER2.

⁽¹⁾ I = Input, O = Output

⁽²⁾ Source for an input signal and destination for an output signal

The PRM logic is reset on any global cold reset. Because the PRM logic is not reset in this case, the PRM registers that are sensitive to a warm reset must also be reset synchronously with the system clock when a global warm reset occurs.

4.5.5.10 PER Power Domain

The PER power domain has two reset input signals (see [Table 4-19](#)).

Table 4-19. PER Power Domain Reset Signal

Name	I/O ⁽¹⁾	Source	Reset Domain
PER_RST	I	PRCM	Resets the UART3, McBSP[2,3,4], GPTIMER[2,...,9], WDTIMER3 modules
PER_RST_RET	I	PRCM	Resets the GPIO [2,...,6] modules

⁽¹⁾ I = Input, O = Output

4.5.5.11 SmartReflex Power Domain

The SmartReflex power domain has one reset input signal (see [Table 4-20](#)).

Table 4-20. SmartReflex Power Domain Reset Signal

Name	I/O ⁽¹⁾	Source	Reset Domain
SR_RST	I	PRCM	Resets the SR1 and SR2 modules

⁽¹⁾ I = Input, O = Output

4.5.5.12 DPLL Power Domains

The DPLL power domains for DPLL1, DPLL2, DPLL3, DPLL4 and DPLL5 each have one reset input signal.

Table 4-21. DPLL Power Domain Reset Signals

Name	I/O ⁽¹⁾	Source	Reset Domain
DPLL1_RSTPWON	I	PRCM	Resets the DPLL1 module
DPLL2_RSTPWON	I	PRCM	Resets the DPLL2 module
DPLL3_RSTPWON	I	PRCM	Resets the DPLL3 module

⁽¹⁾ I = Input, O = Output

Table 4-21. DPLL Power Domain Reset Signals (continued)

Name	I/O ⁽¹⁾	Source	Reset Domain
DPLL4_RSTPWON	I	PRCM	Resets the DPLL4 module
DPLL5_RSTPWON	I	PRCM	Resets the DPLL5 module

They are asserted for any type of global cold reset.

4.5.5.13 EFUSE Power Domain

The EFUSE power domain has one reset input signal (see [Table 4-22](#)).

Table 4-22. EFUSE Power Domain Reset Signal

Name	I/O ⁽¹⁾	Source	Reset Domain
EFUSE_RSTPWON	I	PRCM	Resets the eFuse controller

⁽¹⁾ I = Input, O = Output

This signal is asserted for any type of global cold reset and when the device wakes up from off mode.

4.5.5.14 BANDGAP Logic

The BANDGAP logic has one reset input signal (see [Table 4-23](#)).

Table 4-23. BANDGAP Logic Reset Signal

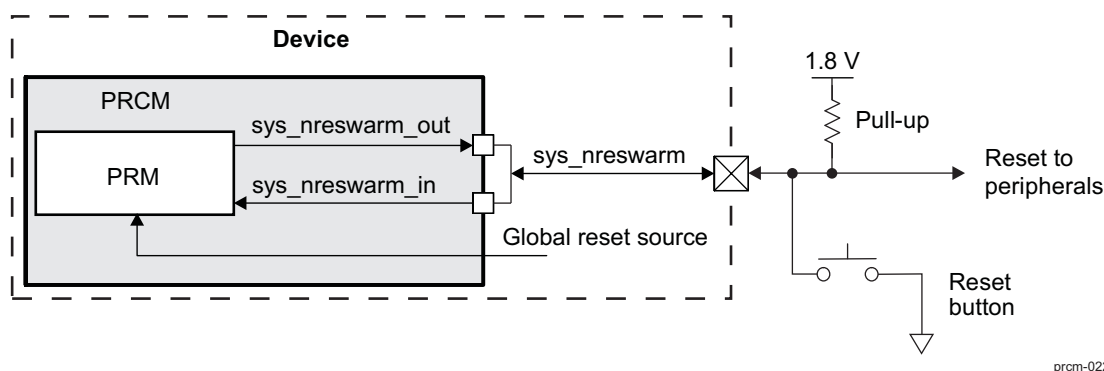

Name	I/O ⁽¹⁾	Source	Reset Domain
BANDGAP_RSTPWON	I	PRCM	Resets the BANDGAP logic

⁽¹⁾ I = Input, O = Output

This signal is asserted for any type of global cold reset and when the device wakes up from off mode.

4.5.5.15 External Warm Reset Assertion

[Figure 4-23](#) shows the external warm reset interface.

Figure 4-23. External Warm Reset Interface

Any global reset source (internal or external) causes sys_nreswarm_out to be driven and maintained at the boundary of the device for at least the amount of time configured in the PRCM.PRM_RSTTIME[7:0] RSTTIME1 bit field. This ensures that the device and its related peripherals are properly reset together.

Note: Because the system warm-reset output is implemented on a bidirectional pad, any input pulse on sys_nreswarm causes a global warm reset.

4.5.6 Reset Logging

The reset in the device is logged in two ways. First, dedicated registers in the PRCM (that is, the RM_RSTST_<power domain> and PRM_RSTST registers) log the reset source. Second, the SCM also logs the device reset activity in dedicated registers, for security purposes.

4.5.6.1 PRCM Reset Logging Mechanism

The reset status registers (RM_RSTST_<power domain> and PRM_RSTST) are reset asynchronously on assertion of a global cold reset. However, a reset status bit is always logged when the reset is released to the domain.

For this reason, after the assertion of a global cold reset, the reset status register is cleared to 0. When the domain reset is released, the register bit to log the global cold reset (that is, the RM_RSTST_<power domain> [0] GLOBALCOLD_RST bit) is updated to 1. For the same reason, the reset status register of domains released from reset by software is updated only when software releases the domain reset.

The assertion of a global cold reset prevents logging any other source of reset until after the release of the domain reset. This is valid in the following situations:

- A source of reset other than global cold reset is asserted before, during, or after the active period of a global cold source of reset and before the release of the domain reset signal.
- A source of reset other than global cold reset was asserted and then released, but a global cold reset source was asserted before the release of the domain reset signal.

4.5.6.2 SCM Reset Logging

The PRM exports reset the activity status signals to the SCM. For security purposes, the SCM uses these signals to log a reset status in the SCM.CONTROL_SEC_STATUS register. The reset activity status signal is asserted high when any source of reset to the power domain is active.

It also provides reset status for the following global reset signals:

- Global cold reset
- Global warm reset
- Global warm secure watchdog reset (SECURE_WD_RST)
- Global warm security violation reset (MPU_SEC_VIOL_RST)

There is one reset activity status signal for each of the following power domains:

- CAM
- CORE
- DSS
- EMU
- SGX
- IVA2
- MPU
- NEON
- PER
- USBHOST

These signals are asserted high on assertion of any source of reset on the domain and logged. For information about the SCM, see the *System Control Module* chapter.

4.5.7 Reset Management Overview

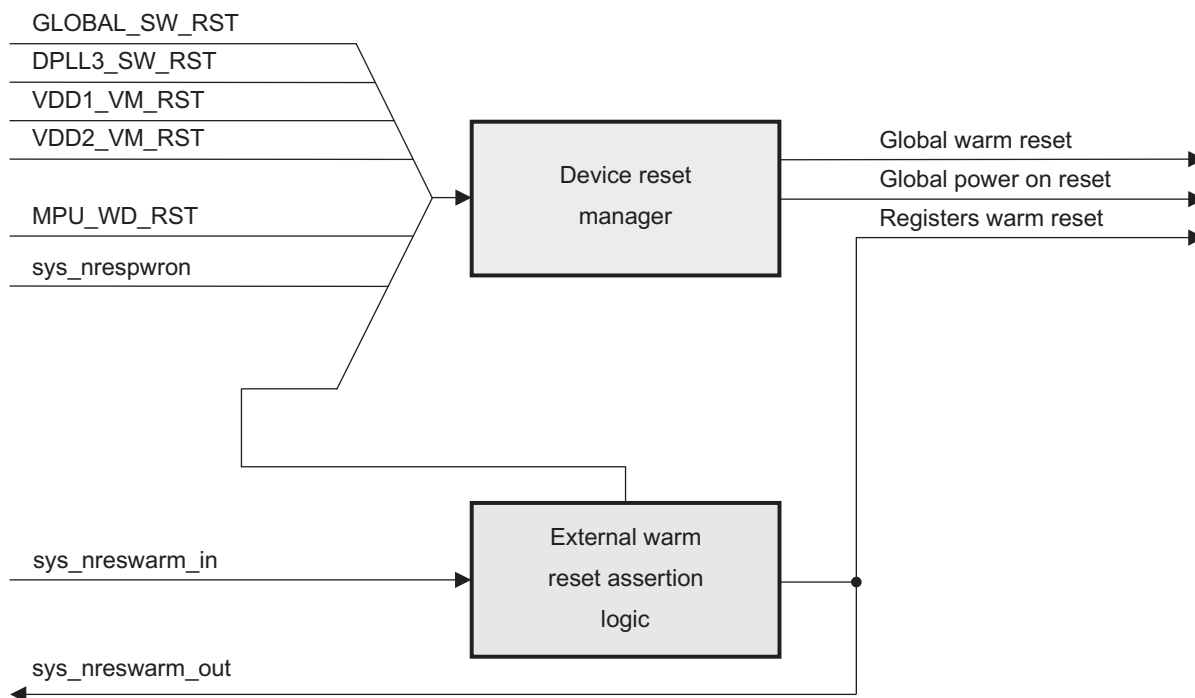

The reset management structure in the device can be considered as a 2-layered structure composed of multiple instances of the reset manager. In the first layer, a top-level reset manager, called the device reset manager, handles all the sources of global reset (cold and warm). It provides reset managers for the second layer, called local reset managers, and the global reset and global power-on reset signals.

Each power domain has a minimum of one local reset manager. The local reset manager also receives resets, such as the software reset and domain power transition reset, from the local reset source for the power domain.

Figure 4-24 through Figure 4-27 provide an overview of reset management in the device. They do not provide reset sequencing between the reset managers.

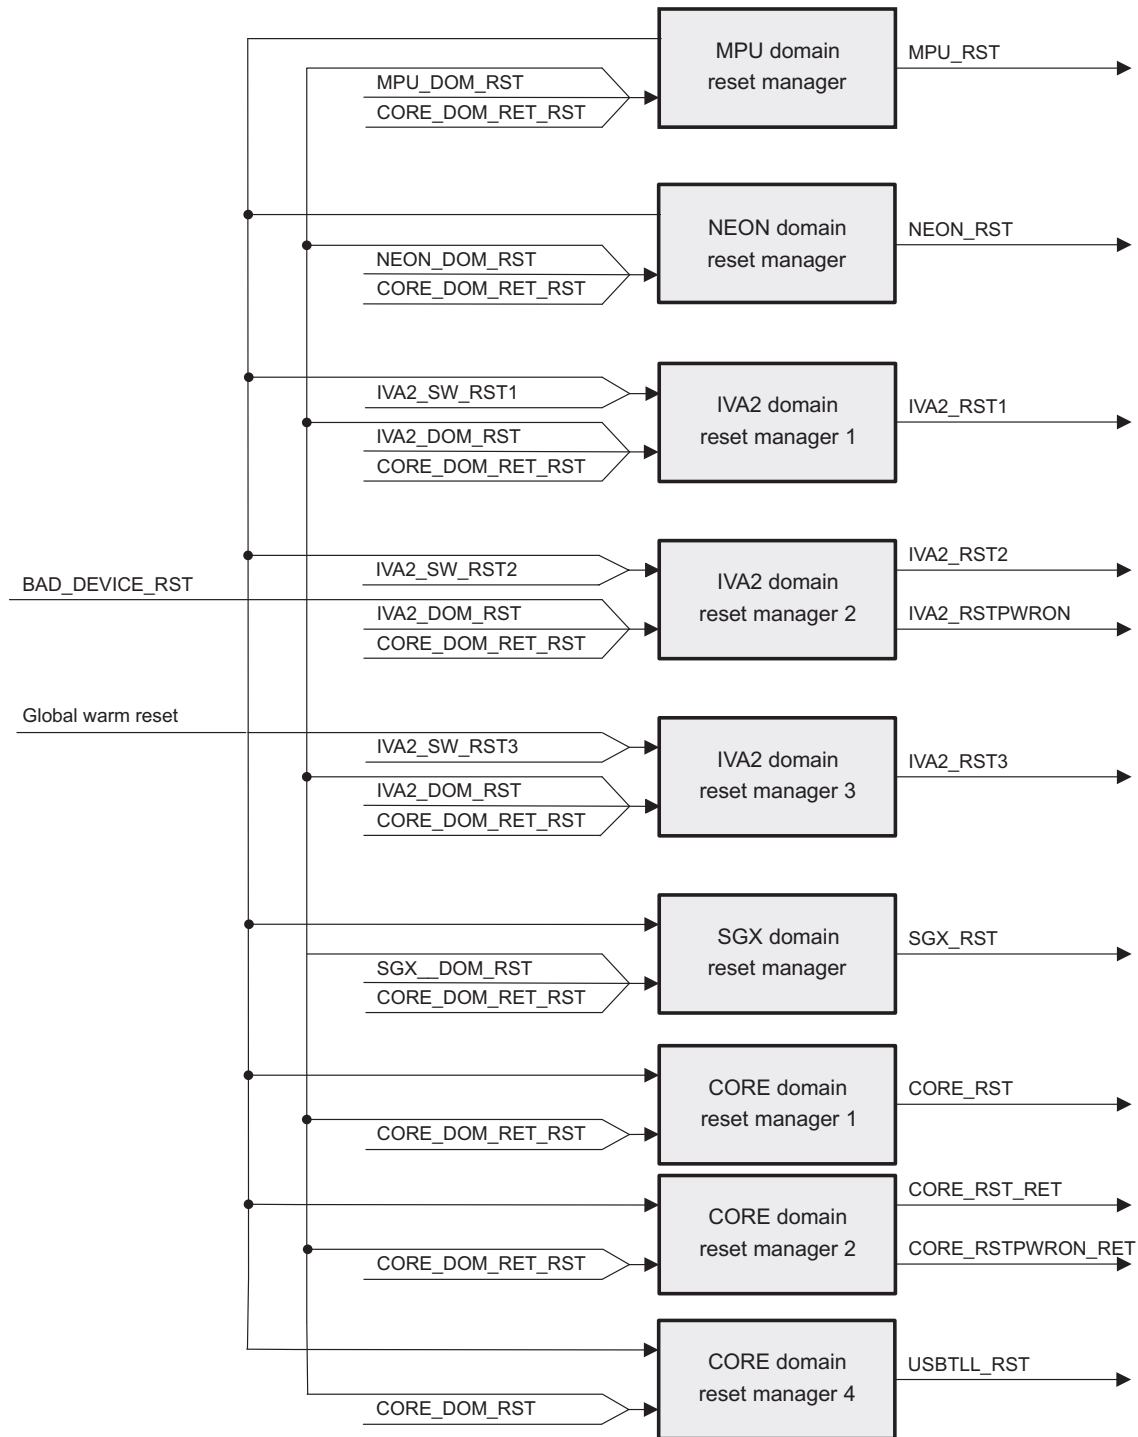

Note: The power domain must be ready (that is, the domain clocks must be active) before its reset is released.

4.5.9 Reset Sequences

4.5.9.1 Power-Up Sequence

The power-up sequence shown in [Figure 4-28](#) is:

Note: For further information regarding sequencing of the input/output signal on the device pads during the power up sequence, please refer to the OMAP35x Data Manual.

1. Voltages ramp up and global power-on reset is asserted by the external power IC:
 - vdds, vdds_mem, vdds_wkup_bg, vdds_sram voltage rails are ramped up.
 - sys_nrespwron is asserted (i.e., to low).
 - vdds_dpll_dll and vdds_dpll_per voltage rails are ramped up before release of sys_nrespwron (i.e. transition to high).
 - The VDD3 voltage domain LDO (WKUP Power domain) tracks vdds_wkup voltage rail and automatically ramps up.
 - After VDD3 voltage domain stabilization, the power IC ramps-up VDD2 voltage domain.
 - After VDD2 voltage domain stabilization, the power IC ramps-up VDD1 voltage domain.
2. Source clock stabilizes:
 - The 32-kHz input clock and the system clock oscillator stabilize.
 - The device reset manager holds the whole device under reset.
 - The system clock (SYS_CLK) is on.
3. The global power-on reset sys_nrespwron released (i.e., to high) when vdds_dpll_dll and vdds_dpll_per voltage rails are stabilized.
4. The eFuse farm reset is released.
5. Internal memory LDO ramps up:
 - Processor memories LDO (VDD4 voltage domain) is ramped up.
 - CORE memories LDO (VDD5 voltage domain) is ramped up.
 - The PRCM module waits for internal memory LDO stabilization.
6. Global resets are released. Global power-on reset and global warm reset are extended (remain asserted) on release of the external power-on reset until the following conditions are met:
 - Voltages are stable in the processor power domains, CORE power domain, and WKUP power domain.
 - System clock is stable.
 - Internal memory LDO is stable.
 - Device reset manager counter overflows (set up by the PRCM.PRM_RSTTIME[7:0] RSTTIME1 bit field).
 - Hardware condition, such as eFuse farm ready, is set.
7. The PRM_RSTPWON reset and DPLL reset of the four DPLLs (DPLL1, 2, 3, and 4) are released.
8. The CM_SYS_CLK clock starts running (gating logic is enabled).
9. The CM_RSTPWON_RET reset is released.
10. The DPLLs reset is released.
11. The DPLL3_ALWON_FCLK clock starts to run (gating logic is enabled).
12. The L3_ICLK clock starts to run.
13. The DPLL1_ALWON_FCLK clock starts to run (logic controlling the clock-gating conditions element is clocked and the clock is requested).
14. The CORE_RST reset is released.
15. The MPU_CLK clock starts to run.
16. The MPU boots.

Notes:

- The IVA2 power domain is held under reset after power up by assertion of the software source of reset.
- Power domains such as DSS, CAM, SGX, and NEON are held under reset after power up until the MPU software enables the power domain interface clocks.

Figure 4-28. Power-Up Sequence

prcm-096

4.5.9.2 Global Warm Reset Sequence

This section describes the global reset sequence (see [Figure 4-29](#)).

The assumptions are:

- vdds, vdds_mem, vdds_dpll_pll, vdds_dpll_per, vdds_wkup_bg and vdds_sram power rails are regulated at 1.8 V.
- VDD2 voltage domain (vdd_core power rail) is regulated at 1.0 V.
- VDD1 voltage domain (vdd_mpu_iva power rail) is regulated at 1.2 V.
- VDD3, VDD4, and VDD5 voltage domains are regulated at 1.2 V.
- The system is running:
 - Resets are released.
 - CORE DPLL and processor DPLL are locked.

The steps of a global warm reset sequence are as follows:

1. Upon assertion of the warm reset source:
 - The device reset manager resets part of the device by asserting the global warm reset.
 - The external warm reset (sys_nreswarm_out) is asserted.
 - All the power domain warm resets are asserted.
 - DPLL1 and DPLL3 transit to bypass mode. DPLL2, DPLL4 and DPLL5 transit to stop mode. The system clock, SYS_CLK, continues running at system clock frequency.
 - The registers sensitive to a warm reset are synchronously reset (PRM and CM register sets).
 - The CM cuts all the clocks not requested, according to the register reset value settings.
2. The global warm reset is released and extended after release of the warm reset source until the following conditions are met:
 - Device reset manager counter overflows (set up by the PRCM.PRM_RSTTIME[7:0] RSTTIME1 bit field)
 - Voltage domains (VDD1, VDD2, VDD4 and VDD5) are stable.

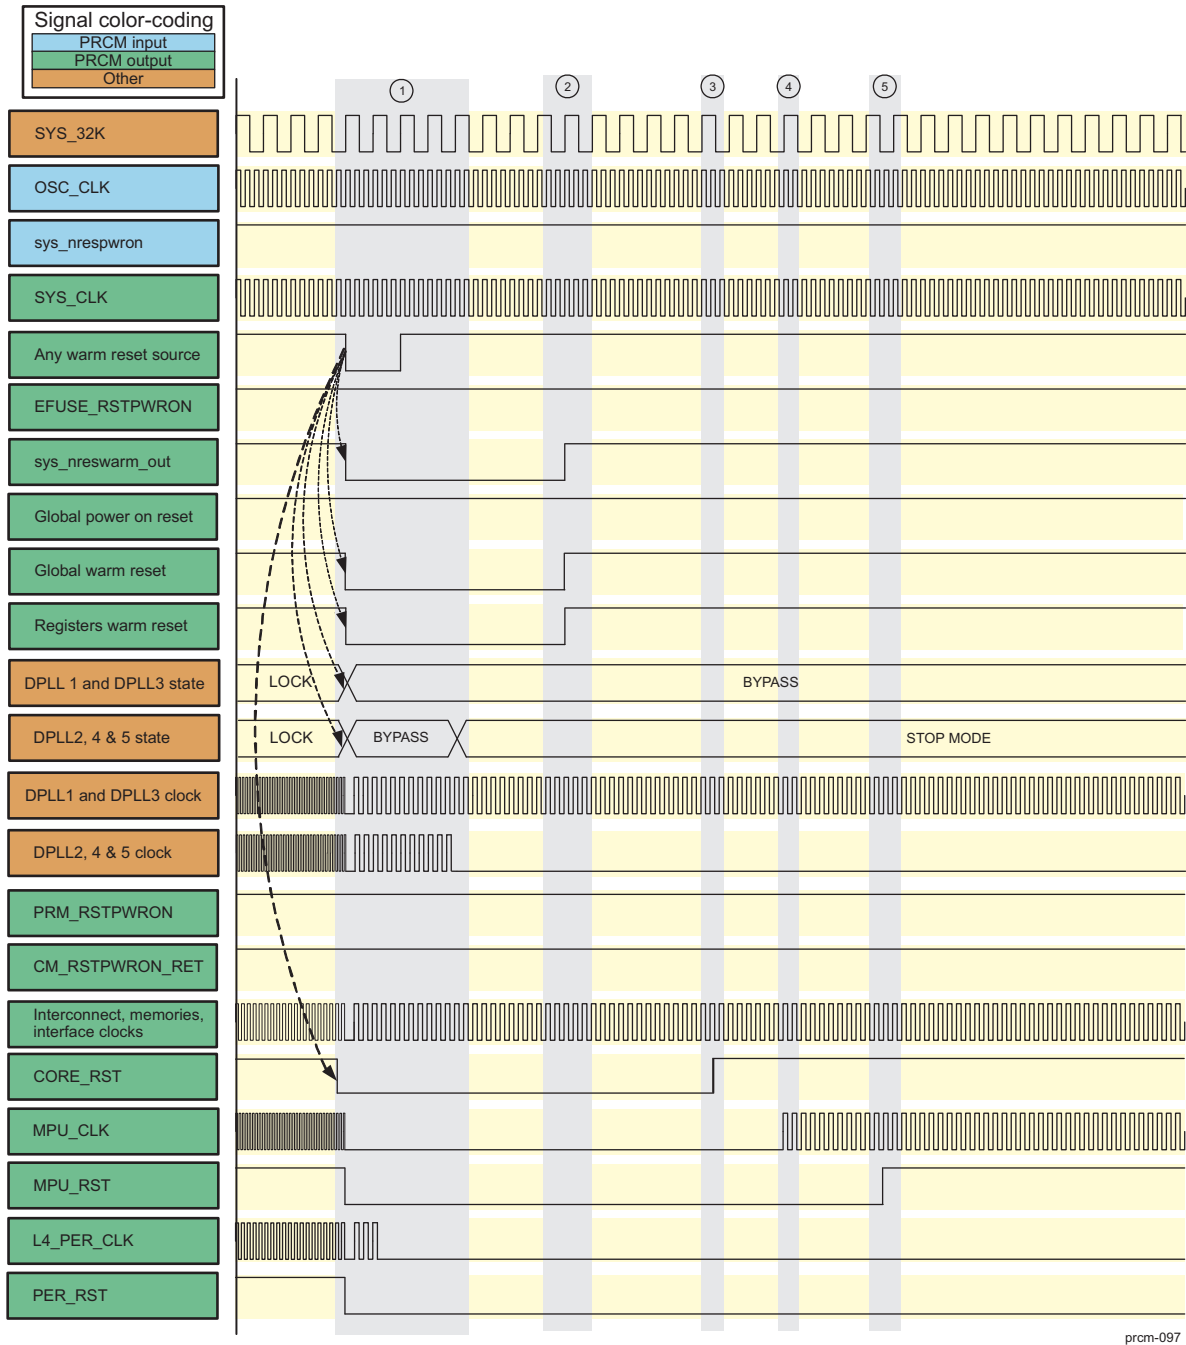

Note: Voltage stabilization is an additional condition if voltage scaling was performed before the assertion of the warm reset.

3. The CORE domain is released from reset (warm sensitive modules in CORE power domain).
4. The MPU_CLK clock is running.
5. The MPU power domain is released from reset. The MPU boots.

Notes:

- The IVA2 power domain is held under reset after global warm reset by assertion of the software source of the reset.
 - Power domains such as PER, DSS, CAM, SGX, and NEON are held under reset after global warm reset until the MPU software enables their interface clock.
-

Figure 4-29. Warm Reset Sequence

4.5.9.3 IVA2.2 Subsystem Power-Up Sequence

Figure 4-30 shows the power-up reset sequence and timing relationships of the IVA2.2 subsystem.

The assumptions are:

- The MPU is running.
- All sources of reset to the IVA2.2 subsystem are released except for the software sources of reset.

The sequence is:

1. Software enables the IVA2.2 subsystem clock.
2. Software clears the PRCM.[RM_RSTCTRL_IVA2](#)[1] RST2_IVA2 bit. The PRM releases the IVA2_RSTPWRON reset signal when reset manager 2 in the IVA2 power domain times out.
3. On release of IVA2_RSTPWRON, the IVA2.2 subsystem performs an initialization sequence.
4. The IVA2.2 subsystem asserts the IVA2_RST_DONE signal when initialization completes.
5. PRM releases the IVA2_RST2 reset signal.
6. The PRCM.[RM_RSTST_IVA2](#)[9] IVA2_SW_RST2 status bit is updated accordingly on release of the IVA2_RST2 reset signal. The MPU software can now program the MMU or download the DSP code.
7. Software clears the PRCM.[RM_RSTCTRL_IVA2](#)[0] RST1_IVA2 bit. The PRM waits for reset manager 1 in the IVA2 power domain to time out.
8. The PRM can release the IVA2_RST1 reset signal. The DSP boots.
9. The PRCM.[RM_RSTST_IVA2](#)[8] IVA2_SW_RST1 status bit is updated accordingly on release of the IVA2_RST1 reset signal.
10. DSP software enables the video hardware accelerator clock.
11. DSP software clears the PRCM.[RM_RSTCTRL_IVA2](#)[2] RST3_IVA2 bit. The PRM waits for reset manager 3 in the IVA2 power domain to time out.
12. After reset manager 3 times out, the PRM can release the IVA2_RST3 reset signal. The SEQ boots.
13. The PRCM.[RM_RSTST_IVA2](#)[10] IVA2_SW_RST3 status register bit is updated accordingly on release of the IVA2_RST3 reset signal.

Figure 4-30. IVA2.2 Subsystem Power-Up Reset Sequence

prcm-029

4.5.9.4 IVA2 Software Reset Sequence

Figure 4-31 shows the software reset sequence and timing relationships of the IVA2.2 subsystem.

The assumptions are:

- The MPU is running.
- All sources of reset to the IVA2.2 subsystem are released.
- The software ensures that the IVA2.2 subsystem software sources of reset are not asserted while the IVA2 power domain clocks are running.
- The software clears the previous reset status.

The sequence is:

1. DSP software puts the SEQ in idle, and can safely assert the IVA2 power domain software reset.
2. The PRM asserts the IVA2_RST3 reset asynchronously.
3. The DSP goes to idle, and the CM can gate the IVA_CLK clock.
4. MPU software can safely assert the IVA2.2 subsystem software reset.
5. The PRM asserts all remaining IVA2 power domain warm resets asynchronously.
6. MPU software enables the IVA2 power domain clock. A partial initialization sequence is performed.
7. MPU software clears the PRCM.RM_RSTCTRL_IVA2[1] RST2_IVA2 bit.
8. The IVA2.2 subsystem asserts the IVA2_RST_DONE signal when initialization completes.
9. The PRM releases the IVA2_RST2 reset signal when reset manager 2 in the IVA2 power domain times out.
10. The PRCM.RM_RSTST_IVA2[9] IVA2_SW_RST2 status bit is updated accordingly on release of the IVA2_RST2 reset signal. MPU software now program the MMU or download the DSP code.
11. Software clears the PRCM.RM_RSTCTRL_IVA2[0] RST1_IVA2 bit. The PRM waits for reset manager 1 in the IVA2 power domain to time out.
12. After reset manager 1 times out, the PRM can release the IVA2_RST1 reset signal. The DSP boots.
13. The PRCM.RM_RSTST_IVA2[8] IVA2_SW_RST1 status bit is updated accordingly on release of the IVA2_RST1 reset signal.
14. DSP software enables the SEQ clock.
15. DSP software clears the PRCM.RM_RSTCTRL_IVA2[2] RST3_IVA2 bit. The PRM waits for reset manager 3 in the IVA2 power domain to time out.
16. The PRM can release the IVA2_RST3 reset signal. The SEQ boots.
17. The PRCM.RM_RSTST_IVA2[10] IVA2_SW_RST3 status bit is updated accordingly on release of the IVA2_RST3 reset signal.

Figure 4-31. IVA2 Software Reset Sequence

prcm-030

4.5.9.5 IVA2 Global Warm Reset Sequence

[Figure 4-32](#) shows the reset sequence of the IVA2.2 subsystem and timing relationships on a global warm reset.

The assumptions are:

- The MPU is running.
- All sources of reset to the IVA2.2 subsystem are released.
- Software clears the previous reset status.

The sequence is:

1. A global warm reset source is asserted (see `sys_nreswarm` in [Figure 4-32](#)).
2. The PRM asserts asynchronously all IVA2 power domain warm reset signals (and all other warm reset signals).
3. The PRCM.[RM_RSTCTRL_IVA2](#) register is reset to its default value. As a result, the IVA2 power domain warm reset signals stay asserted on release of the global warm source of reset.
4. DPLL2 is held under its reset configuration; the IVA2 power domain clocks are stopped.
5. The `sys_nreswarm` global warm source of reset is de-asserted.
6. The PRCM.[RM_RSTST_IVA2](#) status register is updated accordingly when the device reset manager times out.
7. The MPU boots and the MPU software sequence, shown in [Section 4.5.9.4](#), from point 6, starts.

Figure 4-32. IVA2 Global Warm Reset Sequence

prcm-031

4.5.9.6 IVA2 Power Domain Wake-Up Cold Reset Sequence

Figure 4-33 shows the cold reset sequence of the IVA2.2 subsystem when the IVA2 power domain transitions from RETENTION to ON power state.

The assumptions are:

- The MPU is running.
- All sources of reset to the IVA2 are released.
- The software ensures that the IVA2 power domain software sources of reset are not asserted while the IVA2 clocks are running.
- The software clears the previous reset status.

The sequence is:

1. DSP software puts the SEQ into INACTIVE state.
2. MPU software programs the IVA2 power domain to go into RETENTION power state during the next sleep transition.
3. The DSP goes to idle mode, and the CM gates the IVA2 clock. The IVA2 power domain enters the INACTIVE power state.
4. The IVA2 power domain enters the RETENTION power state.
5. The IVA2 power domain is awakened.
6. The PRM asserts the cold reset IVA_RSTPWON and all IVA2 warm resets asynchronously.
7. The PRCM.RM_RSTCTRL_IVA2[2] RST3_IVA2 bit is automatically reset to its reset value.
8. The IVA2 power domain is inactive.
9. IVA2 clocks are automatically reenabled. The IVA2 power domain enters the ACTIVE power state.
10. The PRM releases the IVA2_RSTPWON reset signal when reset manager 2 in the IVA2 power domain times out.
11. On release of IVA2_RSTPWON, the IVA2 performs an initialization sequence.
12. The PRCM.RM_RSTST_IVA2 status register is updated accordingly on release of the IVA2_RSTPWON reset signal.
13. The IVA2.2 subsystem asserts the IVA2_RSTDONE signal when initialization completes.
14. The PRM can release the IVA2_RST1 and IVA2_RST2 reset signals. The DSP boots in autonomous mode.
15. DSP software enables the SEQ clock.
16. DSP software clears the PRCM.RM_RSTCTRL_IVA2[2] RST3_IVA2 bit. The PRM waits for reset manager 3 in the IVA2 power domain to time out.
17. After reset manager 3 times out, the PRM can release the IVA2_RST3 reset signal. The SEQ boots.
18. The PRCM.RM_RSTST_IVA2[10] IVA2_SW_RST3 bit is updated accordingly on release of the IVA2_RST3 reset signal.

Figure 4-33. IVA2 Power Domain Power Transition Reset Sequence

prcm-032

There are two alternate sequences:

- The DSP is held under reset when exiting the RETENTION power state. This is done when MPU software writes 1 to the PRCM.RM_RSTCTRL_IVA2[0] RST1_IVA2 bit. In this case, the MPU software must clear this bit to 0 to reboot the DSP.

- Both the DSP and MMU are held under reset when exiting the RETENTION power state (the MPU software writes 1 to the PRCM.RM_RSTCTRL_IVA2[0] RST1_IVA2 and PRCM.RM_RSTCTRL_IVA2[1] RST2_IVA2 bits). In this case, the MPU software must first clear the PRCM.RM_RSTCTRL_IVA2[1] RST2_IVA2 bit to allow the release of the reset IVA_RSTPWON and subsequently (after initialization) the release of IVA2_RST2. Only after the MPU software reprograms the MMU or downloads the DSP code can it clear the PRCM.RM_RSTCTRL_IVA2[0] RST1_IVA2 bit field to boot the DSP.

Notes:

- Although the IVA2.2 WUGEN module and DPLL2 are part of the IVA2.2 subsystem, they are also part of the CORE power domain and the DPLL2 power domain, respectively. They are reset independently from the IVA2 power domain.
 - The IVA2_RSTPWON reset is released by software by programming the PRCM.RM_RSTCTRL_IVA2[1] RST2_IVA2 bit. Setting the PRCM.RM_RSTCTRL_IVA2[1] RST2_IVA2 bit does not assert IVA2_RSTPWON.
 - IVA2_RST3 is asserted when the IVA2 power domain transitions from OFF or RETENTION state to ON state. The corresponding bit in the PRCM.RM_RSTCTRL_IVA2 register is automatically set to 1 during this transition.
 - The release of the IVA2_RST3 reset is stalled as long as the IVA2_RST2 reset is not released.
 - The release of the IVA2_RST2 and IVA2_RST1 resets causes IVA2 to de-assert the IVA2_RSTDONE signal.
-

4.5.9.7 CPEFUSE Reset Sequence

In the CPEFUSE reset sequence, Customer Programmable EFUSE is coupled with the SCM. Whenever the SCM is reset, the CPEFUSE cells are sensed. This sequence is initiated by the PRCM module and the SCM (hardware-controlled) after a device cold reset or the CORE power domain wakes up from the OFF power state. Under these conditions, the CM part of the PRCM is released from reset, and, according to the configuration of the PRCM.CM_FCLKEN3_CORE[0] EN_CPEFUSE bit, the CPEFUSE functional clock is automatically restarted and the CPEFUSE_RST reset is released (de-asserted). The SCM completes the autoload sequence of the CPEFUSE. Software must poll the autoload completion status bit in the SCM before switching off the CPEFUSE functional clock.

Whenever the software must blow a CPEFUSE, it must ensure that the functional clock is enabled; it starts the autoload sequence by programming the SCM.

Whenever the CORE power domain wakes up from open-switch retention, the CPEFUSE module is reset. However, its functional clock is not restarted, because the CM part of the PRCM is not reset, and the autoload sequence is not performed. Software must first enable the CPEFUSE functional clock; this releases the CPEFUSE_RST reset. Software must then start the autoload sequence by programming the control module, which is not reset in this situation.

For information about the SCM, see the *System Control Module* chapter.

4.6 PRCM Power Manager Functional Description

4.6.1 Overview

4.6.1.1 Introduction

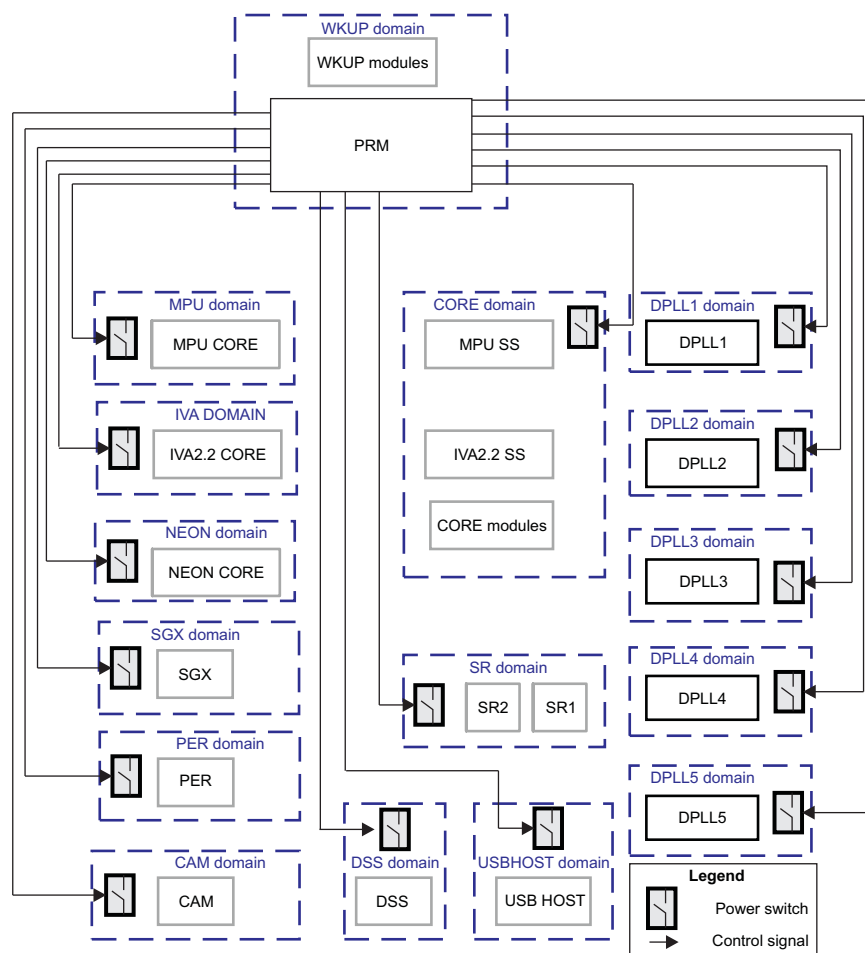

To efficiently manage leakage and reduce dynamic power consumption, the device supports several power-management techniques:

- Dynamic clock-gating conditions
- DVFS
- DPS
- SLM

These power-management techniques require software control and specific hardware features. The hardware features are fully controlled by the PRM part of the PRCM. These features are:

- Device partitioning into 18 power domains
- Device partitioning into several voltage domains communicating through level shifters
- Logic power-switch control
- RFF control
- Memory power-switch control
- Embedded LDOs (SRAMs, wakeup, emulation) control
- I/O off-mode control
- Level shifter control
- External power IC control

[Figure 4-34](#) is an overview of PRM power management in the device:

Figure 4-34. Power Control Overview

4.6.1.2 Device Partitioning

To substantially reduce leakage in sleep modes (SLM strategy) and to optimize active power-consumption savings (DPS strategy), the device is segmented into 18 power domains:

- MPU: Application processor
- NEON: Multimedia coprocessor
- IVA2: DSP
- SGX: Graphics engine
- CORE: Interconnect, memory controllers, peripherals, and clock management
- DSS: Display subsystem
- CAM: Camera controller
- PER: Low-power uses cases peripherals
- WKUP: Wakeup (always active)
- USBHOST: USB HOST power domain
- EMU: Emulation
- SMARTREFLEX: SmartReflex modules
- EFUSE: eFuse farm
- DPLL1: MPU DPLL
- DPLL2: IVA2.2 DPLL
- DPLL3: CORE DPLL

- DPLL4: Peripherals DPLL
- DPLL5: Peripherals DPLL2

Each power domain receives power through an independent switch controlled by the PRM module. In this way, depending on the application scenario, unused power domains) can be switched off or put in RETENTION state while others remain active.

Table 4-26 lists the device modules split over the power domains.

Table 4-26. Power Domain Modules

Power Domain	Modules
MPU	MPU core ICE-crusher CS MPU async bridge (master) SSM

4.6.1.3 Memory and Logic Power Management

Device power domains can have separate control for logic and memory. This depends on the power domain implementation in the device (for details, see [Section 4.6.2, Power Domain Implementation](#)).

Generally, separate switches allow separate management of the logic and memory power states in a power domain.

Memory banks in the MPU (L2 cache), IVA2 (L1, L1 flat, L2, L2 flat), CORE (CORE memory banks 1 to 6), SGX, CAM, DSS, USBHOST, and EMU power domain memories have their own voltage and power control, independent from the logic. However, the user must ensure that memory states are programmed consistently with the logic state.

MPU L1 cache memory does not have an independent control and is supplied with the MPU logic.

CORE memory bank 3,4, 5, and 6 are associated to the domain power state and controlled with the domain logic.

MPU and IVA2 memories are supplied by a common LDO (VDD4). CORE, SGX, CAM, DSS, USBHOST, and EMU memories are supplied by another LDO (VDD5).

4.6.1.4 Power Domain States

Each power domain can be driven by the PRM to four different states, depending on the functional mode required by the user. Power domain states are hardware-defined and depend on the domain clock activity and domain memory/logic switch states.

Table 4-27 defines the power states a power domain can reach in the device.

Table 4-27. Power Domain States

Power State	Power		Clocks
	Logic	Memory	
ACTIVE	On	On, retention, or off	On (at least one)
INACTIVE	On	On, retention, or off	CORE Power Domain Clock-Gating ControlsOff (all clocks)
RETENTION (CSWR)	On	Retention or off	Off (all clocks)
RETENTION (OSWR)	Off/RFF		
OFF	Off	Off	Off (all clocks)

Notes:

- Closed-switch retention (CSWR): Full domain logic supply is maintained, and supply voltage can be dropped to minimize leakage.
- Open-switch retention (OSWR): Full domain logic is switched off, but the context is saved for modules that embed RFFs.

In CSWR and OSWR, memories are put in RETENTION or can also be switched off.

4.6.1.5 Power State Transitions

For each power domain, the PRM manages all transitions controlling domain clocks, domain resets, domain logic power switches, memory power switches, and memory retention.

As previously mentioned, a power domain is characterized by four different power states: ACTIVE, INACTIVE, RETENTION, and OFF.

A transition is a passage from one state to another.

Two types of power state transitions are possible:

- Sleep: Moving from a higher consumption power state (ACTIVE) to a lower consumption power state (INACTIVE, RETENTION, or OFF)
- Wake-up: Moving directly from a lower consumption power state (INACTIVE, RETENTION, or OFF) to the ACTIVE power state

For instance, a power domain with initiators and target modules in standby and idle modes operates an ACTIVE-to-INACTIVE transition. It is then ready to operate an INACTIVE-to-RETENTION or OFF transition, depending on the requirements.

The device supports eight transitions:

- ACTIVE => INACTIVE
- INACTIVE => ACTIVE
- ACTIVE => RETENTION
- RETENTION => ACTIVE
- ACTIVE => OFF
- OFF => ACTIVE

4.6.1.6 Device Power Modes

A device power mode is a specific functional combination of the power states of all the power domains of the device.

Unlike power domain states (see [Section 4.6.1.4](#)), device power modes are not hardware-defined; they are defined by software as relevant combinations of the power domain states.

There are two types of device power modes:

- **Active:** Any valid combination of power domain states in which one or several domains are still active, regardless of whether any software is running
- **Standby:** Any valid combination of power domain states in which all the domains are in INACTIVE, RETENTION, or OFF state

Note: All power domain states are hardware-supported, thereby preventing electrical damage to the device. However, software ensures that the power domain states are set correctly, to result in a valid device power mode and ensure correct functioning.

4.6.1.7 Isolation Between Power Domains

When switching a power domain from one state to another, the PRCM automatically manages domain output isolation to prevent electrical damage.

This mechanism is hardware-supervised and does not require software action.

4.6.2 Power Domain Implementation

4.6.2.1 Device Power Domains

[Table 4-28](#) summarizes the power mode implementation in the device and the control granularity for each power and memory domain.

Table 4-28. Domain Power Control Summary

Functional Domain or Subsystem	Power Domain	PRCM Power Control Type
MPU	MPU	Logic ON-OFF
	NEON	Logic ON-OFF
	CORE	Logic ON-OFF
	EMU	Logic ON-OFF
	L1 cache SRAM	Logic ON-OFF
	L2 cache SRAM	ON-OFF
		BB retention
IVA2.2	IVA2	Logic ON-OFF
		Memory tags retention

		Logic retention
	SRAM bank 1	ON-OFF
		BB retention
	SRAM bank 2	ON-OFF
		BB retention
	OSWR SRAM 3	Logic ON-OFF
PERIPHERALS	PER	BB retention
		ON-OFF
WKUP	WKUP	Logic ON-OFF
	EMU	none
EMULATION	ETB SRAM	Logic ON-OFF
		ON-OFF
SmartReflex	SR1, SR2	BB retention
EFUSE	eFuse farm	Logic ON-OFF
MPU DPLL	DPLL1	none
IVA2.2 DPLL	DPLL2	Logic ON-OFF
CORE DPLL	DPLL3	Logic ON-OFF
Peripherals DPLL	DPLL4	Logic ON-OFF
Peripherals DPLL2	DPLL5	Logic ON-OFF

Notes:

- BB: Back-bias or local memory retention
- OSWR: Open-switch retention
- CSWR: Closed-switch retention
- LDO retention: All memories are in BB mode and the memory array is dropped down.
- Logic ON-OFF: Memory is controlled together with the logic (and does not support retention).
- OSWR SRAM bank 3: Corresponds to memories that must be retained whenever the CORE OSWR mode is activated (the CORE context is maintained only by keeping RFFs alive). These memories are scratchpad, SDMA, and SMS.
- CSWR SRAM bank 4: Corresponds to memories that are retained only in case of CSWR (all logic is maintained with reduced voltage). These memories are USB and MAILBOXES.

The CORE power domain has 6 memory blocks. Of these 6, the power state of only two memory blocks: SRAM bank 1 and SRAM bank 2, can be configured vis-a-vis the domain power state, through software setting of the corresponding bitfields in the PRCM.PM_PWSTCTRL_CORE register. The power states of the rest of the memory banks is automatically controlled by the PRCM (i.e., hardware controlled) and no software setting is possible.

The memory bank 5 of the CORE power domain is used for the USB TLL module save and restore operations. (refer to [Section 4.8.6](#)). Similarly, the memory bank 6 is for the System Control Module save and restore feature (refer to the *System Control Module* chapter).

Note: Before initiating a domain sleep transition (ON to OFF) on both MPU and CORE power domain it must be ensured that the CORE memory banks are configured to automatically switch to ON power state when the CORE power domain wakes-up (OFF to ON). This is need for proper boot-up sequence.

This is done by setting PM_PWSTCTRL_CORE [19:18] MEM2ONSTATE bit field to 0x3 and PM_PWSTCTRL_CORE [17:16] MEM1ONSTATE bit field to 0x3.

4.6.2.2 Power Domain Memory Status

The PRCM module logs the memory status in the SCM.CONTROL_SEC_STATUS register. The memory status is logged for CORE power domain memory banks 1 and 2 (OCM RAM) and for the L1 and L2 caches of the MPU.

Two statuses are logged for each memory bank:

- Memory is destroyed: The memory array is powered down.
- Memory is not accessible: The memory array is powered down or is in RETENTION.

For information about the SCM, see the *System Control Module* chapter.

4.6.2.3 Power Domain State Transition Rules

As previously described, a power domain can reach different states. These states are linked both to the power applied to the domain and to the domain clock activity.

Any power state transition always depends on and starts with power domain clock activity control. Any active clock in a power domain sets the domain as ACTIVE (see [Section 4.6.2.1](#)). Therefore, a sleep transition always starts by shutting down the power domain clocks. For more information about power domain clock controls, see [Section 4.7](#), *Clock Manager Functional Description*.

When all clocks are shut down in a power domain, transitions from INACTIVE-to-OFF or INACTIVE-to-RETENTION can occur.

Similarly, when a wake-up transition occurs between a lower-power domain state and a higher one, the transition to ACTIVE state becomes effective when the required clocks are restarted.

[Section 4.8](#), *Idle and Wake-Up Management*, describes both sleep and wake-up transitions.

4.6.2.4 Power Domain Dependencies

Besides the inner conditions to operate a state transition on a single power domain, the device offers hardwired and software-programmable dependencies between the power domains.

Two kinds of dependencies exist:

- Sleep dependencies: Used to start a sleep transition on a power domain only if the related power domains are in mute mode (not requesting any service from the linked power domain)
- Wake-up dependencies: Used to initiate a wake-up transition on a power domain as a consequence of a linked power domain wake-up transition

Two dedicated sets of registers (PRCM.CM_SLEEPDEP_<domain> and PRCM.PM_WKDEP_<domain>) allow the setting of programmable dependencies.

[Section 4.8.5, Sleep and Wake-Up Dependencies](#), summarizes the possible dependency combinations between power domains.

4.6.2.5 Power Domain Controls

4.6.2.5.1 Power Domain Hardware Control

Each power domain in the device is controlled by a dedicated power state controller (PSCON) in the PRCM module. The PSCON provides circuit level control over the power management features (switches, isolation, retention).

When a state transition occurs for a given power domain, the related PSCON automatically manages the sequence.

Device power domain implementation also depends on hardwired dependencies, both sleep and wake-up transitions, between power domains. This means a single power domain transitions from one power state to another depending on the states and transitions of the linked domains.

For details about the dependencies between power domains, see [Section 4.8, Idle and Wake-Up Management](#), and [Section 4.12, Basic Programming Model](#).

4.6.2.5.2 Power Domain Software Controls

If all conditions are met to initiate a power domain state transition (that is, all the modules are idle/standby and the related clocks are shut down), the PRCM automatically manages the transition according to the following settings:

- Dependencies setting: The PRCM.CM_SLEEPDEP_<domain> registers and PRCM.PM_WKDEP_<domain> registers are used to set/clear programmable dependencies between power domains.

Not all dependencies are programmable by software; some are hardwired and thus do not allow any control. For more information about the dependencies between power domains, see [Section 4.8, Idle and Wake-Up Management](#), and [Section 4.12, Basic Programming Model](#).

- Power state transitions setting: The transitions of each power domain state can be controlled by software through a set of dedicated status registers (PRCM.PM_PWSTCTRL_<domain_name>) that allow the configuration of the power state into which the domain enters after completing a transition (PRCM.PM_PWSTCTRL_<domain_name>[1:0] POWERSTATE bit field). These status registers are used to check the current state of the logic and memories in a power domain and to learn about any ongoing state transition.

Also, if the power domain offers different settings for the logic and memory, the PRCM.PM_PWSTCTRL_<domain_name> registers allow the selection of the state to which the logic and memory will go when the power domain is put in RETENTION. They also allow the selection of the state to which the memory will go when the power domain is put into ON state.

These features depend on each power domain implementation. For details, see [Section 4.12, Basic Programming Model](#), and [Section 4.14, PRCM Registers Manual](#).

- Event generator: Three registers (PRCM.PM_EVGENCTRL_MPU, PRCM.PM_EVGENONTIM_MPU, and PRCM.PM_EVGENOFFTIM_MPU) allow the MPU power domain to be switched between on and off (or placed in inactive mode). The PRCM.PM_EVGENONTIM_MPU and PRCM.PM_EVGENOFFTIM_MPU registers are used to set the durations of the on and off modes, respectively.

For details, see [Section 4.12, Basic Programming Model](#), and [Section 4.14, PRCM Registers Manual](#).

4.7 PRCM Clock Manager Functional Description

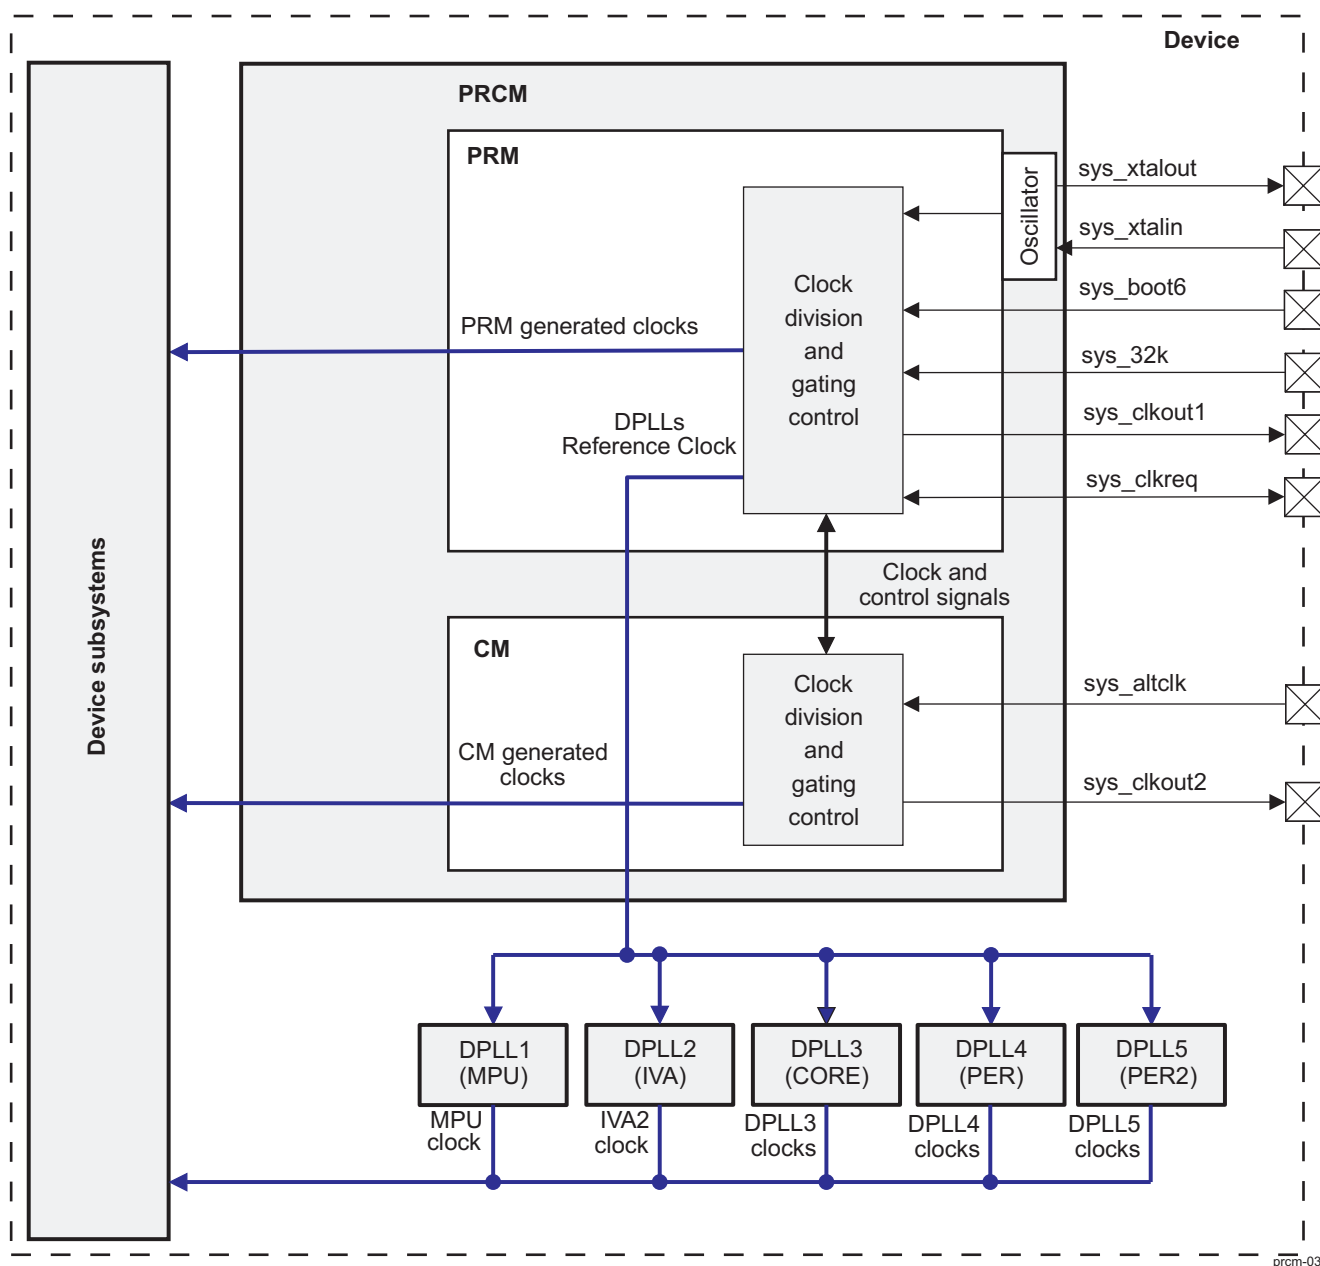

This section gives information about all modules and features in the high-tier device. See Chapter 1, *OMAP35x Family* section, to check availability of modules and features. For power-management saving consideration, ensure that power domains of unavailable features and modules are switched off and clocks are cut off.

4.7.1 Overview

The PRCM module provides control for clock generation, division, distribution, synchronization, and gating. It distributes the clock sources to all the modules in the device.

The device-level clock generation is handled by internal oscillators (the system clock oscillator and the 32-kHz oscillator for secure clock) and DLLs; clock division and gating are handled by the PRM and the CM sections of the PRCM. [Figure 4-35](#) shows the high-level clock-management scheme in the device.

Figure 4-35. PRCM Clock Manager Overview

prcm-034

4.7.1.1 Interface and Functional Clocks

The PRCM propagates two kinds of clocks:

- Interface clock: Ensures proper communication between any module and the system interconnects (L3 or L4). In most cases, the interface clock supplies the interface and registers of the module. For some modules, the interface clock is also used as the functional clock.
- Functional clock: Supplies the functional part of a module or subsystem. In some cases, a module or subsystem may require several functional clocks.

To be operational, a module requires functional clock(s); to communicate with other modules, it requires an interface clock. For example, the functional clock of a general-purpose timer (GPTIMER) must be active for it to run, but its interface clock can be turned off.

A module can use one or more optional functional clocks. Because an optional functional clock is used only for specific features of the module, it can be shut down without stopping the module activity (for example, 54 MHz for the DSS power domain and 96 MHz for the CAM power domain).

4.7.2 External Clock I/Os

Figure 4-36 shows the external clock I/Os of the device.

Figure 4-36. External Clock I/O

4.7.2.1 External Clock Inputs

4.7.2.1.1 32-kHz Always-On Clock

The sys_32k input pin supplies the 32-kHz always-on clock (32K_FCLK clock). This clock is used for low-frequency operation (timers, denouncing, etc.). It also supplies the WKUP power domain for operation in the lowest power mode.

4.7.2.1.2 High-Frequency System Clock

The high-frequency system clock (SYS_CLK) is either supplied to the device from an external clock source through the sys_xtalin input pin or is generated internally by a local system clock crystal oscillator. In the latter case, a crystal is connected between the sys_xtalout and sys_xtalin device pins. The sys_boot[6] pin is used to set the oscillator operating mode (see Figure 4-14).

The source system clock can be 12, 13, 16.8, 19.2, 26, or 38.4 MHz and is internally divided by 2 to provide the standard frequencies (26 MHz and 34.8 MHz become 13 MHz and 19.2 MHz, respectively; the native 12, 13, and 19.2 MHz remain unchanged). It supplies the reference to the DPLLs and is also used by several modules. The system clock is activated in the device after the device power-on reset is released by the reset manager in the PRCM module.

The source-clock selection register (PRCM.PRM_CKSEL [2:0] SYS_CLKIN_SEL bit field) is set by the software to identify the input frequency of the system clock.

Table 4-29 provides the system clock input configurations.

Table 4-29. System Clock Input Configurations

Input Source	Device Pin Mapping	Description
Quartz	sys_xtalin and sys_xtalout	Internal oscillator is enabled.
Square clock (1.8-V CMOS signal)	sys_xtalin (sys_xtalout is not connected)	Internal oscillator is bypassed.

Note: An external pullup or pulldown tied on the sys_boot6 input pin of the device determines whether the internal oscillator is used (oscillator mode) or an external clock source is supplied to the sys_xtalin input pin (bypass mode).

4.7.2.1.3 Alternate Clock

The sys_altdclk pin can be used to provide an alternate 54-MHz, 48-MHz, or any other frequency clock.

4.7.2.2 External Clock Outputs

The device can output two clocks externally:

- sys_clkout1 can output an oscillator clock (12, 13, 16.8, 19.2, 26, or 38.4 MHz) at any time. The output oscillator clock can be controlled either by software or externally using sys_clkreq control. When the device is in OFF state, sys_clkreq can be asserted to enable the oscillator and activate sys_clkout1 without waking up the device. The OFF state polarity of sys_clkout1 is programmable.
- sys_clkout2 can output sys_clk (12, 13, 16.8, 19.2, 26, or 38.4 MHz), core_clk (CORE DPLL output), or 96-MHz or 54-MHz clocks. It can be divided by 2, 4, 8, or 16, and its OFF state polarity is programmable. This output is active only when the CORE power domain is ACTIVE. Also, the selected source clock must be enabled by software. Enabling sys_clkout2 does not automatically request the required source clock.

4.7.2.3 Summary

Table 4-30 summarizes the external clock I/O.

Table 4-30. External Clock I/Os

Name	I/O ⁽¹⁾	Source/Destination	Description
sys_xtalin	I	Oscillator	Main input clock. Crystal oscillator clock (only at 12, 13, 16.8, or 19.2 MHz) or CMOS digital clock (at 12, 13, 16.8, 19.2, 26, or 38.4 MHz).
sys_xtalout	O	Oscillator	Output of oscillator
sys_clkout1	O	PRCM	Configurable output clock 1
sys_clkout2	O	PRCM	Configurable output clock 2
sys_32k	I	PRCM	32-kHz clock input
sys_altdclk	I	PRCM	Alternate selectable clock source for UARTs or NTSC/PAL. It can be 54 MHz, 48 MHz, or any frequency.

⁽¹⁾ I = Input, O = Output

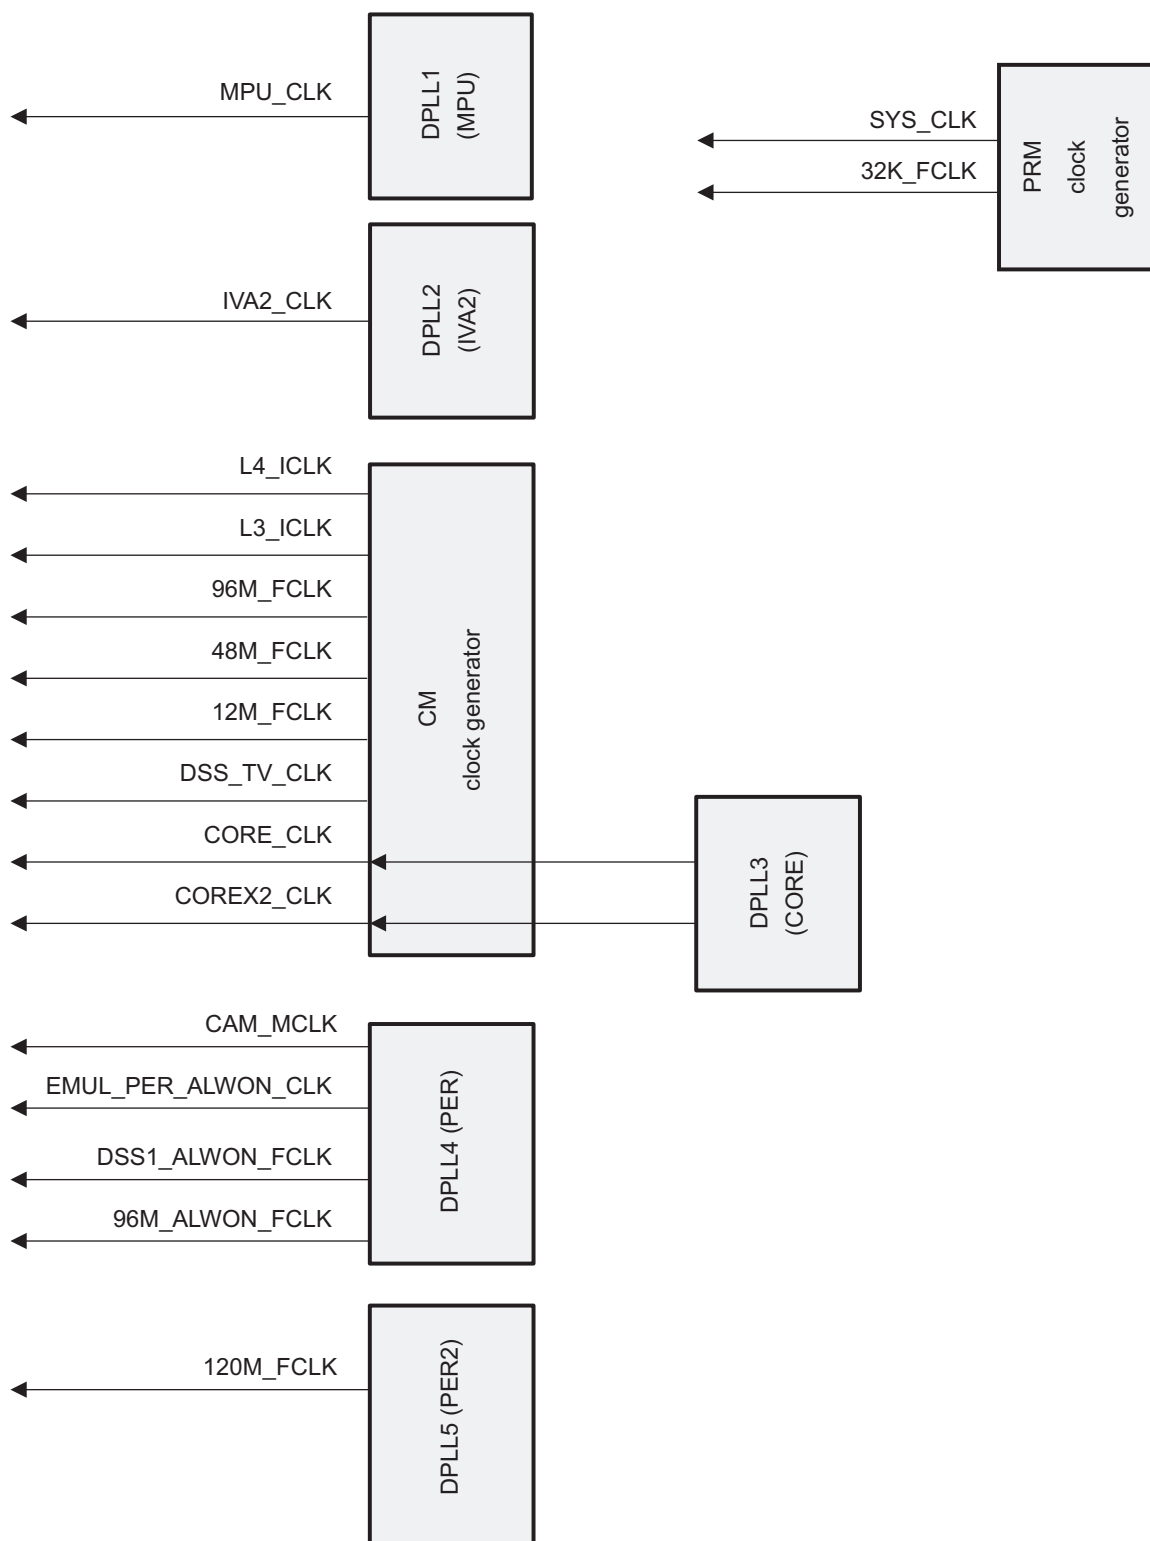

4.7.3 Internal Clock Generation

The device generates internal clocks from four sources:

- PRM
- CM
- DPLLs
- 32-kHz oscillator

[Figure 4-37](#) shows the internal clock generation scheme of the device.

Figure 4-37. Internal Clock Sources

prcm-036

4.7.3.1 PRM

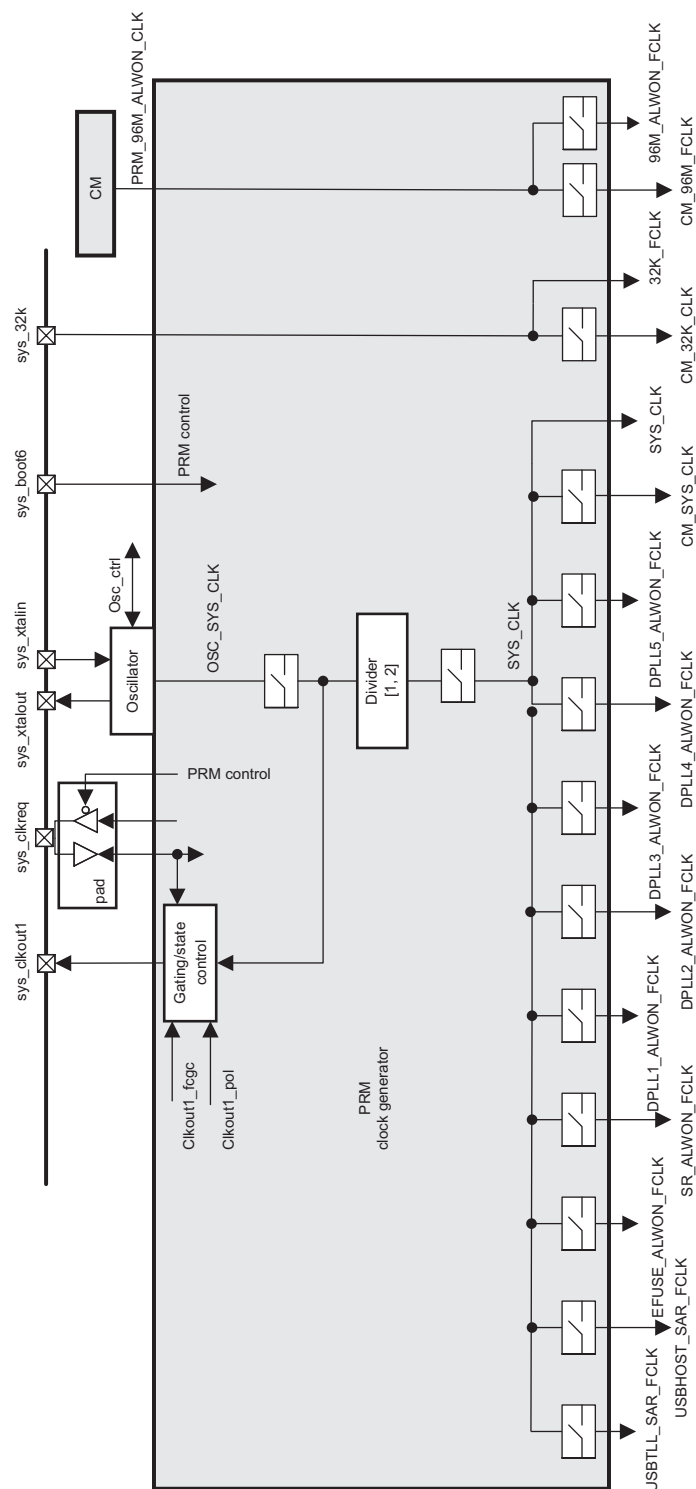

The PRM resides in the WKUP power domain. It handles the generation of the 32-kHz low-frequency clocks and the high-frequency system clocks from the SYS_CLK. It also manages the clock oscillator and the external clock output sys_clkout1.

SYS_CLK is generated by the internal oscillator or supplied as the external clock signal on the sys_xtalin pin. It supplies most of the clocks in the device. Some of the device clocks sourced by SYS_CLK are always powered (clocks are present even when the CORE power domain is in the OFF state). SYS_CLK is also the source of the WKUP power domain interface clocks.

It also handles the gating and distribution of the 96-MHz clock from DPLL4 to the CM and the PER power domain modules.

[Figure 4-38](#) is the functional overview of the PRM. The other clocks in the figure are explained in the following sections.

Figure 4-38. PRCM Clock Generator

prcm-037

4.7.3.2 CM

The CM clock generator generates interface clocks and peripheral functional clocks for most of the modules. It also controls DPLL3, DPLL4, and the external peripheral clock output sys_clkout2 (see [Figure 4-39](#)).

The CM is in the CORE power domain, which can be powered off. When the CORE power domain is powered off, the clocks are not available, and their OFF state is latched. The DPLL controls are also latched. The RFF architecture ensures that the full CM setting is saved when the CORE power domain goes into RETENTION state, and is transparently restored when it reactivates.

DPLL3 receives SYS_CLK from the PRM and generates CORE_CLK through the CM. CORE_CLK is the source for the interface clocks (L3 and L4) and the functional clock. The L3 and L4 interface clocks supply the device interconnects and all module interface clocks. The L4 clock is divided for USB (full-speed clock limitation at 50 MHz) and to supply the reset managers (PRM) in the WKUP power domain. The clocks derived from CORE_CLK are fully balanced over the device.

The 96M_FCLK, 48M_FCLK, and 12M_FCLK clocks are functional unbalanced clocks for a number of modules in the CORE and PER power domains.

The functional 96-MHz clock path can be bypassed with SYS_CLK to allow a peripheral such as I²C to be functional while the DPLL4 is not yet powered-on. The default configuration after initial power-on is bypassed with the system clock. Software must switch to the DPLL-generated clock after programming the proper system settings.

The 96-MHz clock input from PRM to the CM (that is, CM_96M_FCLK) is internally gated by the CM.

[Figure 4-39](#) is the functional overview of the CM.

Submit Documentation Feedback

4.7.3.3 DPLLs

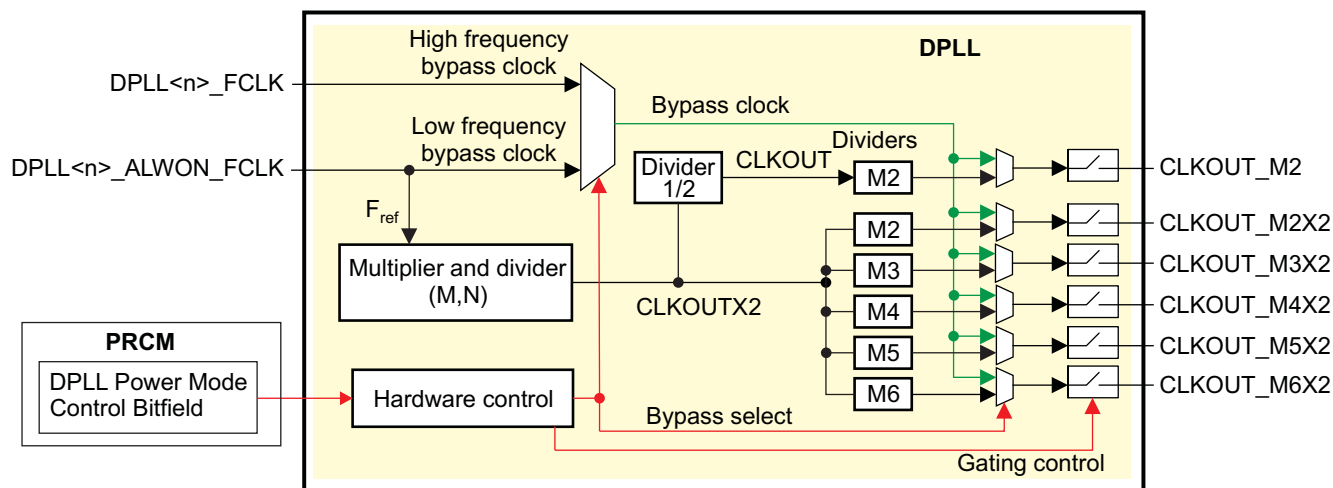

To generate high-frequency clocks, the device supports five on-chip DPLLs controlled directly by the PRCM:

- DPLL1 (MPU)
- DPLL2 (IVA2)
- DPLL3 (CORE)
- DPLL4 (PER)
- DPLL5 (PER2)

Note: This chapter discusses only DPLL1 to DPLL5, because they are directly controlled by the PRCM module. The *Display Interface Subsystem* chapter discusses the DPLLs in the DSS.

Figure 4-40 shows the functional architecture of a generic DPLL.

Figure 4-40. Generic DPLL Functional Diagram

prcm-039

Depending on its hardware configuration, the DPLL may receive one or two clock inputs.

When the DPLL has two clock inputs, it uses one as the reference clock (F_{ref}) to generate the high-frequency clock; the second one serves as the bypass clock when the DPLL is in bypass mode (that is, not locked and generating the high-frequency clock). For example, DPLL1 and DPLL2 receive the high-frequency bypass clock from the DPLL3 output, and the reference clock from the PRM.

When the DPLL has only one clock input, it uses that clock input as the reference clock and bypass clock. For example, DPLL3, DPLL4, and DPLL5 receive only one input clock from PRM, and it is used as both the reference and the bypass clock.

It internally generates two main clocks according to the following equations:

- $CLKOUTX2 = (F_{ref} \times 2 \times M) / (N+1)$
- $CLKOUT = CLKOUTX2/2$

where M is an 11-bit multiplier and N is a 7-bit divider.

Note: When M is set to 0 or 1, the DPLL is forced into bypass mode.

The internal clocks (CLKOUT and CLKOUTX2) of the DPLL may then be used to generate six independent output clocks:

- $CLKOUT_M2 = CLKOUT / M2$
- $CLKOUT_M2X2 = CLKOUTX2 / M2$
- $CLKOUT_M3X2 = CLKOUTX2 / M3$

- $\text{CLKOUT_M4X2} = \text{CLKOUTX2} / \text{M4}$
- $\text{CLKOUT_M5X2} = \text{CLKOUTX2} / \text{M5}$
- $\text{CLKOUT_M6X2} = \text{CLKOUTX2} / \text{M6}$

where M2, M3, M4, M5, and M6 are additional dividers for the DPLL-synthesized clock.

The output clock frequencies defined by these equations are generated by the DPLL only when it is locked. When the DPLL is in bypass mode, however, all clock outputs run at the bypass clock frequency. The bypass clock can either be a high-frequency bypass clock (only for DPLL1 and DPLL2) or the low-frequency reference clock.

The DPLL also provides an independent clock-gating signal for each of the six output clocks. The PRCM provides the DPLL with a clock-gating control signal, and the DPLL returns a clock activity status signal indicating whether the output clock is effectively gated or running.

For an explanation of the DPLL multiplier, divider settings, and gating controls, see [Section 4.7.6, DPLL Control](#).

Each clock-generating DPLL of the device has the following features:

- Independent power domain
- Control by the CM
- Fed by always-on SYS_CLK with independent gating control for the SYS_CLK
- Analog part supplied by a dedicated power supply (VDDPLL and VDDADAC at 1.8 V) and an embedded LDO to eliminate 1-MHz noise
- Up to six independent output dividers for simultaneous generation of multiple output clocks with different frequencies

4.7.3.3.1 DPLL1 (MPU) and DPLL2 (IVA2)

DPLL1 and DPLL2 are in the MPU and IVA2.2 subsystems, respectively. The DPLLs supply the source clocks for their respective subsystems, which use the source clocks to internally generate all subsystem clocks.

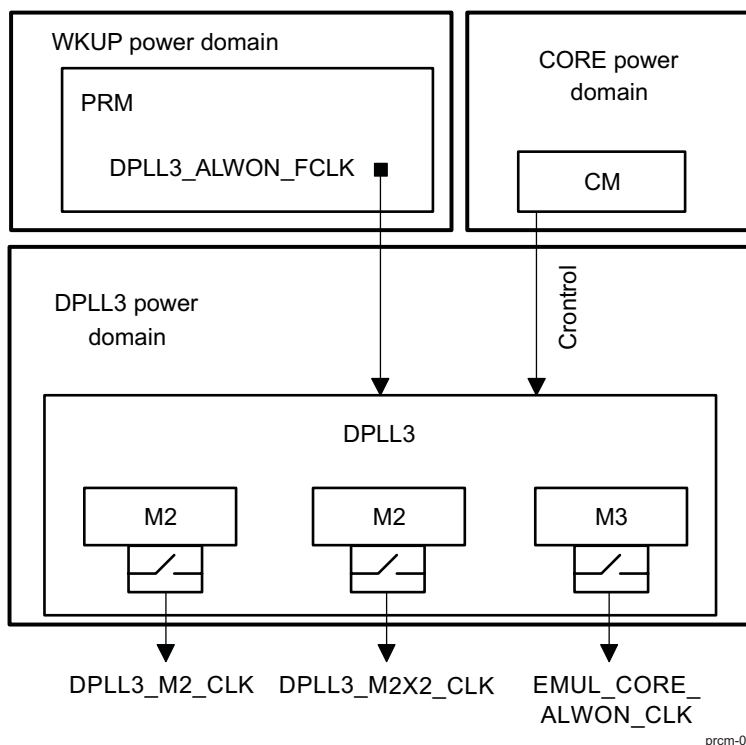

DPLL1 and DPLL2 each use a reference clock to produce their synthesized clocks. They receive these reference clocks (DPLL1_ALWON_FCLK and DPLL2_ALWON_FCLK, respectively) from the PRM, and their high-frequency bypass clocks (DPLL1_FCLK and DPLL2_FCLK, respectively) from the CM. The reference clock is SYS_CLK, and the high-frequency bypass clock is CORE_CLK.

To save on DPLL power consumption by the processors, the high-frequency bypass input clock from DPLL3 (CORE) is used when the DPLLs are set to bypass mode (either statically, or dynamically during relock time) or when the processors are not required to run faster than at L3 clock speed. This use of the high-frequency bypass input clock also optimizes the performance of the DPLLs during frequency scaling.

4.7.3.3.2 DPLL3 (CORE)

Figure 4-41 is the block diagram of DPLL3.

Figure 4-41. DPLL3 Clocks

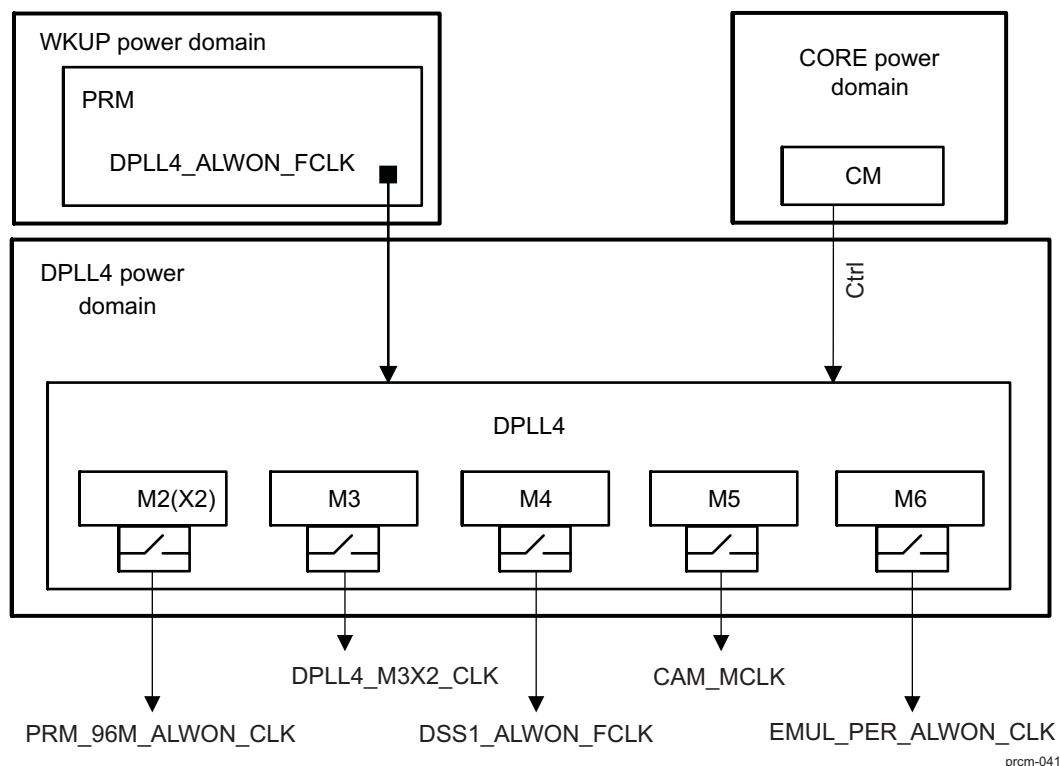

DPLL3 receives its reference clock (DPLL3_ALWON_FCLK), which is the SYS_CLK, from the PRM. DPLL3 does not receive a high-frequency bypass clock, and it uses the reference clock as the low-frequency bypass clock. DPLL3 supplies the source clock for all interfaces and a few functional clocks for the device modules. It also serves as the source of the emulation trace clock. While the CORE power domain is on, the output of DPLL3 can be used as HS bypass clock input to DPLL1 and DPLL2.

4.7.3.3.3 DPLL4 (Peripherals)

Figure 4-43 is the block diagram of DPLL4.

Figure 4-42. DPLL4 Clocks

DPLL4 receives its reference clock (DPLL4_ALWON_FCLK), which is the SYS_CLK, from the PRM. DPLL4 does not receive a high-frequency bypass clock, and it uses the reference clock as the low-frequency bypass clock. DPLL4 generates clocks for the peripherals, supplying five clock sources:

- 96-MHz always-on source clock for the PRM
- 54-MHz to TV DAC
- Display functional clock
- Camera sensor clock
- Emulation trace clock

The clock outputs to the DSS, PER, and EMU power domains are always on.

4.7.3.3.4 DPLL5 (Peripherals)

Figure 4-43 is the block diagram of DPLL5.

Figure 4-43. DPLL5 Clocks

prcm-089

DPLL5 receives its reference clock (DPLL5_ALWON_FCLK), which is the SYS_CLK, from the PRM. DPLL5 does not receive a high-frequency bypass clock, and it uses the reference clock as the low-frequency bypass clock. DPLL5 generates clocks for the peripherals, supplying five clock sources:

- 120-MHz functional clock to the peripheral domain modules
- USIM source clock for the functional clock of the USIM open-core protocol (OCP) in the WKUP power domain

4.7.3.3.5 DPLL Clock Summary

Table 4-31 summarizes the use of the divided output clocks of the five DPLLs in the device.

Table 4-31. DPLL Output Clocks

	CLKOUT_M2	CLKOUT_M2X2	CLKOUT_M3X2	CLKOUT_M4X2	CLKOUT_M5X2	CLKOUT_M6X2
DPLL1		X ⁽¹⁾				
DPLL2	X					
DPLL3	X	X	X			
DPLL4		X	X	X	X	X
DPLL5	X					

⁽¹⁾ X represents the DPLL clock output used.

4.7.3.4 32-kHz Oscillator

An internal 32-kHz always-on oscillator feeds the secure watchdog timer (WDTIMER1) and the secure timer (GPTIMER12). It is not software-controllable, and its activity is stopped only when the I/Os (and, consequently, the WKUP power domain) are not supplied. The oscillator ensures protection for these timers against clock stoppage caused by an external attack.

4.7.3.5 Summary

Table 4-32 summarizes the source clocks in the device.

Table 4-32. Source-Clock Summary

Clock Name	External/Internal Source	Clock Generator	Description
32K_FCLK	sys_32k (input pin)	PRM	
SYS_CLK	Oscillator	PRM	System clock. Serves as primary source clock of the device. Also used as functional and interface clock for PRM.
DSS_TV_CLK	DPLL4/sys_altdclk (input pin)	CM	DSS TV clock
120M_FCLK	DPLL5	CM	
96M_FCLK	DPLL4	CM	
48M_FCLK	DPLL4/sys_altdclk (input pin)	CM	
12M_FCLK	DPLL4/sys_altdclk (input pin)	CM	
96M_ALWON_CLK		DPLL4	Direct from DPLL4
CORE_CLK	DPLL3	CM	DPLL3 clock output frequency
COREX2_CLK	DPLL3	CM	DPLL3 clock output frequency x 2
L3_ICLK	DPLL3	CM	L3 interconnect interface clock
L4_ICLK	DPLL3	CM	L4 interconnect interface clock
MPU_CLK		DPLL1	MPU subsystem source clock
IVA2_CLK		DPLL2	IVA2.2 subsystem source clock
SECURE_32K_FCLK		32-kHz oscillator	Generated internally by an RC oscillator. It is always active.

4.7.4 Clock Distribution

4.7.4.1 Power Domain Clock Distribution

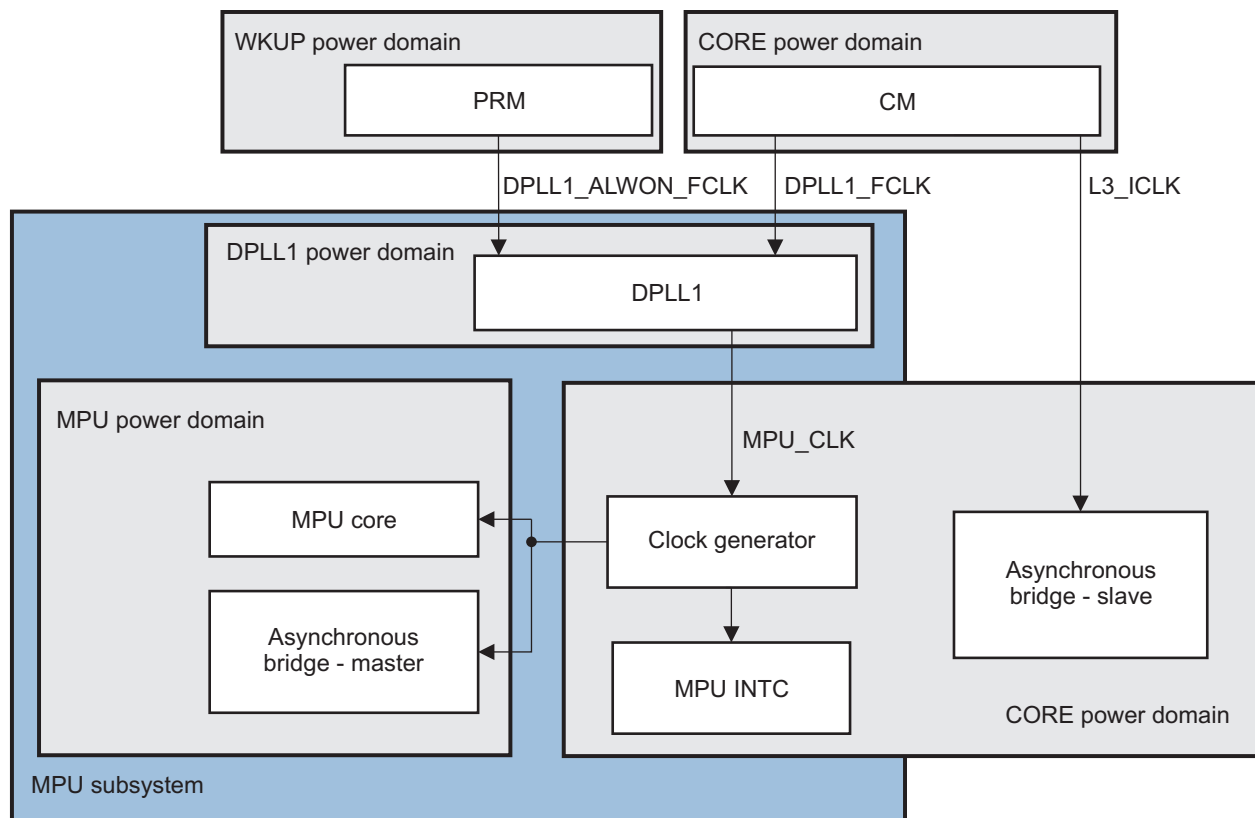

This section describes the PRCM clock distribution over device power domains:

4.7.4.1.1 MPU Power Domain

The PRCM does not directly provide any clock to the MPU power domain. It feeds only DPLL1, which generates MPU_CLK. All clocks are then locally generated by the clock generator in the MPU subsystem.

Figure 4-44 shows the clocking scheme in the MPU power domain.

Figure 4-44. MPU Power Domain Clocking Scheme

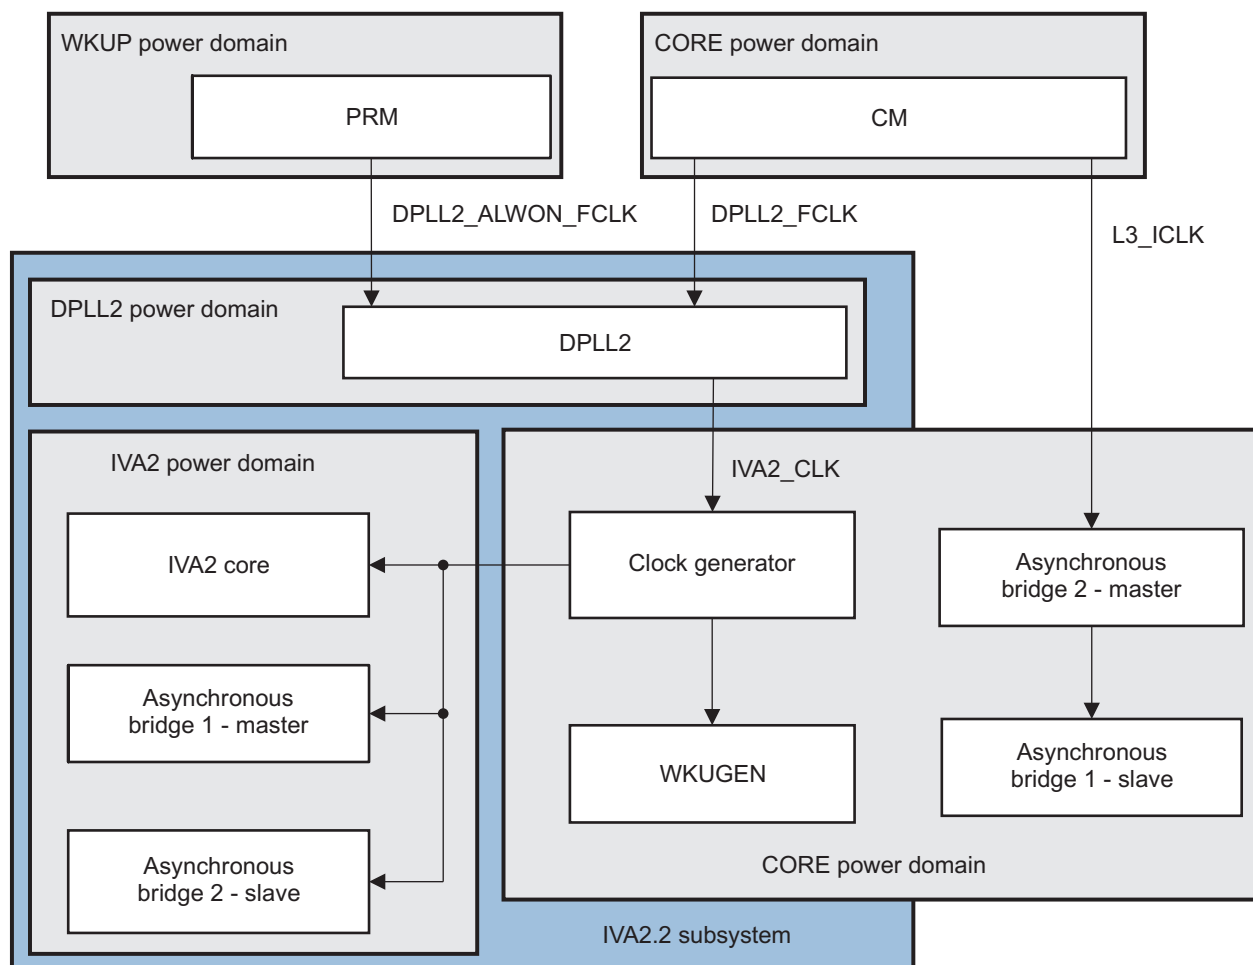

prcm-042

4.7.4.1.2 IVA2 Power Domain

The PRCM does not directly provide any clock to the IVA2 power domain. It feeds only DPLL2, which generates IVA2_CLK. All clocks are then locally generated by a clock generator in the IVA2.2 subsystem.

Figure 4-45 shows the clocking scheme in the IVA2 power domain.

Figure 4-45. IVA2 Power Domain Clocking Scheme

prcm-043

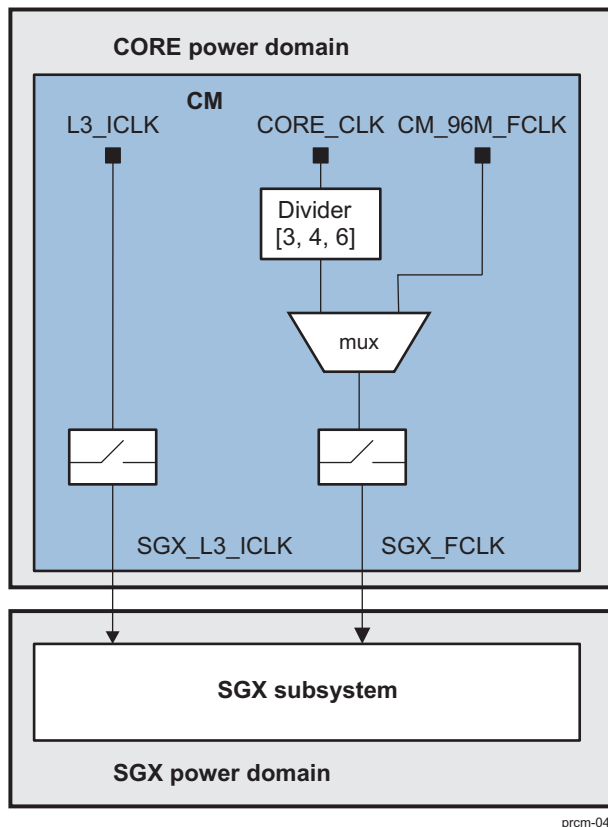

4.7.4.1.3 SGX Power Domain

This section gives information about all modules and features in the high-tier device. See Chapter 1, *OMAP35x Family* section, to check availability of modules and features. For power-management saving consideration, ensure that power domains of unavailable features and modules are switched off and clocks are cut off.

The SGX subsystem interface clock is sourced by the L3 clock, whereas the functional clock source can be selected between CORE_CLK and CM_96M_FCLK. When the functional clock source is CORE_CLK, its frequency can be divided (by 3, 4, or 6).

Figure 4-46 shows the clocking scheme in the SGX power domain.

Figure 4-46. SGX Power Domain Clocking Scheme

prcm-044

4.7.4.1.4 CORE Power Domain

The CORE power domain has both L3- and L4-derived clock domains.

The secure clock domains (SECURITY_L3_ICLK, SECURITY_L4_ICLK1, and SECURITY_L4_ICLK2) allow shutting down all clock domains of the CORE power domain while keeping the secure modules (FPKA1, AES 1, SHAM1, D3D1, and RNG1) clocked and active. This saves power and ensures active security.

The CORE power domain receives several functional clocks (12-, 48-, 96-MHz, system, and 32-kHz) that feed its peripherals and modules, with an exception:

- The McBSP 1 and McBSP 5 modules can be clocked either by CORE_96M_FCLK from the CM or from an external clock, MCBSP_CLKS. The SCM manages the selection between the two sources. For more information about the SCM, see *System Control Module* chapter.

Figure 4-47 through Figure 4-49 show the clock signals and their relationships in the CORE power domain.

Figure 4-47. CORE Clock Signals: Part 1

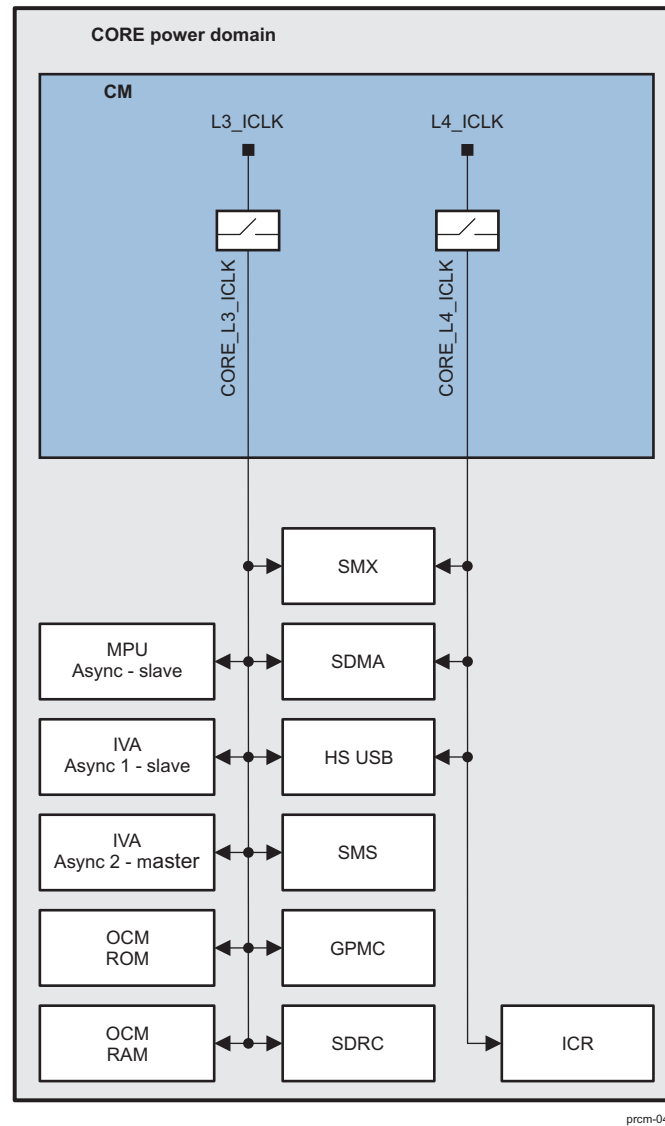

Figure 4-48. CORE Clock Signals: Part 2

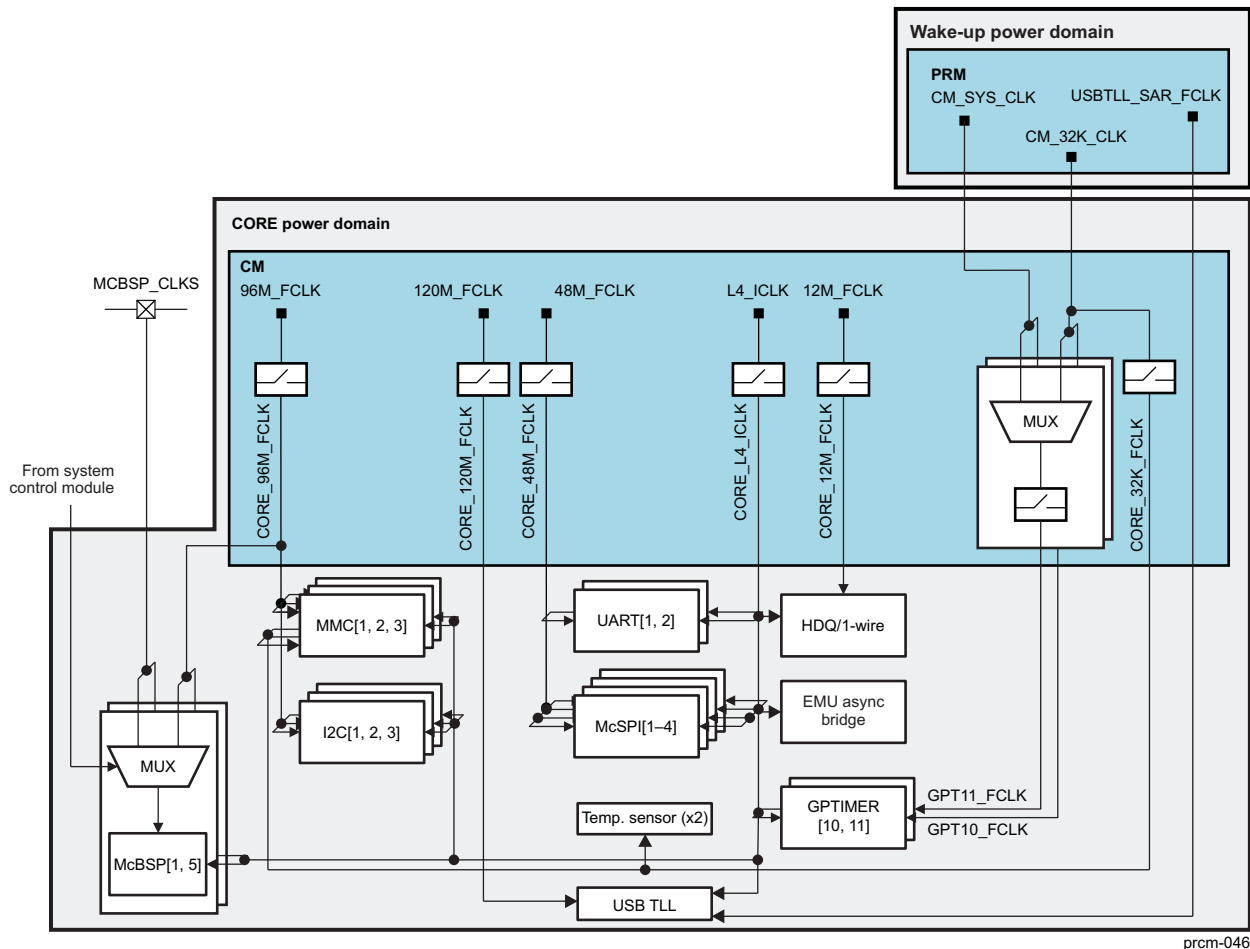

Figure 4-49. CORE Clock Signals: Part 3

prcm-047

4.7.4.1.5 EFUSE Power Domain

Figure 4-50 shows the clock signals and their relationships in the EFUSE power domain.

Figure 4-50. EFUSE Clock Signals

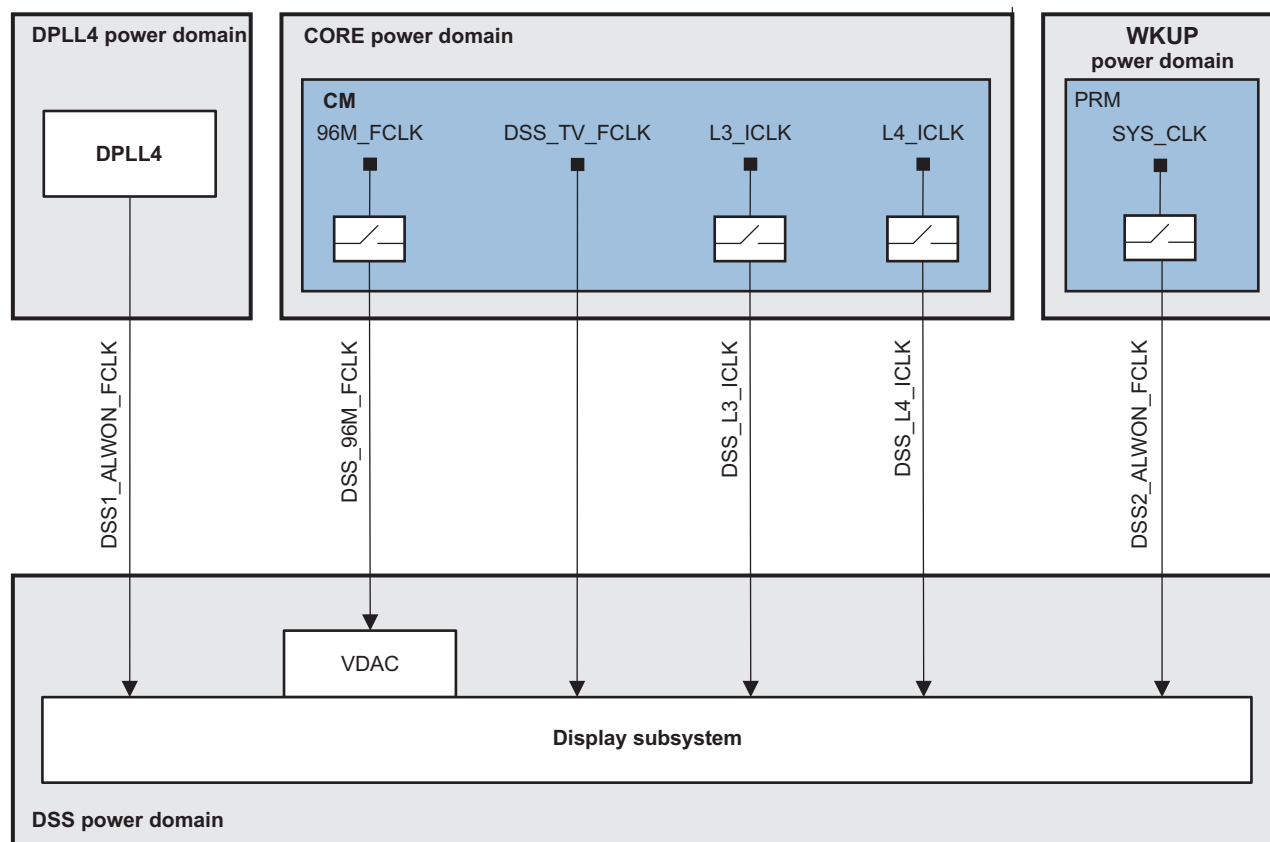

prcm-048

The EFUSE power domain allows the eFuse configuration to be saved even when the CORE power domain is off. The EFUSE sense procedure is performed at device power up and on device wakeup from off mode. During this procedure, the PRM enables the EFUSE_ALWON_FCLK clock.

4.7.4.1.6 DSS Power Domain

This section gives information about all modules and features in the high-tier device. See Chapter 1, *OMAP35x Family* section, to check availability of modules and features. For power-management saving consideration, ensure that power domains of unavailable features and modules are switched off and clocks are cut off.

Figure 4-51 shows the clock signals and their relationships in the DSS power domain.

Figure 4-51. DSS Clock Signals

prcm-049

The DSS subsystem interface is clocked with the L3 and L4 clocks. It receives four functional clocks:

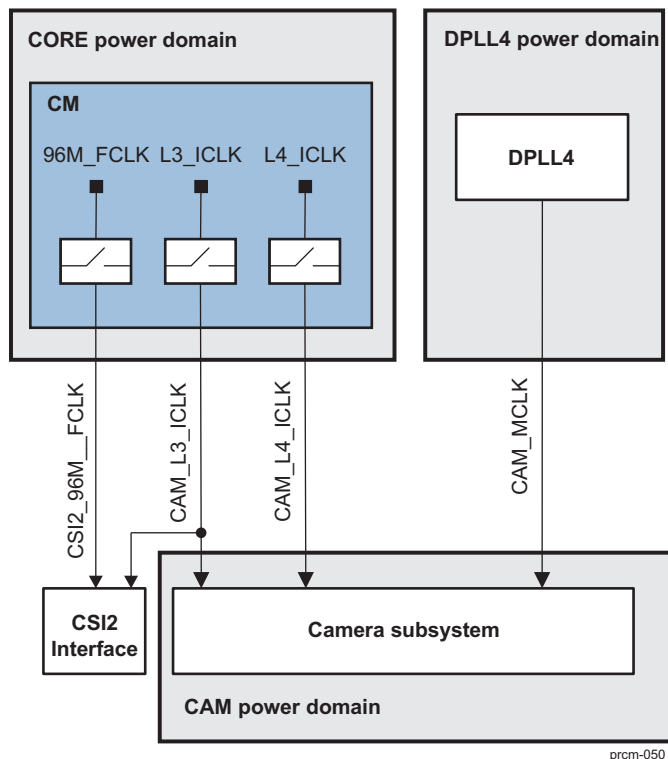

- DSS1_ALWON_FCLK: Issued from DPLL4. Its frequency can be a division by 1 to 16 of the frequency of the DPLL4 synthesized clock.
- DSS2_ALWON_FCLK: The gated SYS_CLK. Used mainly for display in low-power refresh modes.
- DSS_96M_FCLK: Required when TV output is activated
- DSS_TV_FCLK: Required when TV output is activated

4.7.4.1.7 CAM Power Domain

This section gives information about all modules and features in the high-tier device. See Chapter 1, *OMAP35x Family* section, to check availability of modules and features. For power-management saving consideration, ensure that power domains of unavailable features and modules are switched off and clocks are cut off.

Figure 4-52 shows the clock signals and their relationships in the CAM power domain.

Figure 4-52. CAM Clock Signals

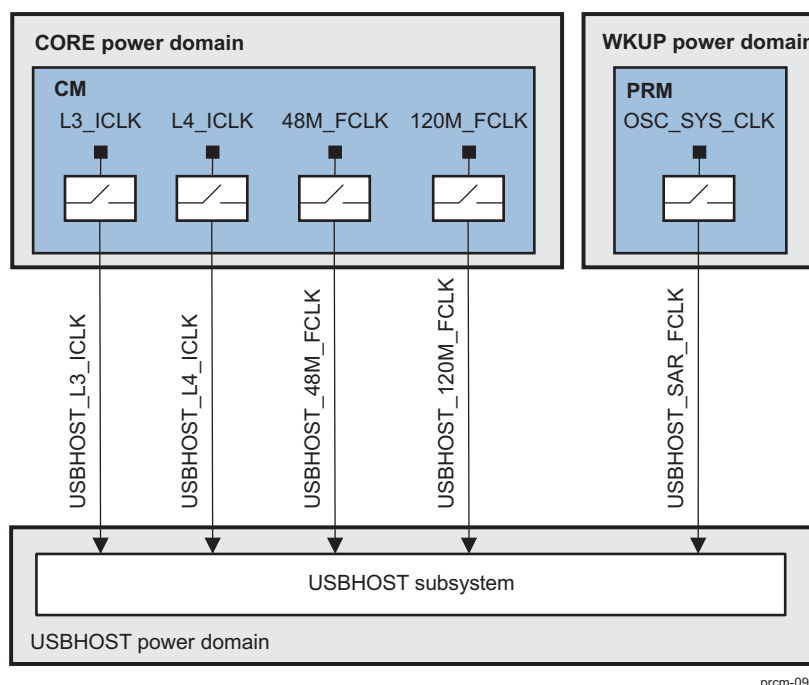

The camera subsystem interface is clocked with the L3 and L4 clocks (CAM_L3_ICLK and CAM_L4_ICLK, respectively). CAM_L3_ICLK is also used as the main functional clock. The functional clock (CAM_MCLK) is also provided by DPLL4 to supply the external sensor.

4.7.4.1.8 USBHOST Power Domain

Figure 4-53 shows the clock signals and their relationships in the USBHOST power domain.

Figure 4-53. USBHOST Clock Signals

prcm-090

The HS USB Host subsystem interface is clocked with the L3 and L4 clocks (USBHOST_L3_ICLK and USBHOST_L4_ICLK, respectively).

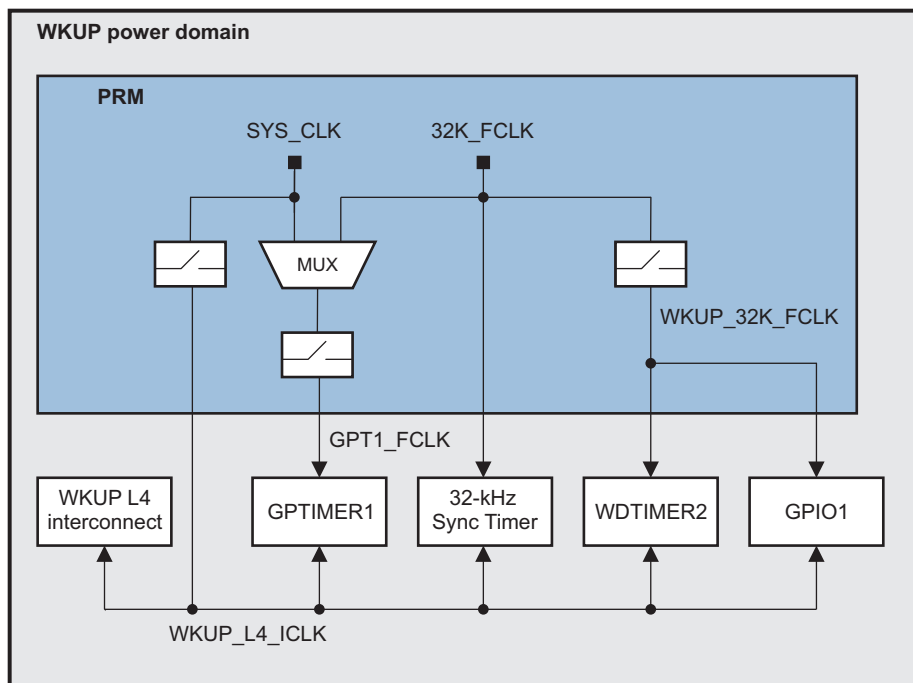

The HS USB Host subsystem requires two functional clocks (USBHOST_120M_FCLK and USBHOST_48M_FCLK) that may or may not be requested simultaneously. Therefore, they are gated independently based on the configuration of the [CM_FCLKEN_USBHOST\[0\]](#) EN_USBHOST1 and [CM_FCLKEN_USBHOST\[1\]](#) EN_USBHOST2 bits.

The HS USB Host subsystem gets an additional functional clock from the PRM (USBHOST_SAR_FCLK). It is dedicated to the save-and-restore mechanism and is automatically gated/enabled by the PRM, based on the HS USB Host save-and-restore bit configuration (that is, the [PM_PWSTCTRL_USBHOST\[4\]](#) SAVEANDRESTORE bit) and on the USBHOST power domain state transitions.

4.7.4.1.9 WKUP Power Domain

Figure 4-54 shows the clock signals and their relationships in the WKUP power domain.

Figure 4-54. WKUP Clock Signals

prcm-051

All clocks in the WKUP power domain are generated by the PRM, except for the functional clock for the secure timers (WDTIMER1 and GPTIMER12). This clock is supplied directly by the internal 32-kHz oscillator (SECURE_32K_FCLK). The functional clock GPT1_FCLK of GPTIMER1 can be selected as either SYS_CLK or 32K_FCLK. The 32-kHz sync timer, WDTIMER2, and GPIO1 receive 32K_FCLK as their functional clock. This is the low-frequency always-on clock.

The voltage controller module in the PRM receives SYS_CLK as its functional clock. The SmartReflex I2C4 module implemented in the voltage controller uses the same functional clock (SYS_CLK).

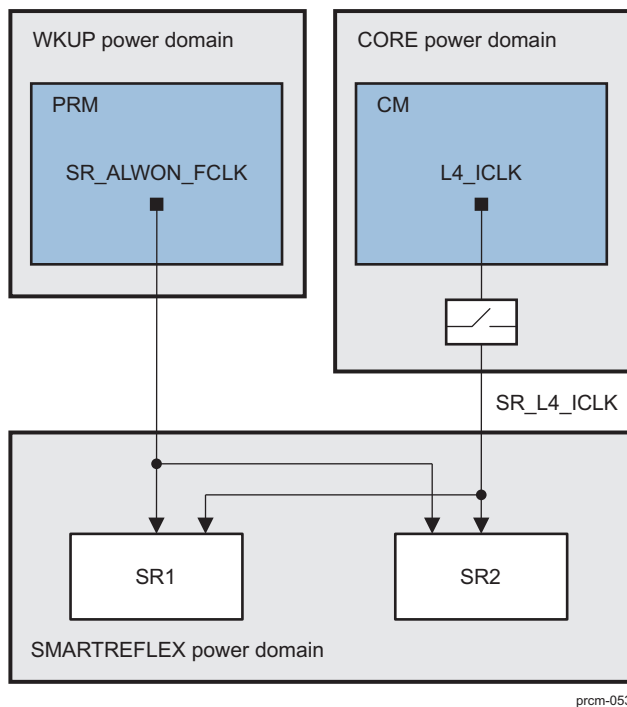

The PRM receives SYS_CLK as the L4 interface clock. For all other modules of the WKUP power domain, the L4 interface clock WKUP_L4_ICLK is derived from SYS_CLK. Communication between the WKUP power domain and CORE L4 interconnects is asynchronous.

The USIM OCP module receives the functional clocks (USIM_FCLK and 32K_FCLK) and the L4 interface clock (WKUP_L4_ICLK) from the PRM.

4.7.4.1.11 SMARTREFLEX Power Domain

The two SmartReflex modules in the device have a common L4 interface clock (SR_L4_ICLK) and a functional clock (SR_ALWON_FCLK) (see [Figure 4-56](#)).

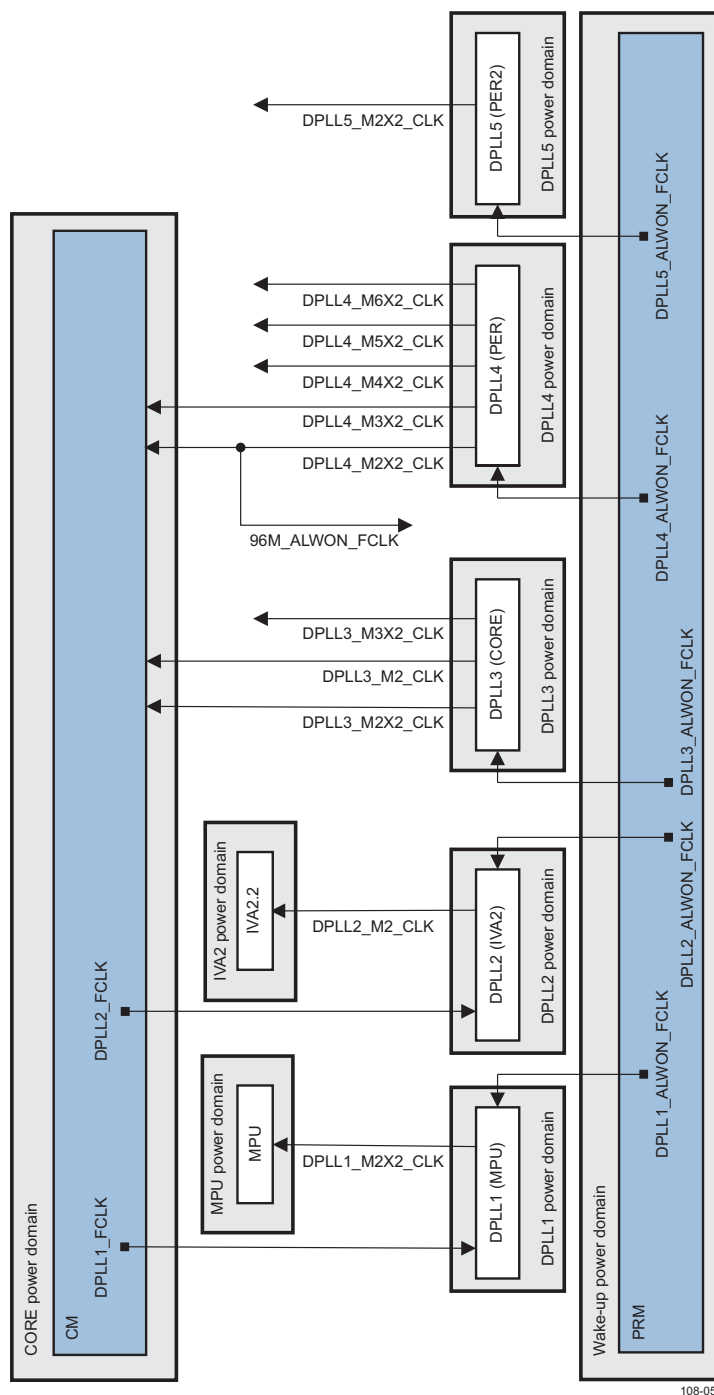

Figure 4-56. SMARTREFLEX Clock Signals

4.7.4.1.12 DPLL Domains

The PRCM provides clock sources for the five DPLLs, as shown in [Figure 4-57](#)

Figure 4-57. DPLL Clock Signals

The PRCM also manages clock-gating control for these DPLL outputs.

The MPU and IVA2 processors use clock outputs locally in their respective subsystems. The CM uses the DPLL3 clock outputs to generate all interface clocks and some functional clocks. The CM uses two of the five clocks generated by DPLL4 and one clock output of DPLL5 to generate functional clocks for the peripheral domain modules. The remaining three clocks of DPLL4 are propagated to their corresponding modules.

4.7.4.2 Clock Distribution Summary

4.7.4.2.1 Power Domain Source Clocks

[Table 4-33](#) summarizes clock distribution for each power domain. The clock type indicates whether a clock is supplied when the CM (CORE power domain) is off. "Normal" means that the clock is gated when the power domain is off, while the "always-on" clock remains active even when the CORE power domain is off.

Table 4-33. Clock Distribution

Power Domain	Clock	Generator	Type	Destination
MPU	MPU_CLK	DPLL1	Normal	MPU subsystem
NEON				NEON
IVA2	IVA2_CLK	DPLL2	Normal	IVA2.2 subsystem
SGX	SGX_FCLK	CM	Normal	SGX subsystem
	SGX_L3_ICLK	CM	Normal	
CORE	CORE_120M_FCLK	CM	Normal	USB TLL
	CORE_96M_FCLK	CM	Normal	McBSP[1,5], MMC[1,2,3], MS-PRO, I2C[1,2,3]
	CORE_48M_FCLK	CM	Normal	UART[1,2], McSPI[1..4]
	CORE_12M_FCLK	CM	Normal	HDQ
	GPT10_FCLK	CM	Normal	GPTIMER10
	GPT11_FCLK	CM	Normal	GPTIMER11
	CPEFUSE_FCLK	CM	Normal	CPEFUSE
	USBTLL_SAR_FCLK	PRM	Always-on	USB TLL
	CM_32K_CLK	PRM	Always-on	Temperature sensor (x2), MMC[1,2,3]
	CORE_L3_ICLK	CM	Normal	SMX, SDMA, MPU Async Bridge(Slave), IVA2 Async Bridge 1 (Slave), IVA2 Async Bridge 2 (Master), HS USB, SMS, GPMC, OCM ROM, SDRC, OCM RAM, CORE L3 interconnect
	CORE_L4_ICLK	CM	Normal	SMX, SDMA, HS USB, AES 2, SHAM2, D3D 2, ICR, McBSP[1,5], MMC[1,2], MS-PRO, I2C[1..3], GPTIMER [10,11], UART[1,2], McSPI[1..4], HDQ, CORE L4 interconnect, MAILBOXES, SCM
	SECURITY_L3_ICLK	CM	Normal	PKA
	SECURITY_L4_ICLK1			
	SECURITY_L4_ICLK2	CM	Normal	AES 1, SHAM 1, D3D 1, RNG1
DSS	DSS_TV_FCLK	CM	Normal	DSS, VDAC
	DSS_96M_FCLK	CM	Normal	VDAC
	DSS1_ALWON_FCLK	DPLL4	Always-on	DSS
	DSS2_ALWON_FCLK	PRM	Always-on	
	DSS_L3_ICLK	CM	Normal	
	DSS_L4_ICLK	CM	Normal	
CAM	CAM_MCLK	DPLL4	Normal	Camera subsystem

Table 4-33. Clock Distribution (continued)

Power Domain	Clock	Generator	Type	Destination
PER	CAM_L3_ICLK	CM	Normal	Camera subsystem, CSI2 interface
	CAM_L4_ICLK	CM	Normal	Camera subsystem
	CSi2_96M_FCLK	CM	Normal	CSI2 interface

DPLL4	DPLL4_ALWON_FCLK	PRM	Always-on	DPLL4
DPLL5	DPLL5_ALWON_FCLK	PRM	Always-on	DPLL5

Notes:

- Modules supplied by the L3 interface clock only:
 - MPU asynchronous bridge
 - IVA2.2 asynchronous bridges
 - All memory controllers (OCM ROM, OCM RAM, SDRC, SMS, and GPMC)
- Modules that require both L3 and L4 clocks:
 - SDMA
 - HS USB
 - All security modules (FPKA, AES, RNG, SHAM, and D3D)
- Modules fed by the L4 clock:
 - SCM
 - Mailboxes
 - ICR
 - All peripherals (McBSP1, McBSP5, MMC1, MMC2, MS-PRO, I2C1, I2C2, I2C3, McSPI1, McSPI2, McSPI3, McSPI4, UART1, UART2, HDQ, GPTIMER10, and GPTIMER11)

4.7.4.2.2 Peripheral Module Clocks

Table 4-34 lists the peripherals, DSS, and CAM functional clock frequency requirements. These frequencies must be operational over the full VDD2 voltage range.

Table 4-34. Peripheral Module Functional Clock Frequencies

Module	Functional Clock	Frequency
MS-PRO	96M_FCLK	96 MHz
MMC-SDIO[1,2,3]	96M_FCLK	96 MHz
McBSP[1, 5]	96M_FCLK	96 MHz
CAM	CAM_MCLK	216 MHz
McSPI[1..4]	CORE_48M_FCLK	48 MHz
UART[1..3]		
Display subsystem	DSS1_ALWON_FCLK	Up to 173 MHz
	DSS2_ALWON_FCLK	System clock
	DSS_96M_FCLK	96 MHz
	DSS_TV_FCLK	54 MHz
I2C[1..3]	CORE_96M_FCLK	96 MHz
HDQ	CORE_12M_FCLK	12 MHz
GPTIMER1	GPT1_FCLK	32-kHz (p) or system clock
GPTIMER[2..9]	GPTn_ALWON_FCLK	32-kHz (p) or system clock
GPTIMER[10, 11]	GPTn_FCLK	32-kHz or system clock
GPTIMER12	SECURE_32K_FCLK	32 kHz (p) (s)
FPKA1	SECURITY_L3_ICLK	L3_ICLK
AES 1	SECURITY_L4_ICLK2	L4_ICLK
D3D 1		
SHAM 1		
RNG1		
AES 2	CORE_L4_ICLK	L4_ICLK
SHAM 2		
D3D 2		
ICR		

Table 4-34. Peripheral Module Functional Clock Frequencies (continued)

Module	Functional Clock	Frequency
WDTIMER1	SECURE_32K_FCLK	32 kHz (p) (s)
WDTIMER2	WKUP_32K_FCLK	32 kHz
WDTIMER3	PER_32K_ALWON_FCLK	32 kHz
GPIO1	WKUP_32K_FCLK	32 kHz
GPIO[2-6]	PER_32K_ALWON_FCLK	32 kHz
32-kHz sync timer	32K_FCLK	32 kHz (p)
Bandgap/temp sensor	32K_FCLK	32 kHz (p)
System control	CORE_L4_ICLK	L4_ICLK

4.7.5 External Clock Controls

Because the use of `sys_32k` and `sys_altclk` was discussed previously (see [Section 4.7.3.1](#), *PRM*, and [Section 4.7.3.2](#), *CM*), these clock signals are not discussed here. This section discusses the remaining external clock signals.

4.7.5.1 Clock Request (`sys_clkreq`) Control

The system clock request signal `sys_clkreq` is bidirectional. In bypass mode in the system clock oscillator (see [Section 4.7.5.2](#)), it is an output signal driven by the device to request an external clock. In this case, the output buffer is driven as long as the system clock is requested by the device; otherwise, it remains in high impedance. In this way, other external peripherals can share the same clock request signal with the device.

If `PRM_POLCTRL.CLKREQ_POL = 1`, the software must configure the SCM to select the internal pulldown on the `sys_clkreq` pad, or an external pulldown is connected to the pad. If `PRM_POLCTRL.CLKREQ_POL = 0`, the internal pull-up on the `sys_clkreq` pad, or an external pull-up is connected to the pad.

In master mode in the system clock oscillator (see [Section 4.7.5.2](#)), `sys_clkreq` is an input. If `PRM_POLCTRL.CLKREQ_POL = 1`, the software must configure the SCM to select the internal pulldown on the `sys_clkreq` pad, or an external pulldown is connected to the pad. If `PRM_POLCTRL.CLKREQ_POL = 0`, the internal pull-up on the `sys_clkreq` pad, or an external pull-up is connected to the pad.

The `PRM.PRM_POLCTRL[1] CLKREQ_POL` bit allows software control over the polarity of `sys_clkreq`. This software setting takes effect when the clock is requested by the device and also when the clock request is driven externally. The output buffer is directly driven by this register when the clock request comes from OMAP.

[Section 14.5.9.4](#) shows the bidirectional control of the `sys_clkreq` Pad:

Table 14.5.9.4. `sys_clkreq` Pad Direction Control

					Description
Oscillator Mode	Sys_boot6	Internal Clock request (always active high)	External Clock request (Note: polarity depends on CLKREQ_POL)	Sys_clkreq Direction	
Master Mode	0	0	0 ⁽¹⁾	Input (Output buffer in Hi-Z) Note: (Input is not driven from outside of OMAP in that case)	The clock is neither requested internally (by OMAP35x) nor externally (external device/peripheral)
	0	0	1 ⁽¹⁾	Input (output buffer in Hi-Z)	The clock is requested externally

⁽¹⁾ Case when `PRM_POLCTRL.CLKREQ_POL = 1` (`sys_clkreq` active high). These values would be inverted in the table above, in case `PRM_POLCTRL.CLKREQ_POL = 0` (`sys_clkreq` active low).

Table 14.5.9.4. sys_clkreq Pad Direction Control (continued)

					Description
	0	1	0 ⁽¹⁾	Output	The clock is requested internally
	0	1	1 ⁽¹⁾	Output Note: (the pad is driven both by OMAP and from outside of OMAP in that case)	The clock is requested both internally and externally
Bypass Mode	1	0	0 ⁽¹⁾	Input (Output buffer in Hi-Z) Note: (Input is not driven from outside of OMAP in that case)	The clock is neither requested internally nor externally
	1	0	1 ⁽¹⁾	Input (output buffer in Hi-Z)	The clock is requested externally
	1	1	0 ⁽¹⁾	Output	The clock is requested internally
	1	1	1 ⁽¹⁾	Output Note: (the pad is driven both by OMAP and from outside of OMAP in that case)	The clock is requested both internally and externally

4.7.5.2 System Clock Oscillator Control

Depending on the hardware configuration, the device can receive the system clock from an external source or generate it locally using the internal system clock crystal oscillator. Thus, the device oscillator has two possible operating modes:

- Master (oscillator enable) mode: The oscillator is enabled and connected to an external quartz. It provides the system clock to the device. The oscillator is activated on a device wake-up or on an external clock request. It is set to the power-down (OFF) state whenever the device switches to off mode (see [Table 4-37](#)), except when the external system clock request is active on sys_clkreq pin.
- Bypass (oscillator inactive) mode: The system clock is supplied by an external device and the oscillator is always set in bypass mode. The oscillator is insensitive to the external system clock request on the sys_clkreq pin.

Note: An external pullup or pulldown tied on the sys_boot6 input pin of the device determines whether the oscillator is in master or bypass mode. See [Section 4.3.1, External Clock Signals](#).

When operating in master mode, the device receives an external clock request (sys_clkreq) and provides the system clock to external peripherals through the sys_clkout1 pin; in bypass mode, the device generates a clock request to the external clock source to request the system clock.

The selected mode of the oscillator can be read from the PRCM.[PRM_CLKSRC_CTRL](#)[1:0] SYSCLKSEL bit field.

Whatever the oscillator mode, the oscillator can be powered down when the device enters inactive, retention or off mode, unless an external system clock request is active (from the sys_clkreq pin). This setting is configured in the PRCM.[PRM_CLKSRC_CTRL](#)[4:3] AUTOEXTCLKMODE bit field. [Table 4-37](#) lists the four possible operation modes of the system clock.

Table 4-36. System Clock Operation Modes

AUTOEXTCLKMODE	System Clock Mode	Oscillator Mode	Description
0x0	Always-active mode	Master	The oscillator is kept active even when the clock is neither requested by the device internally (all device clocks are inactive) nor externally (that is, the sysclkreq input signal is not asserted).
		Bypass	The sys_clkreq output signal is permanently asserted by the device, regardless of its internal clocks state (active or inactive).

Table 4-36. System Clock Operation Modes (continued)

AUTOEXTCLKMODE	System Clock Mode	Oscillator Mode	Description
0x1	Off when device in INACTIVE, RETENTION, or OFF state	Master	The oscillator is switched to off mode when the device is in INACTIVE, RETENTION, or off mode and the sys_clkreq input signal is not asserted.
		Bypass	The sys_clkreq output signal is de-asserted when the device is in idle, retention, or off mode.
0x2	Off when device in RETENTION or OFF state	Master	The oscillator is switched to off mode when the device is in retention or off mode and the sys_clkreq input signal is not asserted.
		Bypass	The sys_clkreq output signal is de-asserted when the device is in retention or off mode.
0x3	Off when device in OFF state	Master	The oscillator is switched to off mode when the device is in off mode and the sys_clkreq input signal is not asserted.
		Bypass	The sys_clkreq output signal is de-asserted when the device is in off mode.

To exit power-down mode, the oscillator requires a device wakeup or an external clock request.

The device allows configuring of the system clock stabilization time to ensure a stable system clock in the device. This delay is configured in the PRCM.PRM_CLKSETUP[15:0] SETUP_TIME bit field.

Figure 4-58 shows the system clock oscillator controls in the device.

Figure 4-58. System Clock Oscillator Controls

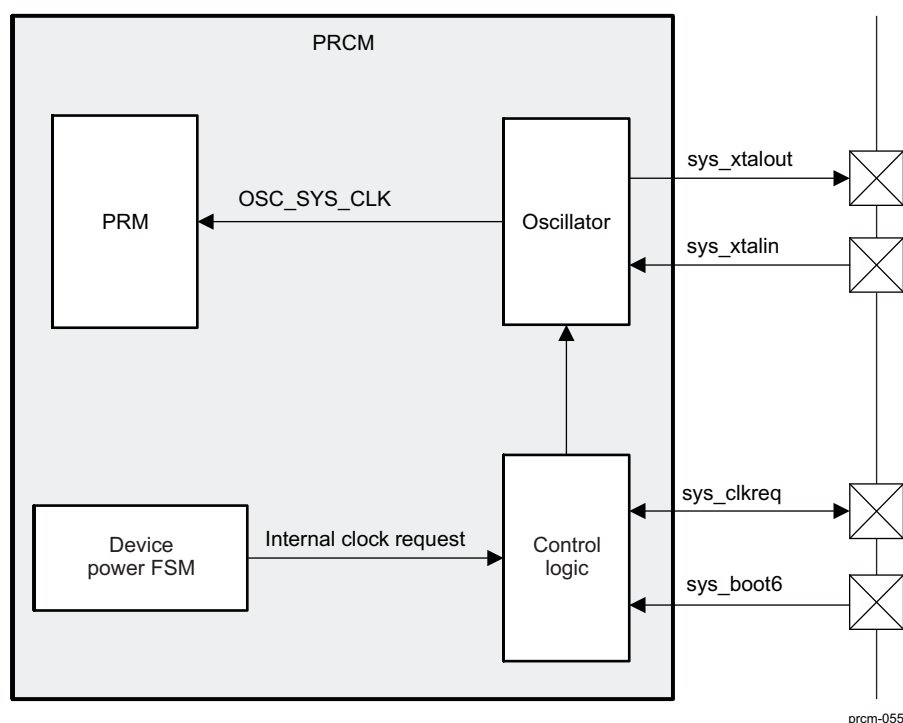

Table 4-37 lists the oscillator controls.

Table 4-37. Oscillator Controls

Oscillator Mode	Internal Clock Request ⁽¹⁾	External Clock Request ⁽¹⁾	Oscillator State	sys_clkreq Pad Direction	sys_clkreq ⁽¹⁾	Description
Master	Not asserted	Not asserted	Off	Both input and output	Not asserted	System clock not requested internally (within the device) and externally (by an external device or peripheral).
	Not asserted	Asserted	Active	Input	Asserted	System clock is requested externally only.
	Asserted	Not asserted	Active	Output	Asserted	System clock is requested internally only.
	Asserted	Asserted	Active	Both input and output (that is, driven internally by device and externally by peripheral)	Asserted	System clock is requested internally and externally.
Bypass	Not asserted	x ⁽²⁾	Bypass	Both input and output (when external request is not asserted) or input (when external request is asserted)	External clock request state	System clock is not requested internally (sys_clkreq input has no effect).
	Asserted	x ⁽²⁾	Bypass	Output (when only internal request is asserted) or both input and output (when external and internal request are asserted)	Asserted	System clock is requested internally (sys_clkreq input has no effect).

(1)

- If the PRCM.PRM_POLCTRL[1] CLKREQ_POL is set to active high (that is, 0x1), Asserted = 1, and Not asserted = 0.
- If the PRCM.PRM_POLCTRL[1] CLKREQ_POL is set to active low (that is, 0x0), Asserted = 0, and Not asserted = 1.

(2)

x indicates that the signal may be asserted or not asserted.

4.7.5.3 External Output Clock1 (sys_clkout1) Control

The sys_clkout1 clock is active if the oscillator clock (OSC_SYS_CLK) is active (stable) and an external system clock request is active. It can be gated by programming the PRCM.PRM_CLKOUT_CTRL[7] CLKOUT_EN bit. The polarity of the sys_clkout1 signal, when the clock is gated, is controllable by programming the PRCM.PRM_POLCTRL[2] CLKOUT_POL bit.

When the device is in standby mode, both SYS_CLK and sys_clkout1 are disabled. In that case, reactivation of sys_clkout1 depends on the oscillator mode:

- Oscillator in active mode (sys_boot6 is 0): The sys_clkout1 clock can be reactivated (after oscillator stabilization), provided its gating was previously enabled by programming the PRCM.PRM_CLKOUT_CTRL[7] CLKOUT_EN bit and asserting an external clock request. This activation does not generate a device wake-up event; an external clock request activates only the internal SYS_CLK oscillator and sys_clkout1.
- Oscillator in bypass mode (sys_boot6 is 1): The sys_clkout1 clock can be reactivated only after the device wakes up (on any wake-up event) and SYS_CLK is active. When the device is active, SYS_CLK is running and sys_clkout1 is enabled as soon as requested by software.

4.7.5.4 External Output Clock2 (sys_clkout2) Control

A second output clock, sys_clkout2, is generated with a frequency that can be the source-clock frequency divided by 1, 2, 4, 8, or 16. Its source clock can be CORE_CLK, CM_SYS_CLK, 96 MHz, or 54 MHz. Unlike sys_clkout1, this second external clock is not active when the device is in off power mode. Also, the selected source clock must be enabled by software. Enabling sys_clkout2 does not automatically request the required source clock. The polarity of the sys_clkout2 signal, when the clock is gated, is controllable by programming the PRCM.CM_POLCTRL[0] CLKOUT2_POL bit.

4.7.6 DPLL Control

The PRCM allows the configuration of the output clock frequencies of the DPLLs by setting their respective multipliers and dividers. It also allows control of the operating mode of the DPLLs and automatic recalibration mode.

4.7.6.1 DPLL Multiplier and Divider Factors

DPLL clock outputs are set by programming the corresponding multiplier and divider factors M, N, M2, M3, M4, M5, and M6. Table 4-38 lists the register bit fields for configuration of the multiplier and divider factors for the DPLLs.

Table 4-38. DPLL Multiplier and Divider Factors

	DPLL1	DPLL2	DPLL3	DPLL4	DPLL5
M	PRCM.CM_CLKSEL1_PLL_MPU[18:8] MPU_DPLL_MULT	PRCM.CM_CLKSEL1_PLL_IVA2[18:8] IVA2_DPLL_MULT	PRCM.CM_CLKSEL1_PLL[26:16] CORE_DPLL_MULT	PRCM.CM_CLKSEL2_PLL[18:8] PERIPH_DPLL_MULT	PRCM.CM_CLKSEL4_PLL[18:8] PERIPH2_DPLL_MULT
N	PRCM.CM_CLKSEL1_PLL_MPU[6:0] MPU_DPLL_DIV	PRCM.CM_CLKSEL1_PLL_IVA2[6:0] IVA2_DPLL_DIV	PRCM.CM_CLKSEL1_PLL[14:8] CORE_DPLL_DIV	PRCM.CM_CLKSEL2_PLL[6:0] PERIPH_DPLL_DIV	PRCM.CM_CLKSEL4_PLL[6:0] PERIPH2_DPLL_DIV
M2	PRCM.CM_CLKSEL2_PLL_MPU[4:0] MPU_DPLL_CLKOUT_DIV	PRCM.CM_CLKSEL2_PLL_IVA2[4:0] IVA2_DPLL_CLKOUT_DIV	PRCM.CM_CLKSEL1_PLL[31:27] CORE_DPLL_CLKOUT_DIV	PRCM.CM_CLKSEL3_PLL[4:0] DIV_96M	PRCM.CM_CLKSEL5_PLL[4:0] DIV_120M
M3	Not used	Not used	PRCM.CM_CLKSEL1_EMU[20:16] DIV_DPLL3	PRCM.CM_CLKSEL_DSS[12:8] CLKSEL_TV	Not used
M4	Not used	Not used	Not used	PRCM.CM_CLKSEL_DSS[4:0] CLKSEL_DSS1	Not used
M5	Not used	Not used	Not used	PRCM.CM_CLKSEL_CAM[4:0] CLKSEL_CAM	Not used
M6	Not used	Not used	Not used	PRCM.CM_CLKSEL1_EMU[28:24] DIV_DPLL4	Not used

4.7.6.2 DPLL Jitter Correction

To satisfy the jitter specification of the DPLL at a specific internal clock frequency, set the corresponding CM_CLKEN_PLL_processor_name>[7:4]processor_name>_DPLL_FREQSEL, CM_CLKEN_PLL[23:20] PERIPH_DPLL_FREQSEL, CM_CLKEN_PLL[7:4] CORE_DPLL_FREQSEL, CM_CLKEN2_PLL[7:4] PERIPH2_DPLL_FREQSEL bit field. Table 4-39 lists the possible values for the bit field and the corresponding internal clock frequency ranges.

Note: The internal clock frequency is the frequency of the internal interface clock Fint, with $F_{int} = \text{CLKINP}/(N + 1)$.

Table 4-39. Internal Clock Frequency

Bit Field Values	Clock Frequency Ranges
0x3	0.75 MHz—1.0 MHz
0x4	1.0 MHz—1.25 MHz
0x5	1.25 MHz—1.5 MHz
0x6	1.5 MHz—1.75 MHz

Table 4-39. Internal Clock Frequency (continued)

Bit Field Values	Clock Frequency Ranges
0x7	1.75 MHz—2.1 MHz
0xB	7.5 MHz—10 MHz
0xC	10 MHz—12.5 MHz
0xD	12.5 MHz—15 MHz
0xE	15 MHz—17.5 MHz
0xF	17.5 MHz—21 MHz
Other cases are reserved.	

Note: In the DPLL programming sequence, the DPLL_FREQSEL must be programmed before the new Multiplier factor M and the Divider factor N are programmed so that the new value is taken into account during current DPLL relock.

4.7.6.3 DPLL Frequency Ramp-Up Delay

When the DPLL switches from bypass mode to lock mode, the clock output frequency changes from bypass clock frequency to normal operating frequency. The frequency ramp-up feature allows the DPLL output frequency to switch gradually (in steps) from the bypass to locked frequency. Before reaching the locked frequency, the DPLL output switches to four intermediate frequencies:

1. $F_{out}/8$
2. $F_{out}/4$
3. $F_{out}/2$
4. F_{out}

The time delay in passing from the bypass clock frequency to normal frequency is the ramp-up delay. The ramp-up delay is configured by setting the [CM_CLKEN_PLL_processor_name>\[9:8\]processor_name>_DPLL_RAMPTIME](#), [CM_CLKEN_PLL\[25:24\]PERIPH_DPLL_RAMPTIME](#), [CM_CLKEN_PLL\[9:8\]CORE_DPLL_RAMPTIME](#), [CM_CLKEN2_PLL\[9:8\]PERIPH2_DPLL_RAMPTIME](#) bit field.

There are three possible values for the bit field and the corresponding ramp-up delays:

- 0x0: The frequency ramp feature is disabled. The frequency switch from bypass to locked occurs in a single step as soon as the DPLL is locked.
- 0x1: The frequency ramp time is 4 micro sec.
- 0x2: The frequency ramp time is 20 micro sec.
- 0x3: The frequency ramp time is 40 micro sec.

Note: If the ramp-up time configured for the DPLL is less than the DPLL lock time, the last frequency step, $F_{out}/2$ to F_{out} , gets stretched to the DPLL lock time.

4.7.6.4 DPLL Modes

DPLL supports several power modes (see [Table 4-40](#)). Each mode results in a tradeoff between power savings and relock time.

Table 4-40. DPLL Power Modes

Mode	Clock Input	Clock Output	DPLL Power State	Power Consumption	Latency
Locked	On	Lock frequency	ON	Maximum	N/A

Table 4-40. DPLL Power Modes (continued)

Mode	Clock Input	Clock Output	DPLL Power State	Power Consumption	Latency
Low-power bypass	On	Bypass frequency	ON	Less than locked	Same as low-power stop
Fast-relock bypass	On	Bypass frequency	ON	Less than locked	Less than low-power bypass
Low-power stop	On	Bypass frequency	ON	Less than locked	Same as low-power bypass
MN bypass	On	Bypass frequency	ON	Less than locked	Maximum
Off	Off	Off	OFF	Minimum	Maximum

A DPLL power mode can be achieved on a software request (manual) and/or automatically (automatic), depending on the specific hardware conditions. After a device power-on reset, the DPLL can be kept in either low-power stop mode (DPLL2 , DPLL4 and DPLL5) or MN bypass mode (DPLL1 and DPLL3).

A DPLL can switch from one mode to the other as a result of the following:

- Software-programmed transition only (manual): The software configures a dedicated register for the next desired DPLL mode. It must ensure that the transition can be performed based on the activity on the device.
- Combined software-programmed and hardware-conditions-based transition (automatic): The PRCM triggers the transition when the software requests it (by configuring the registers) and the hardware conditions are satisfied. When the hardware conditions are no longer met, the PRCM triggers the return transition.

For automatic transition, automatic mode must be enabled by programming the `PRCM.CM_AUTOIDLE_PLL` or the `PRCM.CM_AUTOIDLE_PLLprocessor_name>` registers.

Table 4-41 describes the manual and automatic control of the DPLL power modes by the PRCM.

Table 4-41. DPLL Power Modes Support

Mode	DPLL1	DPLL2	DPLL3	DPLL4	DPLL5
Locked	Software request (manual) or MPU wakes up (automatic).	Software request (manual) or IVA2.2 wakes up (automatic).	Software request (manual) or CORE wakes up (automatic).	Software request (manual) or at least one peripheral clock is used (automatic).	Software request (manual) or at least one peripheral clock is used (automatic).
Low-power bypass	Software request (manual)	Software request (manual)	Software request (manual) or all interface clocks are gated (automatic).	N/A	N/A
Fast-relock bypass	N/A	N/A	Software request (manual).	N/A	N/A
Low-power stop	MPU is idle (automatic).	Software request (manual) or IVA2.2 is idle (automatic) or on global reset release (automatic).	Device is idle (automatic).	(Default state) Software request (manual) or all functional clocks from DPLL are unused or on global reset release (automatic).	(Default state) Software request (manual) or all functional clocks from DPLL (120-MHz clock) are unused or on global reset release (automatic).
MN bypass	Global reset (automatic)	N/A	Global reset (automatic).	N/A	N/A
Off	Device off (automatic)	Device off (automatic)	Device off (automatic).	Device off (automatic)	Device off (automatic)

[Table 4-42](#) lists the bit fields that must be programmed for manual and automatic mode control of the five DPLLs.

Table 4-42. DPLL Power Mode Control

Mode	Manual Control	Auto Control
DPLL1	PRCM.CM_CLKEN_PLL_MPU[2:0] EN_MPU_DPLL	PRCM.CM_AUTOIDLE_PLL_MPU[2:0] AUTO_MPU_DPLL
DPLL2	PRCM.CM_CLKEN_PLL_IVA2[2:0] EN_IVA2_DPLL	PRCM.CM_AUTOIDLE_PLL_IVA2[2:0] AUTO_IVA2_DPLL
DPLL3	PRCM.CM_CLKEN_PLL[2:0] EN_CORE_DPLL	PRCM.CM_AUTOIDLE_PLL[2:0] AUTO_CORE_DPLL
DPLL4	PRCM.CM_CLKEN_PLL[18:16] EN_PERIPH_DPLL	PRCM.CM_AUTOIDLE_PLL[5:3] AUTO_PERIPH_DPLL
DPLL5	PRCM.CM_CLKEN2_PLL[2:0] EN_PERIPH2_DPLL	PRCM.CM_AUTOIDLE2_PLL[2:0] AUTO_PERIPH2_DPLL

Note: The DPLL automatically enters locked mode on a power domain wakeup only if the DPLL is locked before the sleep transition and one of the automatic modes is enabled.

4.7.6.5 DPLL Low-Power Mode

The DPLL can operate in a low-power mode by reducing the operating frequency range. This in turn reduces the power consumption of the DPLL. In this mode, however, there is a period and phase jitter effect.

The DPLL can enter this mode only if the targeted lock frequency of the DPLL is less than 600 MHz. This implies locking or relocking the DPLL to a new targeted locked-frequency when entering or exiting low-power mode. Software must ensure that the DPLL lock-frequency does not exceed 600 MHz in low-power mode.

Software can enable/disable automatic switching of the DPLL between normal mode and low-power mode. The new mode is effective only after the DPLL is relocked. Low-power mode control is considered only during the following transitions:

- From bypass mode to lock
- From stop mode to lock
- From lock to relock

[Table 4-43](#) lists the bit fields that must be programmed for manual control of the five DPLLs.

Table 4-43. LP Mode Control

Mode	Manual Control
DPLL1	PRCM.CM_CLKEN_PLL_MPU[10] EN_MPU_DPLL_LPMODE
DPLL2	PRCM.CM_CLKEN_PLL_IVA2[10] EN_IVA2_DPLL_LPMODE
DPLL3	PRCM.CM_CLKEN_PLL[10] EN_CORE_DPLL_LPMODE
DPLL4	PRCM.CM_CLKEN_PLL[26] EN_PERIPH_DPLL_LPMODE
DPLL5	PRCM.CM_CLKEN2_PLL[10] EN_PERIPH2_DPLL_LPMODE

4.7.6.6 DPLL Clock Path Power Down

DPLL3 and DPLL4 can power down the CLKOUTX2 path. A small section of logic is powered down as the M2 post divider is also shared with the CLKOUT path, which remains functional.

The HSDIVIDER can power down each CLKOUTn path (with n in the range of 3 to 6) independently, therefore allowing further power savings. The clock output path is also powered down when the DPLL is in stop mode, regardless of the software setting.

Software must ensure the proper sequencing of the control. To avoid a glitch at the output, activate this control when the clock is no longer required, and when the output clock is gated. Conversely, ensure a delay between deactivation and reactivation of the clock by using the power-down control.

Table 4-44 lists the bit fields and the corresponding clock outputs of the DPLLs.

Table 4-44. Clock Path Power-Down Control

DPLL	Control Bit Field	Clock Path
DPLL4	PRCM.CM_CLKEN_PLL[27] PWRDN_96M	96-MHz clock output (DPLL4 output M2X2)
	PRCM.CM_CLKEN_PLL[28] PWRDN_TV	DSS TV clock output (DPLL4 output M3X2)
	PRCM.CM_CLKEN_PLL[29] PWRDN_DSS1	DSS1 clock output (DPLL4 output M4X2)
	PRCM.CM_CLKEN_PLL[30] PWRDN_CAM	CAM clock output (DPLL4 output M5X2)
	PRCM.CM_CLKEN_PLL[31] PWRDN_EMU_PERIPH	EMU_PERIPH clock output (DPLL4 output M6X2)
DPLL3	PRCM.CM_CLKEN_PLL[12] PWRDN_EMU_CORE	EMU_CORE clock output (DPLL3 output M3X2)

4.7.6.7 Latencies

Lock mode for the DPLL is frequency lock.

Lock latencies depend on the internal reference frequency (F_{INT}) of the DPLL, calculated as:

$$F_{INT} = F_{ref} / (N+1)$$

where F_{ref} is the reference clock input to DPLL.

Table 4-45 lists the operating modes of the DPLL and the output clock frequency and associated lock latency.

FREQSEL[3] = 0 refers to the following bits:

- CM_CLKEN_PLL_IVA2[7]
- CM_CLKEN_PLL_MPU[7]
- CM_CLKEN_PLL[7]
- CM_CLKEN_PLL[23]
- CM_CLKEN2_PLL[7]

Table 4-45. DPLL Operating Mode and Latency

Mode	CLKOUTX2	Lock Time in FINT cycles (FREQSEL[3] = 0)
OFF	Off	150
M, N reprogramming	bypass clock	150
Low-power stop mode	Off	40
Low-power bypass	bypass clock	40
Fast-relock bypass	bypass clock	10
Active (locked)	$CLKINP \times M / (N+1) / M2 \times 2$	N/A

4.7.6.8 Recalibration

A lock sequence occurs during an initial lock or during a relock following a new multiplier or divider value. Each time the DPLL is reset or performs a lock sequence, it performs a recalibration of the output frequency, based on the voltage and temperature conditions. By compensating for voltage and temperature changes within a certain range, the calibration allows the lock frequency to remain steady. If the voltage or temperature drifts outside the acceptable range, the DPLL asserts a recalibration flag.

For example, a large temperature drift can cause the DPLL to lose its lock and require recalibration. When the DPLL locks at a temperature within the 080 degrees Celsius range, the maximum temperature drift is approximately 55 degrees Celsius. When DPLL starts at a negative temperature, the maximum temperature drift is higher.

If the DPLL locks at 30 degrees Celsius, the temperature can change by 60 degrees Celsius (from 30 to +90 degrees Celsius) and the DPLL will not lose the lock. However, for temperatures above the 60 degrees Celsius range, the DPLL may need to be relocked. A new relock sequence reinitializes the starting temperature.

This compensation mechanism is active only while the DPLL is locked. When the DPLL is in off or bypass mode (low-power or fast-relock), it does not assert the recalibration flag. If the voltage or temperature exceeds the drift limits while the DPLL is not locked, and then the DPLL tries to relock, the DPLL fails to lock within the normal delay and recalibrates automatically before eventually locking. The only difference from a standard relock is the delay.

The DPLL can automatically start recalibration when the recalibration flag is asserted, or recalibration can be managed by the software. The mode of operation is selected by configuring the corresponding registers in the PRCM (see [Table 4-46](#)). The software or manual control mode is selected by default.

Note: Automatic recalibration of the DPLL can start at any time. While relocking, the DPLL switches to bypass mode. For modules that are sensitive to frequency change while operating, this can introduce operational instability. For example, the SDRC is sensitive to a frequency change on DPLL3 because its embedded DLL relocks on a frequency change. Any access during this DLL relock period can be corrupted. It is important, therefore, to stall SDRC access during DPLL recalibration.

To allow the software to recalibrate the DPLL at the correct time depending on the device activity, the PRCM can generate a wake-up event on the MPU power domain, followed by an interrupt on the MPU when the DPLL recalibration flag is asserted.

[Table 4-46](#) summarizes the software programming control over the DPLL recalibration feature.

Table 4-46. DPLL Recalibration Controls

DPLL	Software Control	Description
DPLL1 (MPU)	PRCM.CM_CLKEN_PLL_MPU[3] MPU_DPLL_DRIFTGUARD	Enable/disable the MPU DPLL automatic recalibration feature.
	PRCM.PRM_IRQENABLE_MPU[7] MPU_DPLL_RECAL_EN	Enable/disable the MPU DPLL recalibration interrupt to MPU.
	PRCM.PRM_IRQSTATUS_MPU[7] MPU_DPLL_ST	Status of the MPU DPLL recalibration interrupt
DPLL2 (IVA2)	PRCM.CM_CLKEN_PLL_IVA2[3] IVA2_DPLL_DRIFTGUARD	Enable/disable the IVA2 DPLL automatic recalibration feature.
	PRCM.PRM_IRQENABLE_MPU[8] IVA2_DPLL_RECAL_EN	Enable/disable the IVA2 DPLL recalibration interrupt to MPU.
	PRCM.PRM_IRQSTATUS_MPU[8] IVA2_DPLL_ST	Status of the IVA2 DPLL recalibration interrupt to MPU
	PRCM.PRM_IRQENABLE_IVA2[2] IVA2_DPLL_RECAL_EN	Enable/disable the IVA2 DPLL recalibration interrupt to IVA2.2.
	PRCM.PRM_IRQSTATUS_IVA2[2] IVA2_DPLL_ST	Status of the IVA2 DPLL recalibration interrupt to IVA2.2
DPLL3 (CORE)	PRCM.CM_CLKEN_PLL[3] EN_CORE_DPLL_DRIFTGUARD	Enable/disable the CORE DPLL automatic recalibration feature.
	PRCM.PRM_IRQENABLE_MPU[5] CORE_DPLL_RECAL	Enable/disable the CORE DPLL recalibration interrupt to MPU.
	PRCM.PRM_IRQSTATUS_MPU[5] CORE_DPLL_ST	Status of the CORE DPLL recalibration interrupt
DPLL4 (PER)	PRCM.CM_CLKEN_PLL[19] EN_PERIPH_DPLL_DRIFTGUARD	Enable/disable the PER DPLL automatic recalibration feature.
	PRCM.PRM_IRQENABLE_MPU[6] PERIPH_DPLL_RECAL	Enable/disable the PER DPLL recalibration interrupt to MPU.
	PRCM.PRM_IRQSTATUS_MPU[6] PERIPH_DPLL_ST	Status of the PER DPLL recalibration interrupt
DPLL5 (PER2)	PRCM.CM_CLKEN2_PLL[3] EN_PERIPH2_DPLL_DRIFTGUARD	Enable/disable the PER DPLL2 automatic recalibration feature.

Table 4-46. DPLL Recalibration Controls (continued)

DPLL	Software Control	Description
	PRCM.PRM_IRQENABLE_MPU[25] SND_PERIPH_DPLL_RECAL_EN	Enable/disable the PER DPLL2 recalibration interrupt to MPU.
	PRCM.PRM_IRQSTATUS_MPU[25] SND_PERIPH_DPLL_ST	Status of the PER DPLL2 recalibration interrupt

Note: DPLL recalibration is not necessary in real use (specified operating voltage and temperature range).

4.7.6.9 DPLL Programming Sequence

The DPLL programming sequence follows:

1. Set the multiplier (M) and divider (N) values for the desired CLKOUT frequency (see [Section 4.7.6.1](#)).
2. Set the corresponding output dividers (M2, M3, M4, M5, and M6) (see [Section 4.7.6.1](#)).
3. Set the corresponding FREQSEL bit field to satisfy the jitter specification (see [Section 4.7.6.2](#)).
4. Set the corresponding ramp-up delay (see [Section 4.7.6.3](#)).
5. Enable/disable the auto-recalibration feature (see [Section 4.7.6.8](#)).
6. Enable/disable the autoidle feature (see [Section 4.7.6.4](#)).
7. Mask/unmask the interrupt to the MPU (and the DPLL2 interrupt to IVA2) (see [Section 4.7.6.8](#)).
8. Enable the DPLL lock mode (see [Section 4.7.6.4](#)).

4.7.7 Internal Clock Controls

This section describes the software and hardware controls of the internal source clocks. [Figure 4-59](#) through [Figure 4-74](#) list the clock controls. The *Source selection/division* column lists the PRCM register bits used to select or divide the clocks. The *Software control* column lists the PRCM register bits used to enable/disable the clocks. The *Hardware control* column lists the hardware conditions required to effectively gate the clocks.

In the *Hardware control* column, the boxes labeled CL, GS, GC, and HC indicate specific information about the hardware clock controls:

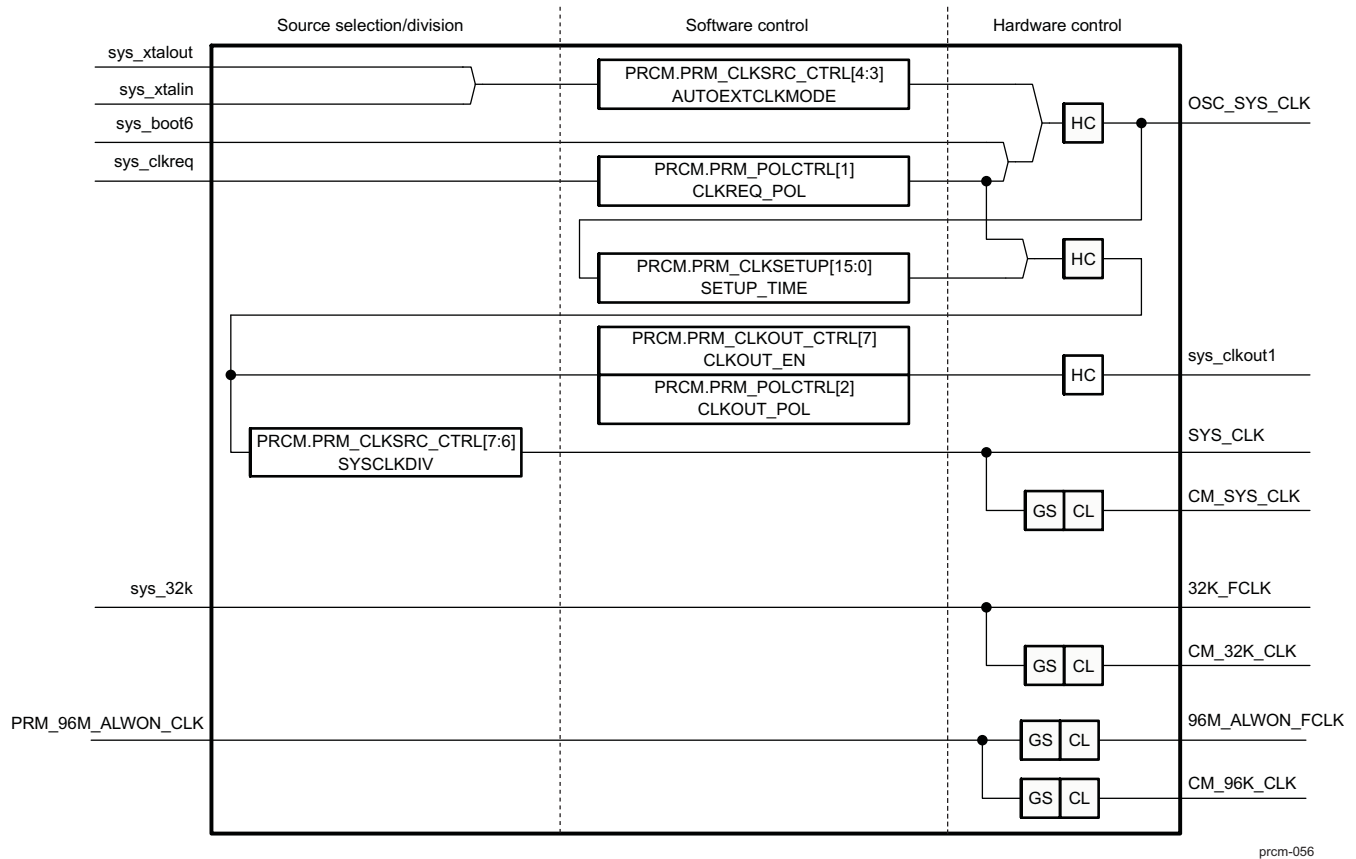

- CL (combinational logic): The functional or interface clock is required by more than one module across more than one power domain. The gating control is the OR combination of all the domain clock requests. If any module of this clock domain requests the clock, the clock is not gated.
- GS (gating selection): The clock is selectable among several possible source clocks for a module. The gating control depends on the software programming of the CM_CLKSEL_<domain_name> type of register. The clock request of the module or domain must be set by the CM_CLKSEL bit.
- GC (gating control): The functional/interface clock is required by a single module across the power domain. The gating control depends only on the software programming of the FCLKEN/ICLKEN bit. For the interface clock, the enable bit is effective only if autoidle mode is not used. If autoidle mode is used, the gating control also depends on the state of the power domain.
- HC (hardware control): A specific rule not covered by CL, GS, or GC.

Note: Because the PRCM must receive hardware acknowledgement from the different modules before it can gate the clock, the clock is not gated immediately after the software requests clock-gating conditions.

4.7.7.1 PRM Source-Clock Controls

Figure 4-59 shows the common source-clock controls for the PRM.

Figure 4-59. Common PRM Source-Clock Controls

prcm-056

Table 4-47 shows the common source-clock gating controls for the PRM.

Table 4-47. Common PRM Source-Clock Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
OSC_SYS_CLK	Running	PRCM.PRM_CLKSRC_CTRL[4:3] AUTOEXTCLKMODE and device power state and sys_clkreq	Gated when the oscillator is programmed to power down with the device sleep/retention/off transition.
sys_clkout1	Running	PRCM.PRM_CLKOUT_CTRL[7] CLKOUT_EN and PRCM.PRM_POLCTRL[2] CLKOUT_POL and sys_clkreq	Active when OSC_SYS_CLK is active, sys_clkout1 is enabled, and sys_clkreq is asserted.
SYS_CLK	Running	Activated after clksetup_count_overflow	Active when OSC_SYS_CLK is active and the SYS_CLK setup time is up.
CM_SYS_CLK	Running	PRCM.CM_CLKSEL_CORE[6] CLKSEL_GPT10, PRCM.CM_CLKSEL_CORE[7] CLKSEL_GPT11, and depends on the clock-gating conditions of GPT10_FCLK and GPT11_FCLK	Active if it is the source clock of the GPT10_FCLK or GPT11_FCLK and the functional clock is active.
32K_FCLK	Running	None	Always-active clock from sys_32k input pin
CM_32K_CLK	Running	PRCM.CM_CLKSEL_CORE[6] CLKSEL_GPT10, PRCM.CM_CLKSEL_CORE[7] CLKSEL_GPT11, and depends on the clock-gating conditions of GPT10_FCLK and GPT11_FCLK	Active if it is the source clock of the GPT10_FCLK or GPT11_FCLK and the functional clock is active.
CM_96M_FCLK	Gated	CM_CLKSEL1_PLL[3] SOURCE_48M bit cleared, and depends on the clock-gating condition of 96M_FCLK, 48M_FCLK, and 12M_FCLK	Active if the derived clocks (96M_FCLK, 48M_FCLK, and 12M_FCLK) are active.

Table 4-47. Common PRM Source-Clock Gating Controls (continued)

Clock Name	Reset	Clock-Gating Control	Gating Description
96M_ALWON_FCLK	Gated	CM_FCLKEN_PER [0] EN_MCBSP2, CM_FCLKEN_PER [1] EN_MCBSP3, and CM_FCLKEN_PER [2] EN_MCBSP4	Gated when none of the three McBSPs [2..4] have their functional clock enable requested.

The oscillator output clock (OSC_SYS_CLK) is gated whenever the PRCM.[PRM_CLKSRC_CTRL](#)[4:3] AUTOEXTCLKMODE bit field is programmed to power down the oscillator when the device enters retention or off mode. In this condition, all the clock trees in the device must be gated, and the four DPLLs (DPLL1, DPLL2, DPLL3, and DPLL4) must enter stop mode before this transition can occur.

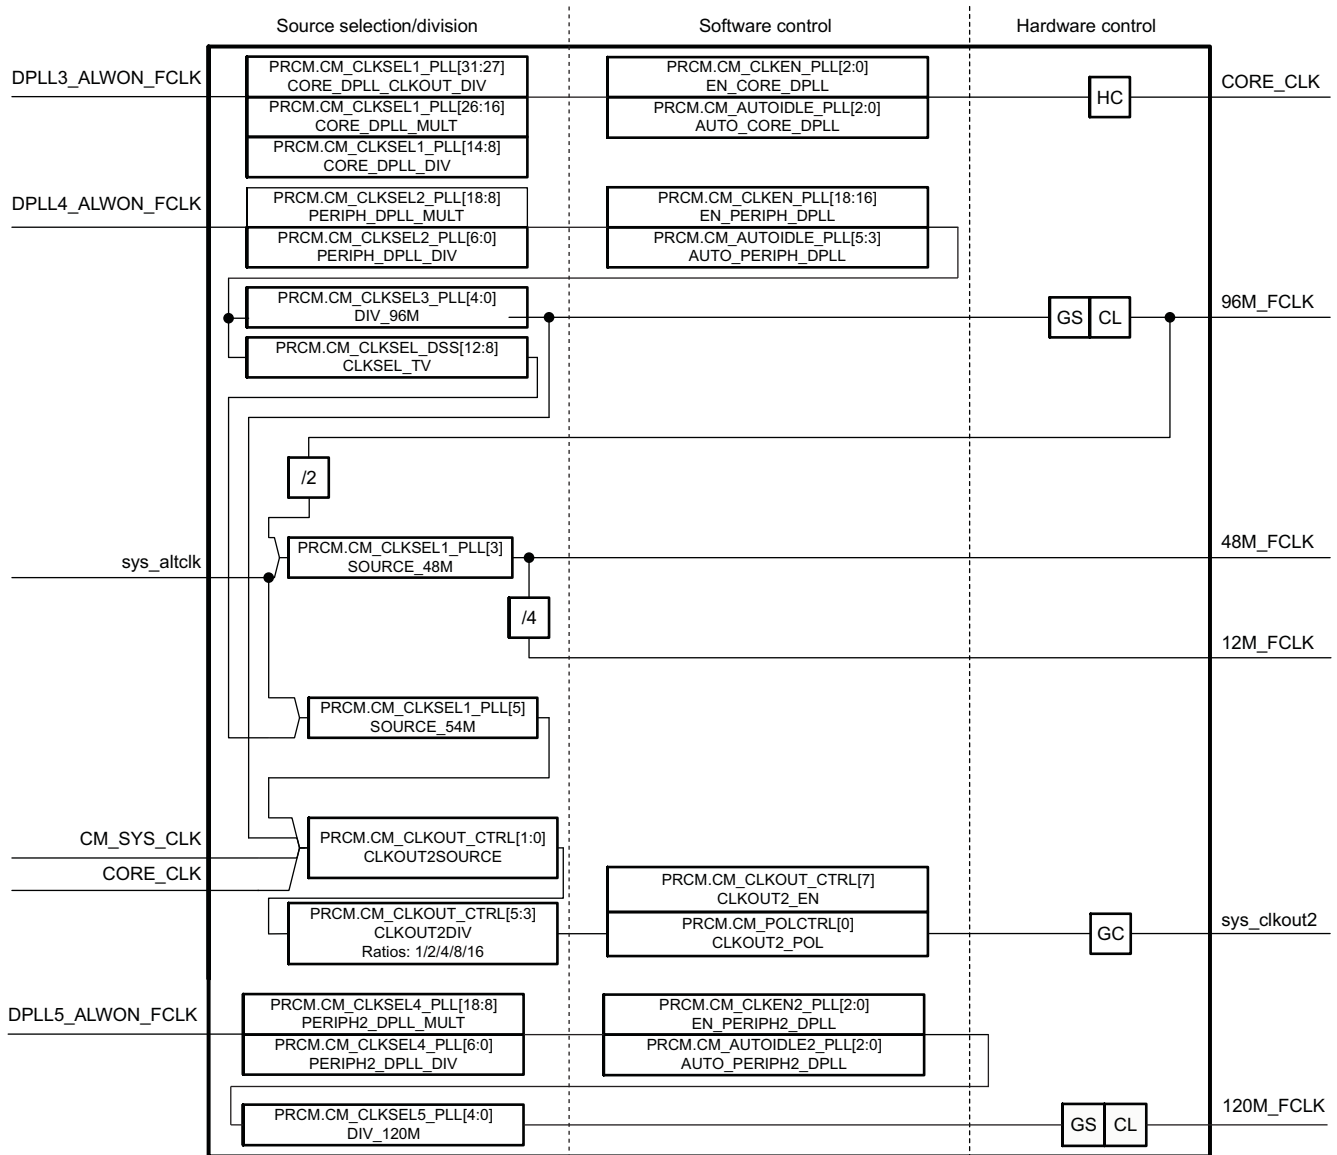

SYS_CLK is gated under the same conditions as the oscillator output clock, but it is enabled only after the oscillator stabilizes. Oscillator stabilization is determined by a counter overflow configured in the PRCM.[PRM_CLKSETUP](#)[15:0] SETUP_TIME bit field.

The sys_clkreq active condition is described in [Section 4.7.5, External Clock Control](#).

4.7.7.2 CM Source-Clock Controls

Figure 4-60 shows the common source-clock controls for the CM.

Figure 4-60. Common CM Source-Clock Controls

prcm-057

Table 4-48 shows the common source-clock gating controls for the CM.

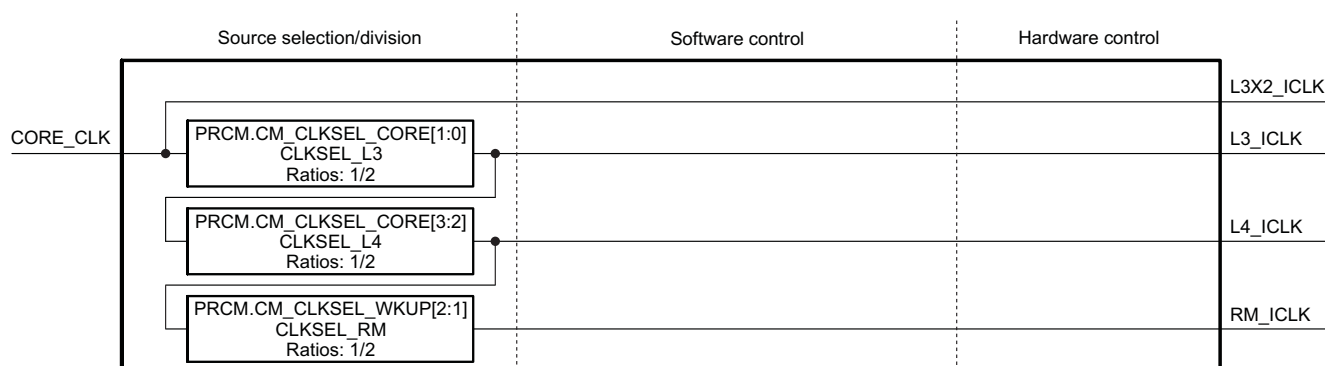

Table 4-48. Common CM Source-Clock Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
CORE_CLK	Running	Depends on the clock-gating conditions of: L3_ICLK and L4_ICLK	Gated when all interface clocks of the different modules of the device are gated
96M_FCLK	Stopped	CM_CLKSEL1_PLL.SOURCE_48M and depends on the clock-gating conditions of: CORE_96M_FCLK, DSS_96M_FCLK, and 48M_FCLK	If the dependent clocks are active, the clock is active. 48M_FCLK is a dependent clock if set by the register configuration.
48M_FCLK	Stopped	Depends on the clock-gating conditions of CORE_12M_FCLK, PER_48M_FCLK and USBHOST_48M_FCLK	If the dependent clocks are active, the clock is active.
12M_FCLK	Stopped	Depends on the clock-gating conditions of CORE_12M_FCLK	If the dependent clock is active, the clock is active.
sys_clkout2	Stopped	PRCM.CM_CLKOUT_CTRL[7] CLKOUT2_EN	Active if enabled
DPLL4_M2_CLK	Stopped	Depends on the clock-gating conditions of: 96M_FCLK	If the dependent clocks are active, the clock is active.
DPLL4_M3_CLK	Stopped	CM_CLKSEL1_PLL.SOURCE_54M and depends on the clock-gating conditions of: DPLL4_M2_CLK and DSS_TV_CLK	If the dependent clocks are active, the clock is active. DSS_TV_CLK is a dependent clock if set by the register configuration.
120M_FCLK	Stopped	CM_FCLKEN_USBHOST[1] EN_USBHOST2, CM_FCLKEN3_CORE[2] EN_USBTLL, CM_FCLKEN_WKUP[9] EN_USIMOCP, CM_CLKSEL_WKUP[6:3] CLKSEL_USIMOCP	If any of the dependent clocks (that is, USIM_FCLK, CORE_120M_FCLK, or USBHOST_12M_FCLK) is active, the clock is active. The USIM_FCLK is a dependent clock if set by the register configuration.

4.7.7.3 Common Interface Clock Controls

Figure 4-61 shows the clock controls for the common interface.

Figure 4-61. Common Interface Clock Controls

prcm-058

Table 4-49 shows the clock-gating controls for the common interface.

Table 4-49. Common Interface Clock-Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
L3X2_ICLK	Running	CORE_CLK gating conditions	Depends on the gating conditions of the CORE_CLK
L3_ICLK	Running	Depends on the clock-gating conditions of: SGX_L3_ICLK, CORE_L3_ICLK, SECURITY_L3_ICLK, CAM_L3_ICLK,	Gated when all L3 interface clocks of the different modules of the device are gated

Table 4-49. Common Interface Clock-Gating Controls (continued)

Clock Name	Reset	Clock-Gating Control	Gating Description
L4_ICLK	Running	Depends on the clock-gating conditions of CORE_L4_ICLK, SECURITY_L4_ICLK, CAM_L4_ICLK, DSS_L4_ICLK, PER_L4_ICLK, SR_L4_ICLK, and WKUP_L4_ICLK	Gated when all L4 interface clocks of the different modules of the device are gated
RM_ICLK	Running	None	Gated with source clock (CORE_CLK)

4.7.7.4 DPLL Source-Clock Controls

Figure 4-62 shows the clock controls for the DPLL power domain.

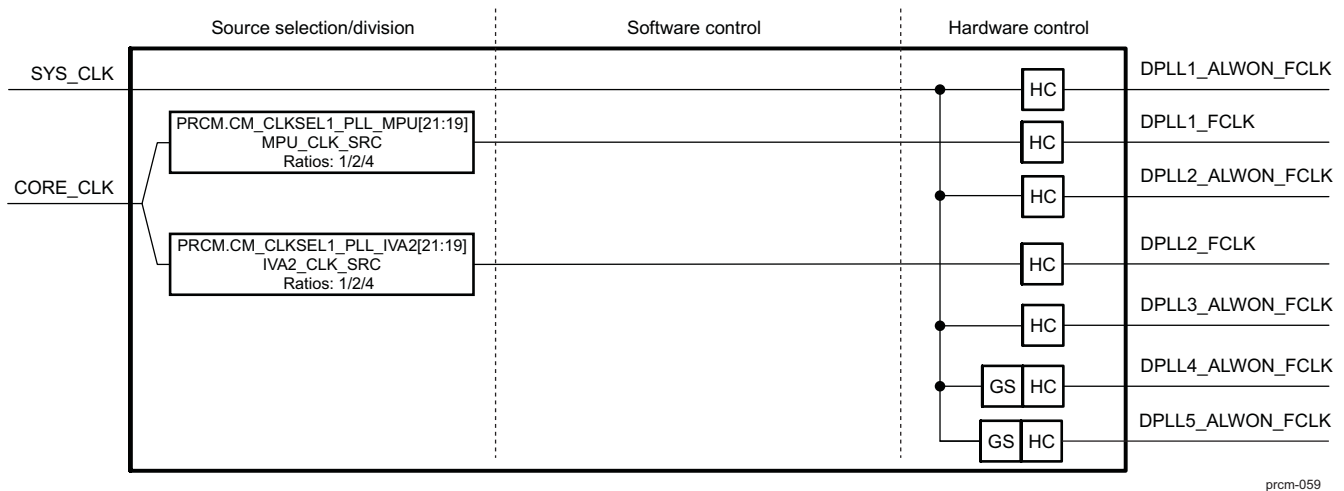

Figure 4-62. DPLL Power Domain Clock Controls

Table 4-50 shows the clock-gating controls for the DPLL power domain.

Table 4-50. DPLL Power Domain Clock-Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
DPLL1_ALWON_FCLK	Running	PRCM.CM_AUTOIDLE_PLL_MPU[2:0] AUTO_MPU_DPLL, PRCM.CM_CLKEN_PLL_MPU[2:0] EN_MPU_DPLL, and MPU domain power state	Gated if the DPLL is set to automatic active control and enabled in lock mode while the MPU power domain goes into retention or off mode. It is also gated if DPLL is set to low-power bypass mode.
DPLL1_FCLK	Stopped		
DPLL2_ALWON_FCLK	Stopped	PRCM.CM_AUTOIDLE_PLL_IVA2[2:0] AUTO_IVA2_DPLL, PRCM.CM_CLKEN_PLL_IVA2[2:0] EN_IVA2_DPLL, and IVA2 power domain power state	Gated if the DPLL is set to automatic active control and enabled in lock mode while the IVA2 power domain goes into retention or off mode. It is also gated if DPLL is set to low-power stop or bypass mode.
DPLL2_FCLK	Stopped		
DPLL3_ALWON_FCLK	Running	PRCM.CM_AUTOIDLE_PLL[2:0] AUTO_CORE_DPLL, PRCM.CM_CLKEN_PLL[2:0] EN_CORE_DPLL, and CORE domain power clocks state	Gated if the DPLL is set to automatic active control and enabled in lock mode while the CORE power domain is idle. It is also gated if DPLL is set to low-power or fast-relock bypass mode.
DPLL4_ALWON_FCLK	Stopped	PRCM.CM_AUTOIDLE_PLL[5:3] AUTO_PERIPH_DPLL, PRCM.CM_CLKEN_PLL[18:16] EN_PERIPH_DPLL, and depends on the clock-gating conditions of DPLL4_M2_CLK	Gated if the DPLL is set to automatic active control and enabled in lock mode while its dependent clock is inactive. It is also gated if DPLL is set to low-power stop mode.

Table 4-50. DPLL Power Domain Clock-Gating Controls (continued)

Clock Name	Reset	Clock-Gating Control	Gating Description
DPLL5_ALWON_FCLK	Stopped	PRCM.CM_AUTOIDLE2_PLL[2:0] AUTO_PERIPH2_DPLL, PRCM.CM_CLKEN2_PLL[2:0] EN_PERIPH2_DPLL, and depends on the clock-gating conditions of DPLL5_M2_CLK	Gated if the DPLL is set to automatic active control and enabled in lock mode while its dependent clock is inactive. It is also gated if DPLL is set to low-power stop mode.

4.7.7.5 SGX Power Domain Clock Controls

This section gives information about all modules and features in the high-tier device. See Chapter 1, *OMAP35x Family* section, to check availability of modules and features. For power-management saving consideration, ensure that power domains of unavailable features and modules are switched off and clocks are cut off.

Figure 4-63 shows the clock controls for the SGX power domain.

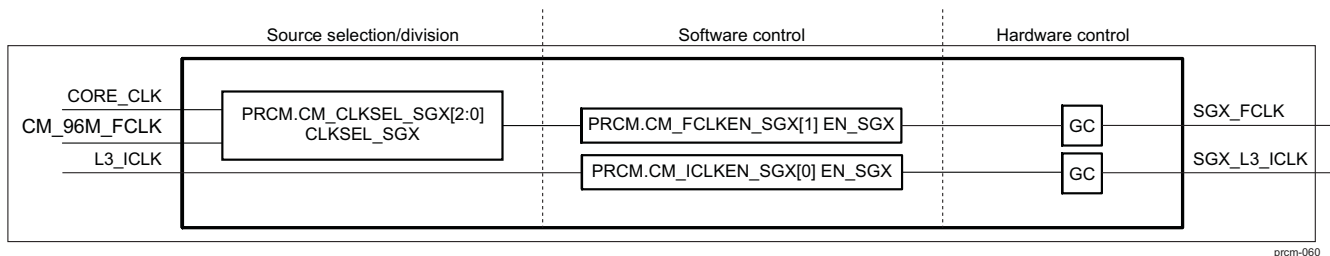

Figure 4-63. SGX Power Domain Clock Controls

Table 4-51 lists the clock-gating controls for the SGX power domain.

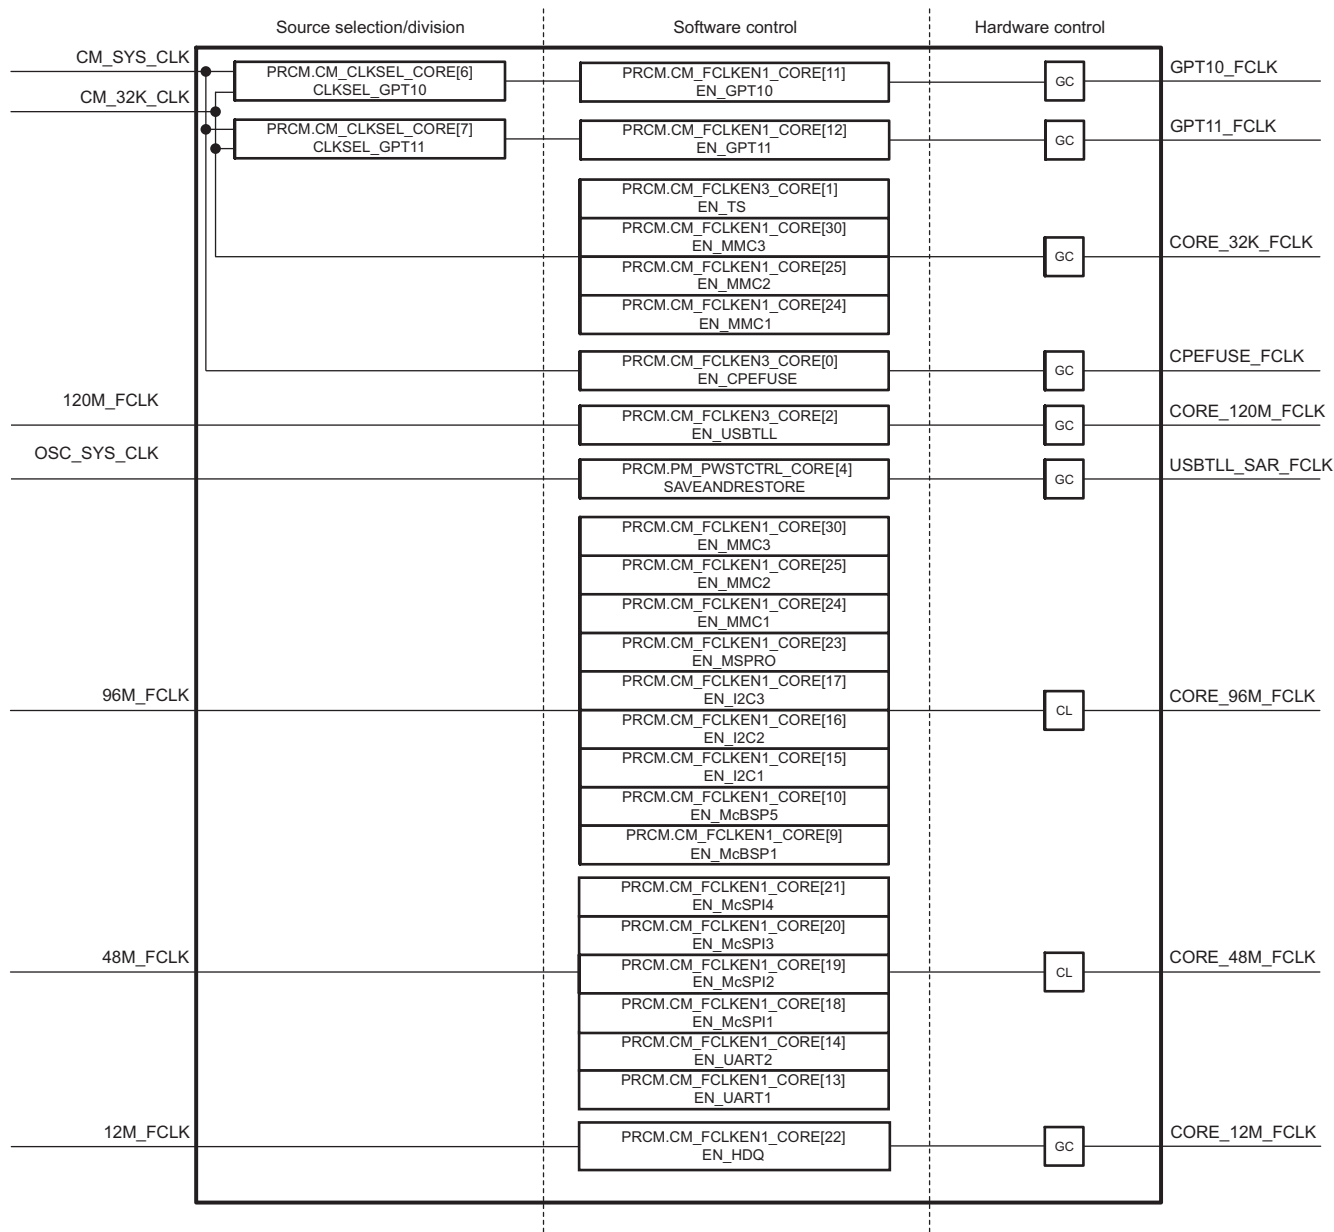

Table 4-51. SGX Power Domain Clock-Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
SGX_FCLK	Stopped	PRCM.CM_FCLKEN_SGX[1] EN_SGX	Gated when the enable bit is set to 0
SGX_ICLK	Stopped	PRCM.CM_ICLKEN_SGX[1] EN_SGX	Gated when the enable bit is set to 0

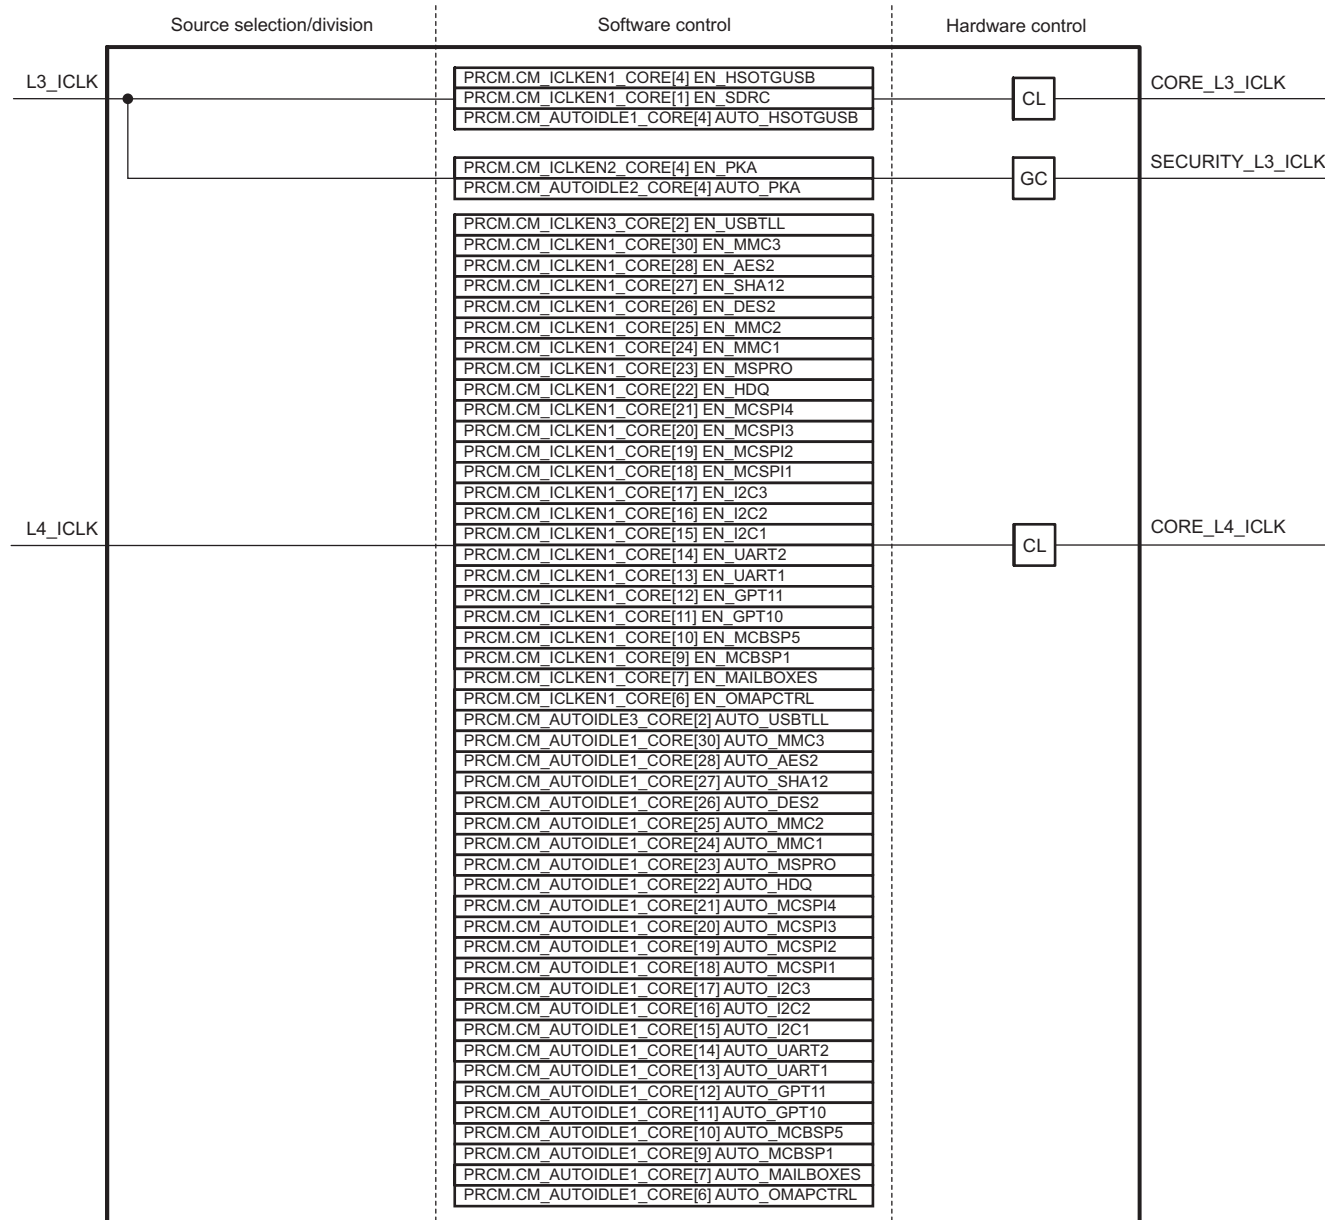

4.7.7.6 CORE Power Domain Clock Controls

Figure 4-64 through Figure 4-66 show the clock controls for the CORE power domain.

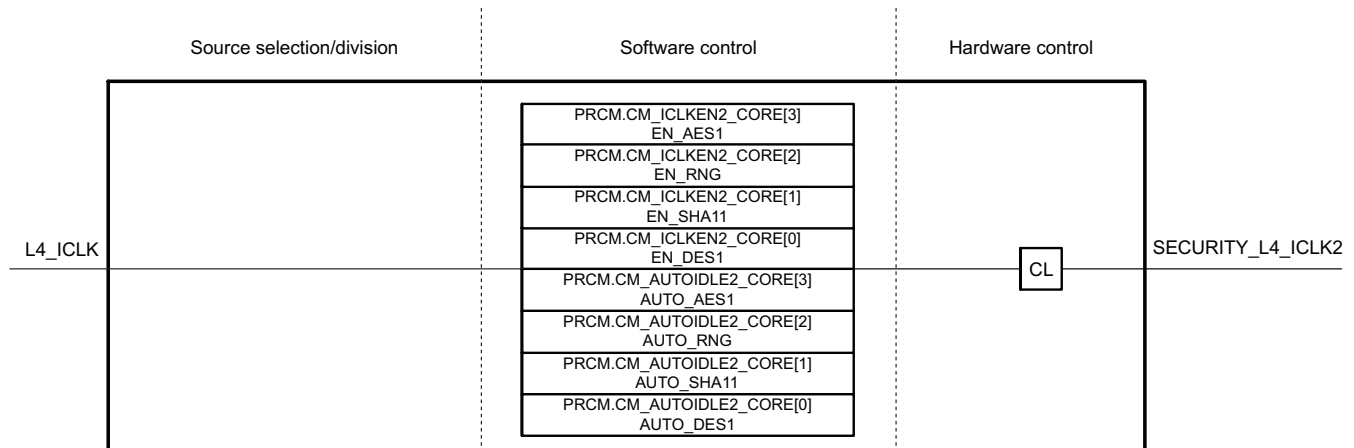

Figure 4-64. CORE Power Domain Clock Controls: Part 1

prcm-061

Figure 4-65. CORE Power Domain Clock Controls: Part 2

prcm-062

Figure 4-66. CORE Power Domain Clock Controls: Part 3

prcm-063

Table 4-52 lists the clock-gating controls for the CORE power domain.

Table 4-52. CORE Power Domain Clock-Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
GPT10_FCLK	Stopped	PRCM.CM_FCLKEN1_CORE[11] EN_GPT10	Gated when the enable bit is set to 0
GPT11_FCLK	Stopped	PRCM.CM_FCLKEN1_CORE[12] EN_GPT11	Gated when the enable bit is set to 0
CORE_96M_FCLK	Stopped	McBSP[1..5] input clock source select (in SCM) and PRCM.CM_FCLKEN1_CORE (MMC[1-2], McBSP[1, 5], I2C[1-3], MS-PRO)	Gated when the enable bits of the module functional clock are set to 0. (The McBSPs can have MCBSP_CLKS as an alternate functional clock.)
CORE_48M_FCLK	Stopped	PRCM.CM_FCLKEN1_CORE (UART[1-2], McSPI[1-4])	Gated when the functional clock enable bits of the module are set to 0
CORE_12M_FCLK	Stopped	PRCM.CM_FCLKEN1_CORE[22] EN_HDQ	Gated when the enable bit is set to 0
CORE_L3_ICLK	Running	PRCM.CM_ICLKEN1_CORE EN_(SDRC, HSOTGUSB), PRCM.CM_AUTOIDLE1_CORE4 AUTO_HSOTGUSB	Gated when: 1. All enable bits are set to 0. 2. The enable-autoidle bit pair is set to 1, the remaining enable bits are set to 0, and the clock is not requested by any module.
CORE_L4_ICLK	Running	PRCM.CM_ICLKEN1_CORE (AES2, SHAM2, D3D2, MMC[1..2], MS-PRO, HDQ, MCSPI[1-4], I2C[1-3], UART[1,2], GPT[10,11], McBSP[1,5], MAILBOXES, OMAPCTRL) and PRCM.CM_AUTOIDLE1_CORE (AES2, SHAM2, D3D2, MMC[1..2], MS-PRO, HDQ, MCSPI[1-4], I2C[1-3], UART[1,2], GPT[10,11], McBSP[1,5], MAILBOXES, OMAPCTRL)	Gated when: 1. All enable bits are set to 0. 2. All enable-autoidle bit pairs are set to 1, and the clock is not requested by any module.
SECURITY_L3_ICLK	Stopped	PRCM.CM_ICLKEN2_CORE[4] EN_PKA ,PRCM.CM_AUTOIDLE2_CORE[4] AUTO_PKA	Gated when:
SECURITY_L4_ICLK2	Running		1. Enable bit is set to 0. 2. Enable-autoidle bit pair is set to 1, and the clock is not requested by any module.

Table 4-52. CORE Power Domain Clock-Gating Controls (continued)

Clock Name	Reset	Clock-Gating Control	Gating Description
SECURITY_L4_ICLK2	Stopped	PRCM.CM_ICLKEN2_CORE EN_(AES1, RNG1, SHAM1, D3D1) and PRCM.CM_AUTOIDLE2_CORE[4] AUTO_(AES1, RNG1, SHAM1, D3D1)	Gated when: 1. All enable bits are set to 0. 2. All enable-autoidle bit pairs are set to 1, and the clock is not requested by any module.
CORE_32K_FCLK	Stopped	CM_FCLKEN1_CORE[24] EN_MMC1, CM_FCLKEN1_CORE[25] EN_MMC2, CM_FCLKEN1_CORE[30] EN_MMC3, CM_FCLKEN3_CORE[1] EN_TS	Gated when: 1. All enable bits are set to 0.
CPEFUSE_FCLK	Stopped	CM_FCLKEN3_CORE[0] EN_CPEFUSE	Gated when CPEFUSE autoload sequence is performed, and the enable bit is set to 0
CM_USIM_CLK	Stopped	CM_FCLKEN_WKUP[9] EN_USIMOC	Gated when the enable bit is set to 0
USBTLL_SAR_FCLK	Stopped	CORE power domain power state and PM_PWSTCTRL_CORE[4] SAVEANDRESTORE	Gated when the save-restore bit is set to 0, or when the CORE power domain is in OFF state after the save operation completes or in ON state after the restore operation completes.
CORE_120M_FCLK	Stopped	CM_FCLKEN3_CORE[0] EN_USBTLL and DPLL5 operating mode	Gated when the enable bit is set to 0, or the DPLL5 is in stop or bypass mode

4.7.7.7 EFUSE Power Domain Clock Controls

Figure 4-67 shows the clock controls for the EFUSE power domain. Table 4-53 lists the clock-gating control for the EFUSE power domain.

Figure 4-67. EFUSE Power Domain Clock Controls

prcm-064

Table 4-53. EFUSE Power Domain Clock-Gating Control

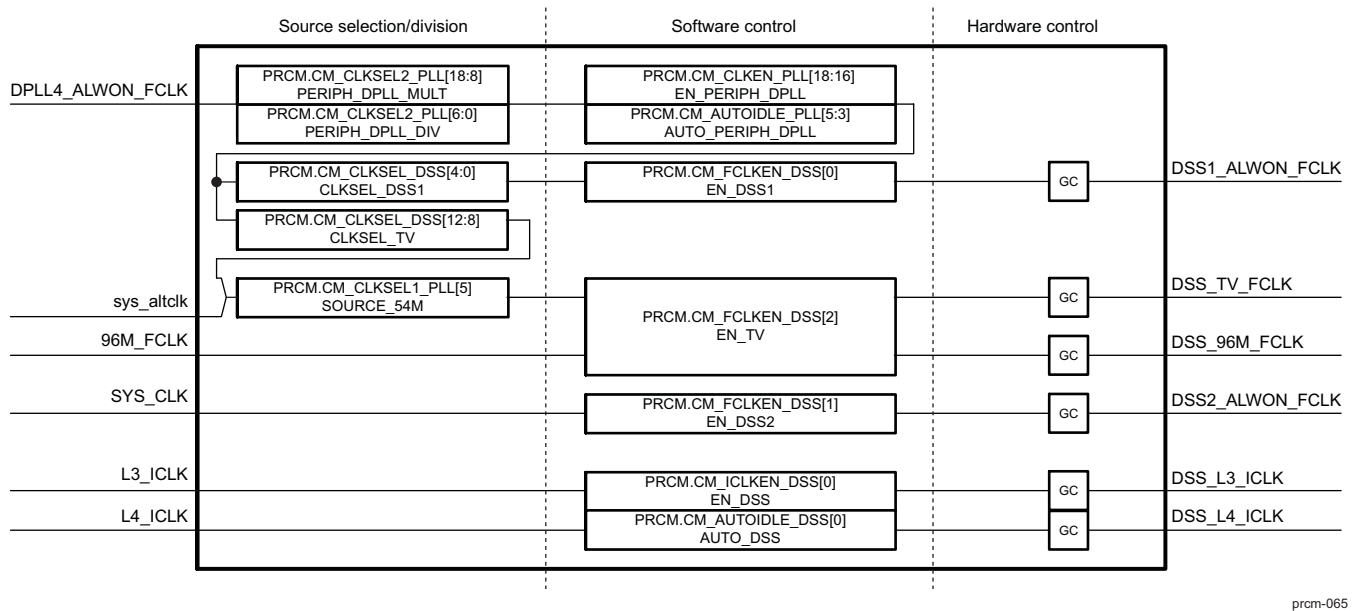

Clock Name	Reset	Clock-Gating Control	Gating Description
EFUSE_ALWON_FCLK	Running	None	Active when VDD1 and VDD2 are switched on and eFuse-ready hardware signal is released

4.7.7.8 DSS Power Domain Clock Controls

This section gives information about all modules and features in the high-tier device. See Chapter 1, *OMAP35x Family* section, to check availability of modules and features. For power-management saving consideration, ensure that power domains of unavailable features and modules are switched off and clocks are cut off.

Figure 4-68 shows the clock controls for the DSS power domain. Table 4-54 lists the clock-gating controls for the DSS power domain.

Figure 4-68. DSS Power Domain Clock Controls

prcm-065

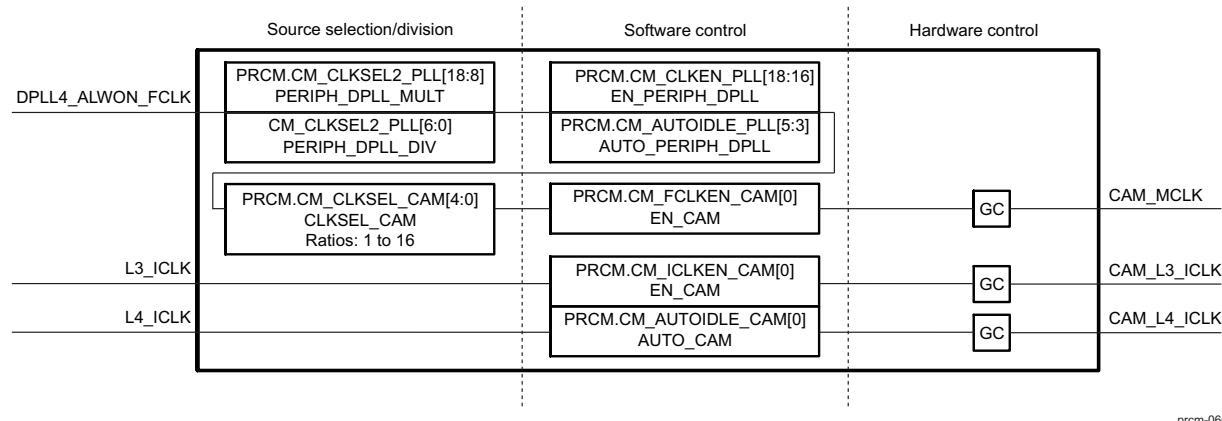

Table 4-54. DSS Power Domain Clock-Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
DSS1_ALWON_FCLK	Stopped	PRCM. CM_FCLKEN_DSS [0] EN_DSS1	Gated when the enable bit is set to 0
DSS2_ALWON_FCLK	Stopped	PRCM. CM_FCLKEN_DSS [1] EN_DSS2	Gated when the enable bit is set to 0
DSS_TV_FCLK	Stopped	PRCM. CM_FCLKEN_DSS [2] EN_TV	Gated when the enable bit is set to 0
DSS_96M_FCLK	Stopped		
DSS_L3_ICLK	Stopped	PRCM. CM_ICLKEN_DSS [0] EN_DSS, PRCM. CM_AUTOIDLE_DSS [0] AUTO_DSS	Gated when: <ul style="list-style-type: none"> 1. Enable bit is set to 0. 2. Enable-autoidle bit pair is set to 1, and the clock is not requested by any module.
DSS_L4_ICLK	Stopped		

4.7.7.9 CAM Power Domain Clock Controls

This section gives information about all modules and features in the high-tier device. See Chapter 1, *OMAP35x Family* section, to check availability of modules and features. For power-management saving consideration, ensure that power domains of unavailable features and modules are switched off and clocks are cut off.

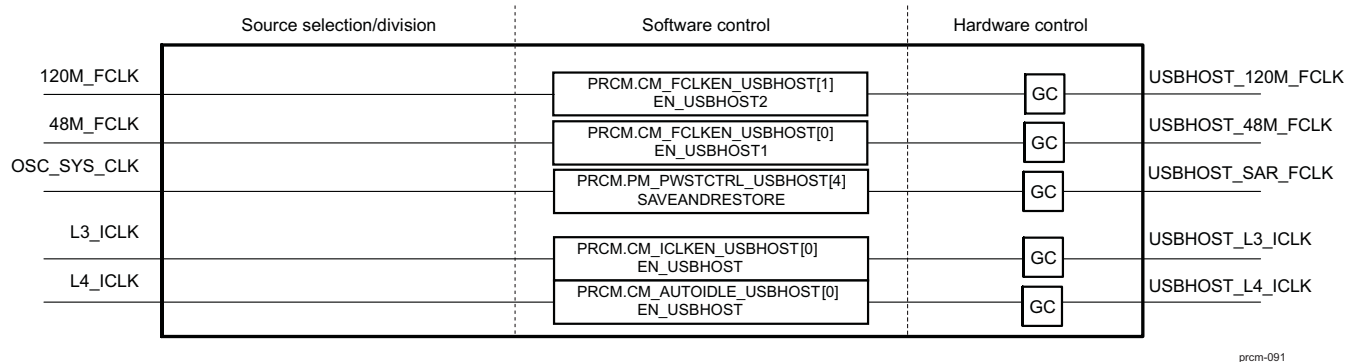

Figure 4-69 shows the clock controls for the CAM power domain. Table 4-55 lists the clock-gating controls for the CAM power domain.

Figure 4-69. CAM Power Domain Clock Controls

Table 4-55. CAM Power Domain Clock-Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
CAM_MCLK	Stopped	PRCM.CM_FCLKEN_CAM[0] EN_CAM	Gated when the enable bit is set to 0
CAM_L3_ICLK	Stopped	PRCM.CM_ICLKEN_CAM[0] EN_CAM, PRCM.CM_AUTOIDLE_CAM[0] AUTO_CAM	Gated when:
CAM_L4_ICLK	Stopped		1. Enable bit is set to 0. 2. Enable-autoidle bit pair is set to 1, and the clock is not requested by subsystem.

4.7.7.10 USBHOST Power Domain Clock Controls

Figure 4-70 shows the clock controls for the USBHOST power domain. Table 4-56 lists the clock-gating controls for the USBHOST power domain.

Figure 4-70. USBHOST Power Domain Clock Controls

GPT9_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_PER[10] EN_GPT9	Gated when the enable bit is set to 0
PER_L4_ICLK	Stopped	PRCM.CM_ICLKEN_PER EN_(GPIO[2..6], WDT3, UART3, GPT[2..9], MCBSP[2..4]) and PRCM.CM_AUTOIDLE_PER AUTO_(GPIO[2..6], WDT3, UART3, GPT[2..9], and MCBSP[2..4])	Gated when: 1. All enable bits are set to 0. 2. All enable-autoidle bit pairs are set to 1, and the clock is not requested by any module.
96M_ALWON_FCLK	Stopped	None	Always-on clock

For audio applications, the McBSP functional clocks are provided externally by the MCBSP_CLKS pin. This clock must be permanently supplied, to allow McBSPs to function when the CORE power domain is in the OFF power state. If the external clock input is selected as the functional clock, the PER power domain sleep transition is prevented.

4.7.7.13 SMARTREFLEX Power Domain Clock Controls

Figure 4-74 shows the clock controls for the SMARTREFLEX power domain. Table 4-59 lists the clock-gating controls for the SMARTREFLEX power domain.

Figure 4-74. SMARTREFLEX Power Domain Clock Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
SR_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_WKUP[6] EN_SR1 and PRCM.CM_FCLKEN_WKUP[7] EN_SR2	Gated when both enable bits are set to 0
SR_L4_ICLK	Running	Depends on L4_ICLK activity (hardware control)	

4.7.8 Clock Configurations

The device supports several clock configurations. A clock configuration is a consistent set of divider ratios programmed into PRCM to obtain a certain combination of clock speed to match the performance requirement.

In the device the MPU and IVA2.2 processors are connected to the interconnects through asynchronous bridges, the functional frequency of these processors can be configured independently of their interface clock frequency.

Therefore, the clock configurations of the device are split into two sections: one for device processor clocks, and the other for device interface clocks.

An operating performance point of the device may be defined as a pair of device operating voltage and corresponding frequency. The device processors are in the VDD1 voltage domain and the interface clocks are generated by the CM clock generator in the VDD2 voltage domain. Hence, the OPPs of the processor clocks are identified for the VDD1 voltage levels, independent of the interface clocks which are associated to the VDD2 voltage levels.

CAUTION

Clock configurations depend on device operating voltage values. Please refer to your device-specific data manual for a description of the supported voltage levels and maximum clock frequencies.

4.7.8.1 Processor Clock Configurations

The processor operating performance points are identified as the pair of VDD1 operating voltage level and the processor clocks frequency.

Five generic processor operating performance points may be defined as:

1. OPP5 (VDD1 = v4 , (MPU_CLK = $f_{\text{mpu}4}$, IVA2_CLK = $f_{\text{iva}4}$))
2. OPP4 (VDD1 = v3 , (MPU_CLK = $f_{\text{mpu}3}$, IVA2_CLK = $f_{\text{iva}3}$))
3. OPP3 (VDD1 = v2 , (MPU_CLK = $f_{\text{mpu}2}$, IVA2_CLK = $f_{\text{iva}2}$))
4. OPP2 (VDD1 = v1 , (MPU_CLK = $f_{\text{mpu}1}$, IVA2_CLK = $f_{\text{iva}1}$))
5. OPP1 (VDD1 = v0 , (MPU_CLK = $f_{\text{mpu}0}$, IVA2_CLK = $f_{\text{iva}0}$))

where $v4 > v3 > v2 > v1 > v0$,

$f_{\text{mpu}4} > f_{\text{mpu}3} > f_{\text{mpu}2} > f_{\text{mpu}1} > f_{\text{mpu}0}$,

$f_{\text{iva}4} > f_{\text{iva}3} > f_{\text{iva}2} > f_{\text{iva}1} > f_{\text{iva}0}$ and

f_{mpu} may not be equal to f_{iva}

The clock configuration for the MPU and the IVA applies to following clocks of the device:

- DPLL1 (MPU DPLL) synthesized clock frequency (CLKOUTX2) configured by setting the M and N parameters of the DPLL
- DPLL1 (MPU DPLL) output clock frequency (MPU_CLK) configured by setting the M2 parameter of the DPLL

Note: The MPU_CLK is divided by 2 inside the MPU subsystem to generate the ARM_FCLK. This divider is only active when the DPLL is locked. (Refer to MPU Subsystem for information on ARM_FCLK).

- DPLL2 (IVA2 DPLL) synthesized clock frequency (CLKOUT) configured by setting the M and N parameters of the DPLL
- DPLL2 (IVA2 DPLL) output clock frequency (IVA2_CLK) configured by setting the M2 parameter of the DPLL

The frequency of the processor clocks (MPU_FCLK and IVA2_FCLK) must be configured according to the selected OPP (the clock frequency associated with the operating voltage VDD1). Table 4-60 identifies the clocks of the processors, their source clocks, and the configuration register bit fields.

Table 4-60. Processor Clock Configuration Controls

Module	Clocks	Reference Clock	Multiplier (factors)	Divider (factors)	Configuration Bits
DPLL1	CLKOUT X2	SYS_CLK	M (0 ... 2047)		PRCM.CM_CLKSEL1_PLL_MPU[18:8] MPU_DPLL_MULT
				N (0 ... 127)	PRCM.CM_CLKSEL1_PLL_MPU[6:0] MPU_DPLL_DIV
	MPU_CLK ⁽¹⁾	CLKOUTX2		M2	PRCM.CM_CLKSEL2_PLL_MPU[4:0] MPU_DPLL_CLKOUT_DIV
DPLL2	CLKOUT	SYS_CLK	M (0 ... 2047)		PRCM.CM_CLKSEL1_PLL_IVA2[18:8] IVA2_DPLL_MULT
				N (0 ... 127)	PRCM.CM_CLKSEL1_PLL_IVA2[6:0] IVA2_DPLL_DIV
	IVA2_CLK	CLKOUT		M2 (1 ... 16)	PRCM.CM_CLKSEL2_PLL_IVA2[4:0] IVA2_DPLL_CLKOUT_DIV

⁽¹⁾ The MPU_CLK is divided by 2 inside the MPU subsystem to generate the ARM_FCLK. This divider is only active when the DPLL is locked. (Refer to MPU Subsystem for information on ARM_FCLK).

Table 4-61. Processor Clock Configurations

CLOCK	BYPASS	LOCKED
MPU_CLK	DPLL1_FCLK (Bypass Clock from DPLL3)	(SYS_CLK * M * 2) / ([N+1] * M2)
ARM_FCLK	MPU_CLK	MPU_CLK / 2
MPUSS Internal Modules Clocks	ARM_FCLK / 2	ARM_FCLK / 2

4.7.8.2 Interface and Peripheral Functional Clock Configurations

The interface clocks operating performance points are identified as the pair of VDD2 operating voltage level and the device interface clocks frequencies.

The DPLL3 (CORE DPLL) generates the CORE_CLK which serves as the source clock for the L3_ICLK and L4_ICLK interface clocks of the device. The CORE_CLOCK is also used by the DPLL1 and DPLL2 as the bypass clock. The L3_ICLK is supplied to the SGX module as SGX_L3_ICLK and is used as its functional clock. The L4_ICLK is used by RM_L4_CLK as its source clock.

The interface and peripheral functional clocks frequencies can be configured according to the device performance requirements for the OPP.

DPLL3 synthesized clock frequencies are configured as:

- $f_{CLKOUT} = (f_{SYS_CLK} \times M) / (N+1)$
- $f_{CLKOUTX2} = f_{CLKOUT} \times 2$

DPLL3 output clock frequencies are configured as:

- $f_{CORE_CLK} = f_{CLKOUT} / M2$
- $f_{COREX2_CLK} = f_{CLKOUTX2} / M2$

L3_ICLK, L4_ICLK and RM_L4_ICLK frequencies are configured as:

- $f_{L3_ICKLK} = f_{CORE_CLK} / DIV_L3$
- $f_{L4_ICKLK} = f_{L3_ICKLK} / DIV_L4$
- $f_{RM_L4_ICKLK} = f_{L4_ICKLK} / DIV_RM$

Table 4-62 identifies the interface clocks, their reference clocks, and the control bits for configuration of the interface clock frequencies.

Table 4-62. Interface Clock Configuration Controls

Module	Clock	Reference Clock	Multiplier (Factor)	Divider (Factor)	Configuration Bits
DPLL3	CLKOUT	SYS_CLK	M (0 ... 2047)		PRCM.CM_CLKSEL1_PLL[26:16] CORE_DPLL_MULT
	CLKOUTX2			N (0 ... 127)	PRCM.CM_CLKSEL1_PLL[14:8] CORE_DPLL_DIV
CORE_CLK	CORE_CLK	CLKOUT		M2 (1 ... 31)	PRCM.CM_CLKSEL1_PLL[31:27] CORE_DPLL_CLKOUT_DIV
	COREX2_CLK	CLKOUTX2			
L3 interconnect	L3_ICLK	CORE_CLK		DIV_L3 (1 ... 2)	PRCM.CM_CLKSEL_CORE[1:0] CLKSEL_L3
L4 interconnect	L4_ICLK	L3_ICLK		DIV_L4 (1 ... 2)	PRCM.CM_CLKSEL_CORE[3:2] CLKSEL_L4
RM clock	RM_L4_ICLK	L4_ICLK		DIV_RM (1 ... 2)	PRCM.CM_CLKSEL_WKUP[2:1] CLKSEL_RM

SGX_FCLK, DPLL1_FCLK (bypass mode) and DPLL2_FCLK (bypass mode) frequencies are configured as:

- $f_{SGX_FCLK} = f_{L3_ICLK} / DIV_SGX$
- $f_{DPLL1_FCLK} = f_{CORE_CLK} / DIV_DPLL1$
- $f_{DPLL2_FCLK} = f_{CORE_CLK} / DIV_DPLL2$

Table 4-63 identifies the functional clocks, their reference clocks and the control bits for configuration of the functional clock frequencies.

Table 4-63. Functional Clock Configuration Controls

Module	Clock	Reference Clock	Divider (Factor)	Configuration Bits
SGX	SGX_FCLK	L3_ICLK	DIV_SGX (3 ... 6)	PRCM.CM_CLKSEL_SGX[2:0] CLKSEL_SGX
MPU HS bypass	DPLL1_FCLK	CORE_CLK	DIV_DPLL1 (1, 2, 4)	PRCM.CM_CLKSEL1_PLL_MPU[20:19] MPU_CLK_SRC
IVA2 HS bypass	DPLL2_FCLK	CORE_CLK	DIV_DPLL2 (1, 2, 4)	PRCM.CM_CLKSEL1_PLL_IVA2[20:19] IVA2_CLK_SRC

The rest of the functional clocks are issued from DPLL4 and DPLL5 and remain invariable, regardless of the interface clock configuration. In all clock configurations, any divider ratio to generate functional clocks is applicable, provided it complies with the maximum frequency specification.

4.8 PRCM Idle and Wake-Up Management

4.8.1 Overview

When a group of modules belonging to a clock domain in a power domain do not require a clock (interface or functional), the PRCM can be programmed to automatically cut the clock to those modules, thereby reducing their power consumption. The PRCM can then switch the power domain to low-power retention or off mode to ensure minimum power consumption. When all clocks in a domain are cut, the domain is idle.

Similarly, when a module belonging to a power domain in low-power idle mode is required to switch to active mode, the PRCM switches on the power to the entire power domain and activates the necessary clock signals to the module. This is a wake-up transition. Generally, a wake-up event triggers the wake-up transition.

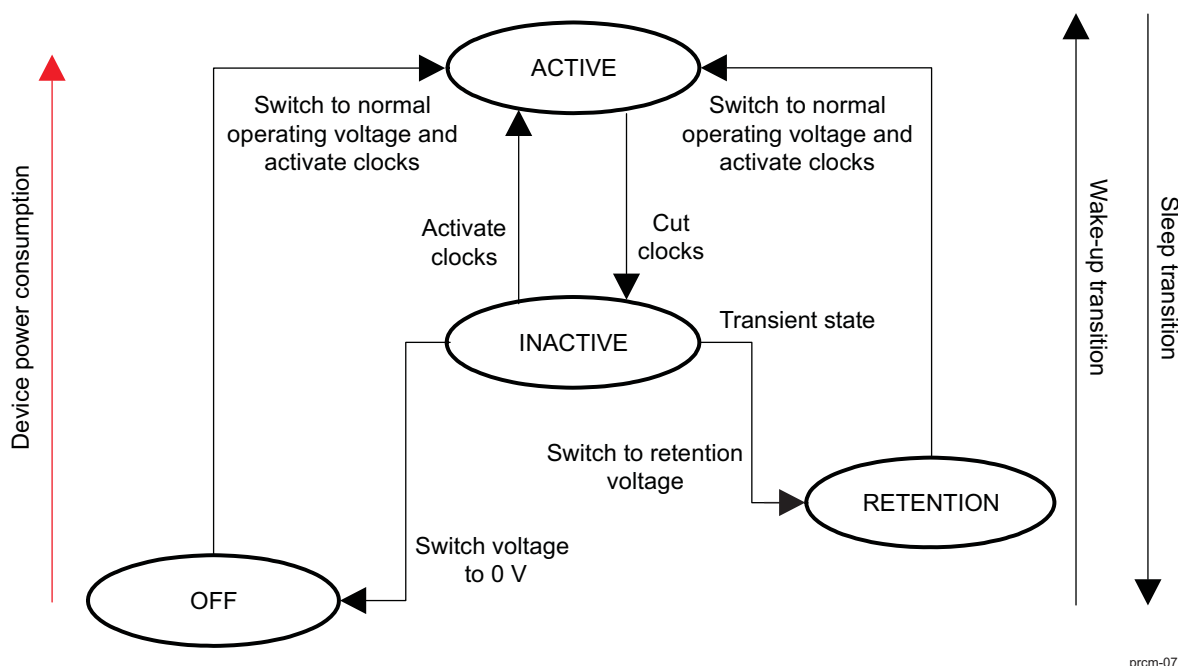

A sleep/wake-up dependency can be defined between different power domains. A sleep dependency ensures that a power domain does not make a sleep transition unless all the dependent power domains are in idle mode and do not require the power domain. Similarly, a wake-up dependency ensures that a power domain wakes up when any of its dependent power domains wakes up.

The PRCM automatically handles the sequence clock-gating conditions and power switching for each power domain, based on the configured dependencies between the domains and the clock-control bits of the modules.

Figure 4-75 shows the sleep/wake-up transition of the power domains. The INACTIVE state is a transient power state of a power domain, while moving from ACTIVE to either RETENTION or OFF power state. In the INACTIVE state all the domain clocks are gated. A power domain can not switch from OFF to RETENTION or RETENTION to OFF power state without passing first to the ACTIVE power state.

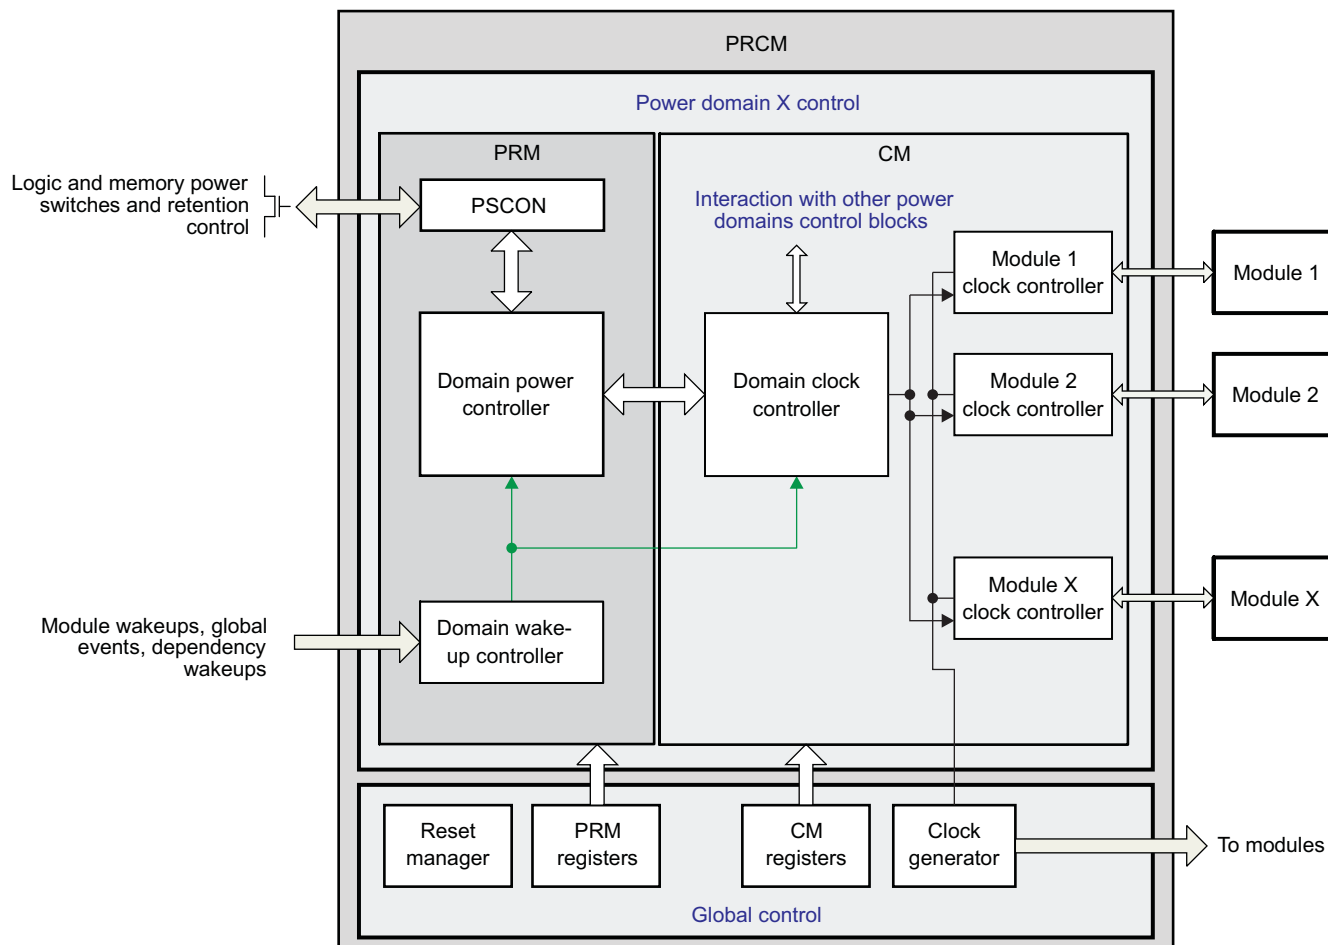

A lower power state, i.e., INACTIVE, RETENTION or OFF, means lesser power consumption. However, the wake-up latency increases as the power domain switches to INACTIVE, RETENTION or OFF power state, respectively.

Figure 4-75. Power Domain Sleep/Wake-Up Transition

Functionally, the PRCM is composed of a single global control block and a power-control block for each power domain. The domain power-control block handles power switching, wake-up events, and clock-gating control for the domain. The domain power controllers communicate with each other for power sequencing, sleep dependencies, and wake-up dependencies. All these blocks interact with the global control block that handles reset management, clock generation and distribution, and all PRCM registers.

Figure 4-76. Device Power Reset and Clock Controllers

prcm-072

Figure 4-76 details the functions within one power domain block:

- A module clock controller (for example, module X clock controller) uses a hardware handshake protocol to communicate directly with the module. It controls the idle transition of the target module and responds to the standby requests of the initiator module (for details, see [Section 4.1.4.2, Autoidle Clock Control](#)). Depending on the mode, the clock controller sends clock commands (enable/disable) to the clock generator. The registers that control the functional and interface clocks in the module are directly mapped to the module clock controller.
- The domain clock controller gathers information from the following:
 - All module clock controllers of the power domain
 - The domain power controller
 - The domain wake-up controller
 - The other power domain control blocks
 The domain clock controller informs the domain power controller when all conditions for the domain power transition are met (domain clocks are idle, no initiator is requesting service, no wake-up event is pending) to allow a domain power transition. On a wake-up event, the domain clock controller starts the module domain clocks, if power is present.
- The domain power controller communicates with the domain clock controller, the domain wake-up

controller, and the PSCON. Depending on the register settings for clock domain activity (idle or active), it sends requests to the PSCON to power down/up the domain logic and memory, or to enable retention mode.

- The PSCON sequences all sleep and wake-up transitions between on, off, and retention modes for both logic and memory. It also ensures that the domain is properly isolated when it enters into off or retention mode.
- The domain wake-up controller gathers all events that can wake up the power domain. Some events are active only when the domain is on (these are used to switch on the clocks, when required); others also allow domain power up. These events can be internal (coming from the modules in the power domain, such as general-purpose [GP] timer time-out), external (coming from another power domain control block dependency), or global (voltage stabilization).
- The reset manager globally controls all resets in the device. It gathers information from all power domain control blocks to sequence power and clocks, and resets the activation of each domain.
- The clock generator generates and distributes clocks over the device, depending on requests from all module clock controllers and on other global conditions.

4.8.2 Sleep Transition

The PRCM can initiate a domain sleep transition on a power domain only if the domain meets the following conditions:

- All initiator modules are idle (they have completed their activity and idled themselves through software requests).
- All target modules are idle (automatically when all initiators are in standby mode or on software request).
- All sleep dependencies with other domains are met (can be set by software).

When the sleep conditions are met (based on the settings of the PRCM.PRM_PWSTCTRL_<power domain>[1,0] POWERSTATE bit field), the PRCM performs the actions described in [Table 4-64](#), either automatically or when instructed by the software.

Table 4-64. Power State Related Sleep Transition Actions

Power Domain State	Action
ON	All functional and interface clocks in the power domain are shut down when the sleep conditions are met. The power domain is idle and is no longer functional.
RETENTION	The power domain is idle and part or all of the logic and memory of the domain is switched to retention mode.
OFF	The domain is idled and all the logic and memory in the domain are switched off.

The power domain state transition can be set to automatic (hardware controlled) or software-controlled by setting the PRCM. CM_CLKSTCTRL_<power domain> CLKTRCTRL_<power domain> bit field.

4.8.3 Wakeup

A wake-up event switches on two domains:

- A power domain (logic and associated memories) that is in INACTIVE state
- A clock domain (including related clock sources, such as a DPLL)

If a domain is already on and the clock domain is idle, only the clocks are reactivated on a wake-up event.

To wake up, a processor requires an interrupt associated with the wake-up event. If its power domain is to transition from OFF or RETENTION state to ACTIVE, it must be reset.

There are three types of wake-up events:

- Global: Generated on a particular device event (device wakeup, voltage transition completed, DPLL recalibration, etc.). Used mainly to wake up the MPU domain

- **Module:** Functional wake-up event issued from a module, which wakes up the domain where the module resides. It can also directly wake up the MPU or the IVA2.2 processor, depending on software settings in the PRCM.PM_MPUGRPSEL_<power domain> and PRCM.PM_IVA2GRPSEL_<power domain> registers.
- **Dependency:** A power domain can wake up on the wakeup of another power domain. The dependency is software-controllable by configuring the PRCM.PM_WKDEP_<power domain> register.

4.8.4 Device Wake-Up Events

This section summarizes the wake-up events for each power domain. [Table 4-65](#) through [Table 4-75](#) list the wake-up events, related control registers, and MPU and IVA2.2 interrupts.

Two registers, PRCM.PRM_IRQENABLE_MPU and PRCM.PRM_IRQENABLE_IVA2, enable the MPU and IVA2.2 interrupts. In some cases, they can also enable the wake-up feature associated with the interrupt (DPLL recalibration requests, voltage controller and processors errors, and device wake-up event).

Notes:

- The PRCM can be configured to generate an interrupt to the MPU or the IVA2 subsystem as a result of a wake-up event from the CORE, WKUP, and PER power domain modules to the MPU and the IVA2. However, these modules may also directly interrupt the MPU and the IVA2 subsystems. To avoid a double interrupt (from the PRCM and one of these modules) as the result of a single event (wakeup), one interrupt must be masked when the other is unmasked. For further information on its interrupt capability, see the chapter of the corresponding module.
- The UART, GPIO, McSPI, and USIM OCP modules generate an asynchronous wake-up event (that is, their interface and functional clocks can be gated during the sleep period). However, because the GPTIMERS generate a synchronous wake-up event, they require their functional clock to be active during the sleep period; their interface clock can be gated. McBSP modules can generate a synchronous or asynchronous wake-up event, based on the mode configurations. For further information on its wake-up capability, see the chapter of the corresponding module.
- The ability of a module to generate a wake-up event depends on the power state of the power domain in which the module resides. If the power domain is inactive (that is, both the functional and interface clocks of the domain are gated), only the asynchronous wake-up modules can wake up the power domain. If only the interface clocks in the domain are gated, both synchronous and asynchronous wake-up modules can generate a wake-up event to activate the interface clock. Similarly, if the power domain is in RETENTION or OFF power state (that is, the domain logic is nonfunctional), no wake-up event can be generated by any module in that power domain.

Table 4-65. MPU Power Domain Wake-Up Events

Internal Wake-Up Events	Source Module	PRCM Software Control	Wake-Up Event	Interrupt/Type	Interrupt to
IVA2, CORE, DSS, and PER domain dependency	PRCM	PM_WKDEP_MPU	Yes	No	N/A
Peripherals wake-up events	Peripherals	PM_MPUGRPSEL1_CORE	Yes	MPU peripheral group event occurred.	MPU
		PM_MPUGRPSEL3_CORE			
		PM_MPUGRPSEL_WKUP			
		PM_MPUGRPSEL_PER			
Event generator on, off time	PRCM	PM_EVGENCTRL_MPU	Yes	Event generator on, off	MPU
Forced wake-up transition	PRCM	CM_CLKSTCTRL_IVA2	No	Wake-up transition is complete (IVA2, NEON, SGX, USBHOST, DSS, CAM, PER, EMU domains).	MPU

Table 4-65. MPU Power Domain Wake-Up Events (continued)

GPTIMER12 wakeup	GPTIMER12		Yes	No	N/A
GPIO1 wakeup	GPIO 1	PM_WKEN_WKUP	Yes	No	N/A

Note: For the GPIO1 module in the WKUP power domain some of its 32 IO pins are connected to the device IO pads logic in the CORE power domain (VDD2) and the reset to the device IO pads logic in the WKUP power domain (VDD3). As a result when the CORE power domain is OFF, the VDD2 supplied IO pins of the GPIO1 can not generate a wake-up event. For more details, see the *General-Purpose Interface Module* chapter.

4.8.5 Sleep and Wake-Up Dependencies

4.8.5.1 Sleep Dependencies

The (clock activity) dependencies between power domains are implemented to manage their sleep and wake-up transitions to ensure stable operation of the device.

A sleep dependency prevents the PRCM from gating the clocks to a power domain (for sleep transition to inactive, retention or off state from on state) if a dependent power domain is active (i.e., its clocks are active). A power domain may depend on several other power domains.

A power domain sleep dependency is programmed by setting the PRCM.CM_SLEEPDEP_<domain> register.

Example:

The PER domain has a programmable sleep dependency with the MPU and IVA2 power domains, and a hardwired sleep dependency with the CORE power domain. Therefore, if all software dependencies are enabled, the PER domain can go into idle mode only if the MPU, IVA2, and CORE-L3 clock domains are idle. If all software dependencies are disabled, the PER domain can go into idle mode, provided that the CORE-L3 clock domain is muted (no access to the PER domain can be pending).

[Table 4-76](#) summarizes the programmable and hardwired sleep dependencies among the domains.

Table 4-76. Sleep Dependencies

		Sleep Dependency With											
Power Domain	Clock Domain	MPU	NEON	IVA2	SGX	CAM	DSS	PER	CORE_L3	CORE_L4	CORE_CM	USB_HOST	WKUP
MPU	MPU												
NEON	MPU												
IVA2	IVA2												
SGX	SGX												
CAM	CAM												
DSS	DSS												
PER	PER												
CORE	CORE_L3												
	CORE_L4												
	CORE_CM												
USBHOST	USBHOST												
WKUP	WKUP												

Notes:

No software control (hardwired values):		Does not depend on
		Depends on
Software controllable		Read and Write
		Not applicable

Note: The first row of the table identifies the dependent power domains for a power domain listed in the first column. Therefore, to identify the sleep dependency of power domain X, identify domain X in the first column and its sleep dependency with power domains (of the first row) is identified by its row.

4.8.5.2 Wake-Up Dependencies

A wake-up dependency allows a power domain to wake up (from off, retention or inactive state to on state) when another power domain wakes up (from off, retention or inactive state to on state). For example, power domain one (PD1) provides a service to power domain two (PD2), which creates a dependency between the two domains. When the dependent power domain (PD2) wakes up, it signals PD1 with a broadcasted wake-up event, causing PD1 to wake up.

A broadcasted wake-up event can originate from one of two sources:

- PD2 internal wake-up event (typically, a peripheral wake-up event)
- Abortion of the mute mode (at least one initiator in the domain exits standby mode) of PD2 when both the sleep dependency and wake-up dependency with PD1 are enabled.

Note: The domain wake-up dependency is a nontransitive property.

If a power domain PD1 has wake-up dependency with power domain PD2, i.e., PRCM.PM_WKDEP_PD1. EN_PD2 bit is set to 1 and if PD2 has wake-up dependency with power domain PD3, i.e., PRCM.PM_WKDEP_PD2. EN_PD3 bit is set to 1.

However, if PD1 does not have a direct wake-up dependency with PD3, i.e., PRCM.PM_WKDEP_PD1. EN_PD3 bit is set to 0. Then if the PD1 and PD2 are in INACTIVE/RETENTION or OFF power state and PD3 is INACTIVE and is woken-up by a wake-up event, the PD2 is also woken-up but not the PD1.

Because a power domain can depend on several other power domains, it can broadcast the wake-up signal to each power domain on which it depends.

A power domain wake-up dependency can either be hardwired (set in the hardware) or programmable through software by configuring the PM_WKDEP_<domain> register for that power domain. Continuing the example of PD2 as dependent on PD1, setting the PM_WKDEP_PD1.PD2 bit means that when PD2 wakes up, PD1 also wakes up.

The MPU power domain can be wakened only by the IVA2, DSS, USBHOST, PER, CORE-L3, CORE-L4, and WKUP power domains. Similarly, the IVA2 power domain can be wakened only by the MPU, DSS, USBHOST, PER, CORE-L3, CORE-L4, and WKUP power domains. All wake-up dependencies of the MPU and the IVA2 power domain are software-configurable.

For the processor power domains (MPU and the IVA2 power domain), when the wake-up dependency with other power domains is software-programmable (that is, with the USBHOST, PER, CORE, and WKUP power domains), two registers may need be configured: PM_WKDEP_<domain> and PM_<processor>GROUPSEL_<domain>.

The PM_WKDEP_<domain> register serves only to enable/disable the global wake-up dependency of the processor power domain on these three power domains. The PM_<processor>GROUPSEL_<domain> register must be configured to enable the particular wake-up event in these domains that will wake up the processor domain. Thus, the global wake-up dependency for a dependent domain must be enabled so that a wake-up event can occur, if it has been enabled in the corresponding GROUPSEL register.

For example, if the wake-up dependency of the MPU power domain is to be enabled for a wake-up event from the GPIO2 module of the PER power domain, the following configuration is required:

- PRCM.PM_MPUGRPSEL_PER[13] GRPSEL_GPIO2
- PRCM.PM_WKDEP_MPU[7] EN_PER

Table 4-77 summarizes the programmable and hardwired wake-up dependencies among the domains.

Table 4-77. Wake-Up Dependencies

Power Domain	Clock Domain	Wake-Up Dependency With											
		MPU	NEON	IVA2	SGX	CAM	DSS	PER	CORE_L3	CORE_L4	CORE_CM	USB HOST	WKUP

4.8.6 USBHOST/USBTLL Save-and-Restore Management

Both USBHOST and USBTLL support a save-and-restore mechanism. When the device enters into off mode (that is, all power domains, except the WKUP power domain, are off), the user may want to save the USBHOST context and restore it when exiting off mode. The save-and-restore mechanism for the HS USB Host is enabled by setting the PRCM.PM_PWSTCTRL_USBHOST[4] SAVEANDRESTORE bit; for the USBTLL, it is configured by the PRCM.PM_PWSTCTRL_CORE[4] SAVEANDRESTORE bit. The save mechanism is initiated as the power domain transitions from ACTIVE to OFF state (or to OSWR state for the USBTLL), whereas the restore mechanism is initiated as the power domain transitions from OFF to ACTIVE power state.

Figure 4-77 shows the generic save-and-restore sequence applicable to both the USBHOST and the USBTLL. The sequence follows:

1. When the PRCM intends to initiate a sleep transition over the power domain (the USBHOST power domain for the HS USB Host subsystem and the CORE power domain for the USBTLL module), it sends a sleep request to the power domain. When the domain modules acknowledge the sleep request, the functional and interface clocks to the modules are gated.
2. The PRCM enables the SAR_FCLK functional clock and initiates the save sequence for the module. SAR_FCLK is gated when the save sequence completes.
3. The PRCM switches the power domain state to OFF power state. When a wake-up event occurs, the PRCM switches on the power domain.
4. The power domain local reset is asserted and then released by the reset manager.
5. The PRCM enables the SAR_FCLK functional clock, and then initiates the restore sequence for the module. SAR_FCLK is gated when the restore sequence completes.
6. The PRCM enables the functional and interface clocks to the modules and releases the sleep request. The modules acknowledge, and the wake-up sequence completes.

Notes:

- The PRCM sleep request and the module acknowledge signals are part of a hardware communication interface to ensure the proper sleep and wake-up sequence.
 - Figure 4-77 shows the save-and-restore sequence. It does not provide the exact timing delays between the switching of the signals and serves only to highlight the sequence of events as they occur.
-

Figure 4-77. Save-and-Restore Sequence

prcm-092

4.8.6.1 USBHOST SAR Sequences

4.8.6.1.1 Save Sequence on Sleep Transition

A precondition to the save sequence on sleep transition is that the save-and-restore mechanism is enabled (the PRCM.PM_PWSTCTRL_USBHOST[4] SAVEANDRESTORE bit is set to 1). The sequence is initiated when the power domain switches from ON to OFF power state.

1. When the USBHOST power domain is idled (all clocks of the power domain are gated), the PRM initiates the power domain transition to OFF power state by setting the PRCM.PM_PWSTCTRL_USBHOST[1:0] POWERSTATE bit field to 0x0.
2. The PRCM activates USBHOST_SAR_CLK and starts the save sequence.
3. When the save sequence completes, USBHOST_SAR_FCLK is gated.
4. The power domain sleep transition to OFF power state completes.

4.8.6.1.2 Restore Sequence on Wake-Up Transition

A precondition to the restore sequence on wake-up transition is that the save-and-restore mechanism is enabled (the PRCM.PM_PWSTCTRL_USBHOST[4] SAVEANDRESTORE bit is set to 1). The sequence is initiated when the power domain switches from OFF to ON power state.

1. Assert the USBHOST domain reset (must override the functional stall conditions of the reset manager). The functional reset is released locally by the RRB modules when the functional clocks are back.
2. Release the USBHOST domain reset.
3. The PRCM activates USBHOST_SAR_CLK and starts the restore sequence.
4. When the restore sequence completes, USBHOST_SAR_FCLK is gated.
5. The power domain wake-up transition to ON power state completes.

4.8.6.2 USB TLL SAR Sequences

4.8.6.2.1 Save Sequence on Sleep Transition

A precondition to the save sequence on sleep transition is that the save-and-restore mechanism is enabled (the PRCM.PM_PWSTCTRL_CORE[4] SAVEANDRESTORE bit is set to 1). The sequence is initiated when the power domain switches from ON to OSWR or OFF power state.

1. When the CORE power domain is idled (all clocks of the power domain have been gated) the PRM initiates the power domain transition to OFF or OSWR power state by setting the PRCM.PM_PWSTCTRL_CORE[1:0] POWERSTATE bit field to 0x0 or 0x1.
2. The PRCM activates USBTLL_SAR_CLK and starts the save sequence.
3. When the save sequence completes, USBTLL_SAR_FCLK is gated.
4. The power domain sleep transition to OFF or OSWR power state completes.

4.8.6.2.2 Restore Sequence on Wake-Up Transition

A precondition to the restore sequence on wake-up transition is that the save-and-restore mechanism is enabled (the PRCM.PM_PWSTCTRL_USBHOST[4] SAVEANDRESTORE bit is set to 1). The sequence is initiated when the power domain switches from OFF or OSWR to ON power state.

1. Assert USBHOST domain reset (must override the functional stall conditions of the reset manager). The functional reset is released locally by RRB modules when the functional clocks are back.
2. Release USBHOST domain reset.
3. The PRCM activates the USBHOST_SAR_CLK and starts the restore sequence.
4. When the restore sequence completes, USBHOST_SAR_FCLK is gated.
5. The power domain wake-up transition to ON power state completes.

4.9 PRCM Interrupts

Table 4-78 lists the interrupts from the PRCM to the MPU and the IVA2.

Table 4-78. Interrupt Descriptions

Interrupt Name	Mapping	Description
PRCM_MPU_IRQ	M_IRQ_11	To MPU interrupt controller (MPU INTC)
PRCM_IVA_IRQ	IVA2_IRQ[12]	To IVA2.2 wake-up controller (IVA2.2 WUGEN)

Table 4-79 and Table 4-80 summarize the event flags (in [PRM_IRQSTATUS_MPU](#) and [PRM_IRQSTATUS_IVA2](#) registers) and mask (in [PRM_IRQENABLE_MPU](#) and [PRM_IRQENABLE_IVA2](#) registers) related to the events generating PRCM interrupts to the MPU and the IVA2.

Table 4-79. MPU Interrupt Event Descriptions

Event Flag	Event Mask	Map to	Automatic MPU Domain Wake-Up Event	Description
PRM_IRQSTATUS_MPU[0] WKUP_ST	PRM_IRQENABLE_MPU[0] WKUP_EN	PRCM_MPU_IRQ	No	MPU peripheral group wakeup

PRM_IRQSTATUS_MPU[13] VP1_NOSMPSACK_ST	PRM_IRQENABLE_MPU[13] VP1_NOSMPSACK_EN	PRCM_MPU_IRQ	No	Voltage processor 1 time-out occurred while waiting for the power IC device acknowledge.

Table 4-79. MPU Interrupt Event Descriptions (continued)

Event Flag	Event Mask	Map to	Automatic MPU Domain Wake-Up Event	Description
PRM_IRQSTATUS_MPU[14] VP1_EQVALUE_ST	PRM_IRQENABLE_MPU[14] VP1_EQVALUE_EN	PRCM_MPU_IRQ	No	Voltage processor 1 new voltage is the same as the current voltage.
PRM_IRQSTATUS_MPU[15] VP1_TRANXDONE_ST	PRM_IRQENABLE_MPU[15] VP1_TRANXDONE_EN	PRCM_MPU_IRQ	No	Voltage processor 1 transaction is complete.
PRM_IRQSTATUS_MPU[16] VP2_OPPCHANGEDONE_ST	PRM_IRQENABLE_MPU[16] VP2_OPPCHANGEDONE_EN	PRCM_MPU_IRQ	No	Voltage processor 2 OPP Change Done event.
PRM_IRQSTATUS_MPU[17] VP2_MINVDD_ST	PRM_IRQENABLE_MPU[17] VP2_MINVDD_EN	PRCM_MPU_IRQ	No	Voltage processor 2 new voltage reached the minimum voltage value allowed.
PRM_IRQSTATUS_MPU[18] VP2_MAXVDD_ST	PRM_IRQENABLE_MPU[18] VP2_MAXVDD_EN	PRCM_MPU_IRQ	No	Voltage processor 2 new voltage reached the maximum voltage value allowed.
PRM_IRQSTATUS_MPU[19] VP2_NOSMPSACK_ST	PRM_IRQENABLE_MPU[19] VP2_NOSMPSACK_EN	PRCM_MPU_IRQ	No	Voltage processor 2 time-out occurred while waiting for the power IC device acknowledge.
PRM_IRQSTATUS_MPU[20] VP2_EQVALUE_ST	PRM_IRQENABLE_MPU[20] VP2_EQVALUE_EN	PRCM_MPU_IRQ	No	Voltage processor 2 new voltage is the same as the current voltage.
PRM_IRQSTATUS_MPU[21] VP2_TRANXDONE_ST	PRM_IRQENABLE_MPU[21] VP2_TRANXDONE_EN	PRCM_MPU_IRQ	No	Voltage processor 2 transaction is done.
PRM_IRQSTATUS_MPU[22] VC_SAERR_ST	PRM_IRQENABLE_MPU[22] VC_SAERR_EN	PRCM_MPU_IRQ	Yes	Slave address in an I ² C frame sent by the voltage controller not acknowledged by the power IC device
PRM_IRQSTATUS_MPU[23] VC_RAERR_ST	PRM_IRQENABLE_MPU[23] VC_RAERR_EN	PRCM_MPU_IRQ	Yes	Register address in an I ² C frame sent by the voltage controller not acknowledged by the power IC device
PRM_IRQSTATUS_MPU[24] VC_TIMEOUTERR_ST	PRM_IRQENABLE_MPU[24] VC_TIMEOUTERR_EN	PRCM_MPU_IRQ	Yes	Last byte of an I ² C frame issued from the bypass port or from the voltage manager FSM ports sent by the voltage controller not acknowledged by the power IC device
PRM_IRQSTATUS_MPU[25] SND_PERIPH_DPLL_RECAL_ST	PRM_IRQENABLE_MPU[25] SND_PERIPH_DPLL_RECAL_EN	PRCM_MPU_IRQ	Yes	DPLL5 recalibration event

Table 4-80. IVA2 Interrupt Event Descriptions

Event Flag	Event Mask	Map to	IVA2 Domain Wake-Up Event	Description
PRM_IRQSTATUS_IVA2[0] WKUP_ST	PRM_IRQENABLE_IVA2[0] WKUP_EN	PRCM_IVA_IRQ	No	IVA2 peripheral group wakeup
PRM_IRQSTATUS_IVA2[1] FORCEWKUP_ST	PRM_IRQENABLE_IVA2[1] FORCEWKUP_EN	PRCM_IVA_IRQ	No	IVA2 power domain forced wake-up transition completion
PRM_IRQSTATUS_IVA2[2] IVA2_DPLL_ST	PRM_IRQENABLE_IVA2[2] IVA2_DPLL_RECAL_EN	PRCM_IVA_IRQ	Yes	DPLL2 recalibration required

Note: The software must first read the event flag to know the interrupt cause, and then write 1 to it to clear the flag.

4.10 PRCM Voltage Management Functional Description

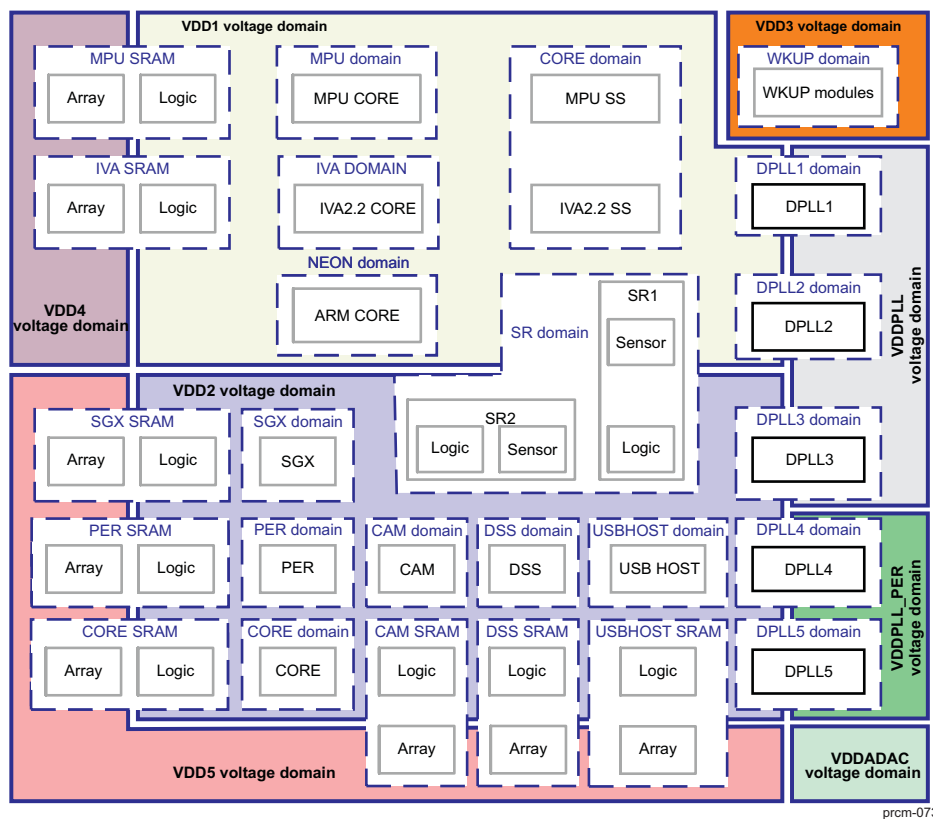

This section describes the voltage domains and voltage control architecture. It also explains the interactions between the device and the external power IC.

Note: For more information regarding the device power pads connection, please refer to your device-specific data manual.

4.10.1 Overview

Figure 4-78 is an overview of the device voltage domains.

Figure 4-78. Overview of Device Voltage Domains

prcm-073

The device is split into voltage domains:

- Three voltage domains for the logic (VDD1, VDD2, and VDD3)
- Two voltage domains for memory (VDD4 and VDD5)
- Two voltage domains for PLLs and analog cells (VDDPLL and VDDPLL_PER)
- Voltage domain for the I/Os

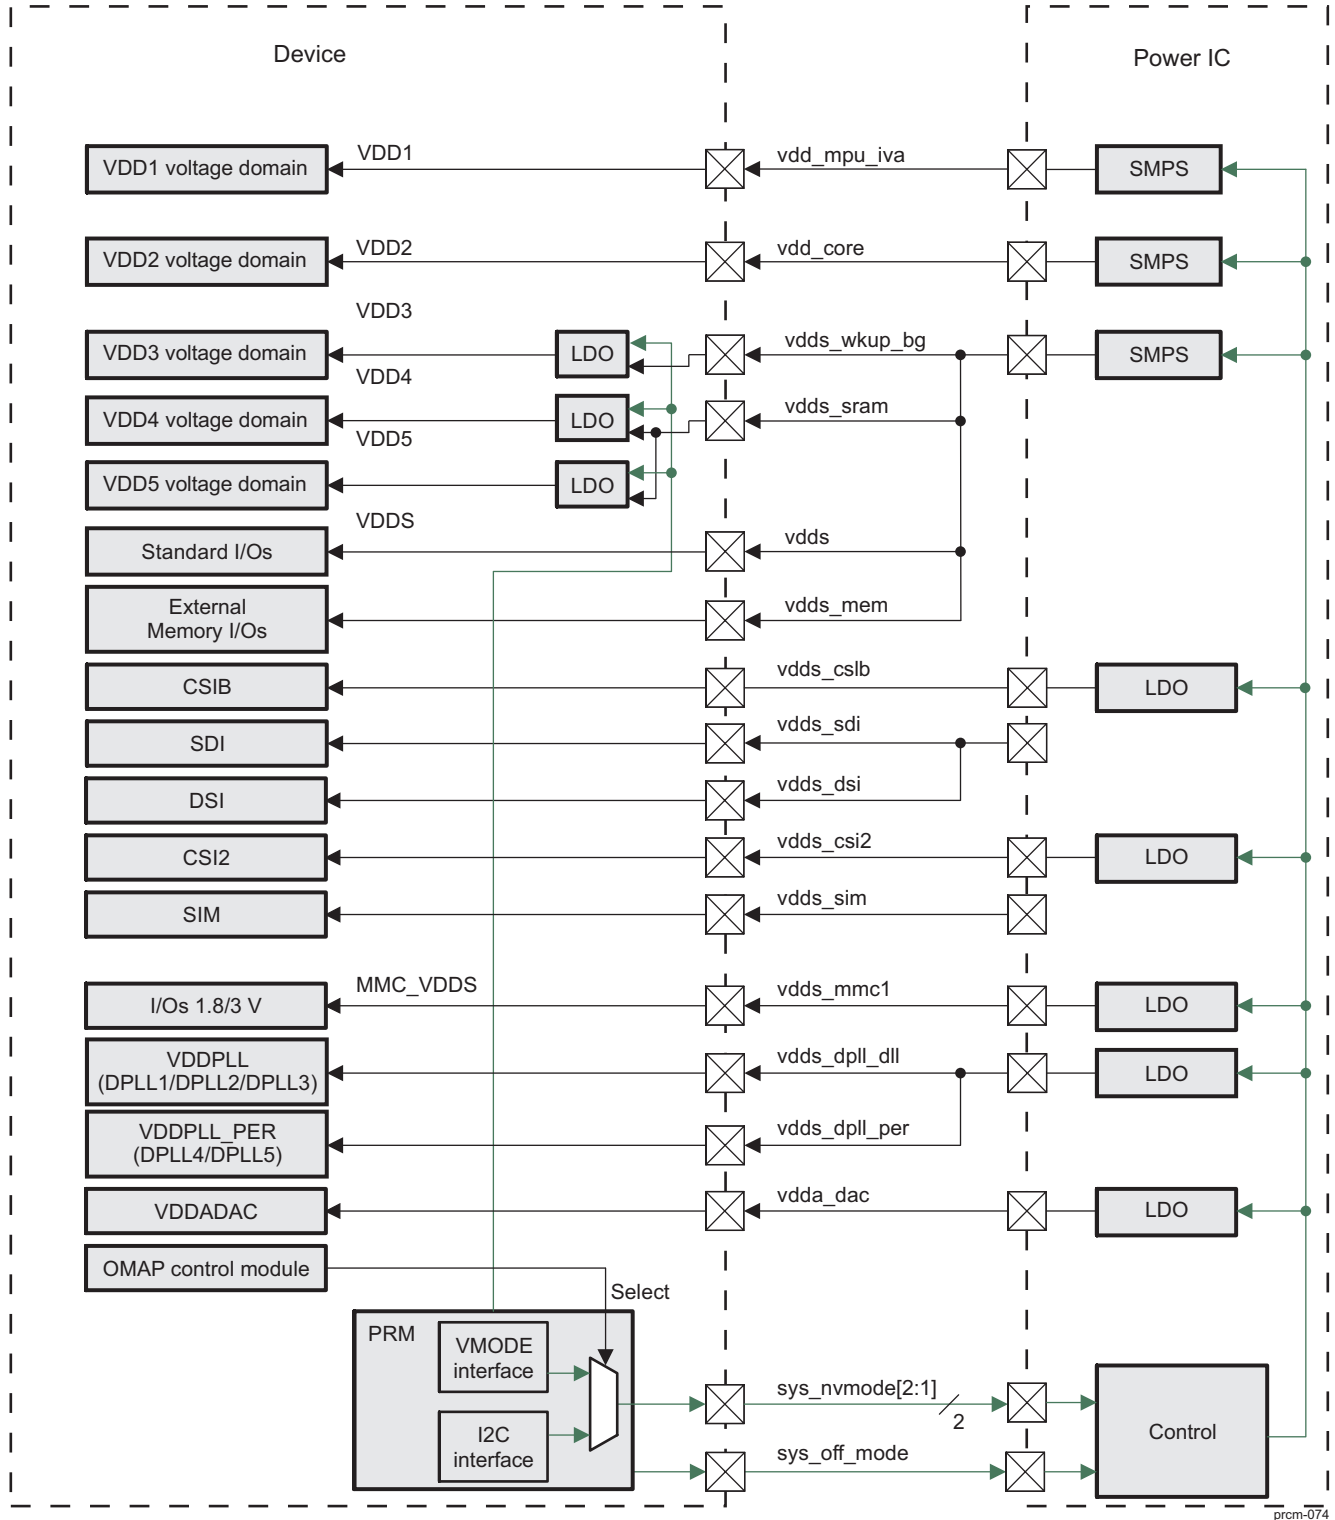

This partition of the voltage domains ensures independent voltage control of each voltage domain through dedicated SMPS or LDO. Functionally, however, voltage control of a voltage domain may depend on the voltage level of another voltage domain; for example, VDD1 voltage-level control may depend on the VDD2 voltage level. Figure 4-78 shows the voltage dependency between domains.

[Figure 4-79](#) is an overview of the device voltage sources and their controls. The PRM directly manages the following voltage sources:

- VDD1: Processor voltage
- VDD2: CORE voltage
- VDD3: Wake-up voltage
- VDD4: Processor SRAM voltage
- VDD5: CORE SRAM voltage

The remaining voltage sources (VDDS, VDDPLL, and MMC-VDDS) are either controlled directly by the external device or software-controlled through an I²C interface independent of the PRM. [Figure 4-79](#) is an overview of the PRCM voltage-control.

Figure 4-79. Overview of Device Voltage Distribution

prcm-074

Note: Memory I/Os (1.8 V) are not supplied with the other I/Os. They come directly from the power IC.

4.10.2 Voltage Domains

Table 4-81 summarizes, for each voltage domain, the voltage level corresponding to its OPP when its power domains are on and the voltage level when its power domains are in RETENTION or OFF power state. Please refer to your device-specific data manual for details.

Table 4-81. Voltage Domain Controls Summary

Voltage Domain (Power Rail)	Operating Point	Control	Supplied Modules
VDD1 (vdd_mpu_iva)	Off	HW and SW	MPU subsystem, IVA2.2 subsystem, digital part of DPLL1 and DPLL2, SmartReflex1
	Retention		
	OPP1		
	OPP2		
	OPP3		
	OPP4		
VDD2 (vdd_core)	Off	HW and SW	Most modules, interconnects, peripherals. SmartReflex2, digital part of DPLL3, DPLL4, and DPLL5
	Retention		
	OPP1		
	OPP2		
	OPP3		
VDD3 (vdds_wkup_bg)	Low-power mode	HW	WKUP, Bandgap, and EMU domains
	Normal mode		
	Emulation mode		
VDD4 (vdds_sram)	All memories off	HW	Processor memories
	All memories in retention		
	VDD1 is in OPP1, OPP2, or OPP3		
	VDD1 in OPP4 or OPP5		
VDD5 (vdds_sram)	Off	HW	CORE, SGX, CAM, DSS, PER, USBHOST and EMU memories
	Retention		
	VDD2 is in OPP1, OPP2, or OPP3		
VDDS (vdds)	Always-on	None	I/Os
VDDADAC (vdda_dac)	Software-driven only ⁽¹⁾	SW	Video DAC
VDDPLL (vdds_dpll_dll)	Always-on ⁽¹⁾	None	Analog part of DPLL1, DPLL2, and DPLL3
VDDPLL_PER (vdds_dpll_per)	Always-on ⁽¹⁾	None	Analog part of DPLL4 and DPLL5
External Memory I/Os (vdss_mem)	Always-on	None	External Memory I/Os
SIM (vdds_sim)	Always-on ⁽¹⁾	None	SIM
MMC_VDDS (vdds_mmc1)	Always-on ⁽¹⁾	None	MMC1

⁽¹⁾ Identifies the voltage domains. Can be switched to 0.0 V when the interface/ module is not in use.

Notes:

- Logic retention (RFFs and some memory registers OSWR) is implemented only for parts of the CORE power domain. Full device logic retention is also feasible by keeping all power domains on and lowering VDD1 and VDD2 to minimum OPP (CSWR). This consumes more power than the first option, but allows for a fast restart.
- When the user programs all memories in retention, VDD4 and VDD5 are automatically set to RETENTION voltage level by the PRM, which allows the memory arrays to be retained.

4.10.3 Voltage Domains Dependencies

Table 4-82 and Table 4-83 summarize the hardware conditions and the software setting required to switch the VDD1 and VDD2 to their respective low-power states.

Table 4-82. VDD1 Voltage Domain Dependencies

VDD1 Domain State	Power Domains State	DPLL State	sys_clk	Software Control	VDD2	VDD3	VDD4	VDD5
SLEEP	Software controlled power domains of VDD1 are in INACTIVE, RETENTION or OFF state.	DPLL1 and DPLL2 are in Stop mode	n/a	AUTO_SLEE P = 1	ON or SLEEP	ON or Overdriven	ON or RETENTION	ON or RETENTION
RETENTION	Software controlled power domains of VDD1 are in RETENTION or OFF state and of VDD2 are in INACTIVE, RETENTION or OFF state	DPLL1 and DPLL2 are in Stop mode	n/a	AUTO_RET = 1	ON or RETENTION	ON or Overdriven	RETENTION	ON or RETENTION
OFF	Software controllable power domains of VDD1 and VDD2 are in OFF state.	All DPLLs are in Stop mode	not required anymore	AUTO_OFF = 1	OFF	SLEEP	OFF	OFF

Table 4-83. VDD2 Voltage Domain Dependencies

VDD2 Domain State	Power Domains State	DPLL State	sys_clk	Software Control	VDD1	VDD3	VDD4	VDD5
SLEEP	Software controlled power domains of VDD1 and VDD2 are in INACTIVE, RETENTION or OFF state	All DPLLs are in Stop mode	not required anymore	AUTO_SLEE P = 1	SLEEP	ON or Overdriven	ON or RETENTION	ON or RETENTION

Table 4-83. VDD2 Voltage Domain Dependencies (continued)

VDD2 Domain State	Power Domains State	DPLL State	sys_clk	Software Control	VDD1	VDD3	VDD4	VDD5
RETENTION	Software controlled power domains of VDD1 are in INACTIVE, RETENTION or OFF state and of VDD2 are in RETENTION or OFF state	All DPLLs are in Stop mode	not required anymore	AUTO_RET = 1	ON or RETENTION	ON or Overdriven	ON or RETENTION	RETENTION
OFF	Software controllable power domains of VDD1 and VDD2 are in OFF state.	All DPLLs are in Stop mode	not required anymore	AUTO_OFF = 1	OFF	SLEEP	OFF	OFF

Notes:

- In voltage domain SLEEP state the current load decreases because of reduced activity level, however the voltage level remains that of ON state.
- In voltage domain overdriven state the domain voltage is raised above the nominal operating voltage to boost performance, however power consumption increases also.
- The AUTO_SLEEP, AUTO_RET and AUTO_OFF, in the Software Control column, refers to the [PRM_VOLTCTRL\[0\]](#) AUTO_SLEEP, [PRM_VOLTCTRL\[1\]](#) AUTO_RET and [PRM_VOLTCTRL\[2\]](#) AUTO_OFF bits.

Table 4-84. Remaining Voltage Domain Dependencies

Voltage	Condition
VDDS	No dependency with other device voltages
External Memory I/Os	
VDDADAC	
VDDPLL	
VDDPLL_PER	
SIM	
MMC_VDDS	

4.10.4 Voltage-Control Architecture

The PRM is split over several blocks that manage the different voltage sources.

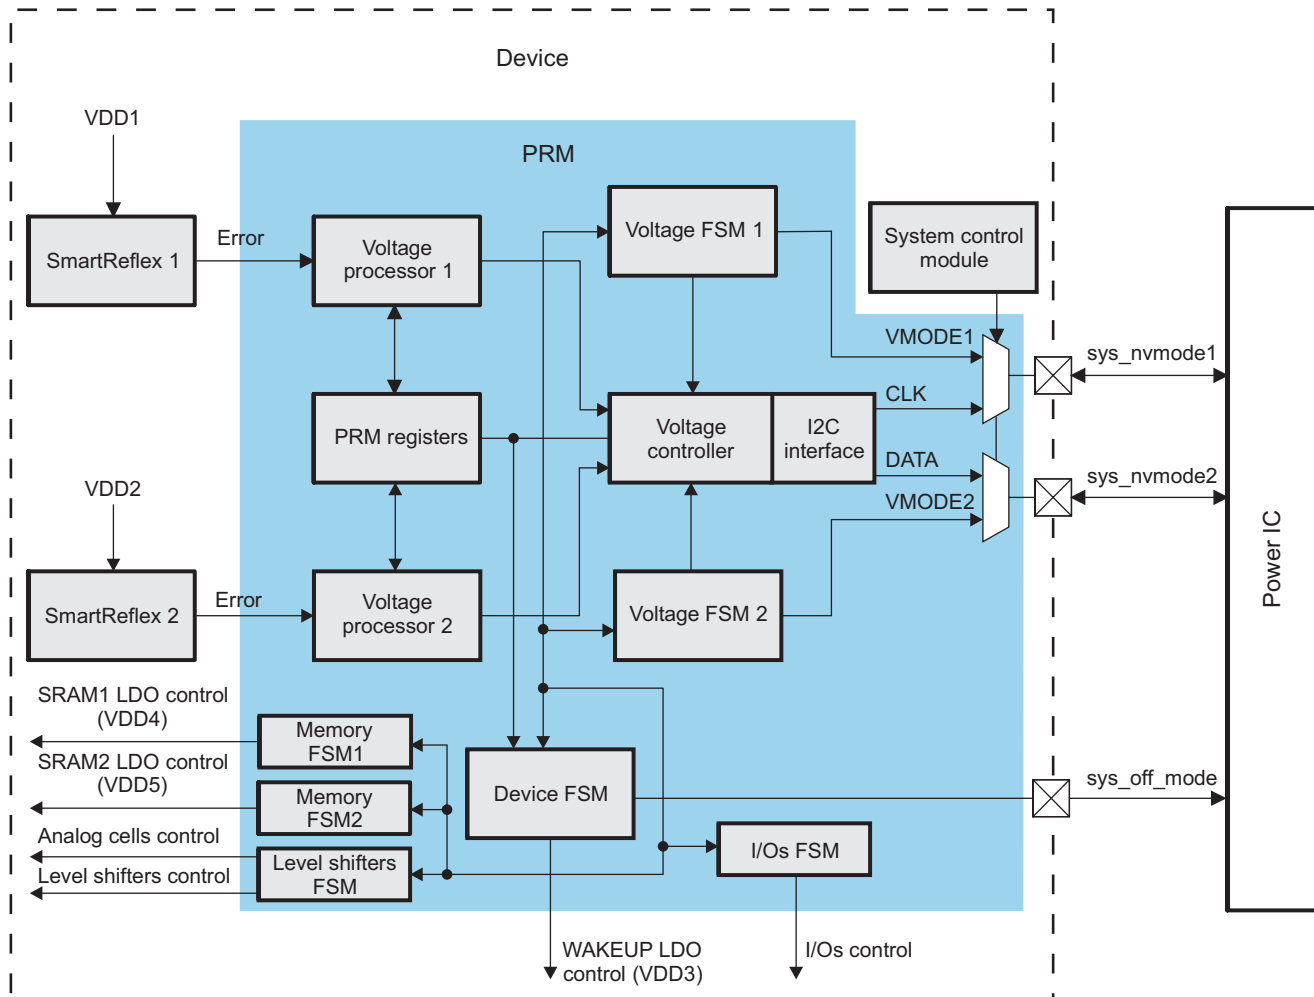

- VDD1 and VDD2 voltages are managed by multiple control sources:
 - Automatic voltage adjustment (for optimal performance at an OPP) and software-requested voltage scaling (for OPP change) are managed by two SmartReflex voltage control modules connected to two voltage processor modules. They generate voltage-adjustment commands based on the desired and current performance levels of the device. These commands are sent to the external power IC through a voltage controller and a dedicated I²C interface.
 - Direct software control of VDD1 and VDD2 is also possible by writing to the registers of the voltage controller, which then sends the voltage commands to the power IC through the dedicated I²C interface.

- Two voltage finite state-machines (FSM 1 and FSM 2) can also manage the VDD1 and VDD2 voltages either by sending commands to the voltage controller (I²C mode) or by sending the sys_nvmode1 and sys_nvmode2 control signals (direct-control mode). The FSMs control voltage-level switching, based on the power state of the device.
- The FSMs in the PRM also control SRAM and wake-up LDOs, sleep mode for analog cells, and level shifters.
- A device FSM sequences the memory, wakeup, voltage, and I/O FSMs during the device off, sleep, and wake-up transitions.

Note: The SmartReflex module allows dynamic voltage adjustments around an OPP voltage level to ensure target performance. It also allows switching from one OPP to another. However, it does not control voltage switching to RETENTION or OFF as the power domains or the device change power states. This is handled by the voltage FSMs.

Figure 4-80 shows the architecture for PRM voltage control.

Figure 4-80. PRM Voltage Control Architecture

* The green region in the figure represents the boundary of the PRM

108-075

CAUTION

It is highly recommended to use the embedded dedicated I2C4 instead of VMODE, which is a legacy mode. The I2C4 provides greater flexibility and higher efficiency in terms of power optimization.

4.10.5 VDD1 and VDD2 Control

The main power-supply sources, VDD1 and VDD2, can be controlled using mutually exclusive modes specified in the SCM:

- Direct control With VMODE Signals or I2C Interface
- Dedicated SmartReflex I²C control

Because both control modes are multiplexed on the same device pins, direct control signals can be used alternately with I²C control signals. The muxes are managed by the SCM.

4.10.5.1 Direct Control with VMODE Signals

In direct-control mode, the VDD1 and VDD2 voltage sources can be controlled by the voltage FSMs in the PRM to trigger a voltage transition based on the power domain states. The voltage FSMs use a VMODE interface to send voltage commands through the sys_nvmode1 and sys_nvmode2 pins of the device to the external power IC. The simple voltage-control commands of the VMODE interface can be used to set two voltage values (VDD1 and VDD2) per voltage domain .

The sys_nvmode[1,2] signals request new voltage levels to the external SMPS. The polarity of the sys_nvmode[1,2] signals from the PRM is configured by the PRCM.PRM_POLCTRL[0] EXTVOL_POL bit, which is active-low by default. When the signal goes low, a lower voltage is supplied, and when it goes high, a higher voltage is supplied.

The VMODE voltage control is enabled by setting the PRM.PRM_VOLTCTRL[4] SEL_VMODE bit, and is triggered when the device switches between low-power (retention or off) mode and normal (on) mode.

Figure 4-81 is an example of a VDD2 voltage transition from an operational voltage at 1.15 V (OPP3) to the lowest functional voltage of the device (0.9 V). In this example, the PRCM is programmed to automatically lower sys_nvmode2 when the device enters sleep mode. The power IC is programmed to ramp the VDD2 voltage down to 0.9 V when sys_nvmode2 is de-asserted and to ramp up the voltage to 1.15 V when sys_nvmode2 is asserted. The PRCM must also wait for the VDD2 regulator to stabilize when sys_nvmode2 is de-asserted and asserted. This stabilization time is programmable by software using the PRCM.PRM_VOLTSETUP1 register.

Figure 4-81. Voltage Transition Controlled by sys_nvmode2

prcm-076

Internally, the PRM manipulates two logical voltage levels (L0 and L1) for each sys_nvmode[1,2] signal. One level is set when all the power domains in the voltage domain are in retention or off mode, while the other is set when a power domain is on. The power IC must be configured to switch to low voltage when the associated sys_nvmode[1,2] signal is received, and vice versa.

For example, if L0 is the lower voltage and an active-low polarity (default setting) on the sys_nvmode[1,2] signal:

- L0 logical level sys_nvmode[1,2] = 1 VDD = 1.15 V
- L1 logical level sys_nvmode[1,2] = 0 VDD = 0.9 V

The polarity of the logical voltage-level signal from the PRM can be controlled by the PRCM.PRM_POLCTRL[0] EXTVOL_POL bit. It is active-low by default (L0 = 1, L1 = 0).

4.10.5.2 Direct Voltage Control with I²C Interface

PRM can send VDD1 and VDD2 sleep commands to the power IC via the dedicated I2C. This allows the power IC to activate sleep mode (the voltage regulator switches in sleep mode, where voltage is maintained but only small load is supported). This allows external Power IC reducing its power consumption as well.

4.10.5.3 Voltage Controller and Dedicated SmartReflex I²C Interface

The dedicated I²C voltage control mode is dedicated to SmartReflex technology. The central modules for the I²C control mode are the voltage controller and the I²C interface. The voltage controller receives voltage control commands from five input ports:

- Voltage processor 1 and 2 ports: The voltage processors send commands to the voltage controller depending on the SmartReflex module calculations (during device activity).
- Voltage FSM 1 and 2 ports: The voltage FSMs send commands to the voltage controller when the device enters RETENTION or OFF power state, and also when the device wakes up.
- PRM register port: The PRM registers give direct software control over the voltage levels of the VDD1 and VDD2 voltage domains.

An arbitration scheme in the voltage controller manages concurrent requests on multiple ports.

Externally, the voltage controller interfaces to a power IC through a dedicated I²C interface (I2C4). To reduce the latency of voltage changes, the voltage controller is configurable to run in HS I²C mode.

Each internal port has a handshake to indicate when the I²C frame that results from the request on that port is acknowledged by the external power IC.

4.10.5.4 SmartReflex Voltage Control

As explained previously (see [Section 4.1.2.2, SmartReflex Adaptive Voltage Control](#)), SmartReflex technology uses adaptive power control to reduce active power consumption by the device. SmartReflex voltage control in the device is based on the dedicated SmartReflex modules and the voltage processors, in addition to the voltage controller and I²C interface, which are shared with the voltage FSMs and voltage control registers.

The SmartReflex modules allow a continuous real-time voltage supply and device performance monitoring to do the following:

- Minimize the supply voltage to reduce the device power consumption.
- Maintain the desired device performance (by dynamically adjusting the device voltage) as the temperature of the device varies.

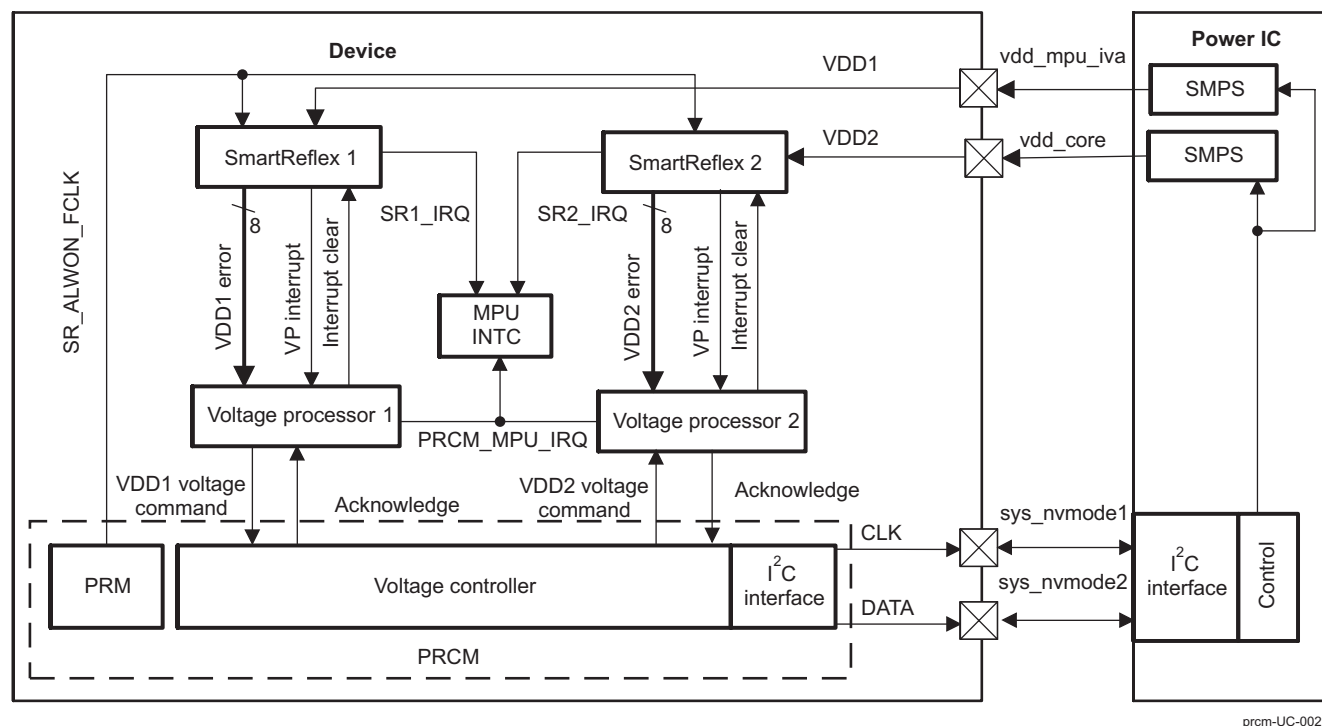

Within the device, the SmartReflex modules can be used to stabilize performance at a given OPP or for the DVFS (that is, switching from one OPP to another).

Because the SmartReflex modules and the voltage processors are dedicated to SmartReflex voltage control, they are described together in this section.

4.10.5.4.1 SmartReflex in the Device

Figure 4-82 shows the SmartReflex integration.

Figure 4-82. SmartReflex Integration

SmartReflex voltage control in the device is implemented for simultaneous control of two independent voltage sources. One SmartReflex module controls the VDD1 voltage, while the second one is dedicated to VDD2 control. Each SmartReflex module is connected to a voltage processor. Voltage commands from both voltage processors are passed to a voltage control, which sends them through a dedicated I²C master interface to the power IC.

4.10.6 Analog Cells, LDOs, and Level Shifter Controls

In addition to the VDD1 and VDD2 voltage controls, the PRM handles the following operations automatically, based on hardware conditions, without any software control:

- Reduces SRAM LDOs voltage when all memories are in retention
- Reduces wake-up LDO voltage when the device enters off mode (wake-up leakage reduction)
- Increases wake-up LDO voltage when emulation trace is active
- Actively isolates level shifters during VDD1 and VDD2 removal
- Activates sleep mode in all analog cells when the device enters off mode

4.10.6.1 SRAM Voltage Control

The two embedded SRAM LDOs supply regulated voltage (VDD4 or VDD5) to memory banks. The processor memory LDO (VDD4) has three reference voltages, while the CORE memory LDO (VDD5) supports two:

- 1.2 V is the normal voltage reference, used for processors OPP1, OPP2, and OPP3.
- Tracking between 1.2 V and 1.35 V: The processor SRAM LDO (VDD4) tracks and follows VDD1 voltage when it exceeds OPP3 (1.2 V) nominal voltage. VDD1 (up to 1.35 V) is the overdrive voltage reference when processors operate at OPP4 and OPP5. This option is not supported by the LDO (VDD5) of the CORE memory.
- 1.0 V is set when all memory banks belonging to the LDO are in RETENTION state. This allows

reducing the memory arrays to 0.6 V to minimize leakage.

When not used (all memories are off), the LDO is shut down. These modes are managed automatically by hardware (PRM).

4.10.6.2 Wake-Up and Emulation Voltage Control

The embedded wake-up LDO (VDD3) supplies both WKUP and EMU power domains. It is permanently active and feeds the WKUP power domain continuously. An embedded switch allows the PRM to control power to the EMU power domain. This switch is closed on a software request command when a debug session starts, or automatically on JTAG plug detection.

This LDO has three reference voltages:

- 1.2 V is the normal voltage reference, used in device active mode.
- 1.35 V is the overdrive voltage reference used when emulation is activated and MPU emulation trace is required.
- 1.0 V is set when the device is in low-power (off) mode, to minimize leakage.

These modes are managed automatically by hardware.

4.11 PRCM Off-Mode Management

4.11.1 Overview

The CORE power domain can be switched from ON to OFF or RETENTION state. When the CORE power domain is INACTIVE, the clock manager does not generate an interface clock, and device interconnects are inactive; therefore, the device is effectively in off mode. In RETENTION state, however, the logic in the CORE domain is retained, and the device wake-up latency is small compared to the latency when the CORE power domain is in OFF state. In waking from the CORE domain OFF state, the CORE logic configuration must be loaded from a scratchpad memory in the WKUP power domain.

Note: Although some modules in the device can be kept active while the CORE power domain is OFF or in RETENTION, this is not recommended.

When the device is put in off mode (the CORE power domain is in RETENTION or OFF state), the device voltage domains can be switched off to minimize leakage currents. However, reactivity to wake-up events must be ensured.

The device supports a unique off-mode management scheme that allows deactivation of all modules, isolation of their outputs, and configuration of a dedicated off mode on the I/O pads of the device, to listen to wake-up events. A wake-up event on any I/O pad is detected by the PRM (in WKUP always-on power domain), which can then wake up the device.

4.11.2 Device Off-Mode Configuration

Any I/O pad of the device can be configured to generate a wake-up event when the device is in off mode. The off-mode scheme is based on the following components of the device:

- I/O pads
- SCM

Figure 4-83 is an overview of the I/O pad off-mode scheme. In this mode, the I/O pads of the device form a daisy chain. The I/O pad logic at the two ends of the chain is connected to the PRM.

When a wake-up event (WUEVT) occurs on an enabled I/O pad in the chain, the event is propagated through the chain to the PRM. Multiple I/O pads can receive a wake-up event simultaneously; however, the PRM receives only the OR output for all the enabled I/O pads. When the device wakes up, the MPU can determine all sources of the current wake-up event logged into the corresponding CONTROL.CONTROL_PADCONF_<IOPad>[15] WAKEUPEVENT0 or CONTROL.CONTROL_PADCONF_<IOPad> [31] WAKEUPEVENT1 bits in the SCM.

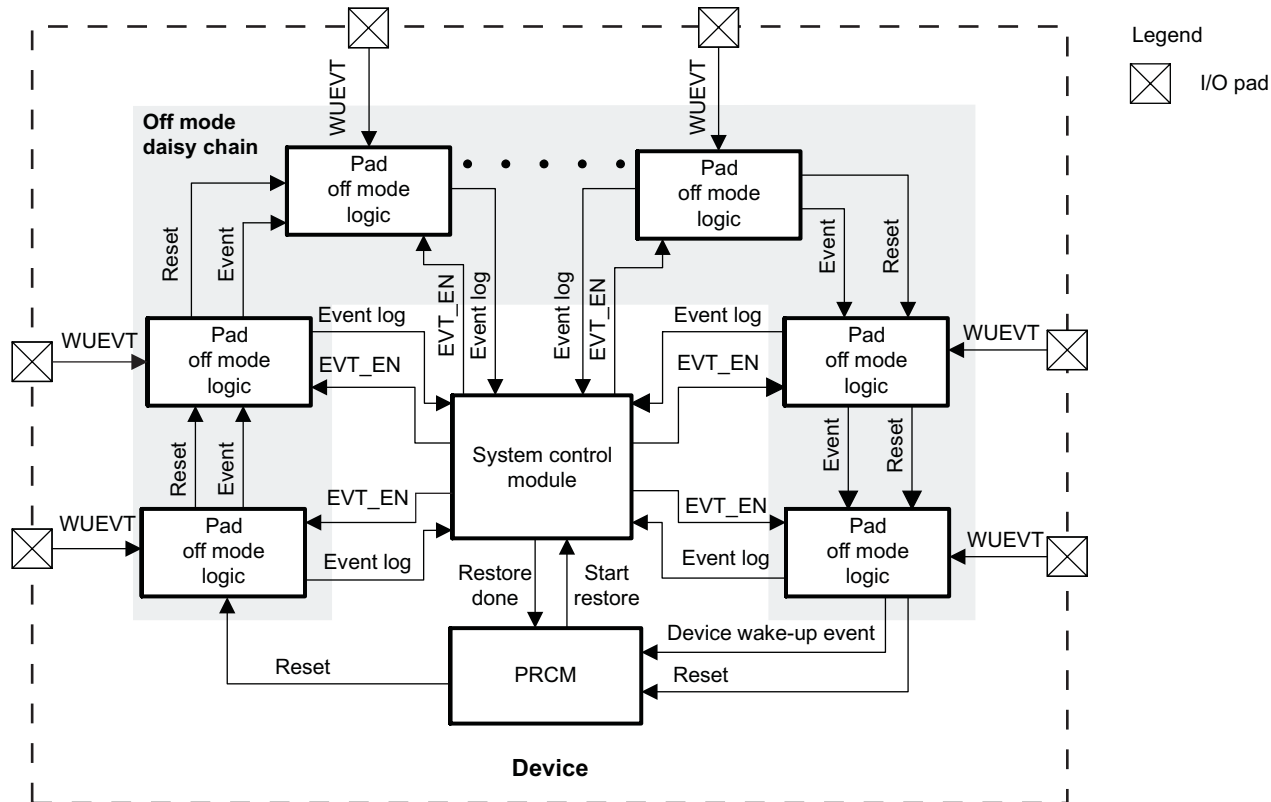

The I/O pad wake-up scheme must be enabled globally by setting the [PM_WKEN_WKUP](#)[8] EN_IO bit. The wake-up event from each I/O pad of the device can be individually enabled/disabled (EVT_EN signal) by writing to the CONTROL.CONTROL_PADCONF_<IOPad>[14] WAKEUPENABLE0 or CONTROL.CONTROL_PADCONF_<IOPad> [30] WAKEUPENABLE1 bits in the SCM.

For information about the SCM, see the *System Control Module* chapter.

Note: As explained previously (see [Section 4.8, Idle and Wake-Up Management](#)), module-specific wake-up events other than the I/O pad wake-up scheme can wake up the device from off mode. For example, the GPIO pads in the WKUP power domain can also wake up the device.

Note: For the wake-up features of the GPIO pads, see Chapter 25, *General-Purpose Interface*.

Figure 4-83. Device Off-Mode Control Overview

prcm-077

4.11.3 CORE Power Domain OFF-Mode Sequences

The off-mode I/O pad configuration can be activated to detect wake-up events when the CORE power domain is switched to RETENTION or OFF state. The OFF state sequences for the CORE power domain include the sequence for going from ON state to RETENTION or OFF power state (while enabling the off-mode I/O pad configuration), and then switching back to the ON power state (while disabling the off-mode I/O pad configuration) on a wake-up event.

4.11.3.1 Sleep Sequences (Transition From ON to RETENTION/OFF)

When the CORE power domain is in RETENTION state, the logic is switched off, its context is saved by the RFFs in the modules, and the memory blocks are retained. In OFF state, however, the logic and memories are switched off, and the RFFs are not saved.

Note: If the PER power domain is kept ON, while CORE power domain is in RETENTION state, all I/O wake-up enable (EVT_EN signals) signals to the I/O pads related to the PER power domain inputs must be disabled (by clearing the CONTROL.CONTROL_PADCONF_<IOpad>[14] WAKEUPENABLE bit in the SCM). In that case, wake-up events are generated by the PER domain and not through the daisy chain.

For information about the SCM, see the *System Control Module* chapter.

The following sequence is used to go from ON to RETENTION or OFF state:

1. The software sets the PRCM.PM_WKEN_WKUP[8] EN_IO bit to enable the I/O pad wake-up scheme.
2. The MPU initiates the sleep sequence. When all conditions are met, the CORE power domain clocks are shut down. At this stage, most of the pads are inactive, but some, such as the PER and DSS power domains, can stay active.

3. The PRM initializes and resets the I/O wake-up detection scheme and saves all RFFs. Its CORE power domain output is isolated from the I/O pads.
4. The PRM switches the CORE power domain to retention/off power state. I/O configuration is saved on wake up power domain registers, see the *Save-and-Restore Mechanism* section of the *System Control Module* chapter for more information.
5. The PRM waits for a wake-up event from the daisy chain. Other possible wake-up sources can be a wake-up event from a module in the wake-up power domain or from a global warm reset.

Note: When the CORE power domain is in RETENTION state, VDD2 voltage must either be at RETENTION or ON voltage level to maintain stable CORE power domain output values to the I/Os.

4.11.3.2 Wake-Up Sequences (Transition from RETENTION/OFF to ON)

The PRM detects a wake-up event from the daisy chain. Several wake-up events can occur simultaneously, but PRM only sees the ORing of them. Depending on whether the CORE power domain is in RETENTION or OFF state, the following sequence is followed to wake up the CORE and MPU power domains:

1. When the CORE power domain wakes up from OFF/Retention power state, reset is asserted for both the MPU and the CORE power domains.
2. Both the MPU and the CORE power domains are switched to ON power state.
3. Domain clocks of both the MPU and the CORE power domains are restarted.
4.
 - a. If the CORE power domain was in the OFF power state, its reset is released before the MPU power domain. This is done so that the SCM can restore the context and I/O configuration.
 - a. Hardware restores the IO pad configuration and some configuration registers of the control module. This configuration has been saved in the scratchpad memory (by the Control Module Save procedure initiated by software control prior to the transition to OFF power state).
 - b. PRCM switches the I/O pads configuration on the normal restored configuration (The I/O pad isolation is released).
 - c. The reset is released for MPU power domain.
 - b. If the CORE power domain is in the Retention power state, the reset is released for both the MPU and the CORE power domains at the same time.
5. When the MPU boots, the software accesses the SCM to read the wake-up event source (identified by the CONTROL.CONTROL_PADCONF_< IOPad>[15] WAKEUPEVENT bits in the SCM corresponding to all enabled pads).
6. The software disables the wake-up daisy chain by clearing the PRCM.PM_WKEN_WKUP[8] EN_IO bit.

Note: A daisy-chain wake-up event always causes the MPU to restart and boot. Other independent wake-up events activated in off mode (for example, a GPIO wake-up event) always cause the CORE power domain to be activated. The MPU is wakened if a wake-up dependency has been set by the user.

4.11.4 Device Off-Mode Sequences

Device off-mode sequencing requires preliminary settings that can be done during device initialization. The following actions are performed once and remain valid for all device off/on transitions:

1. Configure valid off and active pad configuration for each pad by programming the SCM CONTROL.CONTROL_PADCONF_< IOPad> register.
2. Save the active pad configuration by asserting the CONTROL.CONTROL_PADCONF_OFF[1] STARTSAVE bit in the SCM. This process can be repeated each time the active pad configuration of the device is changed.
3. Set the SCM to smart-idle mode by configuring the CONTROL. CONTROL_SYSCONFIG[4:3] IDLEMODE bit field. This ensures that the module clocks remain active during the configuration save

procedure.

4. Disable all the modules running on system clock or switch them on the 32 kHz clock when required.
5. Configure the voltage regulator setup times (the PRCM.PRM_VOLTSETUP1[15:0] SETUP_TIME1 and PRCM.PRM_VOLTSETUP1[31:16] SETUP_TIME2 bit fields).
6. Set sys_off_mode de-assertion time in the PRCM.PRM_VOLTOFFSET[15:0] OFFSET_TIME bit field.
7. Configure the system clock oscillator setup time in the PRCM.PRM_CLKSETUP[15:0] SETUP_TIME bit field.

For information about the SCM, see the *System Control Module* chapter.

4.11.4.1 Sleep Sequences

The sleep sequences exemplify the two types of device transitions from on to off mode:

- Device off-mode transition without using the OFF_MODE signal
- Device off-mode transition using only the OFF_MODE signal

4.11.4.1.1 Device Off-Mode Transition without Using the OFF_MODE Signal

Each time the device enters I/O-pad-off configuration mode, the following sequence must be performed:

1. Software sets the PRCM.PM_WKEN_WKUP[8] EN_IO bit to enable the I/O wake-up scheme.
2. The MPU initiates the sleep sequence. When all sleep conditions are met, all domain clocks are shut down. At this stage, all output pads are inactive and static.
3. The PRM configures the I/O daisy-chain for the wake-up detection scheme.
4. The CORE domain output is isolated.
When conditions for entering off mode are met, the PRM proceeds with the sequence.
5. It switches off all domains, including the CORE power domain, and then switches from active mode pad configuration to off mode pad configuration.
6. It isolates the pads before the removal of VDD1 and VDD2.
7. It shuts down all analog cells (DPLL, DLL).
8. It switches to OFF all the DPLL power domains and the SR power domain.
9. It sends the off command for VDD1 to the voltage controller (sys_nvmode1 is released).
10. It shuts down the SRAM LDOs.
11. The daisy chain is now ready to detect I/O pad wake-up events. At this point, VDD1 shuts down.
12. Upon an I²C transaction acknowledge, the PRM sends the off command for VDD2 to the voltage controller (sys_nvmode2 is released). At this point, VDD2 shuts down.
13. Upon an I²C transaction acknowledge, the PRM ramps down the wake-up LDO to 1 V.
14. It releases sys_clkreq and disables the system clock oscillator (if used).
15. It waits for a wake-up event from the daisy chain.

4.11.4.1.2 Device Off-Mode Transition Using Only the OFF_MODE Signal

Depending on the external power IC capability and the user setting, VDD1 and VDD2 voltage control may use the direct sys_off_mode signal and not send the commands through the I²C interface.

In that case, the initial sequence for device off-mode transition is the same as in [Section 4.11.4.1.1, Device Off-Mode Transition Without Using OFF_MODE Signal](#), up to Step 8. After this, the following steps are executed:

1. It shuts down the SRAM LDOs.
2. It asserts sys_off_mode. At this point, VDD1 and VDD2 are shut down.
3. It ramps down the wake-up LDO to 1 V.
4. It releases CLKREQ and disables the system clock oscillator (if used)
5. It waits for a wake-up event from the daisy chain.

4.11.4.2 Wake-Up Sequences

4.11.4.2.1 Device Wakeup from Off Mode without Using the OFF_MODE Signal

On detection of a wake-up event from the daisy chain, the PRM performs the following steps:

1. It enables the system clock oscillator and asserts sys_clkreq.
2. It waits for the oscillator set-up time.
3. It ramps up the wake-up LDO and waits for its stabilization (internal counter).
4. It sends the on command for VDD2 to the voltage controller (sys_nvmode2 is asserted). At this point, VDD2 ramps up (the reset is not yet asserted on VDD2 logic).
5. It waits for the VDD2 regulator setup time counter to expire.
6. It sends the on command for VDD1 to the voltage controller (sys_nvmode1 is asserted). At this point, VDD1 ramps up (the reset is not yet asserted on VDD1 logic).
7. It waits for the VDD1 regulator setup time counter to expire.
8. It restarts the memory LDOs.
9. It powers up all analog cells on the VDD2 domain and waits for the settling time of the LDO and analog cells (internal counter).
10. The following steps can occur in parallel:
 - The DPLL, CORE, and MPU power domains are powered up.
 - The reset on the eFuse controller, DPLL, CORE, SR, and MPU power domains is asserted.
11. When the CORE, MPU, DPLLs, and SR are on, the PRM releases the eFuse controller reset, and the eFuse scan starts.
12. When the scan completes, the DPLL resets are released. The DPLLs are in bypass and the clocks start flowing (DPLL1 and DPLL3).
13. When the CORE and MPU domains are on, the PRM releases their corresponding domain output isolations.
14. When the CORE power domain is on and DPLL3 is in bypass, the reset timer for the CORE power domain starts.
15. When the MPU power domain is on and DPLL1 is in bypass, the reset timer for the MPU power domain starts.
16. When the CORE reset time expires, the CORE domain reset is released.
17. When the CORE domain exits reset and the SCM context and I/O configuration are restored from ScratchPad, memory starts.
18. When the PRM receives the acknowledge from the SCM, it releases the MPU and CORE domain output isolations and the I/O isolation.
19. The PRM switches the I/O pad configuration from off mode configuration to active mode configuration.
20. When the MPU reset time expires and pad configuration returns to normal mode, the MPU domain reset is released.
21. When the MPU boots, the software accesses the control module to read the wake-up event source.
22. The software disables the I/O wake-up daisy chain by clearing the [PM_WKEN_WKUP\[8\]](#) EN_IO bit.

4.11.4.2.2 Device Wakeup from Off Mode Using Only the OFF_MODE Signal

Depending on the external power IC capability and the user setting, VDD1 and VDD2 voltage control use the direct sys_off_mode signal and do not send commands through the I²C interface.

In that case, the first part of the sequence in [Section 4.11.4.2.1](#) is as follows.

Upon detection of a wakeup from the daisy chain, the PRM performs the following steps:

1. It enables the system clock oscillator and asserts sys_clkreq.
2. It ramps up the wake-up LDO.
3. It releases sys_off_mode.
4. It waits for the system clock oscillator setup time.
5. It waits for VDD1 and VDD2 setup time. The two counts are started in parallel.

6. When both timers expire, the following steps happen in parallel:
 - Reset is asserted on the MPU and CORE power domains.
 - The MPU and CORE power domains are powered up.
 - The PRM restarts the CORE and processor memory LDOs.
 - The PRM powers up all analog cells in the VDD1 and VDD2 domains.

4.12 PRCM Basic Programming Model

The PRCM supports an extensive set of module-specific registers that allow programming control over numerous features of the clocks, resets, and power-management signals for each power domain of the device.

These registers are fully programmable and accessible by the MPU and the IVA2.2 subsystems.

Logically, the registers are grouped into five categories:

- Global
- Clock management
- Reset management
- Power management
- Voltage management

4.12.1 Global Registers

4.12.1.1 Revision Information Registers

- [CM_REVISION](#): Indicates the CM module revision code; it is read-only
- [PRM_REVISION](#): Indicates the PRM module revision code; it is read-only

4.12.1.2 PRCM Configuration Registers

- [CM_SYSCONFIG](#): Holds an AUTOIDLE bit to control the CM internal clock autogating feature
- [PRM_SYSCONFIG](#): Holds an AUTOIDLE bit to control the PRM internal clock autogating feature

4.12.1.3 Interrupt Configuration Registers

The PRM can interrupt the MPU and the IVA2.2 subsystems as a result of four events:

- PRM internal event (event generator, sleep transition, wake-up transition, voltage processors, voltage controller)
- Peripheral wake-up event for a peripheral with interrupt capability (GPTIMER[1..12], GPIO[1..6], McBSP[1..5], UART[1..3], HS USB OTG, I2C[1..3], McSPI[1..4], MMC[1,2], SR[1,2])
- Module/device-level event not associated with any interrupt (DPLL recalibration, I/O wakeup)

The PRM interrupt is enabled by programming the PRM_IRQENABLE_<processor_name> register; the interrupt status can be read from the PRM_IRQSTATUS_<processor_name> register.

The device has four processor interrupt registers:

- [PRM_IRQSTATUS_MPU](#)
- [PRM_IRQENABLE_MPU](#)
- [PRM_IRQSTATUS_IVA2](#)
- [PRM_IRQENABLE_IVA2](#)

4.12.1.3.1 MPU Interrupt Event Sources

The MPU interrupt registers correspond to the interrupt sources connected to the interrupt line mapped to the MPU interrupt controller.

Multiple events can activate this interrupt line:

- MPU peripheral group wake-up event
- Event-generator module end-of-on time and end-of-off time events
- Sleep or wake-up transition (SGX, USBHOST, IVA2, PER, DSS, CAM, NEON, EMU power domains)
- DPLL1/DPLL2/DPLL3/DPLL4/DPLL5 recalibration request
- I/O pad wake-up event
- Voltage processor 1 or 2 OPP Change Done event
- Voltage processor 1 or 2 new voltage reached the minimum voltage value allowed.
- Voltage processor 1 or 2 new voltage reached the maximum voltage value allowed.
- Voltage processor 1 or 2 time-out occurred while waiting for the power IC device acknowledge.
- Voltage processor 1 or 2 new voltage is the same as the current one.
- Voltage processor 1 or 2 transaction is done.
- Slave address in an I²C frame sent by the voltage controller not acknowledged by the power IC device
- Register address in an I²C frame sent by the voltage controller not acknowledged by the power IC device
- Last byte of an I²C frame issued from the bypass port or the voltage manager FSM ports sent by the voltage controller not acknowledged by the power IC device

The end-of-on time period and end-of-off time period events of the event generator module are sources of interrupts to the MPU processor (the corresponding bits in the [PRM_IRQENABLE_MPU](#) are set to 1). The end-of-OFF time period is the source of wake-up events on the MPU domain.

The MPU can force a sleep or wake-up transition on some domains (SGX, USBHOST, IVA2, PER, DSS, CAM, NEON, EMU). The PRM triggers the MPU interrupt when the domain enters a power state. The software must clear the CM_CLKSTCTRL_<domain_name> register only after getting the interrupt. If the software clears this bit before getting the interrupt, the interrupt never occurs, regardless of whether the transition occurs.

An interrupt for a peripheral with wake-up capability is enabled when the wake-up enable bit (PM_WKEN_<domain_name> register type) and group select bit (PM_<processor_name>GRPSEL_<domain_name> type of register) are set to 1.

The PRM triggers its interrupt line on the I/O daisy chain wake-up event. This wake-up event is enabled by setting the corresponding bit in the [PM_WKEN_WKUP](#) register to 1.

The PRM triggers the MPU interrupt as long as the DPLL recalibration flag is set and the corresponding interrupt enable bit in the PRM_IRQENABLE_<processor_name> register is set to 1. The recalibration flag is set by the DPLL and remains active if the DPLL is not reinitialized.

4.12.1.3.2 MPU Interrupt Registers

4.12.1.3.2.1 PRM_IRQENABLE_MPU (MPU Interrupt Enable Register)

The MPU interrupt enable register allows independent masking/unmasking of each MPU internal interrupt source.

Note: If the following interrupts are enabled and the MPU power domain is idled, then when the event occurs, the PRCM sets the interrupt that wakes up the power domain:

- DPLL1/DPLL2/DPLL3/DPLL4/DPLL5 recalibration event
 - Voltage controller errors
-

4.12.1.3.2.2 PRM_IRQSTATUS_MPU (MPU Interrupt Status Register)

The MPU interrupt status register provides the status of all PRCM internal events that can generate an MPU interrupt. Software must read this register to identify the interrupt cause, and then clear the pending interrupt by setting the corresponding bit to 1.

4.12.1.3.3 IVA2.2 Interrupt Event Sources

The IVA2.2 interrupt registers correspond to the interrupt sources connected to the interrupt line mapped to the IVA2.2 interrupt controller.

Three events can activate this interrupt line:

- An IVA2.2 peripheral group wake-up event
- A force wake-up transition completion (IVA2 domain)
- A required IVA2 DPLL recalibration

The PRM also interrupts IVA2.2 if the corresponding bit in the [PM_IVA2GRPSEL_WKUP](#) register is set to 1.

The PRM triggers the interrupt line dedicated to the IVA2 processor when the MPU performs a force wake-up transition on the IVA2 domain. This interrupt is triggered under the same conditions as that of the MPU.

The PRM triggers an IVA2.2 interrupt if the DPLL recalibration flag is set and the corresponding interrupt enable bit in the [PRM_IRQENABLE_<processor_name>](#) register is set to 1. The recalibration flag is set by the DPLL and remains active if the DPLL is not reinitialized.

4.12.1.3.4 IVA2 Interrupt Registers

4.12.1.3.4.1 PRM_IRQENABLE_IVA2 (IVA2.2 Interrupt Enable Register)

The IVA2.2 interrupt enable register allows independent masking/unmasking of each of the three internal interrupt sources.

Note: If the IVA2 DPLL recalibration event interrupt is enabled and the IVA2 power domain is idled, then when the event occurs, the PRCM sets the interrupt, thus waking up the power domain.

4.12.1.3.4.2 PRM_IRQSTATUS_IVA2 (IVA2.2 Interrupt Status Register)

The IVA2.2 interrupt status register provides the status of the three events that can generate an IVA2.2 interrupt. Software must read the register to identify the interrupt cause, and then clear the pending interrupt by setting the corresponding bit to 1.

4.12.1.4 Event Generator Control Registers

For details about the event generator module, see the public *ARM® Cortex™-A8 Technical Reference Manual*.

In the PRCM, three event generator registers allow configuration of the event generator module:

- [PM_EVGENCTRL_MPU](#) (event generator control register): Event-generator settings
- [PM_EVGENONTIM_MPU](#) (event generator on-time register): On-time duration setting
- [PM_EVGENOFFTIM_MPU](#) (event generator off-time register): Off-time duration setting

4.12.1.5 Output Signal Polarity Control Registers

4.12.1.5.1 CM_POLCTRL (CM Polarity Control Register)

The [CM_POLCTRL](#) register allows the setting of the polarity of sys_clkout2 when gated (disabled). sys_clkout2 can be gated to a low level or a high level, depending on the software programming of this register. [Figure 4-84](#) shows the normal behavior of sys_clkout2 when gated.

Figure 4-84. sys_clkout2 Gating Polarity Control

prcm-078

4.12.1.5.2 **PRM_POLCTRL (PRM Polarity Control Register)**

The PRM polarity control register allows the setting of the polarity of the external signals controlled by the PRM. It contains the following polarity control bits:

- OFFMODE_POL: Polarity of sys_off_mode
- CLKOUT_POL: Polarity of sys_clkout1
- CLKREQ_POL: Polarity of sys_clkreq
- EXTVOL_POL: Polarity of both sys_nvmode signals: sys_nvmode1 and sys_nvmode2

At device power up, the reset values of polarity settings are OFFMODE_POL= 1 and CLKREQ_POL = 1. Depending on the system hardware implementation, these signals may or may not be used during device power up. For details about using these signals, see [Section 4.7, Clock Manager Functional Description](#),

4.12.1.6 **SRAM Precharge Time Control Register**

4.12.1.6.1 **PRM_SRAM_PCHARGE (Voltage SRAM Precharge Counter Register)**

The voltage SRAM precharge counter register allows the setting of the precharge duration of the SRAM. It has following bit field:

- PCHARGE_TIME: Number of system clock cycles defined for the SRAM precharge duration

4.12.2 **Clock Management Registers**

4.12.2.1 **System Clock Control Registers**

4.12.2.1.1 **PRM_CLKSRC_CTRL (Clock Source Control Register)**

The clock source control register is dedicated to the clock source controls of the device. It contains the following bit fields:

- SYSCLKSEL: Indicates the oscillator mode (oscillator/bypass) and is automatically updated at power up
- AUTOEXTCLKMODE: Enables autogating for the system clock, depending on the device power state. The clock can be configured to be automatically gated when all power domains are in either OFF or RETENTION state. When the gating condition is satisfied, the internal oscillator is turned off, if it is used. Otherwise, sys_clkreq is asserted to notify the external clock source to turn off.

Note: Power consumption is reduced with the SYS_CLK off; however, wake-up latency is increased because of oscillator stabilization time after the clock is turned on again.

- SYCLKDIV: Input divider (1, 2) of the system clock

4.12.2.1.2 **PRM_CLKSETUP (Source-Clock Setup Register)**

The source-clock setup register allows the setting of the setup time of the oscillator system clock, based on the number of 32-kHz clock cycles. This duration corresponds to the time required by the oscillator to stabilize before propagating the system clock.

Because the reset lasts long enough for oscillator stabilization, this register is not used at power-on reset of the device. This is ensured either by the external reset source (power IC) or by the reset extension in the PRCM (RSTTIME0 timer). The [PRM_CLKSETUP](#) register is cleared on cold reset only.

4.12.2.1.3 **PRM_CLKSEL (Source-Clock Selection Register)**

The PRCM.PRMC_CKSEL[2:0] SYS_CLKIN_SEL bit field is used to select the input frequency of the system clock (12, 13, 16.8, 19.2, 26 or 38.4 MHz).

4.12.2.2 External Clock Output Control Registers

4.12.2.2.1 PRM_CLKOUT_CTRL (Clock Out Control Register)

The PRM clock out control register provides control to enable and disable the gating of the sys_clkout1 output clock.

4.12.2.2.2 CM_CLKOUT_CTRL (Clock Out Control Register)

The CM clock out control register provides control over the device output clock sys_clkout2, which can be used externally for functional or test purposes. The register allows the following:

- Selection of the source clock for sys_clkout2:
 - CORE_CLK
 - SYS_CLK
 - 96-MHz clock
 - 54-MHz clock
- Dividing-down the selected source clock by 1, 2, 4, 8, or 16
- Enabling/disabling of the gating of sys_clkout2

4.12.2.3 DPLL Clock Control Registers

A set of registers controls the clock features of the five DPLLs (DPLL1, DPLL2, DPLL3, DPLL4, and DPLL5):

- CM_CLKSELn_PLL_<processor_name>
- CM_CLKSELn_PLL
- CM_CLKEN_PLL_processor_name>
- [CM_CLKEN_PLL](#)
- CM_AUTOIDLE_PLL_processor_name>
- [CM_AUTOIDLE_PLL](#)
- CM_IDLEST_PLL_<processor_name>
- [CM_IDLEST_CKGEN](#)
- [CM_IDLEST2_CKGEN](#)

The following sections describe the purposes of these registers.

4.12.2.3.1 CM_CLKSELn_PLL_<processor_name> (Processor DPLL Clock Selection Register)

The processor DPLL clock selection register controls the clock configuration of DPLL1 and DPLL2, including the following features:

- The multiplier (M) and divider (N) values of the DPLL
- Selection of the fast bypass clock (CORE_CLK or CORE_CLK/2) in bypass mode
- Configuration of DPLL output clock divider values (M2 factor)

The device has four DPLL clock selection registers for DPLL1 and DPLL2:

- [CM_CLKSEL1_PLL_MPU](#): DPLL1 multiplier, divider, and fast bypass clock selection
- [CM_CLKSEL2_PLL_MPU](#): DPLL1 output clock divider selection
- [CM_CLKSEL1_PLL_IVA2](#): DPLL2 multiplier, divider, and fast bypass clock selection
- [CM_CLKSEL2_PLL_IVA2](#): DPLL2 output clock divider selection

4.12.2.3.2 CM_CLKSELn_PLL (DPLL Clock Selection Register)

The DPLL clock selection register controls the clock configuration for DPLL3, DPLL4, and DPLL5, including the following features:

- The multiplier (M) and divider (N) values of the DPLL

- Configuration of DPLL output clock divider values

The device has following DPLL clock selection registers for DPLL3, DPLL4, and DPLL5:

- [CM_CLKSEL1_PLL](#): DPLL3 multiplier, divider, and output clock division configuration. Source selection for the 54-MHz and 48-MHz clock (48M_FCLK) between DPLL4 output and sys_altclk.
- [CM_CLKSEL2_PLL](#): DPLL4 multiplier and divider configuration
- [CM_CLKSEL3_PLL](#): Divider configuration for 96-MHz clock (96M_FCLK)
- [CM_CLKSEL4_PLL](#): DPLL5 multiplier and divider configuration
- [CM_CLKSEL5_PLL](#): Divider configuration for 120-MHz clock (120M_FCLK)

4.12.2.3.3 [CM_CLKEN_PLL_<processor_name>](#) (Processor DPLL Clock Enable Register)

The processor DPLL clock enable register allows the enabling or disabling of DPLL1 and DPLL2. It allows an immediate setting of the DPLL.

The device has two DPLL clock enable registers, one for DPLL1 and one for DPLL2:

- [CM_CLKEN_PLL_MPU](#): DPLL1 (MPU)
- [CM_CLKEN_PLL_IVA2](#): DPLL2 (IVA2)

The [CM_CLKEN_PLL_<processor_name>](#) register allows programmable control of the following DPLL features:

- Low-power stop mode (only for DPLL2)/low-power bypass mode/lock mode selection
- Automatic recalibration enable/disable
- Programmable internal frequency range of the DPLL
- Frequency ramping feature disabled and enabled with programmable step duration (4 s, 20 s, or 40 s)
- The DPLL LP mode can be enabled or disabled. However, switching between LP and normal mode is effective only when the DPLL has performed a recalibration; therefore, the DPLL must lock or relock. Also, the LP mode control is considered only during the following transitions:
 - From bypass to lock
 - From stop mode to lock
 - From lock to relock

Note: DPLL1 enters its internal power state (MNBYPASS) after being released from reset or when a multiplier value of 0 or 1 is loaded into the DPLL. Therefore, even if the [CM_CLKEN_PLL_MPU\[2:0\] EN_MPU_DPLL](#) bit field is reset to the low-power bypass mode, DPLL1 automatically transitions to MNBYPASS mode, because the multiplier value (the [CM_CLKSEL1_PLL_MPU\[18:8\] MPU_DPLL_MULT](#) bit field) resets to 0.

4.12.2.3.4 [CM_CLKEN_PLL](#) (DPLL Enable Register)

The DPLL enable register allows control of DPLL3 DPLL4, and DPLL5. It allows an immediate setting of the DPLLs. This register controls the following features of the two DPLLs:

- DPLL operation mode:
 - Low-power bypass, fast-relock bypass, and lock modes for DPLL3
 - Low-power bypass and lock modes for DPLL4
- Programmable automatic recalibration
- Programmable internal frequency range for the DPLL
- Frequency ramp-up feature disable/enable with programmable step duration
- The DPLL3 output M3X2 and the DPLL4 outputs M2X2, M3X2, M4X2, M5X2, and M6X2 clock paths can be powered down. However, the setting takes effect only when the output clock is gated. It is also powered down whenever the DPLL is in stop mode, regardless of the software settings.
- The DPLL LP mode can be enabled or disabled. However, switching between LP and normal mode is effective only when the DPLL has performed a recalibration; therefore, the DPLL must lock or relock. Also, the LP mode control is considered only during the following transition:

- From bypass to lock
- From stop mode to lock
- From lock to relock

4.12.2.3.5 **CM_AUTOIDLE_PLL_<processor_name> (Processor DPLL Autoidle Register)**

The processor DPLL autoidle register allows the enabling/disabling of the automatic processor DPLL activity control. In automatic mode, the DPLL automatically enters low-power stop mode when the DPLL clock is not required. It is also restarted automatically.

The following are the device DPLL auto-control registers:

- [CM_AUTOIDLE_PLL_MPU](#): DPLL1 autoidle mode control
- [CM_AUTOIDLE_PLL_IVA2](#): DPLL2 autoidle mode control

4.12.2.3.6 **CM_AUTOIDLE_PLL (DPLL Autoidle Register)**

The DPLL autoidle register allows the enabling/disabling of the automatic mode-switching control for DPLL3 and DPLL4. This automatic mode takes effect only when the DPLLs are locked.

DPLL3 can be configured to automatically switch to either low-power bypass mode or low-power stop mode when the CORE power domain clock is not required.

DPLL4 can be configured to automatically switch to low-power stop mode when the PER power domain clock is not required.

4.12.2.3.7 **CM_AUTOIDLE1_PLL (DPLL5 Autoidle Register)**

The DPLL5 autoidle register allows the enabling/disabling of the automatic mode-switching control. This automatic mode takes effect only when the DPLL is locked.

When enabled, DPLL5 is automatically switched to low-power stop mode whenever the 120-MHz output clock is gated.

4.12.2.3.8 **CM_IDLEST_CKGEN (Source-Clock Idle-Status Register)**

The source-clock idle-status register provides a status of DPLL3 and DPLL4 clock activity. It also provides the status of the functional clocks derived from DPLL4 output.

The activity status for DPLL3 and DPLL4 can be:

- DPLL is bypassed.
- DPLL is locked.

The activity status for the functional clocks can be:

- The functional 96-MHz clock is active, or not.
- The functional 48-MHz clock is active, or not.
- The functional 12-MHz clock is active, or not.
- The functional 54-MHz clock is active, or not.

The functional 96-MHz clock and all other functional clocks derived from it are active only when DPLL4 is locked and the clock is required.

The functional 48-MHz and 12-MHz clocks are qualified as active only if the clock is required and when the external alternate clock is selected as the source clock.

The functional 54-MHz clock (DSS_TV_CLK) is active only when DPLL4 is locked, selected as the source clock, and required.

4.12.2.3.9 CM_IDLEST2_CKGEN (DPLL5 Source-Clock Idle-Status Register)

The source-clock idle-status register provides the status of DPLL5 clock activity. It also provides the status of the functional clocks derived from DPLL5 output.

The activity status for DPLL5 can be:

- DPLL is bypassed.
- DPLL is locked.

The activity status for the functional clocks can be:

- The 120-MHz functional clock is active, or not.
- The USIM functional clock is active, or not.
- The output stage of the 120-MHz functional clock is active, or not.

4.12.2.3.10 CM_IDLEST_PLL_<processor_name> (Processor DPLL Idle-Status Register)

The processor DPLL idle-status register indicates the status of the processor DPLL: whether it is in locked or bypass mode.

The device DPLL idle-status registers are:

- [CM_IDLEST_PLL_MPU](#): DPLL1 activity status
- [CM_IDLEST_PLL_IVA2](#): DPLL2 activity status

4.12.2.4 Power-Domain Clock Control Registers

An identical set of registers controls the clock features of the power domains in the device:

- [CM_CLKSEL_<domain_name>](#)
- [CM_FCLKEN_<domain_name>](#)
- [CM_ICLKEN_<domain_name>](#)
- [CM_AUTOIDLE_<domain_name>](#)
- [CM_IDLEST_<domain_name>](#)
- [CM_CLKSTCTRL_<domain_name>](#)
- [CM_CLKSTST_<domain_name>](#)
- [CM_SLEEPDEP_<domain_name>](#)

The following sections describe the purposes of these registers.

4.12.2.4.1 CM_CLKSEL_<domain_name> (Clock Select Register)

The clock select register controls the selection of the module or subsystem input clock frequency (except for the processor modules). Therefore, it deals only with modules or subsystems for which the frequency is scalable or selectable (the others have fixed and nonprogrammable frequencies). Both functional and interface clocks can be scaled. In most cases, their value is a divided value from the DPLL3 (CORE) or the DPLL4 (PER) output clock.

The device includes the following clock select registers:

- [CM_CLKSEL_CORE](#): L3 and L4 interconnects and GPTIMER10 and 11 functional clocks
- [CM_CLKSEL_CAM](#): Camera subsystem functional clock
- [CM_CLKSEL_DSS](#): DSS functional clock 1 and TV functional clock
- [CM_CLKSEL_PER](#): GPTIMER2, 3, 4, 5, 6, 7, 8, and 9 functional clocks
- [CM_CLKSEL_SGX](#): SGX subsystem functional clock
- [CM_CLKSEL_WKUP](#): GPTIMER1 functional clock and reset manager counter clock and USIMOCP functional clock

The 32-kHz functional clock (32K_FCLK) is selected when the device enters off mode. The functional clock of the GPTIMER1 is selectable between the always-on 32K_FCLK and the system clock (SYS_CLK), but it is used with the 32-kHz clock.

The [CM_CLKSEL_SGX](#) register controls the SGX functional clock divider ratio, which is divided from the L3_ICLK source clock. [Table 4-85](#) summarizes L3_ICLK ratio for different configurations of the register field.

Table 4-85. SGX Functional Clock Ratio Settings

CM_CLKSEL_SGX .CLKSEL_SGX	SGX_L3_FCLK
0x1	L3_ICLK
0x2	L3_ICLK/2
0x3	L3_ICLK/3
0x4	L3_ICLK/4

4.12.2.4.2 [CM_FCLKEN_<domain_name>](#) (Functional Clock Enable Register)

The functional clock enable register allows control of the functional clock activity of each module or subsystem. All module functional clocks are controllable by software, except for the MPU, interconnect, and memory subsystems, for which the clocks are automatically controlled by the PRCM.

The device has the following functional clock control registers:

- [CM_FCLKEN1_CORE](#) and [CM_FCLKEN3_CORE](#): CORE domain nonsecure peripherals set
- [CM_FCLKEN_CAM](#): Camera subsystem
- [CM_FCLKEN_DSS](#): DSS subsystem
- [CM_FCLKEN_PER](#): PER domain peripherals set
- [CM_FCLKEN_IVA2](#): IVA2.2 subsystem
- [CM_FCLKEN_SGX](#): SGX subsystem
- [CM_FCLKEN_WKUP](#): WKUP domain peripherals set
- [CM_FCLKEN_USBHOST](#): HS USB Host subsystem

The software effect is immediate and direct. The functional clock is turned on as soon as the bit is set, and turned off if the bit is cleared and the clock is not required by any module. On module wakeup, the functional clock can be automatically restarted.

Note: The functional clock supplies the functional part of a module or subsystem, which is not operational without its functional clock. In some cases, a module or a subsystem may require multiple functional clocks.

4.12.2.4.3 [CM_ICLKEN_<domain_name>](#) (Interface Clock Enable Register)

The interface clock enable register allows control of the interface clock activity of each module or subsystem. This register provides control over each module in the device.

The device has following interface clock control registers:

- [CM_ICLKEN1_CORE](#), [CM_ICLKEN2_CORE](#), and [CM_ICLKEN3_CORE](#): CORE domain peripherals set
- [CM_ICLKEN_CAM](#): Camera subsystem
- [CM_ICLKEN_DSS](#): DSS subsystem
- [CM_ICLKEN_PER](#): PER domain peripherals set
- [CM_ICLKEN_SGX](#): SGX subsystem
- [CM_ICLKEN_WKUP](#): WKUP domain peripherals set
- [CM_ICLKEN_USBHOST](#): HS USB Host subsystem

This register has an immediate effect, causing the source of the interface clock to be effectively cut (if the appropriate bit is cleared and no module requires this clock) or activated (if the appropriate bit is set).

Independent functional and interface clock control registers provide potential power savings for each module. For example, because the configuration port and interface of the module are still active, disabling a functional clock of a module while keeping its interface clock active (leaving the module inactive but allowing access to its registers) reduces power consumption.

When the interface clock is disabled, the module cannot communicate with the rest of the device; therefore, it is in idle mode. For example, the interface clock of a peripheral can be disabled while its functional clock is active; it is then idled, from the device standpoint, while it can detect any external event. This configuration typically allows a main part of the device to go into idle mode while keeping a peripheral active and ready to wake up from an external event.

Because a module may or may not be able to function without its functional or interface clocks, power-management strategies must be adapted accordingly. This relation is programmable and is defined in the CLOCKACTIVITY bits of the module SYSCONFIG register; therefore, it requires consistent programming of the CM_FCLKEN and CM_ICLKEN registers.

Note: The interface clock ensures proper communication between any module and the interconnect (L3 or L4), in most cases supplying the module interface and registers.

4.12.2.4.4 CM_AUTOIDLE_<domain_name> (Autoidle Register)

The autoidle register holds an AUTOIDLE bit per module that belongs to the related power domain. Each AUTOIDLE bit enables/disables automatic (hardware) gating of a module interface clock.

When AUTOIDLE and ICLKEN are set for a module, the module interface clock is managed automatically (that is, by hardware control) according to the power domain clock activity; for example, stopped before a power domain sleep transition and reenabled on wakeup. [Table 4-86](#) lists the possible autoidle settings for the interface clock.

Table 4-86. Interface Clock Autoidle Settings

CM_AUTOIDLE.AUTO_<module>	CM_ICLKEN.EN_<module>	Interface Clock
0	0	Disabled
0	1	Enabled
1	0	Disabled
1	1	Automatic enabling/disabling

The device has the following autoidle control registers:

- [CM_AUTOIDLE1_CORE](#), [CM_AUTOIDLE2_CORE](#), and [CM_AUTOIDLE3_CORE](#): CORE domain peripherals set
- [CM_AUTOIDLE_CAM](#): Camera subsystem
- [CM_AUTOIDLE_DSS](#): DSS subsystem
- [CM_AUTOIDLE_PER](#): PER domain peripherals set
- [CM_AUTOIDLE_WKUP](#): WKUP domain peripherals set
- [CM_AUTOIDLE_USBHOST](#): HS USB Host subsystem

Note: For SmartReflex1 and 2, IVA2.2, and SGX modules, the automatic idle mode is always enabled, and is not software-controllable.

4.12.2.4.5 CM_IDLEST_<domain_name> (Idle-Status Register)

The idle-status register allows checking whether a target module is in idle mode or if an initiator module is in standby mode. The software should not access to a target module in idle mode. A target access, in this state, can lead to an error.

The idle mode of any module can depend on the configuration of the CM_FCLKEN_<domain_name> and CM_ICLKEN_<domain_name> registers, or may be controlled automatically by hardware, depending on the configuration of the CM_AUTOIDLE_<domain_name> registers.

In the case of IVA2.2 subsystem, standby mode is reached after the IVA2.2 processor has performed its idle instruction.

The device has the following idle status registers:

- [CM_IDLEST_MPU](#): MPU subsystem
- [CM_IDLEST1_CORE](#), [CM_IDLEST2_CORE](#), and [CM_IDLEST3_CORE](#): CORE domain peripherals set
- [CM_IDLEST_CAM](#): Camera subsystem
- [CM_IDLEST_DSS](#): DSS
- [CM_IDLEST_PER](#): Peripheral domain peripherals set
- [CM_IDLEST_NEON](#): NEON subsystem
- [CM_IDLEST_IVA2](#): IVA2.2 subsystem
- [CM_IDLEST_SGX](#): SGX subsystem
- [CM_IDLEST_WKUP](#): WKUP domain peripherals set
- [CM_IDLEST_USBHOST](#): HS USB Host subsystem

4.12.2.4.6 CM_CLKSTCTRL_<domain_name>(Clock State Control Register)

The clock state control register holds a CLKTRCTRL_<clock domain> bit field for each clock domain in the power domain. It controls the hardware- and software-supervised state transitions between active and inactive states. [Table 4-87](#) lists the clock state transition settings.

Table 4-87. Clock State Transition Settings

CM_CLKSTCTRL_<pwr domain>. CLKTRCTRL_<clk domain>	Description
0x0	The automatic hardware-supervised mode is disabled. The clocks in a clock domain cannot be cut automatically. This prevents any power transition on the power domain.
0x1	Starts software-supervised (forced) sleep transition on the domain. All clocks in the clock domain are automatically cut whenever the initiators in the modules are in standby mode.
0x2	Starts software-supervised (forced) wake-up transition on the domain. The clocks in the clock domain are restarted.
0x3	The automatic hardware-supervised mode is enabled, and the clocks in the clock domain are automatically cut whenever the modules and subsystem in the clock domain are in idle or standby mode and the domain dependencies are met.

The hardware-supervised mode and the software-supervised (forced) sleep mode are mutually exclusive. It is a software decision to program one mode or another, and the software programs the PRCM accordingly.

The hardware-supervised mode is coupled to the sleep and wake-up dependencies programmed in the PRCM, whereas the software-supervised mode must be independent of those dependencies. Therefore, the sleep and wake-up dependencies must be disabled before the software forces a sleep transition on a power domain; otherwise, the forced-domain will be wakened immediately because of the wake-up dependency.

The device has the following clock state control registers:

- [CM_CLKSTCTRL_MPU](#): MPU subsystem clock domain
- [CM_CLKSTCTRL_CORE](#): L3, L4, and D2D clock domains
- [CM_CLKSTCTRL_CAM](#): Camera subsystem clock domain
- [CM_CLKSTCTRL_DSS](#): DSS clock domain
- [CM_CLKSTCTRL_PER](#): Peripherals clock domain
- [CM_CLKSTCTRL_NEON](#): NEON clock domain
- [CM_CLKSTCTRL_IVA2](#): IVA2.2 clock domain

- [CM_CLKSTCTRL_SGX](#): Graphics clock domain
- [CM_CLKSTCTRL_EMU](#): Emulation clock domain
- [CM_CLKSTCTRL_USBHOST](#): HS USB Host clock domain

The CORE domain has three clock domains (L3, L4, and D2D); it does not have forced sleep and forced wake-up ability.

Although the sleep transition in the MPU power domain cannot be initiated by software using this register, a software-initiated forced wake-up capability exists. This can be used to wake up the MPU power domain if it does not wake up when the CORE power domain wakes up (the MPU wake-up-dependency [PM_WKDEP_MPU\[0\]](#) EN_CORE bit is set to 0).

If the hardware-supervised mode is enabled, the following occur:

- The MPU domain clock is automatically cut if the MPU executes the wait-for-interrupt instruction.
- The IVA2 domain clock is automatically cut when the DSP completes its idle procedure, and the IVA2.2 subsystem is ready for standby.
- The SGX domain clock is automatically cut when the SGX subsystem is ready for standby (provided the MPU is also in standby mode, if sleep dependency in the MPU power domain is enabled).
- The L3 domain clock is automatically cut when all initiators are in standby mode and slave ports are idled.
- The L4 domain clock is automatically cut when all peripherals and slave ports are idled.
- The CAM domain clock is automatically cut when the camera subsystem is ready for standby mode (provided the MPU is also in standby mode, if sleep dependency in the MPU domain is enabled).
- The DSS interface clock is automatically cut when it stops fetching data from the frame buffer (provided the MPU is also in standby mode, if sleep dependency in the MPU power domain is enabled). The display functional clock is controlled only by the [CM_FCLKEN_DSS](#) register.
- The PER domain clock is automatically cut when all initiators are in standby mode and all slave ports are in idle (provided the MPU and the DSP are in standby mode and the CORE power domain is INACTIVE, if sleep dependency in their domains is enabled).
- Because of the hardwired sleep dependency between NEON and the MPU domain, NEON can go into idle only if the MPU goes into standby mode. The MPU domain must also be configured in automatic hardware supervised mode for the NEON power domain idle transition to occur.
- The USBHOST power domain clock is automatically cut whenever the USBHOST is in standby mode (provided MPU is also in standby mode, if sleep dependency in the MPU domain is enabled, and IVA2 is also in standby mode, if sleep dependency in the IVA2 domain is enabled).

4.12.2.4.7 [CM_CLKSTST_<domain_name>](#) (Clock State Status Register)

The clock state status register logs the activity status of the power domain clock. This includes the activity of the interface clocks running only on the domain.

The device has following clock state status registers:

- [CM_CLKSTST_MPU](#): MPU subsystem clock activity
- [CM_CLKSTST_CORE](#): L3 clock domain activity and L4 clock domain activity
- [CM_CLKSTST_CAM](#): Camera subsystem clock activity
- [CM_CLKSTST_DSS](#): DSS clock activity
- [CM_CLKSTST_PER](#): PER clock domain activity
- [CM_CLKSTST_IVA2](#): IVA2.2 clock domain activity
- [CM_CLKSTST_SGX](#): Graphics subsystem clock activity
- [CM_CLKSTST_EMU](#): Emulation clock activity
- [CM_CLKSTST_USBHOST](#): USBHOST clock activity

4.12.2.4.8 CM_SLEEPDEP_<domain_name> (Sleep Dependency Control Register)

The sleep dependency control register allows the enabling or disabling of the sleep transition dependency of a power domain with respect to other power domains.

The device has following sleep dependency registers:

- **CM_SLEEPDEP_CAM**: CAM power domain sleep dependency with the MPU power domain
- **CM_SLEEPDEP_DSS**: Display power domain sleep dependency with the MPU power domain and the IVA2 power domain
- **CM_SLEEPDEP_PER**: PER power domain sleep dependencies with the MPU, IVA2, and CORE power domains
- **CM_SLEEPDEP_SGX**: SGX power domain sleep dependency with the MPU power domain
- **CM_SLEEPDEP_USBHOST**: USBHOST power domain sleep dependency with the MPU and IVA2 power domains

Although the CORE power domain is composed of L3 and L4 clock domains, the sleep dependency with the L3 clock domain is always enabled (not programmable by software); there is no sleep dependency between the PER power domain and the CORE_L4 clock domain.

The dependencies listed in [Table 4-88](#) can be enabled or disabled by software.

Table 4-88. Sleep Dependency Settings

Dependent Domain	Parent Domain	MPU	IVA2	CORE-L3
CAM		Software controlled		
DSS		Software controlled	Software controlled	
PER		Software controlled	Software controlled	Always enabled
SGX		Software controlled		
USBHOST		Software controlled	Software controlled	

4.12.2.5 Domain Wake-Up Control Registers

The following modules have programmable wake-up control:

- CORE power domain:
 - USBTLL
 - HS USB OTG
 - McBSP 1 and 5
 - GPTIMER[10, 11]
 - UART[1,2]
 - I2C[1..3]
 - McSPI[1..4]
 - MMC[1,2, 3]
- PER power domain:
 - McBSP[2..4]
 - GPTIMER[2..9]
 - UART 3
 - WDTIMER3
 - GPIO[2..6]
- WKUP power domain:
 - GPTIMER[1, 12]
 - GPIO1
 - SR[1,2]
 - I/O pad
 - USIM OCP

- DSS power domain:
 - DSS subsystem
- USBHOST power domain:
 - HS USB Host subsystem

The registers in the following sections control the wake-up settings.

4.12.2.5.1 **PM_WKEN_<domain_name> (Wake-Up Enable Register)**

The wake-up enable register applies only to modules that can generate wake-up events. It allows the enabling or disabling of the wakeup of the related power domain on a module or subsystem wake-up event. Each EN_<module> bit in the register enables/disables the wake-up event from the module to the PRCM.

The device has the following wake-up enable registers:

- [PM_WKEN1_CORE](#) and [PM_WKEN3_CORE](#): CORE domain modules wake-up control
- [PM_WKEN_DSS](#): Display subsystem (DSS) wake-up control
- [PM_WKEN_PER](#): Peripheral domain modules wake-up control
- [PM_WKEN_WKUP](#): WKUP domain modules wake-up control
- [PM_WKEN_USBHOST](#): HS USB Host subsystem wake-up control

Notes:

- The wake-up capability of GPTIMER12 (the secure timer) is not programmable, but is always enabled.
 - The wake-up signals issued from the MPU and IVA2.2 INTCs are nonmaskable in the PRCM. However, they cannot be generated if the corresponding interrupts are masked in the INTCs.
-

4.12.2.5.2 **PM_WKST_<domain_name> (Wake-Up Status Register)**

The wake-up status register logs wake-up events from all modules. Each ST_<module> bit of this register logs a given module-generated wake-up event.

The device has the following wake-up status registers:

- [PM_WKST1_CORE](#) and [PM_WKST3_CORE](#): CORE domain modules wake-up event status
- [PM_WKST_PER](#): Peripheral domain modules wake-up event status
- [PM_WKST_WKUP](#): WKUP domain modules wake-up event status
- [PM_WKST_USBHOST](#): HS USB Host subsystem wake-up control

The functional clock of the module causing the wakeup automatically restarts on the wakeup, but the software must enable the functional clock (CM_FCLKEN_<domain_name> register) before clearing the wake-up status bit.

Notes:

- Software must clear this register before a new sleep transition request; otherwise, the register prevents the sleep transition from occurring.
 - If the PRM interrupt is enabled on a module wakeup, the PM_WKST_<domain_name> must be cleared before clearing the PRM_IRQSTATUS_<processor_name> interrupt status register.
-

4.12.2.5.3 **PM_WKDEP_<domain_name> (Wake-Up Dependency Register)**

The wake-up dependency register allows the enabling/disabling of a wake-up dependency between power domains. When a domain wakes up, it can wake up another domain.

The device has the following wake-up dependency registers:

- **PM_WKDEP_MPU**: MPU power domain wake-up dependency with the following domains:
 - CORE
 - IVA2
 - WKUP
 - DSS
 - PER
- **PM_WKDEP_DSS**: DSS power domain wake-up dependency with the following domains:
 - MPU
 - IVA2
 - WKUP
- **PM_WKDEP_CAM**: The CAM power domain has programmable wake-up dependency with the following domains:
 - MPU
 - IVA2
 - WKUP
- **PM_WKDEP_PER**: The PER power domain has programmable wake-up dependency with the following domains:
 - MPU
 - IVA2
 - WKUP
 - CORE

The PER power domain can be wakened only by a wakeup of the L3 and D2D clock domains, not by an L4 clock domain.
- **PM_WKDEP_NEON**: The NEON power domain has programmable wake-up dependency with the following domain:
 - MPU
- **PM_WKDEP_IVA2**: The IVA2 power domain has programmable wake-up dependency with the following domains:
 - MPU
 - PER
 - WKUP
 - CORE
- **PM_WKDEP_SGX**: The SGX power domain has programmable wake-up dependency with the following domains:
 - MPU
 - IVA2
 - WKUP
- **PM_WKDEP_USBHOST**: The USBHOST power domain has programmable wake-up dependency with the following domains:
 - MPU
 - IVA2
 - WKUP
 - CORE

There is no wake-up dependency control for the WKUP power domain, because it is always on.

Because the CORE power domain wake-up dependencies are not programmable, the CORE power domain always wakes up on a wake-up event on the following domains:

- MPU
- IVA2
- WKUP
- CAM

- DSS
- SGX
- PER
- USBHOST

4.12.2.5.4 **PM_<processor_name>GRPSEL_<domain_name> (Processor Group Selection Register)**

The processor group selection register allows defining the group of modules in the domain that can wake up a processor domain (MPU or IVA2). This bit is effective only if the module wake-up capability is enabled (PM_WKEN_<domain_name> register).

The device has the following processor group selection registers:

- **PM_MPUGRPSEL1_CORE** and **PM_MPUGRPSEL3_CORE**: CORE power domain modules MPU wake-up control
- **PM_IVA2GRPSEL1_CORE** and **PM_IVA2GRPSEL3_CORE**: CORE power domain modules IVA2 wake-up control
- **PM_MPUGRPSEL_PER**: PER power domain modules MPU wake-up control
- **PM_IVA2GRPSEL_PER**: PER power domain modules IVA2 wake-up control
- **PM_MPUGRPSEL_WKUP**: WKUP power domain modules MPU wake-up control
- **PM_IVA2GRPSEL_WKUP**: WKUP power domain modules IVA2 wake-up control
- **PM_MPUGRPSEL_USBHOST**: HS USB Host subsystem MPU wake-up control
- **PM_IVA2GRPSEL_USBHOST**: HS USB Host subsystem IVA2 wake-up control

Notes:

- The wake-up capability of GPTIMER12 (the secure timer) is always attached to the MPU group.
- The wake-up capability of the DSS is always attached to the MPU group; it cannot be attached to the IVA2.2, and therefore is not programmable.

4.12.3 Reset Management Registers

4.12.3.1 Reset Control

4.12.3.1.1 **PRM_RSTTIME (Reset Time Register)**

The reset time register provides control over reset duration. Two durations are configurable:

- **RSTIME1**: Minimum duration (by default, two cycles of the 32-kHz clock) of the global warm reset (sys_nreswarm) assertion for external devices, such as flash memories. At power-up reset, DPLLs are reset and the power domains are switched on and stabilized during this duration.
- **RSTIME2**: Minimum duration (by default, 16 cycles of the RM_ICLK clock) to control power domain resets when the domain clocks are on.

For global cold and warm resets, the reset is applied for the RSTIME1 + RSTIME2 duration. In the other cases, when a power domain individually goes from off to active, the reset is applied only for the RSTIME2 duration (plus the power domain wake-up duration).

RSTIME1 and RSTIME2 can be reprogrammed for different behavior after the initial power up.

4.12.3.1.2 **RM_RSTCTRL_<domain_name> (Reset Control Register)**

The reset control register provides control over the local domain software reset.

Most device modules include an individual software reset that can be controlled using the related module SYS_CONFIG register.

The `RM_RSTCTRL_<domain_name>` register is used for specific subsystems or modules that do not support this local reset or that require a specific system control (the IVA2.2 subsystem).

The `PRM_RSTCTRL` register also handles the global software warm reset control.

The device includes the following reset control registers:

- `PRM_RSTCTRL`: This register allows control of the assertion of the global software reset and the DPLL3 software reset. These bits are automatically cleared. Assertion of the DPLL3 software reset triggers a device global cold reset. The reset condition of this register depends on the bit field:
 - The `RST_GS` bit is set on any global source of reset (warm or cold).
 - The `RST_DPLL3` bit is set only on a global cold source of reset.
- `RM_RSTCTRL_IVA2`: IVA2 power domain software resets the IVA2.2 and Video hardware accelerator subsystems. Both subsystems are held under reset after power up and are released by software.

4.12.3.1.3 `RM_RSTST_<domain_name>` (Reset Status Register)

The reset status register logs any source that has generated a reset in the related power domain. Depending on the domain, several causes of reset can be logged:

- Global device cold reset
- Global device warm reset
- Power domain transition (OFF to ACTIVE, and INACTIVE to ACTIVE)
- Software reset
- Processor emulation reset

The `PRM_RSTST` register logs the source of the global reset:

- VDD1/VDD2 voltage manager reset
- External warm reset
- Secure watchdog reset
- MPU watchdog reset
- Security violation reset
- Global software reset and DPLL3 software reset
- Global cold reset

The device includes the following reset status registers:

- `RM_RSTST_MPU`
- `RM_RSTST_CORE`
- `RM_RSTST_DSS`
- `RM_RSTST_CAM`
- `RM_RSTST_IVA2`
- `RM_RSTST_PER`
- `RM_RSTST_NEON`
- `RM_RSTST_SGX`
- `RM_RSTST_EMU`
- `PRM_RSTST`
- `RM_RSTST_USBHOST`

Only the `RM_RSTST_CORE`, `RM_RSTST_IVA2`, and `PRM_RSTST` registers log software sources of reset.

Each bit of these registers is set on the effective release of the respective reset signal.

4.12.4 Power Management Registers

4.12.4.1 PM_PWSTCTRL_<domain_name> (Power State Control Register)

The power state control register allows controlling the power state transition of the domain.

This register holds the following bit fields:

- **POWERSTATE**: Power state (ON, RETENTION, or OFF) to be applied for the next transition
- **LOGICRETSTATE**: Logic is retained or switched off when the domain goes into retention. This feature is domain-dependent and is not necessarily programmable (read only).
- **MEMRETSTATE[1 to X]**: Memory block i is retained (RAM state retained) or switched off (RAM state not retained) when the domain goes into retention. This feature is domain-dependent and is not necessarily programmable (read only).
- **MEMONSTATE[1 to X]**: Memory block i in the domain is on (RAM active), retained (RAM inactive but state retained) or switched off (RAM state not retained) when the domain is on. This feature is domain-dependent and is not necessarily programmable (read only).
- **MEMORYCHANGE**: Allows updating the memory state according to latest MEMONSTATE[1 to X] setting.

The device has the following power state control registers:

- [PM_PWSTCTRL_MPU](#): MPU domain power management
- [PM_PWSTCTRL_CORE](#): CORE domain power management
- [PM_PWSTCTRL_SGX](#): SGX domain power management
- [PM_PWSTCTRL_DSS](#): DSS domain power management
- [PM_PWSTCTRL_CAM](#): CAM domain power management
- [PM_PWSTCTRL_PER](#): PER domain power management
- [PM_PWSTCTRL_NEON](#): NEON domain power management
- [PM_PWSTCTRL_IVA2](#): IVA2 domain power management
- [PM_PWSTCTRL_USBHOST](#): USBHOST domain power management

MPU domain power management has the following features:

- The power state is programmable to ON, RETENTION, and OFF states.
- Logic and L1 cache state are switchable to off and retention states when the power domain is in RETENTION state.
- L2 cache state is switchable to off and retention states when the power domain is in RETENTION state.
- L2 cache state is switchable to off and on states when the power domain is in ON state.
- L2 cache state can be switched dynamically when the domain state is ON (no power transition is required).
- The L1 cache is always on when the power domain state is ON.

CORE domain power management has the following features:

- The power state is programmable to ON, RETENTION, or OFF states.
- nonretained logic is switchable to off and retention states when the power domain is in RETENTION state.
- Memory bank 1 and 2 states are switchable to off and retention states when the power domain is in RETENTION state.
- Memory bank 1 and 2 states are switchable to off, retention, and on states when the power domain is in ON state.
- Memory bank 1 and 2 states can be switched dynamically when the domain state is ON (no power transition is required).

SGX domain power management has the following features:

- The power state is programmable to ON, RETENTION, and OFF states.
- The logic is always in retention state when the power domain is in RETENTION state.

- The memory is always in retention state when the power domain is in RETENTION state.
- The memory is always in on state when the power domain is in ON state.

DSS domain power management has the following features:

- The power state is programmable to ON, RETENTION, and OFF states.
- The logic is always in retention state when the power domain is in RETENTION state.
- The memory is always in retention state when the power domain is in RETENTION state.
- The memory is always in on state when the power domain is in ON state.

CAM domain power management has the following features:

- The power state is programmable to ON, RETENTION, and OFF states.
- The logic is always in retention state when the power domain is in RETENTION state.
- The memory is always in retention state when the power domain is in RETENTION state.
- The memory is always in on state when the power domain is in ON state.

PER domain power management has the following features:

- The power state is programmable to ON, RETENTION, and OFF states.
- The logic is always in retention state when the power domain is in RETENTION state.

NEON domain power management has the following features:

- The power state is programmable to ON, RETENTION, and OFF states.
- The logic is always in retention state when the power domain is in RETENTION state.

IVA2 domain power management has the following features:

- The power state is programmable to ON, RETENTION, and OFF states.
- Logic state is switchable to off and retention states when the power domain is in RETENTION state.
- L1 cache state is switchable to off and retention states when the power domain is in RETENTION state.
- L1 flat memory state is switchable to off and retention states when the power domain is in RETENTION state.
- L2 cache state is switchable to off and retention states when the power domain is in RETENTION state.
- L2 flat memory state is switchable to off and retention states when the power domain is in RETENTION state.
- L1 cache state is always on when the power domain is in ON state.
- L1 flat memory state is always on when the power domain is in ON state.
- L2 cache state is switchable to off and on states when the power domain is in ON state.
- L2 flat memory state is always on when the power domain is in ON state.
- L2 cache memory state can be switched dynamically to off state and back to on state when the domain state is ON (no domain power transition is required).

USBHOST domain power management has the following features:

- The power state is programmable to ON, RETENTION, and OFF states.
- The logic is always in retention state when the power domain is in RETENTION state.
- The memory is always in retention state when the power domain is in RETENTION state, and the memory is always on when the power domain is in ON state.

The EMU power state is not programmable. The EMU domain is always powered down when the software or hardware conditions that allow a power transition are met. Thus, the EMU domain is automatically powered down after the power-up sequence if no emulation hardware is connected.

Note: The L1 cache memory bank can be configured to be either entirely or partially cache or flat memory. This configuration is done in the IVA2.2 subsystem. The part that is configured as cache memory can be retained; however, because tag and validity bit information are not retained in the case of L1 cache, this part cannot be retrieved after wakeup. It is important to configure the L1 cache memory state with a consistent value depending on the chosen configuration when the domain is in RETENTION state:

- If the L1 cache memory bank is entirely configured as cache memory, set the [PM_PWSTCTRL_IVA2\[8\] SHARED_L1_CACHE_FLAT_RET_STATE](#) bit to the same value as the [PM_PWSTCTRL_IVA2\[2\] LOGIC_RET_STATE](#) bit.
- If the L1 cache memory bank is entirely or partially configured as flat memory, set the [PM_PWSTCTRL_IVA2\[8\] SHARED_L1_CACHE_FLAT_RET_STATE](#) bit to the same value as the [PM_PWSTCTRL_IVA2\[9\] L1_FLAT_MEM_RET_STATE](#) bit.

The same mechanism applies to the L2 cache memory bank.

Because the L2 cache may not be useful in a system when the DSP frequency and interconnect frequencies are in the same range, this memory bank can be switched off when the domain is on.

4.12.4.2 PM_PWSTST_<domain_name> (Power State Status Register)

The power state status register provides the status of the power state transition of the domain.

This register holds the following bit fields:

- **POWERSTATESTATUS:** Indicates the current power state of the domain (ON, RETENTION, OFF)
- **LOGICSTATESTATUS:** Indicates the current logic power state
- **MEMORYSTATESTATUS:** Indicates the current memory power state
- **INTRANSITION:** Indicates an ongoing power state transition from ON power state to INACTIVE, OFF, or RETENTION, and from INACTIVE, OFF, or RETENTION power states to ON power state

The memory power state is updated by performing a dynamic memory change (the [PM_PWSTCTRL_<domain_name> MEMORYCHANGE](#) bit). Software clears the [PM_PREPWST_<domain_name>](#) register (this forces a memory change to the same value).

The device has the following power state status registers:

- [PM_PWSTST_MPU](#): MPU domain power state status
- [PM_PWSTST_CORE](#): CORE domain power state status
- [PM_PWSTST_SGX](#): SGX domain power state status
- [PM_PWSTST_DSS](#): DSS domain power state status
- [PM_PWSTST_CAM](#): CAM domain power state status
- [PM_PWSTST_PER](#): PER domain power state status
- [PM_PWSTST_NEON](#): NEON domain power state status
- [PM_PWSTST_EMU](#): EMU domain power state status
- [PM_PWSTST_IVA2](#): IVA2 domain power state status
- [PM_PWSTST_USBHOST](#): USBHOST domain power state status

The MPU domain power state status register indicates the current domain, logic, L1 cache (ON or OFF), and L2 cache (ON, RETENTION, or OFF) power state.

The CORE domain power state status register indicates the current domain, logic (ON or OFF), and memory banks 1 and 2 (ON, RETENTION, or OFF) power state.

The SGX, DSS, CAM, PER, NEON, USBHOST, and EMU domain power state status registers indicate the current domain (ON, INACTIVE, RETENTION, or OFF) power state or that the power domain transition is in progress. Because the SGX memory state is not programmable and reflects the power state, the SGX power domain does not require a memory power state.

The IVA2 domain power state status register indicates the current domain (ON, INACTIVE, RETENTION, or OFF), logic (ON or OFF), L1 cache and flat memory (ON, RETENTION, or OFF), L2 cache and flat memory (ON, RETENTION, or OFF) power state status.

4.12.4.3 PM_PREPWSTST_<domain_name> (Previous Power State Status Register)

The previous power state status register indicates the power state entered during the last sleep transition. The information in this register is useful when the domain switches back to on state (following a wake-up transition). This register must only be read when the domain power state is ON.

This register has the following bit fields:

- LASTPOWERSTATEENTERED: Last domain power state entered after the last sleep transition
- LASTLOGICSTATEENTERED: Last logic power state entered after the last sleep transition
- LASTMEMORYSTATEENTERED: Last memory power state entered after the last sleep transition or before the last memory change update

The device has the following previous power state status registers:

- PM_PREPWSTST_MPU: The MPU power domain previous power state status
- PM_PREPWSTST_CORE: The CORE power domain previous power state status
- PM_PREPWSTST_SGX: The SGX power domain previous power state status
- PM_PREPWSTST_DSS: The DSS power domain previous power state status
- PM_PREPWSTST_CAM: The CAM power domain previous power state status
- PM_PREPWSTST_PER: The PER power domain previous power state status
- PM_PREPWSTST_NEON: The NEON power domain previous power state status
- PM_PREPWSTST_IVA2: The IVA2 power domain previous power state status
- PM_PREPWSTST_USBHOST: The USBHOST power domain previous power state status

The previous power state status register for the MPU power domain indicates the previous domain, logic, L1 cache (ON or OFF), and L2 cache (ON, RETENTION, or OFF) power state.

The previous power state status register for the CORE power domain indicates the previous domain, logic (ON or OFF), and memory banks 1 and 2 (ON, RETENTION, or OFF) power state.

The previous power state status registers for the SGX, DSS, CAM, PER, NEON, USBHOST and EMU power domains indicate the current domain (ON, INACTIVE, RETENTION, or OFF) power state. The SGX power domain does not require a memory power state status, because the SGX memory state is not programmable and reflects the power state.

The previous power state status register for the IVA2 power domain indicates the previous domain (ON, INACTIVE, RETENTION, or OFF), logic (ON or OFF), L1 cache and flat memory (ON, RETENTION, or OFF), and L2 cache and flat memory (ON, RETENTION, or OFF) power state status.

The current memory state depends on the setting of the PM_PWSTCTRL_<domain_name> MEMONSTATE bit during the last wake-up transition or during the last memory change operation.

This register must be cleared by software by writing any value to it; this operation must be done when the domain power state is ON. Clearing this register does the following:

- Resets the PM_PREPWSTST_<domain_name> LASTPOWERSTATEENTERED bit field and the PM_PREPWSTST_<domain_name> LASTLOGICSTATEENTERED bit to the ON state
- Sets the bit fields corresponding to the last memory state of the power domain to the current memory state

Note: Performing a memory change (the PM_PWSTCTRL_<domain_name>[3] MEMORYCHANGE bit for MPU, IVA2, and CORE) has the same effect as clearing this register.

4.12.5 Voltage Management Registers

4.12.5.1 External Voltage Control Register Descriptions

4.12.5.1.1 PRM_VOLTSETUP (Voltage Setup Time Register)

The device has two voltage setup registers:

- [PRM_VOLTSETUP1](#)
- [PRM_VOLTSETUP2](#)

These registers allow controlling the setup time of the VDD1 and VDD2 power supplies when the device exits the off mode or when the voltage is scaled. It is a constant value that depends on the connected power IC. At power-up reset, this register is not used, because the external power supply is already stable. After boot up, the software must set the correct value to ensure proper sequences when performing voltage scaling or sleep transitions.

The [PRM_VOLTSETUP1](#) register has the following bit fields:

- **SETUPTIME1**: The setup time of the VDD1 regulator. It is computed as 8 x NbCycles (number of cycles of the system clock), where NbCycles is configured in the register bit field.
- **SETUPTIME2**: The setup time of the VDD2 regulator. It is computed as 8 x NbCycles (number of cycles of the system clock), where NbCycles is configured in the register bit field.

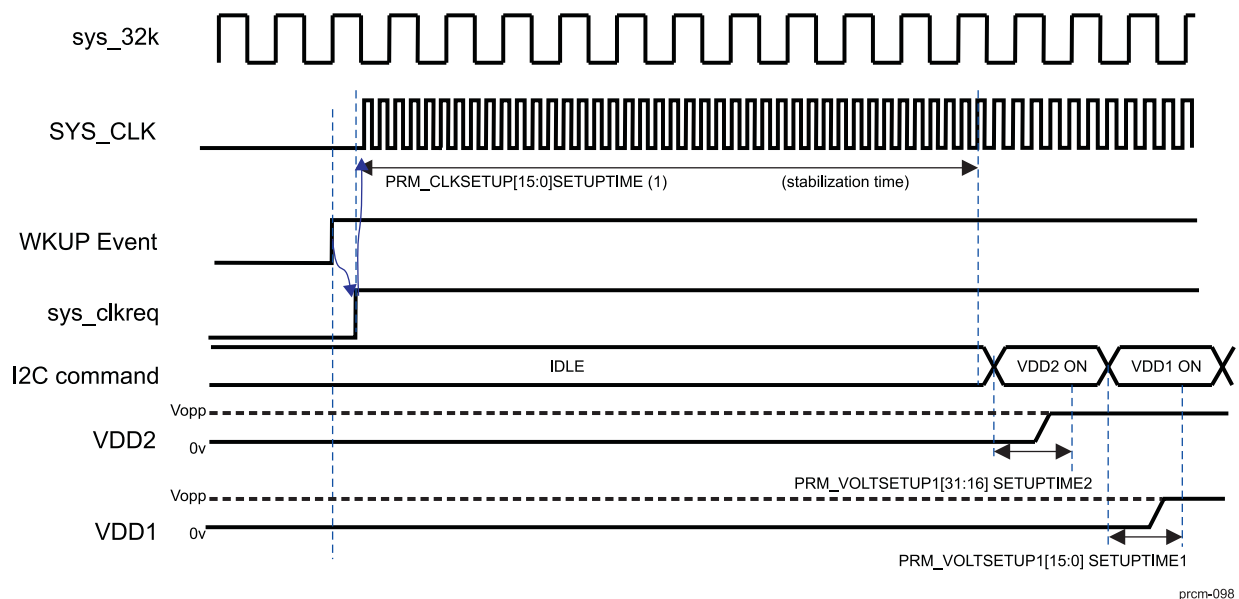

The [PRM_VOLTSETUP1](#) register is used when the device exits the off mode and manages the sequencing of the voltage regulation steps (the [PRM_VOLTCTRL](#)[3] SEL_OFF bit is set to 0).

The [PRM_VOLTSETUP2](#) register has the following bit field:

- **OFFMODESETUPTIME**: The number of 32-kHz clock cycles for the overall setup time of the VDD1 and VDD2 regulators.

The [PRM_VOLTSETUP2](#) register is used only when the device exits off mode and an external power IC manages the sequencing of the voltages regulation steps ([PRM_VOLTCTRL](#)[3] SEL_OFF is set to 1).

Section 4.12.5.1.2 shows off mode wakeup using I²C.

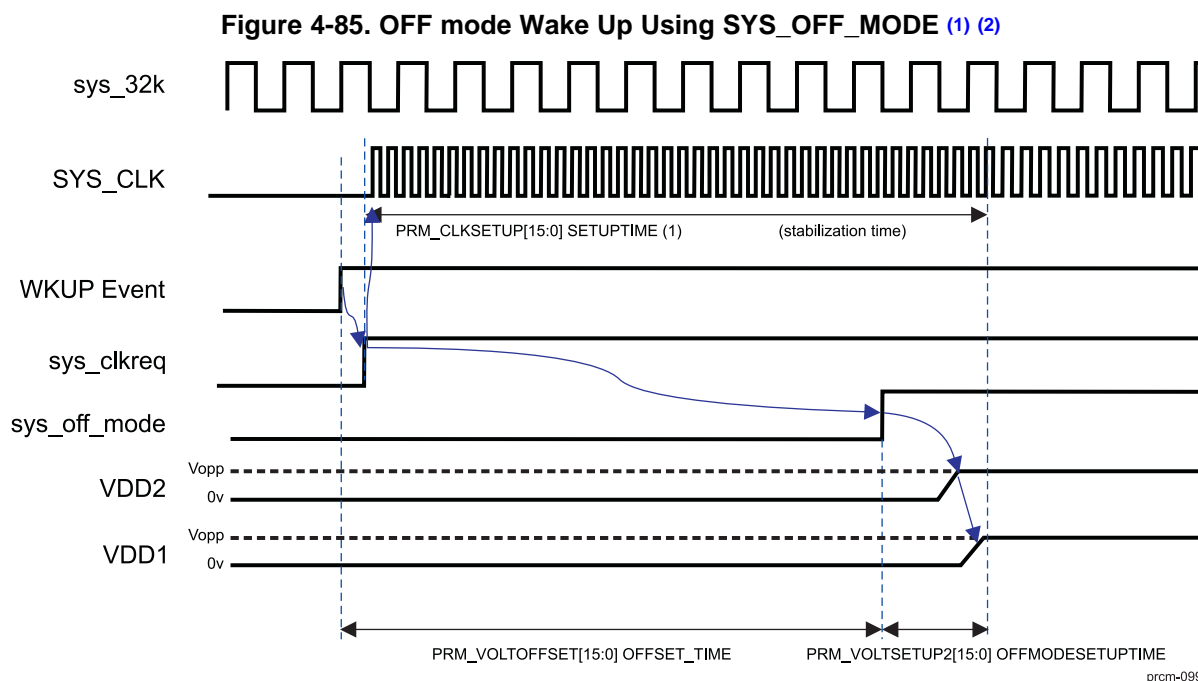

- (1) PRM_VOLTSETUP1[31:16] SETUPTIME2 and PRM_VOLTSETUP1[15:0] SETUPTIME1 are not used during voltage scaling (between different OPPs).

4.12.5.1.3 PRM_VOLTOFFSET (Voltage Offset Register)

This register allows setting the offset time. It is the time duration between de-assertion of sys_off_mode and the start of the VDD1 and VDD2 regulators, when the device is exiting off mode.

The OFFSET_TIME bit field of this register is configured as the number of 32-kHz clock cycles time delay in assertion of sys_off_mode. This register is used on device wakeup from off mode when the off sequence is supervised by the power IC.

Figure 4-85 shows off mode wakeup using SYS_OFF_MODE.

- (1) $\text{PRM_CLKSETUP}[15:0] \text{ SETUPTIME} = \text{PRM_VOLTOFFSET}[15:0] \text{ OFFSET_TIME} + \text{PRM_VOLTSETUP2}[15:0] \text{ OFFMODESETUPTIME}$.
- (2) $\text{PRM_CLKSETUP}[15:0] \text{ SETUPTIME}$ is not used during device cold boot-up sequence.

4.12.5.1.4 PRM_VOLTCTRL (Voltage Source Control Register)

This register allows control of the power IC. The following are the register bit fields:

- **AUTO_SLEEP:** Automatically sends the sleep command when the voltage domain is in the appropriate standby mode
- **AUTO_RET:** Automatically sends the retention command when the voltage domain is in the appropriate standby mode
- **AUTO_OFF:** Automatically sends the off command when the voltage domain is in the appropriate standby mode
- **SEL_OFF:** Controls whether the off command is sent through the voltage controller I²C interface or the signal sys_off_mode is asserted when entering off mode
- **SEL_VMODE:** Allows control of the power IC through either the voltage controller I²C interface or the VMODE interface

4.12.5.2 Voltage Controller Registers

A specific set of registers allows control of the voltage controller. This register set provides programming flexibility to address different power IC device types through an I²C interface.

The register set is composed of the following registers:

- Registers to store the addresses on the I²C bus:
 - [PRM_VC_SMPS_SA](#)
 - [PRM_VC_SMPS_VOL_RA](#)
 - [PRM_VC_SMPS_CMD_RA](#)
- Registers to store the voltage values or voltage commands:
 - [PRM_VC_CMD_VAL_0](#)
 - [PRM_VC_CMD_VAL_1](#)

- Register to configure the VDD channel:
 - [PRM_VC_CH_CONF](#)
- Register to configure the I²C interface:
 - [PRM_VC_I2C_CFG](#)
- Register to use the bypass command:
 - [PRM_VC_BYPASS_VAL](#)

4.12.5.2.1 **PRM_VC_SMPS_SA (Voltage Controller SMPS Slave Address Register)**

This register stores the I²C slave address value of the power IC device. Two address values can be stored in case two different power IC chips are used to control the two VDD channels (VDD1 and VDD2).

4.12.5.2.2 **PRM_VC_SMPS_VOL_RA (Voltage Controller SMPS Voltage Register Address Register)**

This register stores the address value of the voltage configuration registers in the power IC device. Two different register address values can be configured.

4.12.5.2.3 **PRM_VC_SMPS_CMD_RA (Voltage Controller SMPS Command Register Address Register)**

This register stores the address value of the command configuration register in the power IC device. Two different register address values can be configured.

4.12.5.2.4 **PRM_VC_CMD_VAL_0 and PRM_VC_CMD_VAL_1 (Voltage Controller Command and Voltage Value Register 0 and 1)**

The voltage controller can store two sets of voltage-level commands for each of the four power states (on, low power, retention, and off) for the power IC. The voltage commands depend on the power IC device used.

4.12.5.2.5 **PRM_VC_CH_CONF (Voltage Controller Channel Configuration Register)**

This register consists of a set of select bits for the VDD1 and VDD2 channels, the slave address, command register address, voltage register address, and voltage-level command settings for power modes (on/low power, on/retention/off). A pair of bit fields can be configured for each of these parameters. The [PRM_VC_CH_CONF](#) register allows the allocation of either of the two bit fields (for each of these parameters) to each voltage channel (VDD1 and VDD2). For example, when [PRM_VC_CH_CONF\[0\] SA0 = 0x1](#), the voltage controller allocates [PRM_VC_SMPS_SA\[22:16\] SA1](#) as the slave address for the VDD1 channel. When [PRM_VC_CH_CONF\[0\] SA0 = 0x0](#), the voltage controller allocates [PRM_VC_SMPS_SA\[6:0\] SA0](#) as the slave address for the VDD1 channel.

4.12.5.2.6 **PRM_VC_I2C_CFG (Voltage Controller I²C Interface Configuration Register)**

This register allows the setting of the I²C interface configuration parameters:

- Master code value when I²C interface is used in HS mode
- Enable and disable the HS mode
- Enable and disable the repeated start-operation mode
- Enable and disable the HSMaster mode

4.12.5.2.7 **PRM_VC_BYPASS_VAL (Voltage Controller Bypass Command Register)**

This register is used to address directly the power IC device through the I²C interface. It has the following bit fields:

- SLAVEADDR: Slave address value of the I²C interface of the power IC device (similar to [PRM_VC_SMPS_SA](#))

- REGADDR: Address of the command or voltage value register of the power IC device (similar to [PRM_VC_SMPS_VOL_RA](#) or [PRM_VC_SMPS_CMD_RA](#))
- DATA: Data to be written to the command or voltage value register
- VALID: Voltage command transaction enable and acknowledge bit

4.12.6 Generic Programming Examples

4.12.6.1 Clock Control

The module clock management is controlled through three programmable steps:

- Enabling or disabling the functional clocks
- Enabling or disabling the interface clocks
- Enabling or disabling the automatic idle mode for the interface clocks

4.12.6.1.1 Enabling and Disabling the Functional Clocks

The flow chart in [Figure 4-86](#) shows how to enable or disable a functional clock.

The first step before enabling a functional clock is to select the proper source clock using the corresponding clock selection register (CM_CLKSEL_<domain_name>). It can be either an external source clock or an internal clock; that is, sys_altdclk or DPLL4_M3X2_CLK for the DSS_TV_FCLK functional clock of the DSS.

If the source clock is a DPLL3 or DPLL4 output clock, the DPLL multiplier, divider, and output clock ratios are set in the CM_CLKSELn_PLL register, where n is from 1 to 3. The DPLL operating mode is set in the [CM_CLKEN_PLL](#) register.

The functional clock is enabled or disabled by writing the dedicated bit in the CM_FCLKEN_<domain_name> register. This bit has a direct effect on the clock activity:

- The functional clock is turned on if the bit is enabled and the clock is not yet active.
- The functional clock is turned off if the bit is disabled and the clock is not required by any other module.

Figure 4-86. Functional Clock Basic Programming Model

* Clock domain Idle conditions are:
a. No other module sharing the same clock domain needs the clock.
(All modules of the clock domain are idled)
b. No wake-up event.

prcm-085

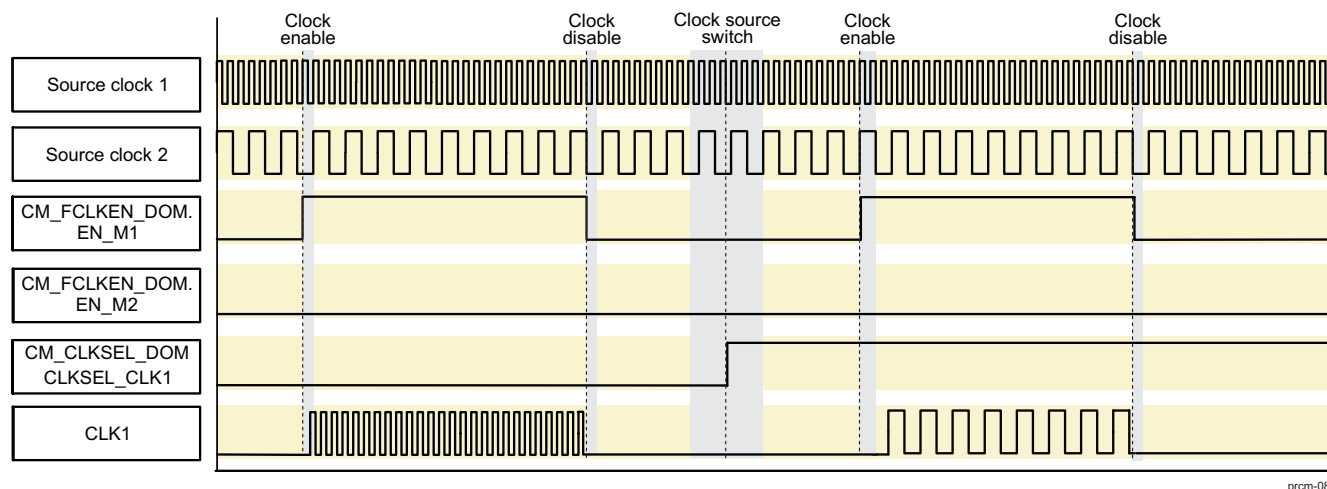

The functional clock must be disabled before switching or scaling its source clock. This means that all the modules using the particular functional clock must not be active during clock switching. To switch a source clock, perform the following sequence:

1. Disable the functional clock by setting the CM_FCLKEN_<power domain>EN_<module> bits to 0.
2. Modify the CM_CLKSEL_<power domain>CLKSEL_<clock> bits to select the new clock source or clock divider.
3. Enable the functional clock by setting the CM_FCLKEN_<power domain>EN_<module> bits to 1.

The timing diagram in Figure 4-87 is a generic example of this sequencing for a functional clock (CLK1). The source clock can be switched between source clock 1 and source clock 2 using the CM_CLKSEL_DOM.CLKSEL_CLK1 bit (source clock 1 is selected when the bit is set to 0; otherwise, source clock 2 is selected). CLK1 can be requested by two modules, M1 and M2. The CM_FCLKEN_DOM.EN_M1 and CM_FCLKEN_DOM.EN_M2 bits control the functional clock enable for the two modules.

Note: The activation or deactivation of the clock is implementation-dependent, not one cycle of the source clock, as shown in Figure 4-87.

Figure 4-87. Functional Clock Switching

prcm-080

The following functional clocks require this switching sequence:

- sys_clkout2
- 48M_FCLK (and all gated versions of it)
- 12M_FCLK (and all gated versions of it)
- DSS_TV_CLK
- GPTx_FCLK (with x = 1, 10, and 11)
- GPTx_ALWON_FCLK (with x = 2 up to 9)

4.12.6.1.2 Enabling and Disabling the Interface Clocks

The flow chart in [Figure 4-88](#) shows the enable/disable sequence of the interface clock.

The first step before enabling an interface clock is to select the proper source clock using the corresponding clock selection register (CM_CLKSEL_<domain>). This register allows selection of the interconnect frequency (L3_ICLK, L4_ICLK) from among several divider ratios.

The interface clock is enabled or disabled by writing the dedicated bit in the CM_ICLKEN_<domain> register. This bit has a direct effect on the clock activity:

- The interface clock is turned on if the bit is enabled and the clock is not yet active.
- The interface clock is turned off if the bit is disabled and the clock is not required by any other module.

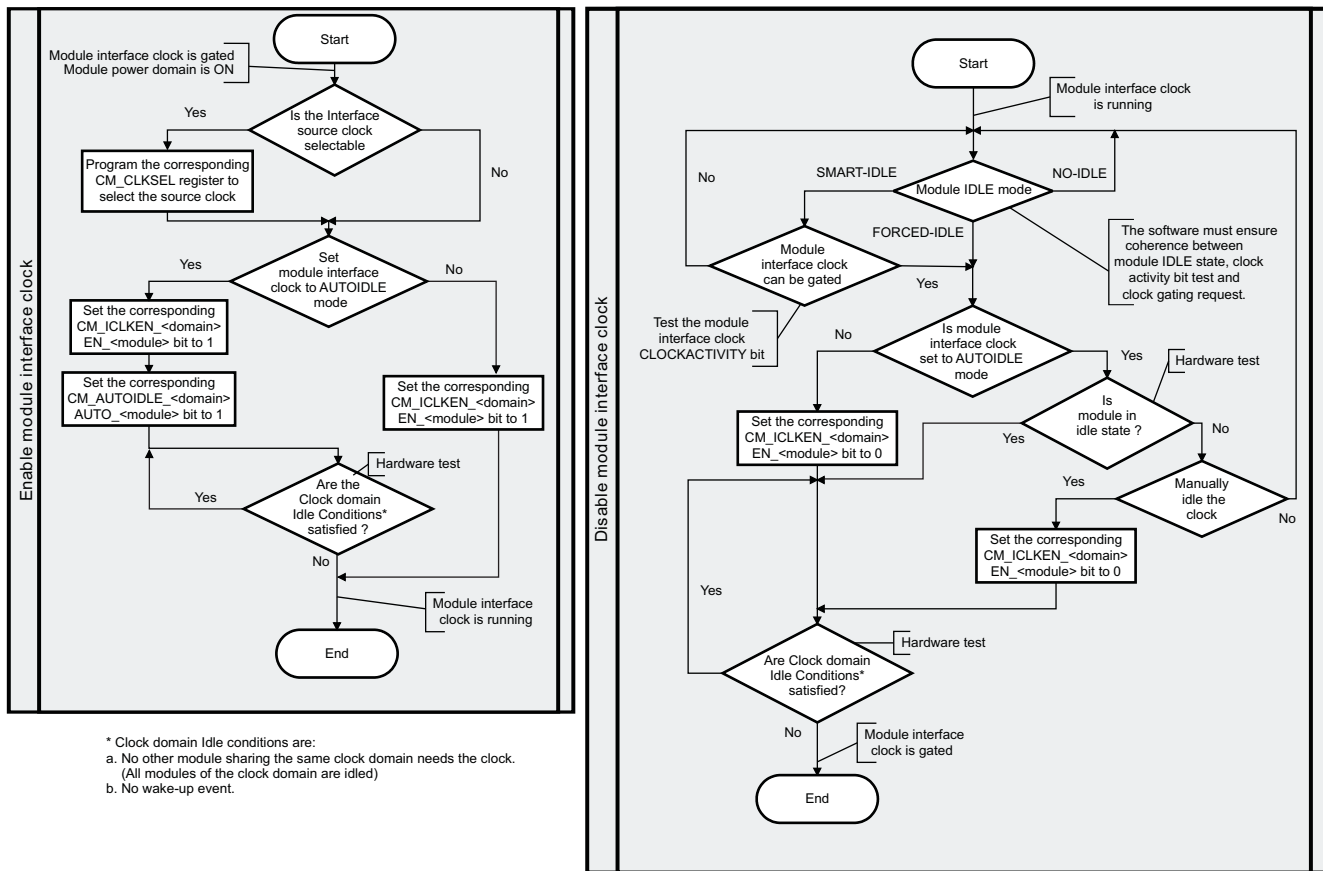

The interface clock can be automatically enabled or disabled by the PRCM, based on hardware conditions. This automatic clock activity control mode is enabled by writing the corresponding bit in the CM_AUTOIDLE_<domain> register. It takes effect only if the interface clock is enabled (the corresponding bit in the CM_ICLKEN_<domain> is set to 1).

The hardware conditions for automatic gating (deactivation) of the clock are as follows:

- The module activity; that is, the module is inactive.
- The domain activity; that is, all modules in the domain are inactive.

The software can read the idle status register CM_IDLESTAT_<domain> at any time to know whether the module is accessible. A module is inaccessible if its idle status bit is set. Accessing an idle module generates an error (if the interface clock is still running) or a time-out (if the interface clock is cut).

Figure 4-88. Interface Clock Basic Programming Model

prcm-086

The frequency ratio between the CORE_CLK, the L3_ICLK, and the L4_ICLK is configured by setting the corresponding **CM_CLKSEL_CORE** register bit fields. This configuration must be done before switching DPLL3 to lock mode. In this way, the clock ratio is switched while DPLL3 is operating at system clock frequency, and then only DPLL3 is switched to high-frequency locked mode.

If the configuration of the interface clock needs to be changed, first put DPLL3 in bypass mode, select the new configuration, and then relock DPLL3.

Note: When performing frequency scaling, the clock division can be done directly by programming the DPLL output divider. In this case, there is no need to change the configuration of the interface clock.

4.12.6.1.3 Enabling and Disabling the INACTIVE State

The flow chart in Figure 4-89 shows how to put a domain into INACTIVE state. This state is required before any power transition from ON state to RETENTION or OFF state.

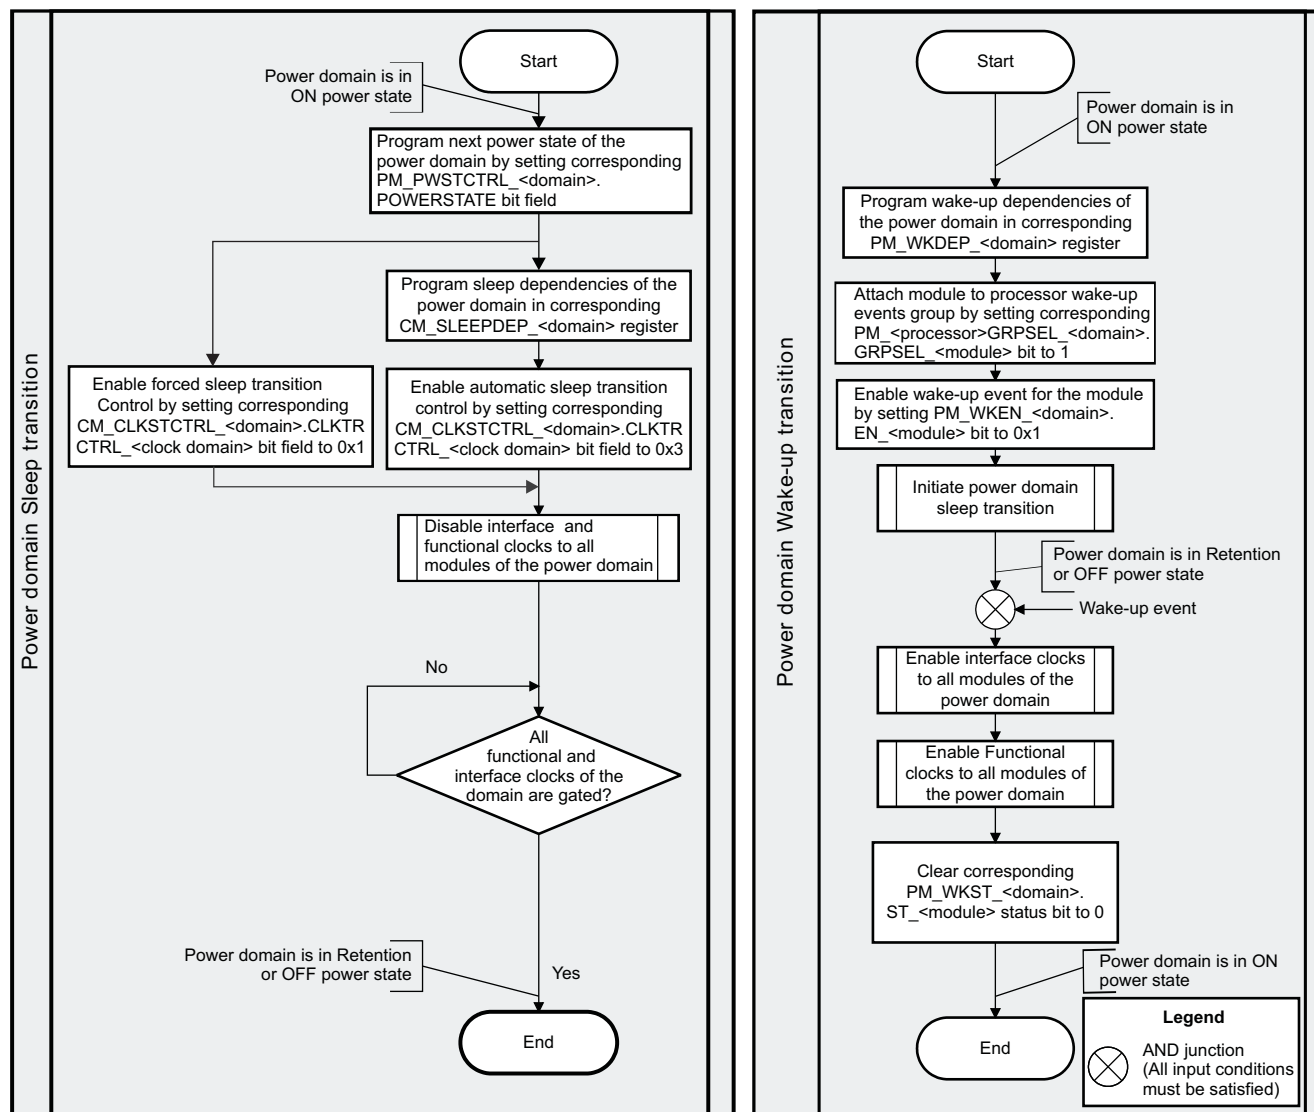

A domain is said to be in INACTIVE state if:

- All the functional and interface clocks of the domain are gated (deactivated).
- All the initiator modules are in standby mode.
- All the dependent domains have reached their mute state. The sleep dependency between the power domains is configured by programming the CM_SLEEPDEP_<domain> register.

The domain transition from ACTIVE state to INACTIVE state is effective only if the CM_CLKSTCTRL_<domain> register is programmed for hardware-supervised state transition.

The CM_CLKSTST_<domain> register identifies whether a power domain or a clock domain within the power domain is accessible. A domain is inaccessible if its corresponding bit in the CM_CLKSTST_<domain> register is set to 1.

Figure 4-89. Domain INACTIVE STATE Basic Programming Model

prcm-087

4.12.6.1.4 Processor Clock Control

The flow chart in [Figure 4-90](#) shows the control sequence of the processor clock.

The processor source clock is generated by the dedicated processor DPLL (DPLL1 and DPLL2). After power up, the processor DPLL is in bypass or stop mode. This means the processor clock is either the system clock or is shut off.

The first step is to program the multiplier and divider ratios of the processor DPLL. Those two values are written in the CM_CLKSEL1_PLL_processor> register.

For frequency scaling, the processor DPLL integrates an additional divider to scale down the synthesized clock. The value of this second divider is written in the CM_CLKSEL2_PLL_processor> register. This divider can be configured dynamically (while the processor executes instructions), and the DPLL output clock is scaled without any glitches.

The processor DPLL must be locked at a desired frequency, provided the clock frequency is higher than the system clock. It can then be set to low-power bypass mode when the high-frequency clock is not required. The DPLL operating mode (locked or bypassed) is controlled by programming the CM_CLKEN_PLL_processor> register.

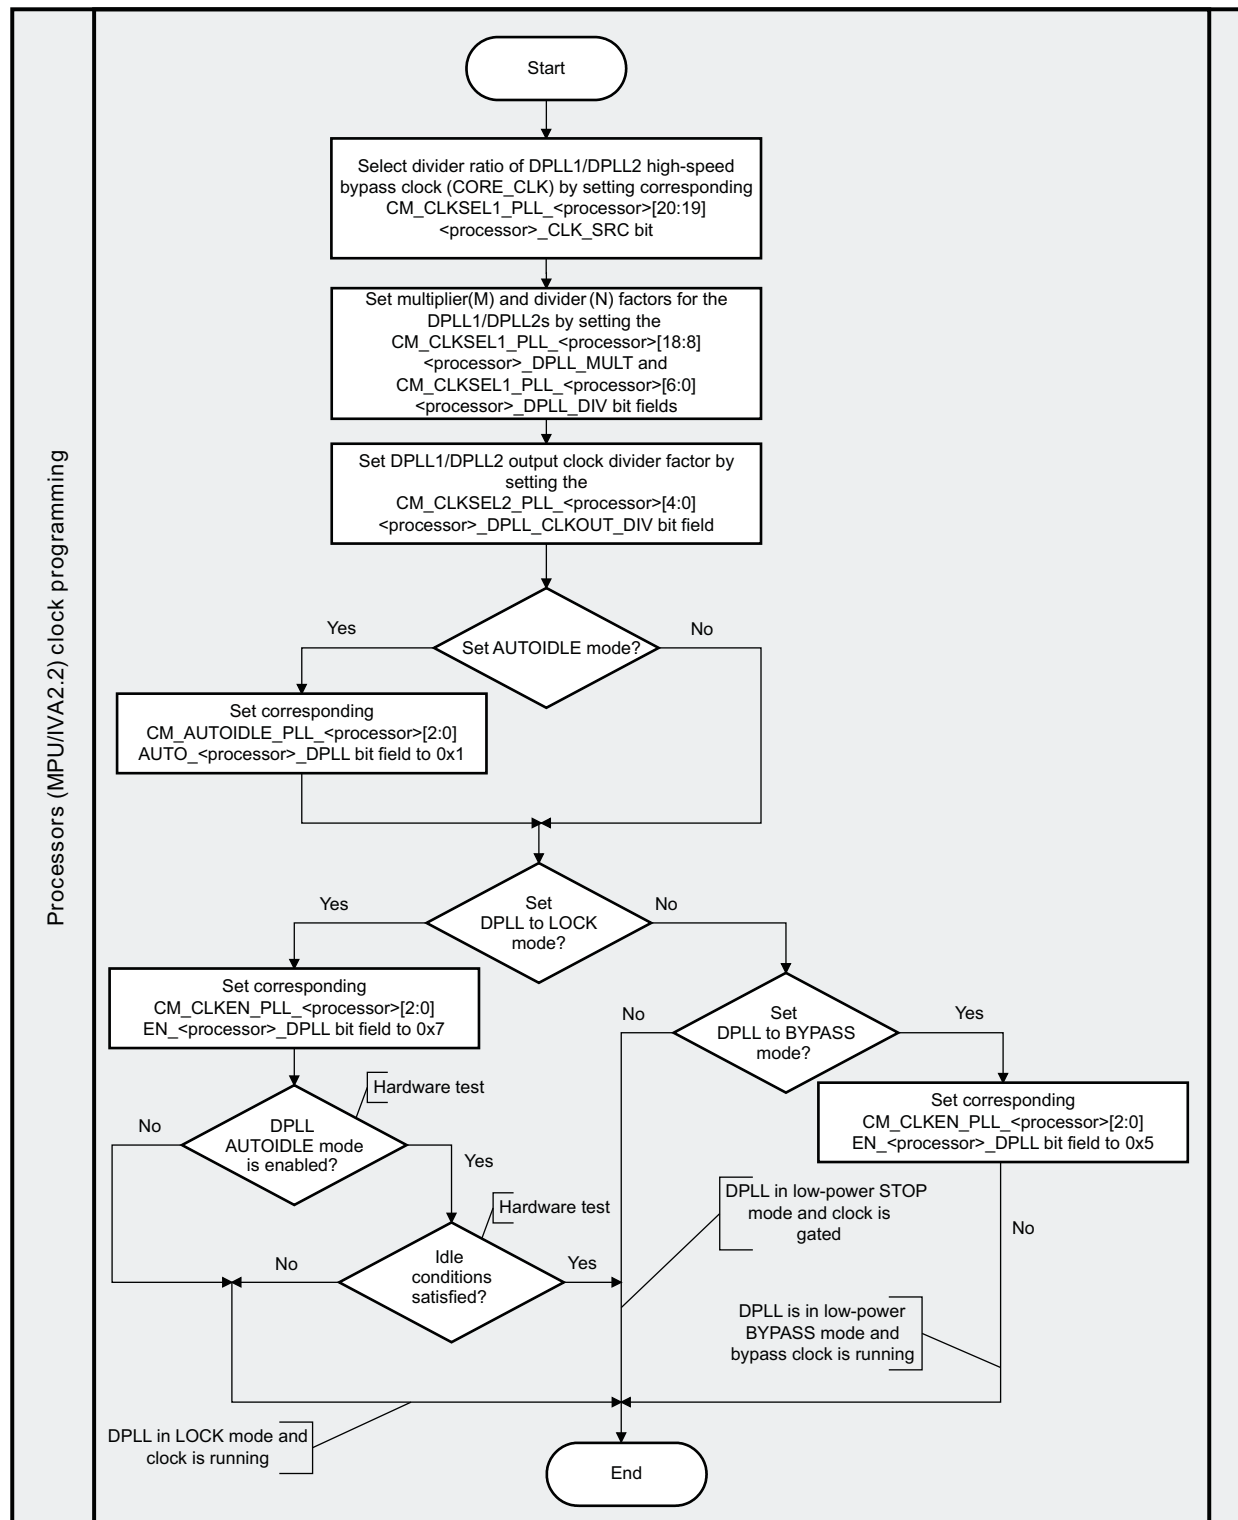

The processor clock can be switched automatically, based on hardware conditions, between the processor DPLL synthesized clock and a bypass clock. This mode is enabled by programming the corresponding mode in the CM_AUTOIDLE_PLL_processor> register. It takes effect only if the processor DPLL is locked (the CM_CLKEN_PLL_processor> register is set in lock mode).

The HS bypass clock for the processor DPLL can be:

- The DPLL3 output clock (CORE_CLK)
- The DPLL3 output clock (CORE_CLK) divided by 2

The HS bypass clock is selected by programming the CM_CLKSEL1_PLL_processor > register.

The software can read the CM_IDLEST_PLL_<processor > register at any time to determine whether the DPLL is in lock mode (DPLL output is a high-frequency synthesized clock) or bypass mode (DPLL output is not the synthesized clock; the DPLL output is the bypass clock, or the DPLL is in transitioning state).

Figure 4-90. Processor Clock Basic Programming Model

prcm-088

4.12.6.2 Reset Management

The reset sequence is hardware-driven. On power on, once all the reset sources have been released, the PRCM holds the entire device under reset long enough to ensure the stabilization of the power IC voltages and the oscillator system clock frequency. This reset delay is programmed in the [PRM_RSTTIME](#) register.

The IVA2.2 domain resets are held active after power up. They are released by writing to the corresponding bits in the `RM_RSTCTRL_<domain>` register.

A domain reset status register (`PRM_RSTST_<domain>`) identifies the source of the current reset applied to the domain. The software must clear this status bit after reset.

A global reset status register ([PRM_RSTST](#)) provides information on the global source of resets. All sources of warm reset are logged separately in this register, and all sources of cold reset are logged in a common status bit.

4.12.6.3 Wake-Up Control

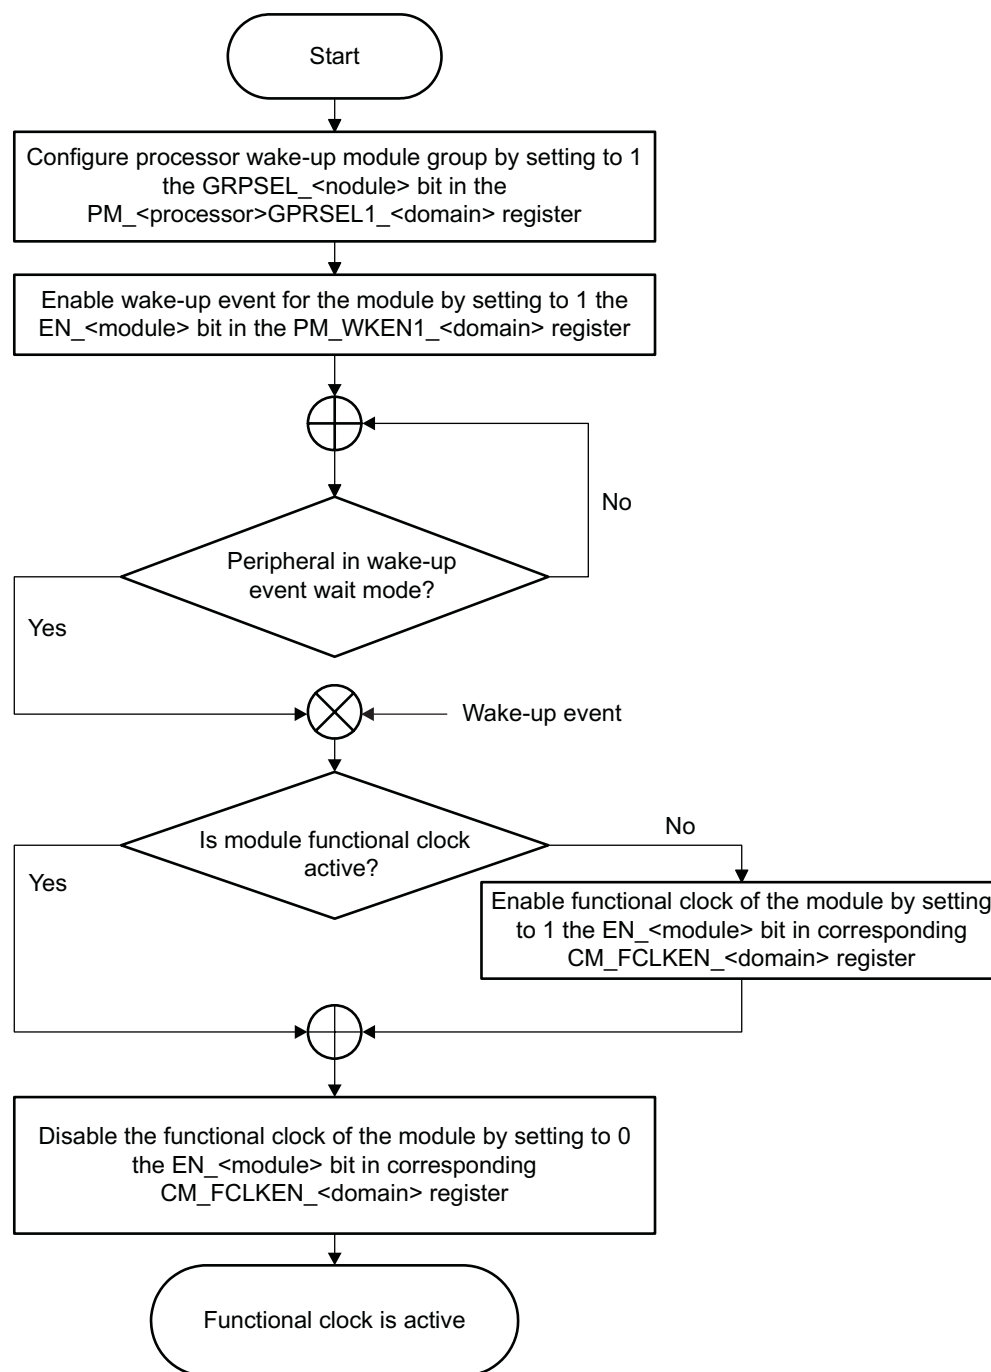

The flow chart in [Figure 4-91](#) shows the control sequence of the module wake-up event.

This procedure consists of the following steps:

1. Program the PRCM to consider the wake-up event.
2. Switch to idle mode and wait for the wake-up event.
3. Wake up on the wake-up event and activate the module functional clock.
4. Acknowledge the wake-up event.

The peripheral that can generate a wake-up event must be attached to a group of wake-up event generating modules for one or both processors by programming the `PM_<processor>GRPSEL` register. Writing 1 to this register allows the corresponding processor to be wakened on a peripheral wake-up event, assuming that the peripheral wake-up capability has been enabled by programming the register `PM_WKEN_<domain>`.

After this is configured, the PRCM initiates a wake-up procedure on receiving the peripheral wake-up event. The peripheral functional clock must be reenabled by programming the `CM_FCLKEN_<domain>` register, and then the wake-up event can be acknowledged by clearing the `PM_WKST_<domain>` register.

Figure 4-91. Wake-Up Basic Programming Model

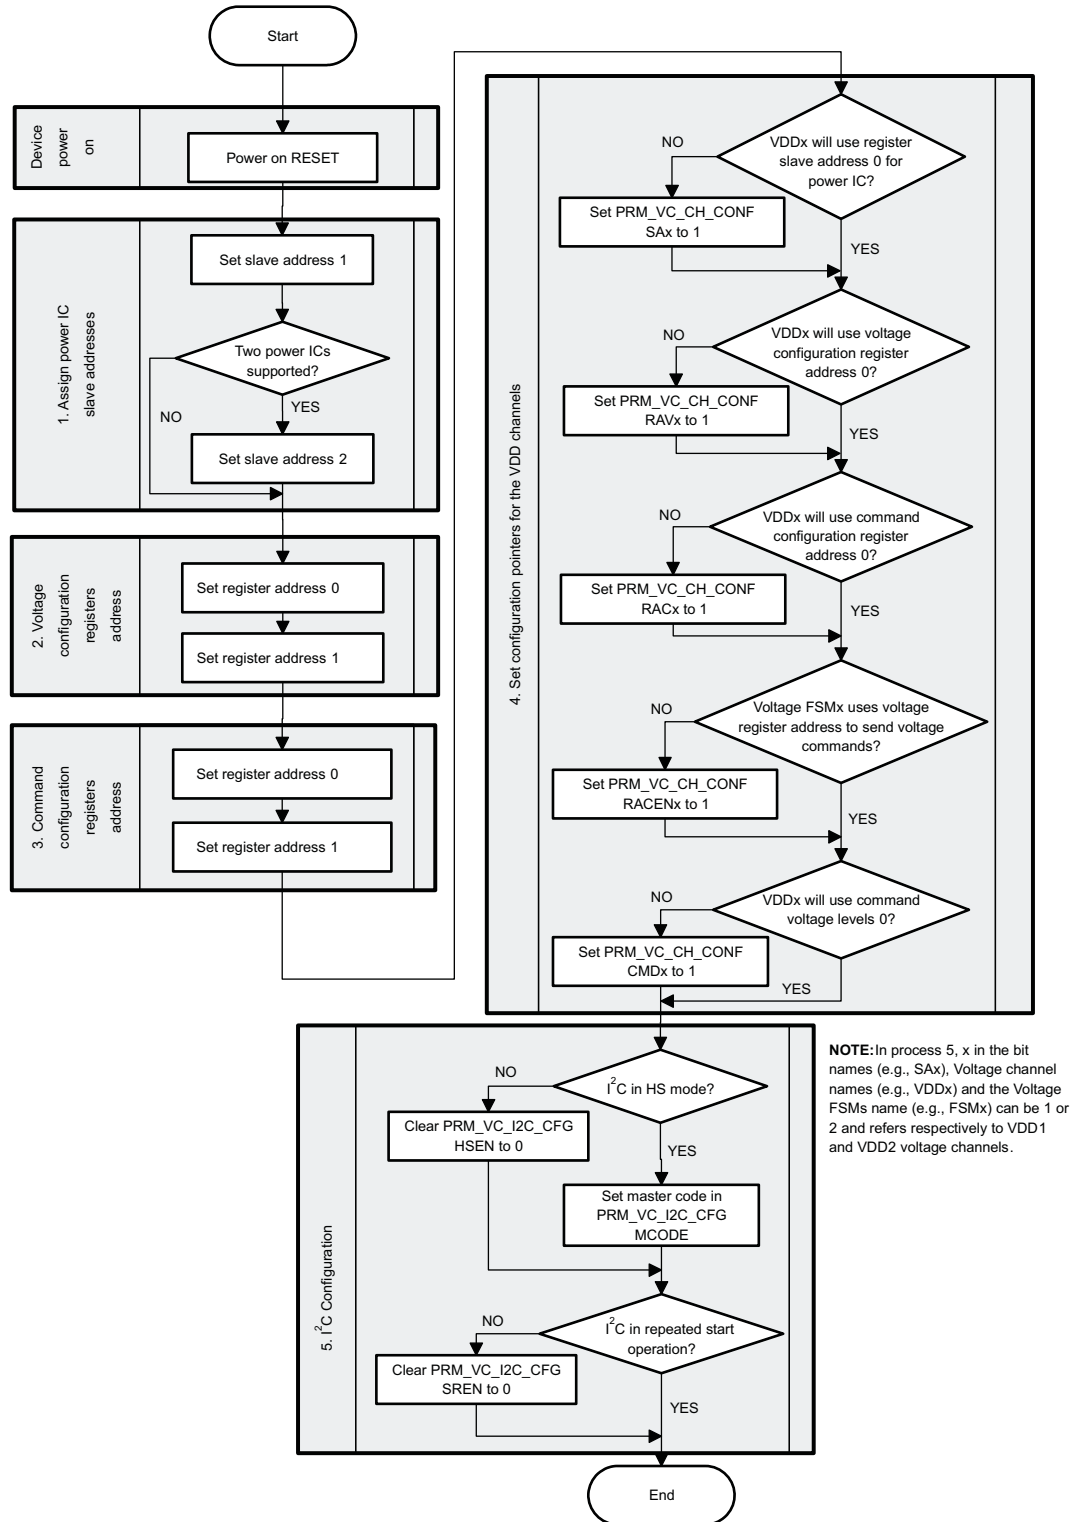

prcm-084

A power domain A can have a functional dependency on a power domain B. Thus, when power domain A wakes up, it may be necessary to wake up power domain B. This wake-up dependency is hardcoded for the CORE power domain, but is programmable for the other power domains through the PM_WKDEP_<domain> register.

4.12.6.4 Voltage Controller Initialization Basic Programming Model

Figure 4-92 is the flow chart for voltage controller initialization.

Figure 4-92. Voltage Controller Initialization Flow Chart

prcm-UC-008

1. Assign power IC slave addresses.

To support the I²C communication with external power ICs, the slave address of the power ICs must be configured in the voltage controller registers. The voltage controller can support two slave addresses to control VDD1 and VDD2 independently, from two different power ICs. At least one valid slave address is required to communicate with a power IC.

Note: The slave address for the following depends on the configured slave address of the power IC:

- PRCM.PRM_VC_SMPS_SA[6:0] SA0
- PRCM.PRM_VC_SMPS_SA[22:16] SA1

2. Set voltage configuration register addresses.

The addresses of the voltage configuration registers of the power ICs are set in the corresponding bit fields. The voltage controller can support addresses of two different voltage configuration registers (belonging to same or different power ICs).

PRCM.PRM_VC_SMPS_VOL_RA[7:0] VOLRA0		Depend on the characteristics of the connected power ICs.
PRCM.PRM_VC_SMPS_VOL_RA[23:16] VOLRA1		

3. Set command configuration register addresses.

The addresses of the command configuration registers of the power ICs are set in the corresponding bit fields. The voltage controller can support addresses of two different command configuration registers (belonging to same or different power ICs).

PRCM.PRM_VC_SMPS_CMD_RA[7:0] CMDRA0		Depend on the characteristics of the connected power ICs.
PRCM.PRM_VC_SMPS_CMD_RA[23:16] CMDRA1		

4. Set configuration pointers for the VDD channels.

The configuration pointers allow the selection of one of four configurations for each voltage channel (VDD1 and VDD2):

- Two slave I²C interfaces (slave address)
- Two voltage configuration registers
- Two command configuration registers
- Two power-mode voltage levels

PRCM.PRM_VC_CH_CONF[16] SA1		Slave address pointer (SA1 for VDD2, and SA0 for VDD1)
PRCM.PRM_VC_CH_CONF[0] SA0		
PRCM.PRM_VC_CH_CONF[17] RAV1		Voltage configuration register address pointer (RAV1 for VDD2, and RAV0 for VDD1)
PRCM.PRM_VC_CH_CONF[1] RAV0		
PRCM.PRM_VC_CH_CONF[18] RAC1		Command configuration register address pointer (RAC1 for VDD2, and RAC0 for VDD1)
PRCM.PRM_VC_CH_CONF[2] RAC0		
PRCM.PRM_VC_CH_CONF[19] RACEN1		Select voltage or command configuration register for FSM commands (RACEN1 for VDD2, and RACEN0 for VDD1)
PRCM.PRM_VC_CH_CONF[3] RACEN0		
PRCM.PRM_VC_CH_CONF[20] CMD1		Command voltage level selection pointer (CMD1 for VDD2, and CMD0 for VDD1)
PRCM.PRM_VC_CH_CONF[4] CMD0		

5. Configure I²C.

At power-on reset, the I²C4 is in HS mode. In HS mode, a master code value must be configured for the preamble I²C HS transmission. If the external power ICs do not support I²C HS mode, the interface can be switched to fast/standard (F/S) mode. By default, a repeated-start operation for communication is enabled. If necessary, it can be disabled.

For more information, see the *Inter-Integrated Circuit (I²C)* chapter.

PRCM.PRM_VC_I2C_CFG[2:0] MCODE		Master code for I ² C HS preamble
PRCM.PRM_VC_I2C_CFG[3] HSEN	0x0	Switch to F/S mode.
PRCM.PRM_VC_CH_CONF[4] SREN	0x0	Disable repeated start operation.

4.12.6.5 Event Generator Programming Examples

The event generator feature allows the MPU power domain to be switched between on and off (or placed in idled mode). This is intended to implement an efficient activity modulation of the MPU power state with minimum software support.

When the event generator is activated, the PRCM ensures that the CORE power domain always follows the MPU power domain activity.

The PRCM.PM_EVGENONTIM_MPU and PRCM.PM_EVGENOFFTIM_MPU registers of the event generator counter allow the configuration of the on and off durations (the number of system clock cycles) for the MPU power domain. The PRCM.PM_EVGENCTRL_MPU register allows the enabling/disabling of the event generator feature and control of the way on and off values are loaded in the counter.

There are three ways to load the counter with the next counting value:

- Load on update of the corresponding PRCM.PM_EVGENONTIM_MPU or PRCM.PM_EVGENOFFTIM_MPU register.
- Load the on-time value when the MPU power domain wakes up, and the off-time value when the MPU power domain starts the sleep transition (the MPU executes the WFI instruction).
- Automatically load the on-time value when the off-time value expires, and automatically load the off-time value when the on-time value expires.

When the counter times out at the end of the on/off time, it triggers the interrupt/wake-up transition, respectively. The software can use the on-time interrupt to trigger the WFI processor instruction to idle the processor clock. Similarly, the wake-up event at the end of the off time restarts the processor clock and interrupts the processor. To enable the corresponding interrupts, the MPU interrupts mask must be set in the PRCM.PRM_IRQENABLE_MPU register.

4.13 PRCM Use Cases and Tips

4.13.1 Voltage Control Using VMODE

4.13.1.1 Introduction

The PRCM allows direct simple control of VDD1 and VDD2 through the dedicated signals sys_nvmode1 and sys_nvmode2. A single voltage value can be linked in the external power IC to a given state of sys_nvmode1 or sys_nvmode2. This allows direct voltage management (see [Table 4-89](#)).

Table 4-89. VDD1 and VDD2 Voltage Control Through VMODE

sys_nvmode Signals	Voltage Values	Comments
sys_nvmode1 is high.	VDD1 value 1	VDD1 value 1 depends on the power IC programming.
sys_nvmode1 is low.	VDD1 value 2	VDD1 value 2 depends on the power IC programming.
sys_nvmode2 is high.	VDD2 value 1	VDD2 value 1 depends on the power IC programming.
sys_nvmode2 is low.	VDD2 value 2	VDD2 value 2 depends on the power IC programming.

Note: The polarity of sys_nvmode1 and sys_nvmode2 is programmable. This means that the PRCM sets them high or low, depending on the user settings. For this reason, the external power IC must be configured to provide a given voltage level depending on the states of the sys_nvmodex signals.

Assertion of sys_nvmode1 and sys_nvmode2 (low or high, depending on the chosen polarity) occurs immediately after a device sleep or wake-up transition. When the PRCM triggers a sleep transition (on to off, or on to retention), it de-asserts sys_nvmode1 and sys_nvmode2. When the PRCM detects a device wake-up transition (retention to on, or off to on), it asserts sys_nvmode1 and sys_nvmode2.

Note: sys_nvmode1 and sys_nvmode2 are managed as one signal from the PRCM standpoint. In other words, their settings and assertion conditions are managed globally, without any granularity. The power IC software sets different values for VDD1 and VDD2, if necessary.

From the PRCM standpoint, using the VMODE signals is mutually exclusive with using the dedicated I2C4 interface to the external power IC; sys_nvmodex signals share the same physical interface as I2C4 at device boundary.

Using VMODE voltage control is an easy way to switch VDD1 and VDD2 voltage values upon device power state transitions. The following section gives the programming steps to achieve voltage management through VMODE signals.

4.13.1.2 Programming Sequence

4.13.1.2.1 Initialization Procedure

1. Configure sys_nvmode1 and sys_nvmode2 at the device level.

CONTROL.CONTROL_PADCONF_I2C4_SCL[15:0]	Mux mode1
CONTROL.CONTROL_PADCONF_I2C4_SCL[31:16]	Mux mode1

The correct multiplexing mode is selected at the device level to select sys_nvmode1 and sys_nvmode2 on the balls. This is done in the SCM registers, as indicated. For further details, see the *System Control Module* chapter.

2. Activate VMODE control.

PRM_VOLTCTRL[4] SEL_VMODE	0x1
---------------------------	-----

VMODE control is selected in the PRCM. This also ensures the other interfaces to the power IC are correctly deactivated and managed.

3. Set the polarity of sys_nvmode1 and sys_nvmode2.

PRM_POLCTRL[0] EXTVOL_POL	0x1 => sys_nvmodex signals are active high
---------------------------	--

Depending on the polarity set, the VMODE signals remain high or low until a transition is initiated. Their states then automatically toggle to the opposite state and return when the reverse transition is initiated.

4. Set the voltage stabilization delays.

PRM_VOLTSETUP1[31:16] SETUP_TIME2	VDD2 voltage stabilization time
PRM_VOLTSETUP1[15:0] SETUP_TIME1	VDD1 voltage stabilization time

SETUP_TIME1 and SETUP_TIME2 are power IC-dependent parameters for voltage stabilization time for VDD1 and VDD2, respectively. For further details, see the power IC documentation.

5. Configure the power IC.

This step relies entirely on power IC software settings. The purpose here is to link a voltage value to both VDD1 and VDD2 depending on the state of the sys_nvmodex signals. For further details, see the power IC documentation.

4.13.1.2.2 VMODE Signals Toggling

1. Has a sleep/wake-up transition been initiated?

As stated previously, when VMODE voltage control is selected, the PRCM automatically toggles sys_nvmodex signals and device sleep and wake-up transitions. This means the user has nothing more to control except the device transitions, as explained in this document. When a transition is initiated, sys_nvmode1 and sys_nvmode2 toggle according to their programmed polarity and alert the power IC to switch VDD1 and VDD2 to the programmed values.

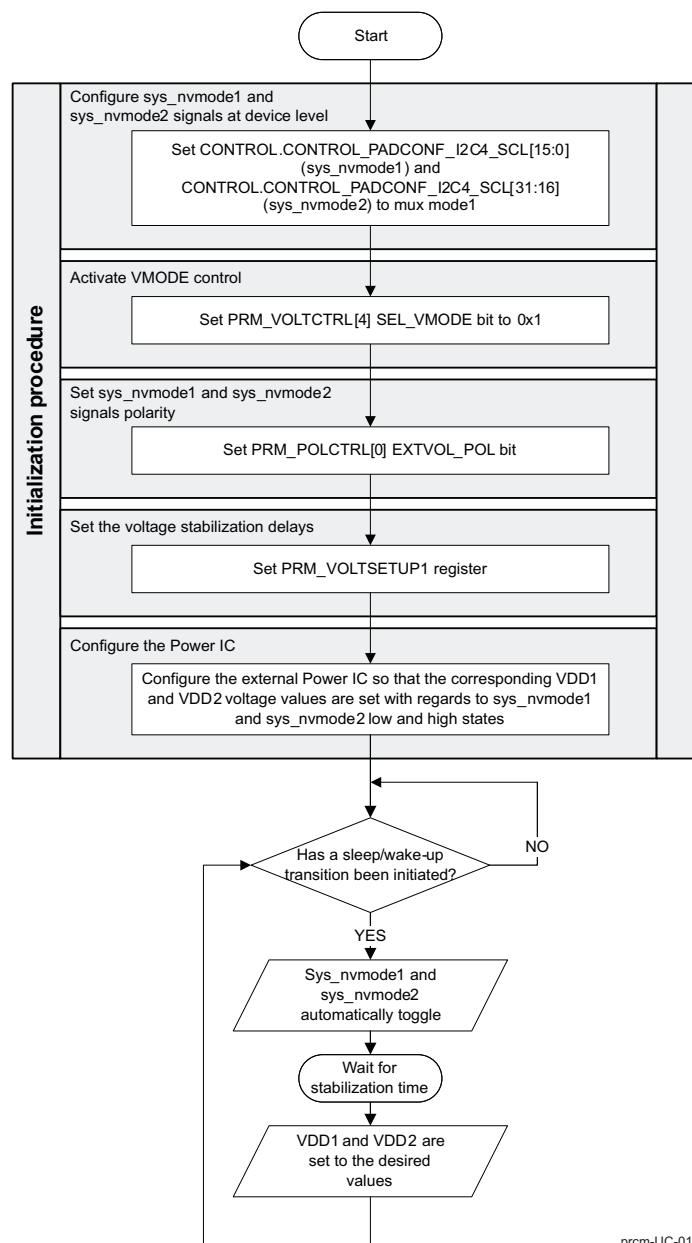

2. Wait for stabilization time.

Depending on the SETUP_TIME1 and SETUP_TIME2 settings, the PRCM starts a countdown immediately after the VMODE signal state changes. This ensures that the voltages provided by the power IC are stable before switching the device to the desired power state.

4.13.1.2.3 Summary Flow Chart

Figure 4-93 is a flow chart of VMODE voltage control.

Figure 4-93. Voltage Control through VMODE Flow Chart

4.14 PRCM Registers

This section gives information about all modules and features in the high-tier device. See Chapter 1, *OMAP35x Family* section, to check availability of modules and features. For power-management saving consideration, ensure that power domains of unavailable features and modules are switched off and clocks are cut off.

[Table 4-90](#) lists the physical addresses of the CM modules. [Table 4-91](#) through [Table 4-295](#) provide register mapping summaries of the CM registers and describe the bits in the individual registers.

[Table 4-297](#) lists the physical addresses of the PRM modules. [Table 4-298](#) through provide register mapping summaries of the PRM registers and describe the bits in the individual registers.

4.14.1 CM Module Registers

Table 4-90. CM Instance Summary

Module Name	Base Address (hex)	Size
IWA2_CM	0x4800 4000	8192 bytes
OCP_System_Reg_CM	0x4800 4800	8192 bytes

Interconnect

This chapter describes the OMAP35x Applications Processor Interconnect.

Note:

- The L3 interconnect is an instantiation of the **SonicsMX®** interconnect from **Sonics, Inc.**
- The L4 interconnects are instantiations of the **Sonics3220™** interconnect from **Sonics, Inc.**

This document contains materials that are 2003-2007 Sonics, Inc., and that constitute proprietary information of **Sonics, Inc.**

5.1 Interconnect Overview

This chapter gives information about all modules and features in the high-tier device. To flag interconnect response being blocked, the time-out of target agents attached to unavailable modules can be enabled with the lowest setting.

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

5.1.1 Terminology

The following terminology is critical to understanding the interconnect:

- **Initiator:** Module able to initiate read and write requests to the chip interconnect (typically: processors, DMA, etc.).
- **Target:** Unlike an initiator, a target module cannot generate read/write requests to the chip interconnect, but it can respond to these requests. However, it may generate interrupts or a DMA request to the system (typically: peripherals, memory controllers).

Note: A module can have several separate ports; therefore, a module can be both an initiator and a target.

- **Agent:** Each connection of one module to one interconnect is done using an agent, which is an adaptation (sometimes configurable) between the module and the interconnect. A target module is connected by a target agent (TA), and an initiator module is connected by an initiator agent (IA).
- **OCP:** Open-core protocol (www.ocpip.org) is point-to-point standard protocol between one master port and one slave port.
- **OCP master port:** Port that can generate OCP commands. An initiator includes at least one master port.
- **OCP slave port:** Port that responds to OCP commands. A target includes one slave port.
- **Interconnect:** The decoding, routing, and arbitration logic that enables the connection between multiple initiator modules and multiple target modules connected on it.
- **Register target (RT):** Special TA used to access the interconnect internal configuration registers.
- **Dataflow signal:** Any OCP signal that is part of a clearly identified OCP transfer or dataflow (typically: command, address, byte enables, etc.). The signal behavior is defined by the OCP protocol semantics.
- **Sideband signal:** Any OCP signal whose behavior is not associated to a precise OCP transaction or dataflow. The OCP standard does not define specific semantics for these signals.
- **Out-of-band error:** Any OCP signal whose behavior is associated to an error-reporting scheme of the device, as opposed to in-band errors.

Note: Interrupt requests and DMA requests are not routed by the interconnect in the device.

- **Firewall:** A programmable security feature integrated in a target agent for each module requiring a secure data path. A firewall can be configured using three criteria:
 - Initiator requesting access
 - Address space access
 - Type of access
- **Thread:** Logical entities that allow to have separate independent data flows on a single port.
- **Multithreaded ports:** A physical port able to simultaneously handle several outstanding transactions. On a multithreaded port, one physical channel (port) is used concurrently for several logical channels (threads). The transfer in each thread must remain in order with respect to each other, but the order between threads can change between requests and responses. Thread management is used for

performance optimization purposes and is automatically handled by the system.

- ConnID: Any transaction in the system interconnect is tagged by an in-band qualifier ConnID, which uniquely identifies the initiator at a given interconnect point. A ConnID is transmitted inband with the request and is used for security and error-logging mechanism.
- Firewall comparison mechanism: A comparison made in the firewall between access in-band qualifiers and access permissions that are programmed in the firewall configuration registers. If the comparison is successful, access is allowed; otherwise, access is denied.
- MCmd qualifier: Command bus that indicates the type of transfer requested. [Table 5-1](#) lists the commands encoded.

Table 5-1. MCmd Qualifier Description

MCmd[2:0]	Transaction Type
0 0 0	Idle
0 0 1	Write
0 1 0	Read
0 1 1	ReadEx
1 0 0	Not used
1 0 1	Write nonposted
1 1 0	Not used
1 1 1	Not used

- MReqInfo qualifier: Four MReqInfo qualifiers describe the access during the use of the firewall comparison mechanism, as described in [Table 5-2](#).

Table 5-2. MReqInfo Qualifier Description

Qualifiers	Description
MReqType	0: Data access 1: Opcode fetch
MReqSupervisor	0: User mode 1: Supervisor mode
MReqDebug	0: Functional access 1: Debug access
MReqSecure	0: Public transaction 1: Secure transaction ⁽¹⁾

⁽¹⁾ In GP device MReqSecure = 1 (Secure value), is not supported.

- [L3_PM_REQ_INFO_PERMISSION_i](#): Register that configures the combination of the MReqInfo, allowing access permission to the TM based on the MReqInfo in-band qualifier values.
- SError: Target that indicates an error condition to the initiator.
- SResp qualifier: Response from the target to the initiator concerning the transaction.

Table 5-3. SResp Qualifier Description

SResp[1:0]	Description
0 0	No response
0 1	Data valid/accept
1 0	Not used
1 1	Error

5.1.2 Architecture Overview

The device memory hierarchy includes four levels:

- L1 is internal to the CPUs. It concerns data exchange with the internal Level1 cache memory subsystem, and it is the closest memory to the microprocessor unit (MPU) core and the IVA2.2 core.
- L2 is included in the IVA2.2 subsystem and the MPU subsystem.
- The chip-level interconnect consists of one L3 interconnect and four L4 interconnects. It enables communication among the modules and subsystems in the device. [Figure 5-1](#) shows an overview of the L3 and L4 interconnect architecture.
 - L3 handles many types of data transfers, especially exchanges with system-on-chip/external memories. L3 transfers data with a maximum width of 64 bits from the initiator to the target. The L3 interconnect is a little-endian platform
 - L4 is composed of the L4-Core, L4-Per, L4-Wakeup, and L4-Emu interconnects and handles data transfers to peripherals. It supports 32-bit data width transfer and is optimized to support the interconnection of many peripheral targets. These backplanes assume little-endian transactions for narrower targets (8-bit, 16-bit) when doing data packing and unpacking.

Figure 5-1. Interconnect Architecture Overview

100-022

Modules are connected to the interconnect through an IA for the initiator module and a TA for target modules. Each module/subsystem connection is statically configured to tune the access depending on the characteristics of the module.

To secure a data path, some TAs include configurable firewalls (FWs) for security purposes. A firewall restricts or filters the accesses allowed to an initiator according to different access criteria. The firewalls can usually be configured by software.

The L3 and L4 interconnect default setting is fully functional; it enables all possible functional data paths and a minimal default security setting. However, it is possible to modify the interconnect parameters to fit user expectations.

5.1.3 Module Distribution

IAs and TAs provide the interface to connect the different modules and the interconnect.

[Table 5-4](#) through [Table 5-13](#) list the device modules, subsystems, and associated agents. The agents are listed for each interconnect domain:

- L3 initiator and target agents
- L4-Core initiator and target agents
- L4-Per initiator and target agents
- L4-Emu initiator and target agents
- L4-Wakeup initiator and target agents

5.1.3.1 L3 Interconnect Agents

[Table 5-4](#) and [Table 5-5](#) list the IAs and TAs, respectively, of the L3 interconnect.

Table 5-4. L3 Initiator Agents

Module Name	Description
MPU SS	MPU subsystem port
Display SS	Display subsystem port
IVA2.2 SS	IVA2.2 subsystem port
SGX SS	Graphics subsystem port
CAMERA SS	Camera subsystem port
SAD2D	Die-to-die port
sDMA read	System DMA read port
sDMA write	System DMA write port
High-Speed (HS) USB OTG	Universal Serial Bus High-Speed port OTG Controller
High-Speed (HS) USB Host	Universal serial bus High-Speed port Host Controller
DAP	Debug access port (JTAG/Emulation access to system resources)

Table 5-5. L3 Target Agents

Module Name	Description
SMS	SDRAM memory scheduler port
GPMC	General-purpose memory controller (for flash memory, SRAM, SROM, etc.) port
OCM-ROM	On-chip memory ROM port
OCM-RAM	On-chip memory RAM port
SGX	Graphics subsystem port
IVA2.2	Image video and audio accelerator subsystem port
RT	Register target port to configure L3
L4-Core	Port for L4-Core interconnect

Table 5-5. L3 Target Agents (continued)

Module Name	Description
L4-Peripherals	Port for L4-Per interconnect
L4-Emu	Port for L4-Emu interconnect

For more details on the register target module, see [Section 5.4.2, Register Target](#).

5.1.3.2 L4-Core Agents

Table 5-6. L4-Core Initiator Agent

Module Name	Description
L3 interconnect	L3 interconnect port

Note: A unique L3 port is used for communication with the L4-Core. For the list of initiators allowed to access the L4 Core peripherals, see [Table 5-14](#).

Table 5-7. L4-Core Target Agents

Module Name	Description
Display subsystem	Display subsystem configuration port
Camera subsystem	Camera subsystem port
High-Speed (HS) USB OTG	Universal serial bus High-speed port OTG
High-Speed (FS) USB Host	Universal serial bus High-Speed port Host controller
UART1	Universal asynchronous receiver transmitter port 1
UART2	Universal asynchronous receiver transmitter port 2

SPI3	Serial peripheral interface 3
SPI4	Serial peripheral interface 4
sDMA	System DMA controller
L4-Wakeup	L4-Wakeup interconnect
CM	Clock manager
SCM	System control module

5.1.3.3 L4-Per Agents

Table 5-8. L4-Per Initiator Agent

Module Name	Description
L3 interconnect	L3 interconnect port

Note: A unique L3 port is used for communication with L4-Per. For the list of initiators allowed to access the L4-Per peripherals, see [Table 5-14](#).

Table 5-9. L4-Per Target Agents

Module Name	Description
UARTIrDA	Universal asynchronous receiver/transmitter and infrared data association port
McBSP2	Multichannel buffered serial port 2
McBSP3	Multichannel buffered serial port 3
GPTIMER2	General-purpose timer 2
GPTIMER3	General-purpose timer 3
GPTIMER4	General-purpose timer 4
GPTIMER5	General-purpose timer 5
GPTIMER6	General-purpose timer 6
GPTIMER7	General-purpose timer 7
GPTIMER8	General-purpose timer 8
GPTIMER9	General-purpose timer 9
GPIO2	General-purpose I/O 2
GPIO3	General-purpose I/O 3
GPIO4	General-purpose I/O 4
GPIO5	General-purpose I/O 5
GPIO6	General-purpose I/O 6

5.1.3.4 L4-Emu Agents

Table 5-10. L4-Emu Initiator Agents

Module Name	Description
L3 interconnect	L3 interconnect port
DAP	DAP port

Note: The L3 and DAP ports are used for communication with L4-Emu. For the list of initiators allowed to access the L4-Emu peripherals, see [Table 5-14](#).

Table 5-11. L4-Emu Target Agents

Module Name	Description
L4-Wakeup	L4 wake-up interconnect
SDTI	System debug trace interface
ETB	Embedded trace buffer
TPIU	Trace port interface unit
MPU	ARM9
DAPCTL	Debug access port

5.1.3.5 L4-Wakeup Agents

Table 5-12. L4-Wakeup Initiator Agent

Module Name	Description
L4-Core interconnect	L4-Core interconnect port
L4-Emu interconnect	L4-Emulation interconnect port

Note: The L4-Emu and L4-Core ports are used to communicate with the L4-Wakeup. For the list of initiators allowed to access the L4-Wakeup peripherals, see [Table 5-14](#).

Table 5-13. L4-Wakeup Target Agents

Module Name	Description
PRM	Power reset management
GPIO1	General-purpose I/O 1
GPTIMER1	General-purpose timer 1
GPTIMER12 ⁽¹⁾	General-purpose timer 12
WDTIMER1 ⁽¹⁾	Secure watchdog timer
WDTIMER2	MPU subsystem watchdog timer
32KTIMER	32-kHz timer
USIM	Universal Subscriber Identity Module

⁽¹⁾ Not available in GP device.

5.1.4 Connectivity Matrix

[Table 5-14](#) lists the functional paths between the L3 interconnect initiator modules and the L3 and L4 TAs. The functional paths are indicated by the use of the following:

- Cell contains a + sign when a functional path exists.
- Cell is blank when no functional path exists.

Table 5-14. Connectivity Matrix

Initiator Ports	L4-Core Target ⁽¹⁾	L4-Per Target ⁽¹⁾	L4-Emu Target ⁽¹⁾	L4-Wakeup Target ⁽¹⁾	SMS Target	GPMC Target	OCM RAM Target	OCM ROM Target	RT Target	IVA2.2 Target	SGX Target	MAD2D
MPU IA	+	+	+	+	+	+	+	+	+	+	+	+
SGX IA					+	+	+					+
IVA2.2 IA	+	+	+	+	+	+	+		+	+		+
DSS IA					+		+					+
CAM IA					+		+					+
HS USB Host IA					+	+	+					+
HS USB OTG IA					+	+	+					+
sDMA RD IA	+	+	+	+	+	+	+			+	+	+
sDMA WR IA	+	+	+	+	+	+	+			+	+	+
DAP IA	+	+	+	+	+	+	+	+	+	+	+	+
SAD2D IA	+	+	+	+	+	+	+					

- ⁽¹⁾ A functional data path always exists from L4 IAs (Core, Per, Emu, and Wakeup) to any L4 target module (Core, Per, Emu, and Wakeup). As a consequence, all L3 initiator modules for which a data path exists to an L4 TA can access L4 peripherals. Restrictions on peripheral access depend on the security settings and L4 protection mechanism programming. For more details, see [Section 5.9.3, L4 Security and Firewalls](#).

5.2 L3 Interconnect

This section describes the L3 interconnect and its components. With the exception of register points, each component includes functionality for both the request and response network.

5.2.1 Overview

The L3 interconnect links cores in a flexible topology that couples low power with high performance. Innovative physical structures and advanced protocols ensure bandwidth and latency to individual IP cores, providing dedicated connections between IP cores and logical connections over a shared interconnect.

Figure 5-2 shows the L3 interconnect.

Figure 5-2. L3 Interconnect Overview

100-007

The following are the main features of the L3 interconnect:

- 64-bit multipath interconnect to eliminate on-chip bottlenecks
- Special internal target for access to L3 registers (RT)
- Guaranteed quality of service for real-time hardware operators, while maintaining optimal memory latency for MPU accesses to memory resources
- True little-endian platform
- Transaction error tracking and logging
- Built-in security features:
 - Allow access only to authorized initiator
 - Distributed region-based firewalls for system resource sharing and protection management
- Signaling support for chip-level power management infrastructure
- Two interrupt line signaling transaction error

5.3 L3 Interconnect Integration

5.3.1 Clocking, Reset, and Power-Management Scheme

5.3.1.1 Clocks

The power, reset, and clock management (PRCM) module provides the L3_ICLK as the main clock to the L3 interconnect.

In addition to L3_ICLK, four additional sample signals are provided to module agents to allow internal synchronization. The modules are as follows:

- L4-Core
- L4-Per

For more details on the L3 clock and its setting, see the *Power, Reset, and Clock Management* chapter.

Table 5-15. L3 Interconnect Clocks

Type	Name	Source	Description
Interface/functional	L3_ICLK	PRCM	Main clock for L3 interconnect

5.3.1.2 Resets

The L3 interconnect receives a single reset signal, CORE_RST, from the PRCM module. CORE_RST is the reset signal to the core power domain. (For more details, see the *Power, Reset, and Clock Management* chapter.) When asserted, CORE_RST resets the L3 internal registers. There is no software reset for the L3 interconnect.

Table 5-16. L3 Interconnect Reset

Type	Reset Domain	Source	Description
Hardware	CORE_RST	PRCM	Asynchronous reset for the entire interconnect

5.3.1.3 Power Domain

The L3 interconnect connects into the CORE power domain, which can dynamically switch among supported OPPs. For more details on power voltage scaling, see the *Power, Reset, and Clock Management* chapter.

Table 5-17. L3 Interconnect Power Domain

Interconnect	Power Domain
L3 interconnect	CORE

5.3.1.4 Power Management

As part of the system-wide power-management scheme, the L3 interconnect enters an idle state at the request of the PRCM module. (For more details, see the *Power, Reset, and Clock Management* chapter.) The L3 interconnect is always in smart-idle mode; that is, it goes into idle state after receiving the request from the PRCM module once all transfer requests are serviced. This functionality is handled by hardware. The L3 interconnect sends an acknowledge signal back to the PRCM module when it enters the idle state.

5.3.2 Hardware Requests

5.3.2.1 Interrupt Requests

Three interrupt lines are present at the boundary of the L3 interconnect (see [Table 5-18](#)). They are used for hardware error management.

Table 5-18. L3 Interconnect Hardware Requests

Type	Name	Destination	Description
Interrupt	M_IRQ_9	MPU interrupt controller for debug errors	L3 interconnect provides a mechanism to group core-detected and internal interconnect errors. See Section 5.9.4, Error Handling .
Interrupt	M_IRQ_10	MPU interrupt controller for application errors	
Interrupt	IVA2_IRQ [39]	IVA2.2 interrupt controller for application errors	

5.4 L3 Interconnect Functional Description

5.4.1 Initiator Identification

An InitiatorID is assigned to every thread on every initiator socket. The ID uniquely identifies the initiator and thread for an interconnect transfer see [Table 5-19](#). The interconnect uses InitiatorIDs for a number of purposes, including the following:

- Initiator source identification for the protection mechanism (see [Section 5.4.3, L3 Security and Firewalls](#))
- Response route generation (performed internally to the TAs)
- Firewall error logging
- L3 interconnect error logging

Table 5-19. InitiatorID Definition

Initiator	InitiatorID
HS USB Host	0
HS USB OTG	2
sDMA rd	3 , 4 , 5, 6
sDMA wr	7, 8
DAP	9
CAM	10, 11, 12
SGX	13
IVA2.2 SS DMA	14, 15, 16, 17, 18, 19
IVA2.2 SS	20, 21, 22
MPU SS	23, 24, 25, 26, 27
SAD2D	28
LCD	29

5.4.2 Register Target

An RT is a specialized TA used to access L3 interconnect internal configuration registers.

RT configuration options are a subset of those available for TAs. For more details, see [Section 5.6.5](#).

5.4.3 L3 Security and Firewalls

Security in the device relies heavily on L3 firewalls and their configuration. Nine targets are protected through the use of firewalls. The number of protected regions varies on the target, with a maximum of eight regions. [Table 5-20](#) lists the security configuration and the number of protected regions for each target.

Table 5-20. Target Firewall and Region Configuration

Target	Firewall	Number of Regions
SMS	Included in the SMS module	See the <i>Memory Subsystem</i> chapter.
GPMC	Yes	8
OCM-RAM	Yes	8
OCM-ROM	Yes	2
MAD2D	Yes	8
IVA2.2 target	Yes	4
L4-Core	Included in the L4 module	See Section 5.7 , L4 Interconnect.
L4-Wakeup	Included in the L4 module	See Section 5.7 , L4 Interconnect.

Table 5-20. Target Firewall and Region Configuration (continued)

Target	Firewall	Number of Regions
L4-Emu	Included in the L4 module	See Section 5.7 , L4 Interconnect.
RT	Yes	2

The protection mechanism designates protection regions within the address space of certain targets. Access to these regions is granted only for certain initiators, based on transaction attributes (transmitted through MReqInfo). Each protection region is characterized with several configurable attributes (base address, size, specific access rights, and priority setting).

The protection mechanism uses the following attributes of a request:

- The address field and the address space field are used to determine which region has been hit. The region ID selects one table entry of the firewall look-up table.
- The region ID points to a unique set of permission registers: Read_Permission, Write_Permission, ReqInfo_Permission.
- The Initiator ID is used to determine the permission of the initiator (read/write permission) with respect to the concerned region.
- The access types (read or write) and the transaction attributes (MReqInfo in-band qualifiers) are used to grant or reject the access.

The first check determines whether the type of incoming request (read or write) is allowed, according to the Initiator MConnID and its read and write permissions. The second check determines whether the MReqInfo bits of the incoming request are within the allowed pattern established by the MReqInfo permission bits. If both check results are positive, the request is allowed to access the target. Otherwise, the access is denied, the request is not forwarded to the target, an out-of-band error indication is reported, and an in-band error response is returned to the initiator (except for writes that were posted at the IA).

[Figure 5-3](#) shows the flow used to identify and accept a new request.

Figure 5-3. Flowchart of the Protection Mechanism

100-014

To summarize, firewalls accept or reject a request depending on the following:

- Initiator originating the request
- Command (read or write) requested
- MReqInfo bus state
- Region access in the target memory space

Software must configure the L3 firewalls properly to allow the right initiators, with the right MReqInfo access, on the well-defined size region. All the registers relative to the L3 firewalls are grouped in the protection mechanism (PM) register block.

Note: The PM qualifies the protection mechanism register associated with a firewall target. The targets protected by a firewall are listed in [Table 5-20](#). These PM registers do not exist if no firewall is associated with the target.

5.4.3.1 Protection Region

Two types of regions are distinguished in a target firewall (see [Figure 5-4](#)):

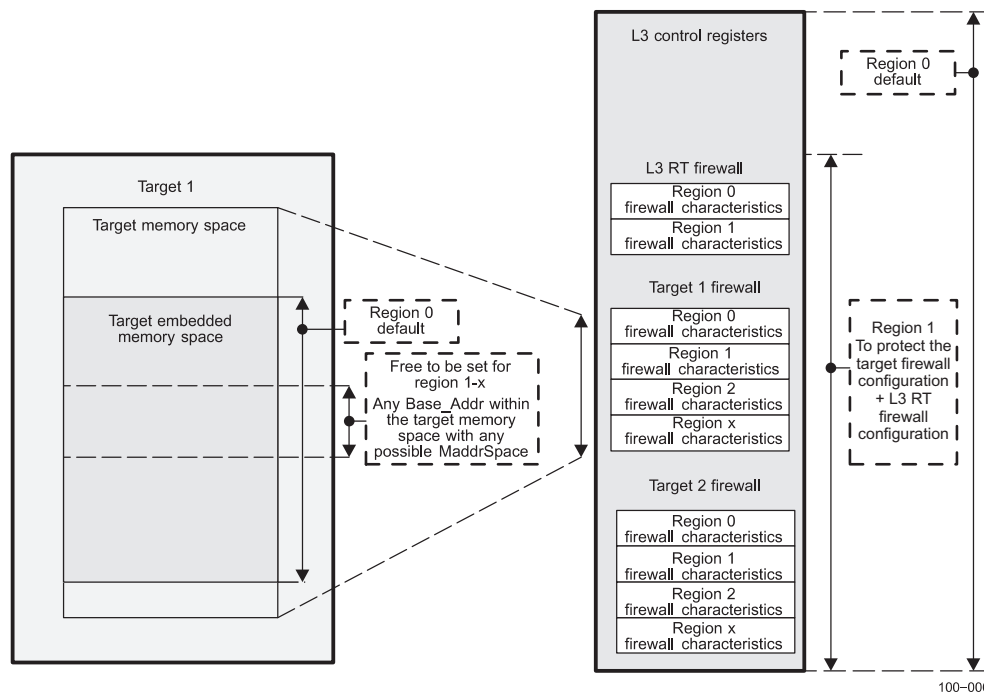

- Default region: Available in all targets; spans the entire target address range
- Normal region: Number varies in a target; they have identical capabilities

Each region has the following characteristics:

- A base address, relative to the target address itself, and an address space

- A size
- Specific access rights, as defined through the MReqInfo qualifiers
- A priority level, from 0 (lowest) to 3 (highest)

Figure 5-4. L3 Firewall Implementation

5.4.3.1.1 Default Region/Region0

Region 0 is the default region of a whole target; it spans the entire target address space.

The default region is always the lowest priority. This region is systematically overlapped when other regions are set.

The [L3_PM_ADDR_MATCH_k](#) register is not accessible. Its configuration corresponds to all the possible addresses for the target, including all of ADDR_SPACE. It is not possible to program multiple ADDR_SPACE addresses in a normal region.

5.4.3.1.2 Normal Regions

Normal regions have identical features.

A given request either maps into a specific protection region or is considered to have hit the default protection region if no normal region is hit.

The protection regions can only be configured for a memory space that is power-of-two in size and size-aligned using the SIZE bit field [L3_PM_ADDR_MATCH_k](#) [7:3] (as listed in [Table 5-21](#)). When the SIZE bit field [L3_PM_ADDR_MATCH_k](#) [7:3] is set to 0, the region is disabled.

Note: k denotes the region number. Depending on the target, n varies from 0 to 7.

[Table 5-21](#) lists the size encoding for each value set in the SIZE bit field.

Table 5-21. L3 Firewall Size Parameter Definition

Size ⁽¹⁾	Region Size	Possible Configuration	
		Base_Addr ⁽²⁾	
0x0	Region disabled	Any (nonsignificant)	
0x1	1K-byte secure	0x0000000	
		0x0000400	
		0x0000800	
		.	
0x2	2K-byte secure	0x0000000	
		0x0000800	
		0x0001000	
		...	
...	
0x17	2 ^{^(17-1)} K-byte secure		
Others	Not allowed	-	

⁽¹⁾ When the size parameter is set to 0, the region is disabled.

⁽²⁾ The base address depends on user settings.

5.4.3.2 Priority Level Overview

Each L3 firewall region is prioritized. Depending on its priority level, a region can override the settings of another region.

- Region 0 is the only allowed priority 0 region (lowest priority).
- Region 1 is the only allowed priority 3 region (highest priority).
- Others regions are defined as priority 1 or 2.

CAUTION

LEVEL bitfield value of ADDR_MATCH_1 register (Region 1 firewall configuration) must be kept to his default reset value and must not be changed; otherwise, the result will be unpredictable and can create unexpected security holes or denial of service.

Protection level is defined by the LEVEL bit [L3_PM_ADDR_MATCH_k](#) , where n is greater than 2. [Figure 5-5](#) represents the priority level with associated regions.

When an address hits two or more regions with different priority levels, the highest priority region protections are applied. The overlay region can overlap all or a part of a nonoverlay region.

CAUTION

Configuring two overlapping protection regions with the same priority level leads to undefined behavior.

Hardware behavior in the case of overlapping protection regions is undefined. A region with higher priority must be used to mask a region that is being reprogrammed, and any security holes must be avoided during this reconfiguration.

To change the protection settings of a region, follow this procedure:

1. Ensure that a free region is available to be used as a high-priority region.

2. Program this region as a high-priority region so its parameters match the region to be changed. The final programming must be the [L3_PM_ADDR_MATCH_k](#) register, which includes the priority attribute and the size parameter to enable the region.
3. Disable the region to be configured or reconfigure it by setting the SIZE bit field to 0.
4. Set up all region control registers with the new configuration. The final programming must be the [L3_PM_ADDR_MATCH_k](#) register, which includes the size parameter to enable the region.
5. Disable the high-priority region by setting its size to 0.

This procedure must be used each time there is an overlap between the originally defined region and the newly defined region. The use of a high-priority region is required to keep security active during programming.

Figure 5-5. L3 Region Overlay and Priority Level Overview

100-008

5.4.3.3 Read and Write Permission

Read permission and write permission are configured using two registers:

- [L3_PM_READ_PERMISSION_i](#)
- [L3_PM_WRITE_PERMISSION_i](#)

The [L3_PM_READ_PERMISSION_i](#) and [L3_PM_WRITE_PERMISSION_i](#) registers allow the setting of read and write permission to one or more initiators. To grant read or write access, set the bit associated with the initiator to 1.

5.4.3.4 REQ_INFO_PERMISSION Configuration

The firewall comparison mechanism enables access to a protected target only when a correct combination of four MReqInfo in-band parameters is transmitted.

MReqInfo is a combination of a fixed 4-bit pattern that corresponds to a combination of the parameters MReqSecure, MReqDebug, MReqType, and MReqSupervisor.

Note: In GP device MReqSecure = 1 (Secure value), is not supported.

Different valid MReqInfo combinations can be defined for each L3 firewall region based on the [L3_PM_REQ_INFO_PERMISSION_i](#) value, which is programmed by software.

For each region, [L3_PM_REQ_INFO_PERMISSION_i](#) lists the possible MReqInfo combinations. Setting a Reqbit in this register determines the type of access allowed to the initiator.

[Table 5-22](#) lists the MReqInfo combinations available and the Reqbit associated with it.

Table 5-22. MReqInfo Parameter Combinations

Reqbit	MReqInfo			
	MReqSupervisor	MReqSecure ⁽¹⁾	MReqDebug	MReqType
0	User	Public	Functional	Data
1	User	Public	Functional	Code
2	User	Public	Debug	Data
3	User	Public	Debug	Code
4	User	Secure ⁽¹⁾	Functional	Data
5	User	Secure ⁽¹⁾	Functional	Code
6	User	Secure ⁽¹⁾	Debug	Data
7	User	Secure ⁽¹⁾	Debug	Code
8	Supervisor	Public	Functional	Data
9	Supervisor	Public	Functional	Code
10	Supervisor	Public	Debug	Data
11	Supervisor	Public	Debug	Code
12	Supervisor	Secure ⁽¹⁾	Functional	Data
13	Supervisor	Secure ⁽¹⁾	Functional	Code
14	Supervisor	Secure ⁽¹⁾	Debug	Data
15	Supervisor	Secure ⁽¹⁾	Debug	Code

⁽¹⁾ In GP device MReqSecure = 1 (Secure value), is not supported.

[Figure 5-6](#) shows an example of the [L3_PM_REQ_INFO_PERMISSION_i](#) setting. In this example, [L3_PM_REQ_INFO_PERMISSION_i](#) is set to 0x0C14 (16'b0000_1100_0001_0100) for a specific region, which will grant access only if the request:

- User + Public + Debug + Data
- User + Secure + Functional + Data

- Supervisor + Public + Debug + Data
- Supervisor + Public + Debug + Code

Figure 5-6. Example of REQ_INFO_PERMISSION Register

As another example, to configure a target accessible only for data and in a public mode, Reqbit 0, 2, 8, and 10 must be set. Therefore, the [L3_PM_REQ_INFO_PERMISSION_i](#) register must be set to 0x5050.

5.4.3.5 L3 Firewall Registers Overview

[Table 5-23](#) lists the L3 firewall permission-setting registers. [L3_PM_ADDR_MATCH_k](#), which is shown in this table, is not an accessible register.

Table 5-23. L3 Firewall Permission-Setting Registers

Register Name	Register Field Name	Field Modifiability	Parameter Comments	Region Comments
Region 0				This region is the default region. The default setting can be changed only with correct access according to L3 RT register.
L3_PM_ADDR_MATCH_k (k=0)	ADDR_SPACE[2:0]	Hard coded	Corresponds to all the target memory space	
	SIZE[7:3]	Hard coded	Corresponds to all the target memory space	
	Reserved		Default region: Level 0	
	BASE_ADDR[63:10]	Hard coded	Target-dependent	
L3_PM_REQ_INFO_PERMISSION_i (i=0)	REQ_INFO[15:0]	Yes	Type of access permitted. See Table 5-22 .	
L3_PM_READ_PERMISSION_i (i=0)	READ_PERMISSION[15:0]	Yes	Initiator read permission, depending on connections. See Table 5-14 .	
L3_PM_WRITE_PERMISSION_i (i=0)	WRITE_PERMISSION[15:0]	Yes	Initiator write permission, depending on connections. See Table 5-14 .	The default settings can be changed only with correct access based on the L3 RT register.
Region 1-7				
L3_PM_ADDR_MATCH_k	ADDR_SPACE[2:0]	Yes		
	SIZE [7:3]	Yes	The regions are power-of-two in size and size-aligned with Base_Addr reference. When Size = 0x0, the firewall is deactivated.	
	LEVEL[9]	Yes	Protection region level 0x0: Level 1 0x1: Level 2 Region 1 is always Level 3.	
	BASE_ADDR[63:10]	Yes	Target-dependent	
L3_PM_REQ_INFO_PERMISSION_i	REQ_INFO[15:0]	Yes	Type of access permitted. See Table 5-22 .	
L3_PM_READ_PERMISSION_i	READ_PERMISSION[15:0]	Yes	Initiators read permission ,depending on connections. See Table 5-14 .	
L3_PM_WRITE_PERMISSION_i	WRITE_PERMISSION[15:0]	Yes	Initiators write permission, depending on connections. See Table 5-14 .	

5.4.3.6 L3 Firewall Error-Logging Registers

Table 5-24 lists the L3 firewall error-logging registers.

Table 5-24. L3 Firewall Error Logging Registers

Register Name	Register Field Name	Field Modifiability	Parameter Comments
L3_PM_ERROR_LOG	CMD[2:0]	Read only	Log the OCP command of the request that caused a protection violation. See Table 5-1.
	REGION[6:4]	Read only	Log the region number targeted by the request that caused the protection violation.
	INITIATOR_ID[15:8]	Read only	Log the InitiatorID request that caused the protection violation. See Table 5-19
	REQ_INFO[20:16]	Read only	Log the MReqInfo bits of the request that caused the protection violation. See Table 5-22.
	CODE[27:24]	Read/write	Log the error that occurred. See Table 5-26.
	MULT[31]	Read/write	If a second error is detected before the first is cleared, the MULT bit is set. Once set by hardware, the CODE and MULT bits can be cleared only by software or a full hardware reset. Software clears the CODE and MULT bits by writing a non-zero value to the CODE field and writing 1 to the MULT bit.

Note: This error log can be cleared in public mode by a read access. For more details, see [Section 5.5.3.2, Acknowledging Errors](#).

5.4.3.7 L3 Firewall and System Control Module

When a security violation occurs, an interrupt is sent to the MPU and IVA2.2 interrupt controller (if enabled). An in-band error is sent back, and an out-band error is logged in the CONTROL.CONTROL_SEC_ERR_STATUS register. Two logging registers are used, depending on the functional mode:

- In application mode:
 - CONTROL.CONTROL_SEC_ERR_STATUS [00]: OCM-ROM security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS [01]: OCM-RAM security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS [02]: GPMC security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS [04]: SMS security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS [05]: MAD2D security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS [06]: IVA2.2 security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS [07]: L4-Core security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS [12]: L3 RT security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS [15]: SAD2D security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS [16]: L4-Per security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS [17]: L4-Emu security violation
- In debug mode:
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [00]: OCM-ROM security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [01]: OCM-RAM security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [02]: GPMC security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [03]: SMS security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [05]: MAD2D security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [06]: IVA2.2 security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [12]: L3 RT security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [16]: L4-Per security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [17]: L4-Emu security violation

When a violation occurs, these bits are cleared when the L3 or L4 firewall embedded error log registers are cleared.

The L3 interconnect allows the inputting of the reset value of some of its internal registers from the system control module. This feature is used to configure the L3 firewalls in a secure state at start-up when required for the different targets. For more information on these registers, see the *System Control Module* chapter.

CAUTION

The exported reset value registers in the system control module can be accessed only when the MPU is in secure mode. They cannot be accessed on general-purpose devices. Outside secure mode, a read to this register returns 0.

5.4.4 Error Handling

5.4.4.1 Error Detection and Logging

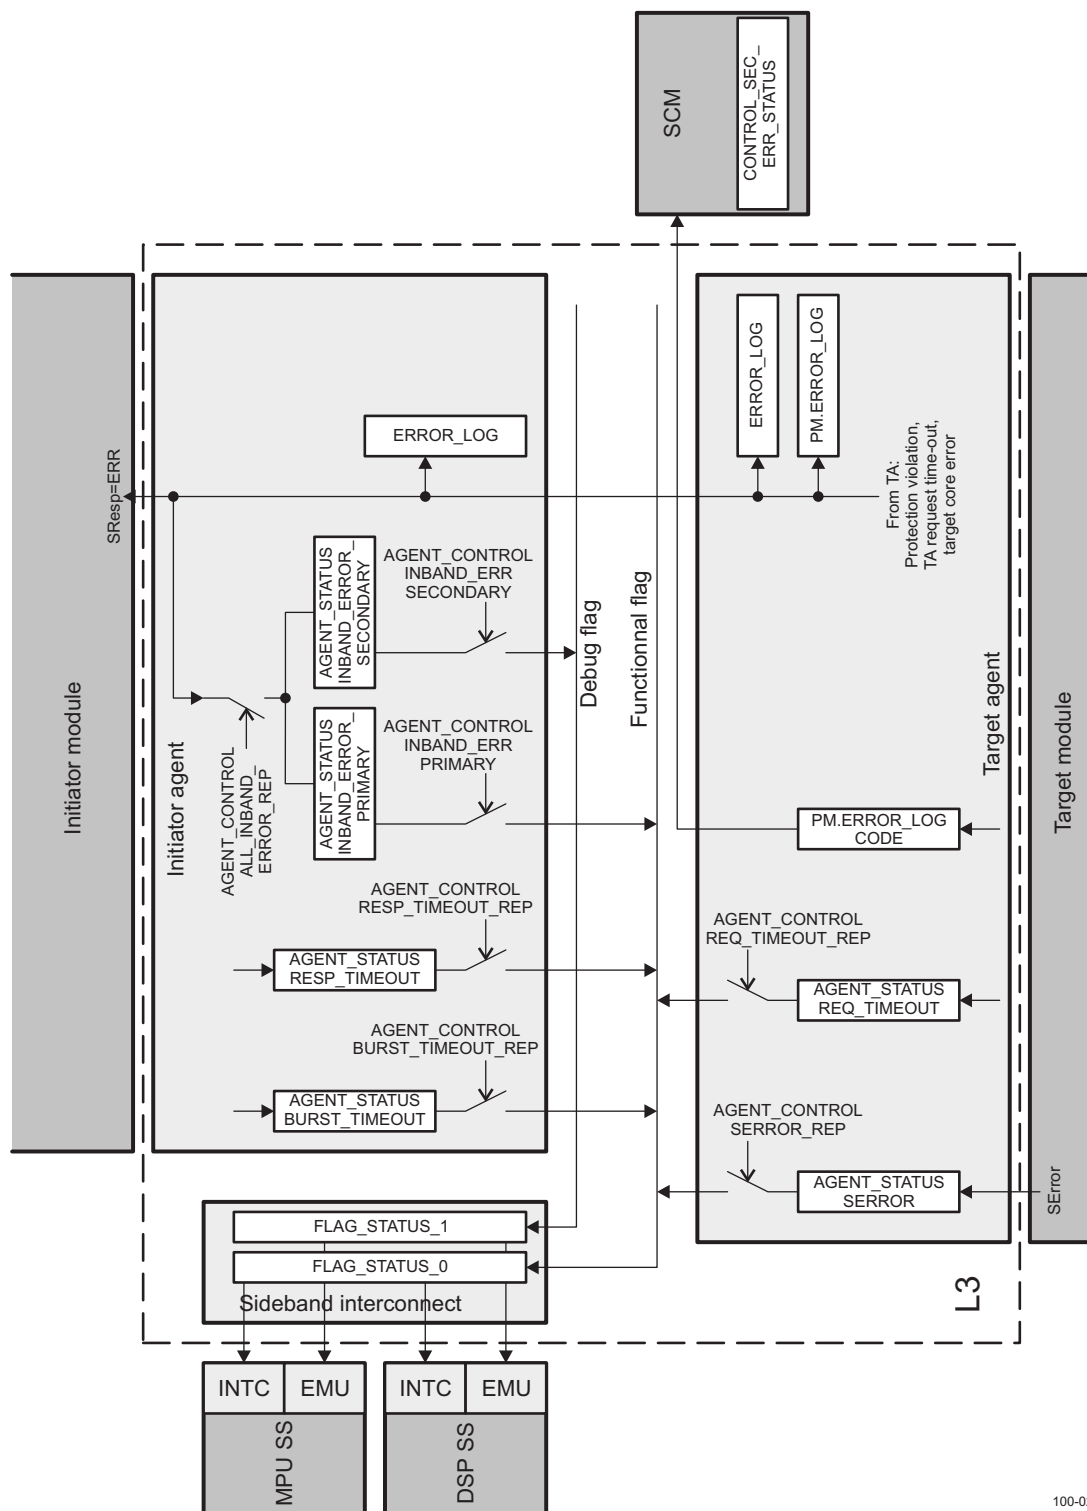

The L3 interconnect provides mechanisms for the detection, logging, and distribution of module-detected and internal interconnect errors. Hardware support is provided to assist in logging errors and cleaning up the state to allow error recovery software to run.

Two types of errors are identified by the L3 interconnect:

- Errors detected by modules and passed along by the interconnect:
 - SResp error: Using the SResp in-band qualifier from the target, the initiator is informed that its request was unsuccessful (see [Table 5-3](#)). This error is nonspecific and further analysis is required to find its cause.
 - SError: This out-of-band qualifier reports that the target is denied service due to an internal cause. No further analysis can be done in the L3 itself.
- Errors detected by the L3 interconnect:
 - Unsupported command: This error reports that the initiator sent a command that cannot be processed, because the target cannot accept it and no conversion to another command is possible. This error is detected only once per burst.
 - Address hole: This error reports an unknown address for a request. The address map is local to each IA; therefore, an address hole error is reported each time an initiator requests an access to a target it is not logically connected to, even if this address exists in the global L3 address map. This error is detected only once per burst.
 - Protection violation: This error indicates a request was rejected by a firewall.
 - Requests time-out: This error reports that the module did not end or respond to the request presented by the TA in the correct time interval. If the time interval for any request exceeds the time-out period, a time-out occurs. The target stops servicing requests.
 - Response time-out: This error reports that the module did not end the response presented by the IA in the correct time interval. If the time interval for any response exceeds the time-out period, a time-out occurs. The initiator stops servicing responses.
 - Burst open time-out: This error reports that a burst or ReadEx/Write pair is open and no command is presented to the module to end it. If the time interval for any command exceeds the time-out period, a time-out occurs. The initiator does not complete a burst or ReadEx/Write pair.

[Figure 5-7](#) shows a global view of the register link to the error reporting structure in an initiator and the target agents.

Figure 5-7. L3 Error Reporting Structure

100-023

Most errors are reported to the IA that originated the request, except for the following:

- Initiator time-outs are reported only out-of-band. Any time-out in the IA results in flagging it as unavailable. A software reset of the agent is required to accept any new requests from the attached core.

- Posted write request, because the IA immediately generates a valid response to the initiator core. This error is only in out-of-band.

Table 5-25 lists where the errors are detected and logged.

Table 5-25. Error Types

Error	Detection	Logging	In-band Report	Out-of-band Report
SResp error	None needed	At IA	Yes ⁽¹⁾	Yes
SError assertion from target	None needed	At TA	No	Yes
Unsupported command	At IA	At IA	Yes	Yes
Address hole	At IA	At IA	Yes	Yes
Protection violation	At TA	At protection mechanism agent	Yes ⁽¹⁾	Yes
Request time-out	At TA	At TA	Yes ⁽¹⁾	Yes
Response time out	At IA	At IA	No	Yes
Burst time-out	At IA	At IA	No	Yes

⁽¹⁾ In case of a posted write, errors cannot be reported in-band.

The time-out errors (request/response and burst) are persistent and require the software to reset both the module and the agent. No request can be processed in the agent until the reset is performed.

Other errors affect only the current request. Subsequent requests are treated normally. Errors are logged, however, and the information about the error used for debugging is kept until the software acknowledges the error.

Table 5-26 lists the information logged for each error code. Information logged in the two error-logging registers (L3_IA_ERROR_LOG, L3_IA_ERROR_LOG_ADDR, L3_TA_ERROR_LOG and L3_TA_ERROR_LOG_ADDR for each IA and TA) depends on the error itself. The CODE field ERROR_LOG[27:24] identifies the type of error occurring for the IA and TA.

Table 5-26. CODE Field Definition

		Type of Agent			Information Logged				
CODE[3:0]	Error Type	IA	TA	PM	REQ_INFO	Secondary	InitiatorID	CMD	Address
0	No error	x	x						
1	Unsupported command	x			x	x	x	x	x
2	Address hole	x			x	x	x	x	x
3	Protection violation			x	x		x	x	
4	In-band error	x				x	x		
5	Not used								
6	Not used								
7	Request time-out not accepted		x		x		x	x	x
8	Request time-out, no response		x				x		
9-15	Not used								

5.4.4.2 Time-Out

This section gives information about all modules and features in the high-tier device. See the *OMAP35x Family* chapter to check availability of modules and features. To flag interconnect response being blocked, the time-out of target agents attached to unavailable modules can be enabled with the lowest setting.

A time-out mechanism can be enabled in the target agent and initiator agent register. When the mechanism is enabled for a target agent or initiator agent and commands are not accepted or responses are not returned within the expected delay, the L3 interconnect generates an error event.

The error is logged in the target agent REQ_TIMEOUT bit [L3_TA_AGENT_STATUS\[8\]](#) for a target agent time-out, the BURST_TIMEOUT bit [L3_IA_AGENT_STATUS\[16\]](#) for an initiator burst time-out, and the RESP_TIMEOUT bit [L3_IA_AGENT_STATUS\[8\]](#) for an initiator response time-out. The affected agent enters an error state that causes it to send error responses to any new request. To recover from this state, the target agent must be reset by system software.

The time-out is counted starting from the moment a command is presented to the target, whatever the target response to this command is. The L3 interconnect implements a centralized time-base circuit that broadcasts a set of four periodic pulse signals to all connected target agents. These four signals are referred to as 1x time-base, 4x time-base, 16x time-base, and 64x time-base.

The time-base circuit offers four possible sets of four time-base signals selected by programming the TIMEOUT_BASE field [L3_RT_NETWORK_CONTROL\[10:8\]](#). [Table 5-27](#) lists all of the values in the number of L3 clock cycles.

Each target agent can be programmed to refer to one of the four time-base signals. A time-out condition is detected when either the command acceptance or the response is not received after a delay of between one and three time-base periods. After the time-out is detected and logged, the behavior of the attached module is ignored. A new request to the module arriving at the timed-out target agent receives an error response. If the request is addressed to the agent internal registers, it is processed normally.

To recover from a time-out error, the software is assumed to reset first the faulty module using its internal soft-reset bit, and then the agent using software reset.

Table 5-27. L3 Timeout Register Target and Agent Programming

REQ_TIMEOUT[2:0], BURST_TIMEOUT[2:0], and RESP_TIMEOUT[2:0]					
TIMEOUT_BASE[2:0]	0	1	2	3	4
0	All L3 time-out features are disabled.				
1	Locally disabled	64	256	1024	4096
2		256	1024	4096	16384
3		1024	4096	16384	65536
4		4096	16384	65536	262144

5.4.4.3 Error Steering

The error reporting structure consist of errors logged individually in the initiator or TAs. Some errors can be enabled and reported out-of-band by setting the following bits to 1:

- [L3_IA_AGENT_CONTROL.BURST_TIMEOUT_REP](#) bit for burst time-out
- [L3_IA_AGENT_CONTROL.RESP_TIMEOUT_REP](#) bit for response time-out
- [L3_TA_AGENT_CONTROL.REQ_TIMEOUT_REP](#) bit for request time-out
- [L3_TA_AGENT_CONTROL.ERROR_REP](#) bit for request time-out

Setting the [L3_IA_AGENT_CONTROL.ALL_INBAND_ERROR_REP](#) bit causes all in-band errors returned to the IA to be reported out-of-band.

IAs connected to processors capable of generating the debug-flagged requests (the MPU and IVA2.2 subsystems) use error steering. Any error linked to an application (nondebug) request is qualified as primary; any error linked to a debug request is qualified as secondary. Setting the [IA.INBAND_ERROR_PRIMARY_REP](#) or [INBAND_ERROR_SECONDARY_REP](#) bit to 1 allows the reporting of in-band to out-of-band primary and secondary errors.

The level of the current error is indicated in SECONDARY bit [L3_IA_ERROR_LOG\[30\]](#). If an error occurs while another error is pending, the following occurs:

- If the pending error is primary, the new error is discarded at the IA level. MULTI bit [L3_IA_ERROR_LOG\[31\]](#) is set in the initiator error log register to indicate that another error has been detected; no further information can be stored.

- If both the pending error and the new error are secondary, the latest error is discarded and MULTI bit [L3_IA_ERROR_LOG\[31\]](#) is set.
- If the pending error is secondary and the incoming error is primary, MULTI bit [L3_IA_ERROR_LOG\[31\]](#) is set and all useful information about the new error (MCmd, MAddr, MReqInfo, etc.) is stored. All information relative to the secondary error is discarded.

For protection violation, errors are detected at the TA and steered to the control module (see [Section 5.4.3.7](#), *L3 Firewall and System Control Module*).

5.4.4.4 Global Error Reporting

An out-of-band error refers to any flag output from the L3. It is not a formal error in the sense that it is not processed directly by the interconnect module; however, it is interpreted as such by one or several processors, typically by mapping it to an interrupt controller. All L3 out-of-band errors are ORed together and the result is transmitted to one or several interrupt controllers. All out-of-band errors are active high and must be acknowledged through a register access to be de-asserted.

Out-of-band errors are reported through error or flag signals, asynchronously to any other data flow, but synchronously to the clock.

All errors are reported out-of-band to the IVA2.2 and MPU subsystems simultaneously. The processors must check whether an error is relevant to the subsystems. These errors are routed not only to the IVA2.2 and MPU subsystem interrupt controllers, but also to their emulation logic (see [Figure 5-8](#)). Two composite flags help in asserting the error origin and criticality:

- The L3 application error flag reports application or nonattributable (not related to a request such as a time-out, SError) errors.
- The L3 debug error flag reports debug errors.

Figure 5-8. Global Error Routing

100-011

In addition to the SResp qualifier error reporting, some external targets use an SError signal to indicate that an internal error has occurred. Some resetting action may be required before any new request can be accepted, depending on the module and on the error itself. These signals are routed as flags internally to the L3. [Table 5-28](#) lists the possible errors reported through an SError, propagated externally to the L3 interconnect, and aggregated to the L3 application error flag.

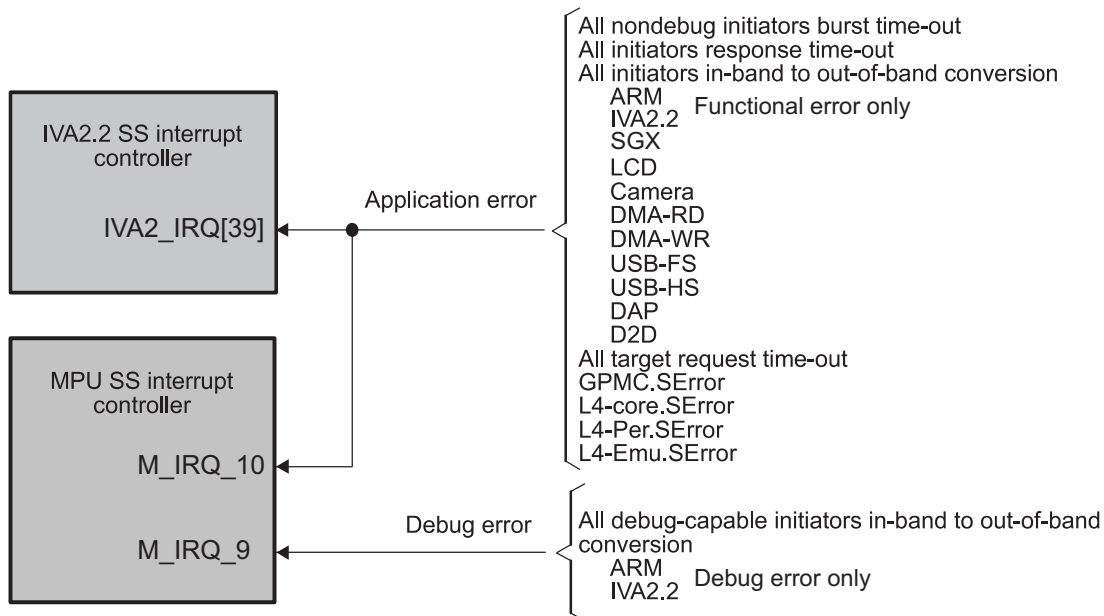

Table 5-28. L3 External Input Flags

Target	Flag	Description	Software Visible?
GPMC	SErrors	General-purpose error occurs in GPMC module	Yes, in FLAG_STATUS register and in L3 TA SERROR bit AGENT_STATUS[24]
L4-Core	SErrors	General-purpose error occurs on L4-Core	Yes, in FLAG_STATUS register and in L3 TA SERROR bit AGENT_STATUS[24]
L4-Emu	SErrors	General-purpose error occurs on L4-Emu	Yes, in FLAG_STATUS register and in L3 TA SERROR bit AGENT_STATUS[24]
L4-Per	SErrors	General-purpose error occurs on L4-Per	Yes, in FLAG_STATUS register and in L3 TA SERROR bit AGENT_STATUS[24]

Note: The user must ensure that the corresponding IRQ lines are set correctly in the interrupt controllers of the MPU and IVA2.2 subsystems.

Figure 5-9 shows the routing of errors to the application and debug error composite flags. Because both debug capable processors, the MPU and IVA2.2 subsystems have access to the full error report mechanism; they can be debugged independently of one another.

Figure 5-9. L3 Error Routing

100-005

Table 5-29 lists the bit and source for the STATUS bit field [L3_SI_FLAG_STATUS_0](#)[63:0] for an application error, and [Table 5-30](#) lists the bit and source for the STATUS bit field [L3_SI_FLAG_STATUS_1](#)[63:0] for an application error for a debug error.

Protection errors are reported in-band to the IA when possible. This may not be possible for posted writes, however. These errors are also reported asynchronously to the module.

Additionally, all protection errors (even posted writes) are seen by the in-band-to-out-of-band conversion logic in the IAs. Therefore, all protection errors feed into the L3 application error and L3 debug error composite flags, and hence back to the MPU and IVA2.2 subsystems.

The SMS, L4-Core, L-4 Per, and L4-Emu interconnects have internal firewalls that use the same reporting scheme. These errors are not routed directly to the L3 interconnect but are reported in-band to the initiator, which routes them to the composite flags. The SMS, L4-Core, L4-Per, and L4-Emu interconnects always provide an error on the in-band SResp qualifier for protection violations.

Table 5-29. L3_SI_FLAG_STATUS_0 for Application Error

Flag Bit Number	Source		Flag Bit Number	Source

5.5 L3 Interconnect Basic Programming Model

5.5.1 General Recommendation

The L3 interconnect registers must be read or written with little-endian attributes; otherwise, the result is undefined.

CAUTION

Overlapping between protection regions with the same priority level leads to unpredictable behavior and must be avoided.

5.5.2 Initialization

At the release of power on reset, the L3 firewall default configuration enables all accesses to target modules, except for a section of the OCM ROM for which default Region 0 is configured to enable access for the MPU with the secure attribute only (this section corresponds to the secure boot ROM in the device memory mapping).

Therefore, the settings of Region 1 in the OCM ROM firewall allow access to 32K bytes of the OCM (this accessible 32K bytes corresponds to the public boot ROM in memory space mapping). For more details, see the *Memory Mapping* chapter.

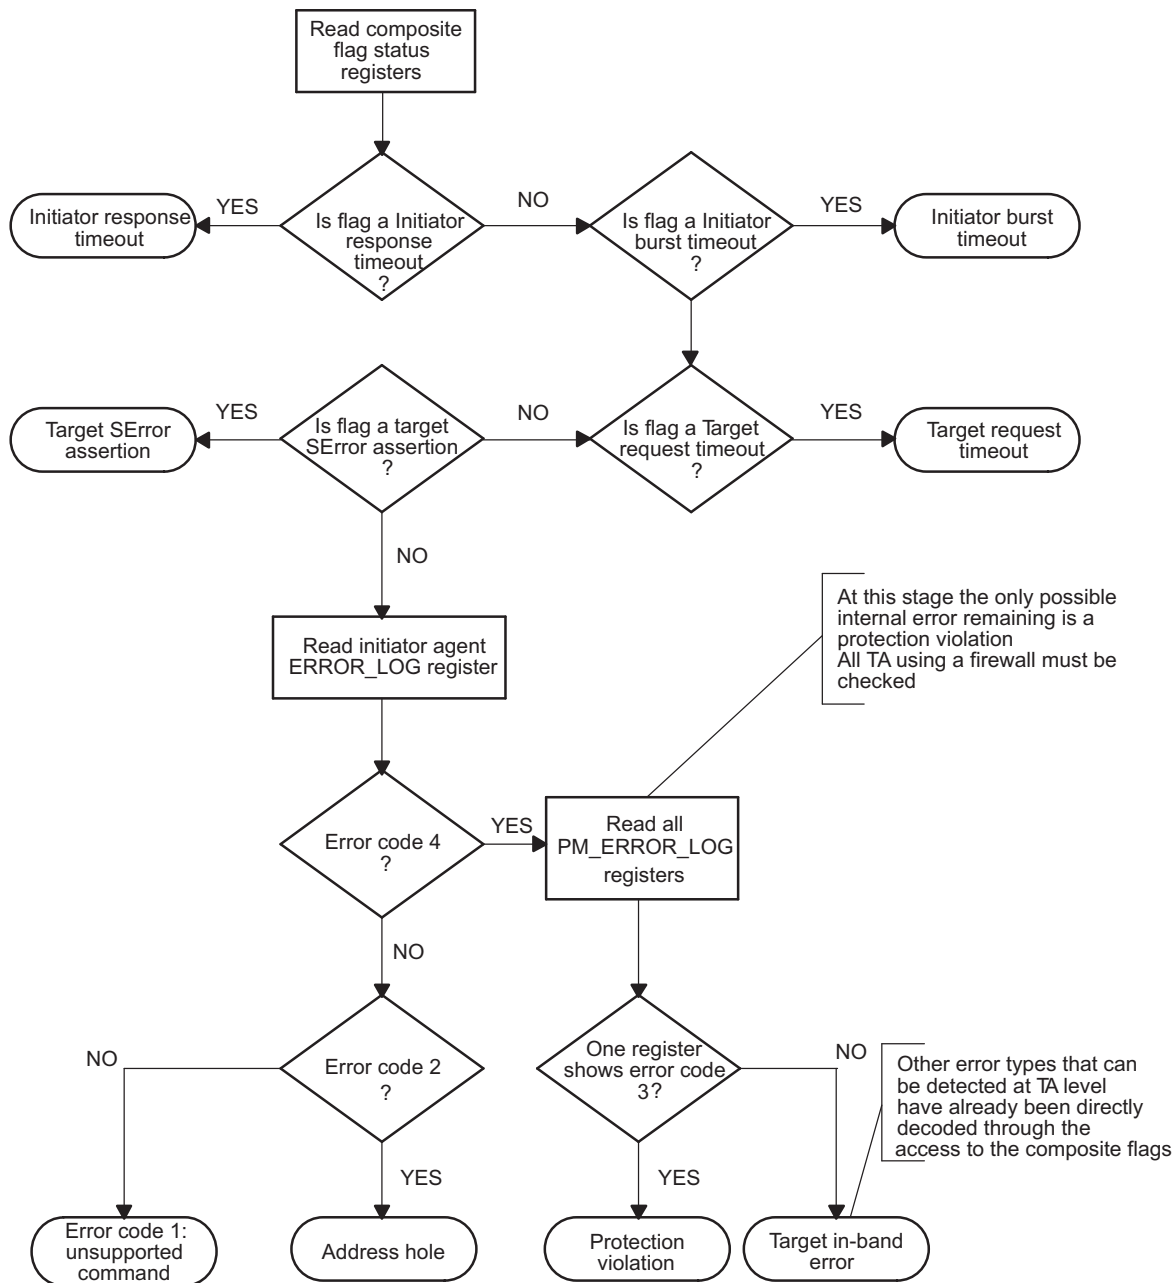

Generally, software must configure the firewall properly to avoid poor use of the hardware resources.

L3 time-out capabilities are also disabled at reset.

5.5.3 Error Analysis

The information required to analyze an error source is logged in several registers (see [Table 5-26](#)). The number of registers to access depends on the error source. When investigating the origin of an error, software reads a set of error log registers. At each stage, the register either states the current error or points to the next agent in which the error is logged. [Figure 5-10](#) shows the software sequence required in most cases.

Figure 5-10. Typical Error Analysis Sequence

100-012

Errors that do not result from an in-band to out-of-band conversion can be extracted immediately from the application or debug error flag by reading the STATUS field [L3_SI_FLAG_STATUS_0\[63:0\]](#) and [L3_SI_FLAG_STATUS_1\[63:0\]](#) register; therefore, they do not require the whole analysis sequence shown in [Table 5-26](#).

When analysis leads to a TA error, software must read the initiator agent ADDR field [L3_IA_ERROR_LOG_ADDR\[39:0\]](#) to extract the TA address causing the error.

5.5.3.1 Time-out Handling

This section gives information about all modules and features in the high-tier device. See the *OMAP35x Family* chapter to check availability of modules and features. To flag interconnect response being blocked, the time-out of target agents attached to unavailable modules can be enabled with the lowest setting.

Example 1

In this example, the MPU interrupt handler detects an error from the L3 interconnect. A read access from the [L3_SI_FLAG_STATUS_0](#) register reports a value of 0x40000. As described in [Table 5-29](#), the error detected is a burst time-out from the sDMA read port.

As with any time-out error, the affected module is now considered to be out-of-service. If necessary, the error can be cleared by sending a soft reset command to the agent (set [CORE_RESET](#) bit [L3_IA_AGENT_CONTROL](#)[0] to 1, and then to 0). During this time the initiator is off-line. Although the rest of the system still behaves normally, a time-out error is usually severe enough to require a complete reset of the chip.

Before resetting the agent or the system, the error log registers can learn the status of the interconnect and determine the type of failure. Reading the [IA_SDMA_RD.L3_IA_AGENT_STATUS](#) register shows whether the time-out was detected during a burst or during a read/write sequence.

Example 2

In this example, the MPU interrupt controller detects an error from the L3 interconnect. A read access from the [L3_SI_FLAG_STATUS_0](#) register reports a value of 0x100. This is a functional error from the IVA2.2 subsystem initiator.

The [IA_IVA2.2.L3_IA_ERROR_LOG](#) register should be read next. The value stored in it is 0x12_0400_1302.

- CMD field [IA_IVA2.2.L3_IA_ERROR_LOG](#)[2:0]: Value 0x2. Not applicable for an in-band error.
- INITID field [IA_IVA2.2.L3_IA_ERROR_LOG](#)[15:8]: Value 0x13. The origin of the error is the IVA2.2 subsystem sDMA.
- CODE field [IA_IVA2.2.L3_IA_ERROR_LOG](#)[27:24]: Value 0x4. Error is an in-band error.
- SECONDARY bit [IA_IVA2.2.L3_IA_ERROR_LOG](#)[30]: Value 0x0. The error is functional.
- MULTI bit [IA_IVA2.2.L3_IA_ERROR_LOG](#)[31]: Value 0x0. No additional error has been detected.
- REQ_INFO field [IA_IVA2.2.L3_IA_ERROR_LOG](#)[43:32]: Value 0x12. Not applicable for an in-band error.

There is no simple way to determine which target originated the in-band error. An SError assertion or a request time-out would have been detected and logged in the [L3_SI_FLAG_STATUS_0](#) register. Because no such error is asserted (bits 60:48 are still 0), the error can only be a firewall error or have originated in the target itself. The user must read all of the [PM_xxx.L3_PM_ERROR_LOG](#) registers.

CAUTION

The PM register blocks are sensitive registers and are usually protected. Ensure that the processor used to debug the error is allowed to access these registers and has entered a correct security mode. If not, the access will be rejected and another error will be generated.

All [PM_xxx.L3_PM_ERROR_LOG](#) registers are clear (bits 27:24 equal 0x0) except for [PM_OCMRAM.L3_PM_ERROR_LOG](#), which reads 0x0302_1301. The error occurred while trying to access the OCM RAM.

Note: If all [PM_xxx.L3_PM_ERROR_LOG](#) registers are clear, the error is unrelated to the interconnect. Further analysis must be done in the targets.

- Bits 27:24: Value 0x3. There is a protection error.
- Bits 2:0: Value 0x1. The offending command was a posted write.
- Bits 6:4: Value 0x0. The address is protected by Region 0 (default region) of the firewall.
- Bits 15:8: Value 0x13. The origin of the error is the IVA2.2, thread 2. This is consistent with the error log on the initiator side, and confirms this error report is the correct one.
- Bits 20:16: Value 0x2. The security parameters were data, debug, public, and user.
- Bit 31: Value 0x0. This is the only error detected.

A check on the security configuration confirms that this access was not allowed, either because the initiator was not given write access or because the access security parameters were not compatible with the PM_OCMRAM.REQINFO_PERMISSIONS_0 settings.

A security violation is not terminal from the interconnect point of view. If the modules responsible for the global chip security do not reset the system (including the IVA2.2 subsystem and the OCM RAM), it continues to run normally. A simple clearing of the error on both the IA and PM sides is required to return to a clean status.

5.5.3.2 Acknowledging Errors

Time-out errors can never be acknowledged. To return to a normal operation after an error, the faulty agent must be reset. An agent can be reset by asserting CORE_RESET bit [L3_IA_AGENT_CONTROL\[0\]](#) or [L3_TA_AGENT_CONTROL\[0\]](#), or by resetting the L3 interconnect through the PRCM.

Functional errors, including an in-band signal reporting a protection error, must be inactivated through software. Setting the INBAND_ERROR_PRIMARY and INBAND_ERROR_SECONDARY bits [L3_IA_AGENT_STATUS\[28-29\]](#) in an IA, or setting the SERROR bit [L3_IA_AGENT_STATUS\[24\]](#) in a TA clears the reported error. [Table 5-31](#) lists the bit to clear and the associated type of error.

The [L3_IA_ERROR_LOG](#) or [L3_TA_ERROR_LOG](#) register must also be cleared by writing a nonzero value simultaneously to the CODE bit field and the values currently stored in the MULTI and SECONDARY fields.

Table 5-31. Error Clearing

Agent Type	Error	Register Field
Initiator	In-band primary (application) error	INBAND_ERROR_PRIMARY
	In-band secondary (debug) error	INBAND_ERROR_SECONDARY
Target	Target asserts SError	SERROR

The procedure to clear protection errors depends on the system security configuration:

- Write a nonzero value simultaneously into CODE bit field [L3_PM_ERROR_LOG\[27:24\]](#) and the value currently stored in the MULTI bit [L3_PM_ERROR_LOG\[31\]](#) of the corresponding PM register block.
- Alternately, read either [L3_PM_ERROR_CLEAR_SINGLE](#) or [L3_PM_ERROR_CLEAR_MULTI](#), depending on the current value of the MULTI field in the [L3_PM_ERROR_LOG](#) register. This solution, which allows the clearing of protection errors without having a write access on other protection registers, preserves security.

[L3_SI_FLAG_STATUS_0](#) or [L3_SI_FLAG_STATUS_1](#) must be checked at the end of any error acknowledging sequence to confirm that the acknowledgement was successful and that no other error is pending.

5.5.4 Typical Example of Firewall Programming Example

All four regions in the IVA2.2 target firewall can be configured with no restrictions. However, protection is required for a 14K-byte region starting at address 0x0 in address space 2, and it must accept any access from any initiator for the rest of the target. The protection restricts allowed accesses as follows:

- Only the IVA2.2 and the MPU can read from this memory.
- Only the MPU can write to this memory.
- The security parameters must include supervisor and functional.

Only accesses declared as supervisor and functional are allowed to pass through the protected region of the firewall. There is no restriction on type (data or code) or secure (public or secure) attributes.

[Table 5-32](#) lists the possible parameter combinations, whether they are allowed to pass or not, and why they are rejected.

Table 5-32. MReqInfo Security Parameter Example

Reqbit	MReq Supervisor	MReqSecure ⁽¹⁾	MReqDebug	MReqType	Access Allowed	Reason for Rejection
0	User	Public	Functional	Data	No	Not supervisor
1	User	Public	Functional	Code	No	Not supervisor
2	User	Public	Debug	Data	No	Not supervisor
3	User	Public	Debug	Code	No	Not supervisor
4	User	Secure ⁽¹⁾	Functional	Data	No	Not supervisor
5	User	Secure ⁽¹⁾	Functional	Code	No	Not supervisor
6	User	Secure ⁽¹⁾	Debug	Data	No	Not supervisor
7	User	Secure ⁽¹⁾	Debug	Code	No	Not supervisor
8	Supervisor	Public	Functional	Data	Yes	
9	Supervisor	Public	Functional	Code	Yes	
10	Supervisor	Public	Debug	Data	No	Not functional
11	Supervisor	Public	Debug	Code	No	Not functional
12	Supervisor	Secure ⁽¹⁾	Functional	Data	Yes	
13	Supervisor	Secure ⁽¹⁾	Functional	Code	Yes	
14	Supervisor	Secure ⁽¹⁾	Debug	Data	No	Not functional
15	Supervisor	Secure ⁽¹⁾	Debug	Code	No	Not functional

⁽¹⁾ In GP device MReqSecure = 1 (Secure value), is not supported.

Only combinations with codes 8, 9, 12, and 13 are allowed to access a target. REQ_INFO field PM_IVA2.2.L3_PM_REQ_INFO_PERMISSION_i[15:0] for the protected region must be set to ((0x18) | (0x19) | (0x112) | (0x113)); that is, 0x3300.

Solution 1

Set Region 0 to accept all accesses:

- PM_IVA2.2.L3_PM_REQ_INFO_PERMISSION_i (i=0)= 0xFFFF
- PM_IVA2.2.L3_PM_READ_PERMISSION_i (i=0)= 0x140E
- PM_IVA2.2.L3_PM_WRITE_PERMISSION_i (i=0)= 0x140E

Set Region 1 to cover the first 8K bytes of the protected region:

- PM_IVA2.2.L3_PM_ADDR_MATCH_k (k=1) = 0x22 (start address 0x0, size 8K bytes, address space 2)
- PM_IVA2.2.L3_PM_REQ_INFO_PERMISSION_i (i=1) = 0x3300
- PM_IVA2.2.L3_PM_READ_PERMISSION_i (i=1) = 0x0406 (IVA2.2 DMA and MMU and MPU are allowed)
- PM_IVA2.2.L3_PM_WRITE_PERMISSION_i (i=1) = 0x0002 (only MPU is allowed to write)

Set Region 2 to cover the next 4K bytes:

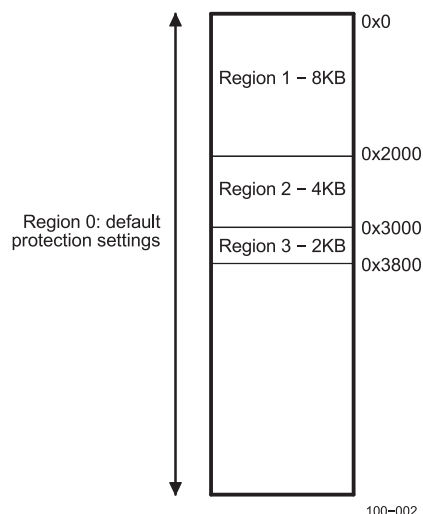

- PM_IVA2.2.L3_PM_ADDR_MATCH_k (k=2) = 0x201A (start address 0x2000, level 1, size 4K bytes, address space 2)
- PM_IVA2.2.L3_PM_REQ_INFO_PERMISSION_i (i=2) = 0x3300
- PM_IVA2.2.L3_PM_READ_PERMISSION_i (i=2) = 0x0406
- PM_IVA2.2.L3_PM_WRITE_PERMISSION_i (i=2) = 0x0002

Set Region 3 to cover the last 2K bytes:

- PM_IVA2.2.L3_PM_ADDR_MATCH_k (k=3)= 0x3012 (start address 0x3000, level 1, size 2K bytes, address space 2)
- PM_IVA2.2.L3_PM_REQ_INFO_PERMISSION_i (i=3) = 0x3300
- PM_IVA2.2.L3_PM_READ_PERMISSION_i (i=3) = 0x0406
- PM_IVA2.2.L3_PM_WRITE_PERMISSION_i (i=3) = 0x0002

Figure 5-11 shows the firewall configuration for Solution 1.

Figure 5-11. Firewall Configuration Solution 1

Solution 2

Set Region 0 to accept all accesses:

- `PM_IVA2.2.L3_PM_REQ_INFO_PERMISSION_i` (i=0) = 0xFFFF
- `PM_IVA2.2.L3_PM_READ_PERMISSION_i` (i=0) = 0x140E
- `PM_IVA2.2.L3_PM_WRITE_PERMISSION_i` (i=0) = 0x140E

Set Region 2 to cover 16K bytes:

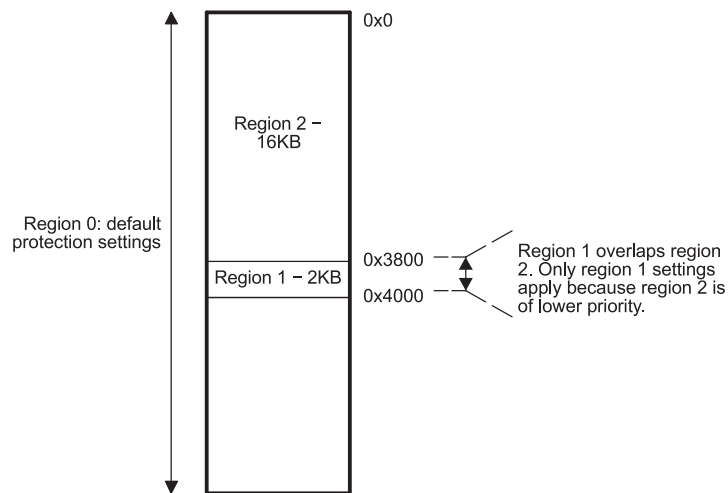

- `PM_IVA2.2.L3_PM_ADDR_MATCH_k` (k=2) = 0x2A (start address 0x0, level 1, size 16K bytes, address space 2)
- `PM_IVA2.2.L3_PM_REQ_INFO_PERMISSION_i` (i=2) = 0x3300
- `PM_IVA2.2.L3_PM_READ_PERMISSION_i` (i=2) = 0x0406 (IVA2.2 DMA and MMU and MPU are allowed)
- `PM_IVA2.2.L3_PM_WRITE_PERMISSION_i` (i=2) = 0x0002 (only MPU is allowed to write)

Set Region 1 to mask the last 2K bytes:

- `PM_IVA2.2.L3_PM_ADDR_MATCH_k` (k=2) = 0x3812 (start address 0x3800, size 2K bytes, address space 2)
- `PM_IVA2.2.L3_PM_REQ_INFO_PERMISSION_i` (i=1) = 0xFFFF

5.6.1 L3 Initiator Agent (L3 IA) Register Mapping Summary

This section describes the IA register block. Each IA in L3 interconnect has its own IA register block.

The following are the IA registers:

- MPU subsystem port
- IVA2.2 subsystem port
- SGX subsystem port
- High-Speed USB Host
- High-Speed USB OTG
- System DMA read port
- System DMA write port
- Display subsystem port
- Camera subsystem port
- DAP port
- Die-to-die

Table 5-34 through Table 5-37 list the IA registers and their physical addresses, depending on the module instance.

Table 5-34. Initiator Agent Common Register Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	IA_MPUSS Physical Address	IA_IVA2.2 Physical Address	SGX Physical Address

5.6.3 L3 Target Agent (L3 TA) Register Mapping Summary

This section describes the TA register block. Each TA in L3 interconnect has its own register block.

The following are the TA registers:

- SDRAM memory scheduler (TA_SMS module)
- General-purpose memory controller (TA_GPMC module)
- On-chip memory RAM (TA_OCM_RAM module)
- On-chip memory ROM (TA_OCM_ROM module)
- Master D2D (TA_MAD2D module)
- IVA2.2 subsystem (TA_IVA2.2 module)
- SGX subsystem (TA_SGX module)
- L4-Core interconnect (TA_L4_CORE module)
- L4-Per interconnect (TA_L4_PER module)
- L4-Emu interconnect (TA_L4_EMU module)

[Table 5-46](#) through [Table 5-49](#) lists all initiator target registers and their physical addresses depending on the module instance.

[Table 5-50](#) through [Table 5-56](#) describe the individual common registers in the module instance.

Table 5-46. Target Agent Common Register Mapping Summary

5.6.5 Register Target (RT) Register Mapping Summary

This section describes the RT module.

[Table 5-58](#) lists the RT registers and their physical addresses.

[Table 5-59](#) through [Table 5-63](#) describe the individual registers in the module instance.

Table 5-58. RT Register Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address
L3_RT_NETWORK	R	64	0x010	0x6800 0010
L3_RT_INITID_READBACK	R	64	0x070	0x6800 0070
L3_RT_NETWORK_CONTROL	RW	64	0x078	0x6800 0078

5.6.7 Protection Mechanism (PM) Register Mapping Summary

This section describes the protection mechanism register block.

The following are the protection mechanism registers:

- Register target (PM_RT module)
- General-purpose memory controller (PM_GPMC module)
- On-chip RAM (PM_OCM_RAM module)
- On-chip ROM (PM_OCM_ROM module)
- IVA2.2 subsystem (PM_IVA2.2 module)

Table 5-65 and Table 5-67 list the protection registers and their physical addresses, depending on the module instance.

Table 5-68 through Table 5-78 describe the individual common registers in the module instance.

Table 5-65. Protection Mechanism Common Register Mapping Summary

Register Name	Type	Register Width (Bits)	PM_RT Physical Address	PM_GPMC Physical Address
L3_PM_ERROR_LOG	RW	64	0x6801 0020	0x6801 2420

5.7 L4 Interconnects

5.7.1 Overview

To connect peripheral modules, the device uses four separate L4 interconnect structures. Although all L4 interconnects handle transfers with peripherals, the interconnects are in different power domains. The L4 interconnect is composed of the following:

- L4-Core: Includes the majority of the peripherals and the configuration interface for L3 interconnect system modules
- L4-Per: Includes peripherals that do not need to be mapped in the CORE power domain
- L4-Wakeup: Includes the peripherals attached to the WKUP power domain
- L4-Emu: Includes emulation peripherals attached to the EMU power domain

The following are the main features of the L4 interconnects:

- Single port to connect to L3 interconnect
 - L4-Core
 - L4-Per
- Dual ports for the following:
 - L4-Emu to connect to the L3 interconnect and DAP
 - L4-Wakeup to connect to the L4-Core and L4-Emu
- Single 32-bit initiator for the L3 port
- Multi target ports (one per target interface on the L4 interconnect)
- 8-, 16-, or 32-bit data, single, or burst transactions
- Little-endian
- Non-blocking with fair arbitration between threads
- Target interfaces: Fully synchronous or divided synchronous
- Peak bandwidth of 2x M bytes/sec of L4 frequency (in MHz)
- Latency: Three cycles on request, one cycle on response
- Security logic provides user-configurable access control to targets by each initiator:
 - Firewall in L4-Core protects the core and wake-up peripherals.
 - Firewall in L4-Per protects per peripherals.
 - Firewall in L4-Emu protects emulation and wake-up peripherals

Note: L4-Wakeup has two input ports from L4-Core and L4-Emu. Therefore, wake-up peripherals appear in two locations in the memory mapping. Normally, L4-Emu limits its access except when debugging.

Figure 5-13 shows an overview of the L4 interconnects and the peripherals attached to them.

Figure 5-13. L4 Interconnect Overview

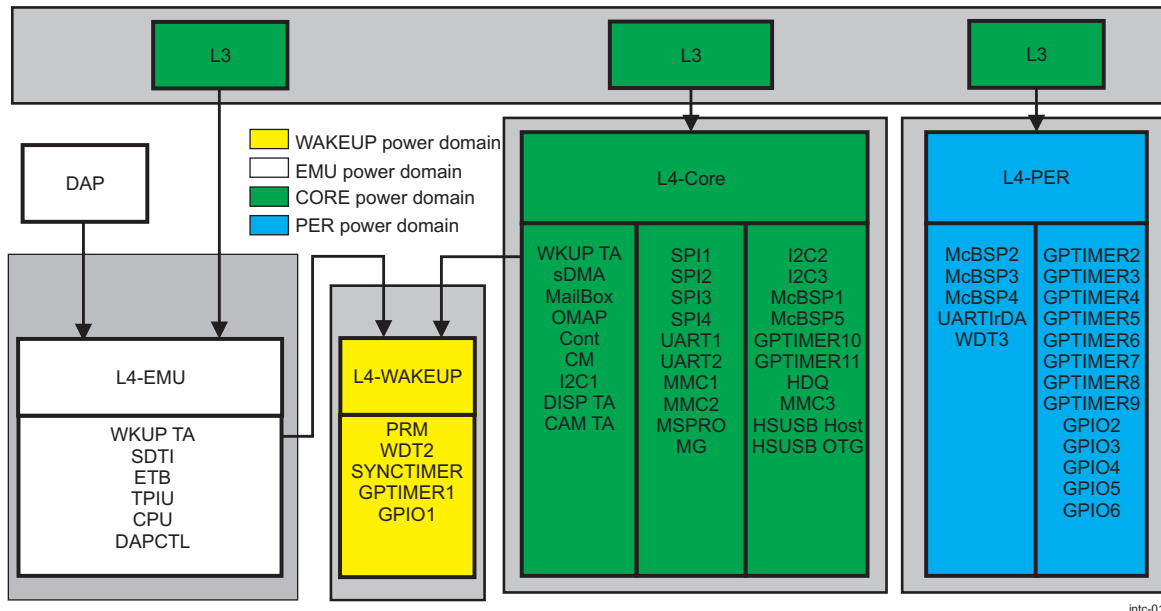

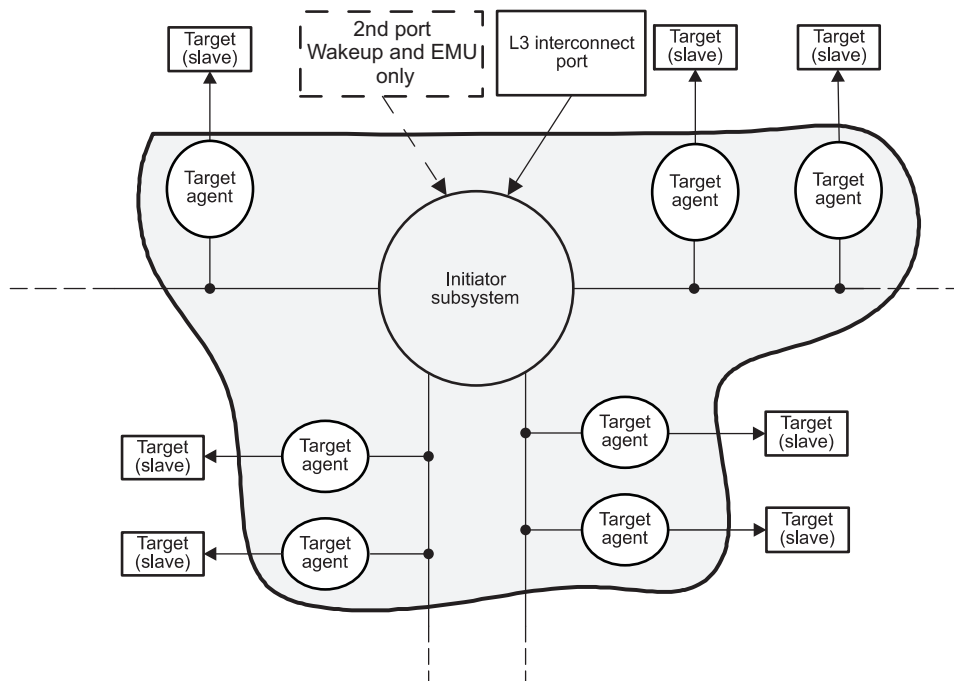

Figure 5-14 shows an internal view of the L4 interconnects in the overall interconnect. This architecture, with only one initiator module (the initiator subsystem) distributing transactions to all target modules (peripherals), enables the firewall functions of the L4 interconnects to be centralized at the L4 initiator level. The L4 firewall filters the accesses according to the configurable protection groups defined in the L4 address protection (AP) registers. Each module or agent is assigned to a protection group. Configuration is also defined in the L4 AP and is programmable on a module-per-module basis.

Figure 5-14. L4 Initiator-Target Connectivity for L4-Core and L4-Per

Note: As [Figure 5-14](#) shows, targets are attached to branches. These branches have no functional effect and are present for timing closure reasons only.

5.7.1.1 L4-Core Interconnect

The L4-core interconnect handles only transfers to peripherals in the CORE power domain. [Table 5-94](#) lists the TAs.

Table 5-94. L4-Core Target Agents

Module Name	Description
Display subsystem	Display subsystem configuration port
Camera subsystem	Camera subsystem port
USBHS OTG	Universal serial bus High-Speed port OTG
USBHS Host	Universal serial bus High-Speed port Host
USBTLL	USB Transceiver Less Link
UART1	Universal asynchronous receiver transmitter port 1
UART2	Universal asynchronous receiver transmitter port 2
I2C1	Multimaster inter-integrated circuit 1
I2C2	Multimaster inter-integrated circuit 2
I2C3	Multimaster inter-integrated circuit 3
McBSP1	Multichannel buffered serial port 1
McBSP5	Multichannel buffered serial port 5
GPTIMER10	General-purpose timer 10
GPTIMER11	General-purpose timer 11
SPI1	Serial peripheral interface 1
SPI2	Serial peripheral interface 2
MMCHS1	Multimedia memory controller SDIO 1
MMCHS2	Multimedia memory controller SDIO 2
MMCHS3	Multimedia memory controller SDIO 3
HDQ/1-Wire	Single wire serial link low rate
MS-PRO	Memory Stick PRO
MLB (mailbox)	Mailbox
RNG1	Random number generator 1
RNG2	Random number generator 2
D3D1	Data encryption standard 1
D3D2	Data encryption standard 2
SHA1MD5	Secure hash algorithm and message digest 5
SHA1MD5	Secure hash algorithm and message digest 5
AES	Advanced encryption
MG	MagicGate
FastPKA	Public key access
SPI1	Serial peripheral interface 1
SPI2	Serial peripheral interface 2
SPI3	Serial peripheral interface 3
SPI4	Serial peripheral interface 4
sDMA	System DMA controller
L4-Wakeup	L4-Wakeup interconnect
CM	Clock manager
SCM	System control module

Note: A unique port is used for communication between the L3 interconnect and the L4-Core interconnect to allow the L3 initiators to access the L4-Core targets.

For the list of initiators authorized to access the L4-Core peripherals, see [Table 5-14](#). For details on restricted access, see [Section 5.9.3.1, Protection Mechanism](#).

5.7.1.2 L4-Per Interconnect

The L4-Per interconnect handles only transfers to peripherals in the PER power domain. [Table 5-95](#) lists the TAs.

Table 5-95. L4-Per Target Agents

Module Name	Description
UARTIrDA	Universal asynchronous receiver/transmitter and infrared data association port
McBSP2	Multichannel buffered serial port 2
McBSP3	Multichannel buffered serial port 3
GPTIMER2	General-purpose timer 2
GPTIMER3	General-purpose timer 3
GPTIMER4	General-purpose timer 4
GPTIMER5	General-purpose timer 5
GPTIMER6	General-purpose timer 6
GPTIMER7	General-purpose timer 7
GPTIMER8	General-purpose timer 8
GPTIMER9	General-purpose timer 9
GPIO2	General-purpose I/O 2
GPIO3	General-purpose I/O 3
GPIO4	General-purpose I/O 4
GPIO5	General-purpose I/O 5
GPIO6	General-purpose I/O 6

Note: A unique port is used for communication between the L3 interconnect and the L4-Core interconnect to allow the L3 initiators to access the L4-Per targets.

For the list of initiators authorized to access the L4-Per peripherals, see [Table 5-14](#). For details on restricted access, see [Section 5.9.3.1, Protection Mechanism](#).

5.7.1.3 L4-Emu Interconnect

The L4-Emu interconnect handles only transfers to peripherals in the EMU power domain. [Table 5-96](#) lists the TAs.

Table 5-96. L4-Emu Target Agents

Module Name	Description
L4-Wakeup	L4-Wakeup interconnect
SDTI	System debug trace interface
ETB	Embedded trace buffer
TPIU	Trace port interface unit
MPU	ARM9
DAPCTL	Debug access port

Not all initiators can access all the targets in the L4-Emu interconnect. Additional restrictions affect the ability of these initiators to access the L4-Emu peripherals. [Table 5-97](#) lists which initiators can access the L4-Emu interconnect.

Note: For the list of initiators authorized to access the L4-Emu peripherals, see [Table 5-14](#). For details on restricted access, see [Section 5.9.3.1](#), *Protection Mechanism*.

Table 5-97. L4-Emu Initiator Agents

Module Name	Description
L3 interconnect	L3 interconnect port
DAP	DAP port

5.7.1.4 L4-Wakeup Interconnect

The L4-Wakeup interconnect handles only transfers to peripherals in the WKUP power domain. [Table 5-98](#) lists the TAs.

Table 5-98. L4-Wakeup Target Agents

Module Name	Description
PRM	Power reset manager
GPIO1	General-purpose I/O 1
GPTIMER1	General-purpose timer 1
GPTIMER12 ⁽¹⁾	General-purpose timer 12
WDTIMER1 ⁽¹⁾	Secure watchdog timer
WDTIMER2	MPU subsystem watchdog timer
32KTIMER	32-kHz timer
USIM	Universal Identity Subscriber Module

⁽¹⁾ Not available in GP device.

Initiators that can access the L4-Core or L4-Emu can access all the targets in the L4-Wakeup interconnect. [Table 5-99](#) lists the initiators that can access the L4-Wakeup interconnect. For details on restricted access, see [Section 5.9.3.1](#), *Protection Mechanism*.

Table 5-99. L4-Wakeup Initiator Agents

Module Name	Description
L4-Core interconnect	L4-Core interconnect port
L4-Emu interconnect	L4-Emu interconnect port

5.8 L4 Interconnects Integration

5.8.1 Clocking, Reset, and Power-Management Scheme

5.8.1.1 Clocks

Four functional clocks are used in each L4 interconnect (see [Table 5-100](#)).

Table 5-100. L4 Interconnect Clocks

Clock	Frequency	Name	Comments
L4-Core interconnect clock	Up to Core_L3_ICLK/2	CORE_L4_GICLK	Source, control, and gating handled by PRCM module
L4-Per interconnect clock	Up to Core_L3_ICLK/2	PER_L4_GICLK	Source, control, and gating handled by PRCM module
L4-Emu clock		L4_EMU	Clock for emulation
L4-Wakeup interconnect clock		WKUP_L4_GICLK	Source, control, and gating handled by PRCM module

5.8.1.2 Resets

5.8.1.2.1 Hardware Reset

L4 interconnects receive a reset signal from the PRCM module, which is the reset signal to the CORE power domain. For more details, see the *Power, Reset, and Clock Management* chapter.

[Table 5-101](#) lists the hardware reset for the L4-Core interconnect.

Table 5-101. L4 Interconnect Hardware Reset

Interconnect	Reset Domain
L4-Core interconnect	CORE_RST
L4-Per interconnect	PER_RST
L4-Wakeup interconnect	WKUP_RST
L4-Emu interconnect	EMU_RST

5.8.1.2.2 Software Reset

The L4 interconnects have hardware reset capabilities, but do not have software reset capabilities. The hardware reset capabilities are controlled by the PRCM module and are applied to the L4 interconnects and the connected L4 TAs and L4 target modules.

5.8.1.3 Power Domain

For more details on power voltage scaling, see the *Power, Reset, and Clock Management* chapter.

[Table 5-102](#) lists the power domains for the L4-Core and L4-Wakeup interconnects.

Table 5-102. L4 Interconnect Power Domains

Interconnect	Power Domain
L4-Core interconnect	CORE
L4-Per interconnect	PER
L4-Emu interconnect	EMU

Table 5-102. L4 Interconnect Power Domains (continued)

Interconnect	Power Domain
L4-Wakeup interconnect	WKUP

5.8.1.4 Power Management

5.8.1.4.1 Module Power-Saving

The L4 interconnect automatically performs internal clock autogating to reduce power consumption. Though not recommended, it is possible to deactivate clock autogating by writing 1 to the `CLOCK_GATE_DISABLE` bit `L4_LA_NETWORK_CONTROL_H[24]` of each L4 interconnect. Clock autogating is enabled by default.

5.8.1.4.2 System Power Management and Wakeup

As part of the system-wide power-management scheme, the L4 interconnect enters an idle state at the request of the PRCM module (for more information, see the *Power, Reset, and Clock Management* chapter). The L4 interconnect is always in smart-idle mode; that is, it goes into idle state after receiving the request from the PRCM module once all the transfer requests are complete. This functionality is handled by hardware. The L4 interconnect sends an acknowledge signal back to the PRCM module when it enters idle state.

5.9 L4 Interconnects Functional Description

5.9.1 L4-Interconnects Initiator Identification

In the device interconnect, a ConnID is an initiator module identifier. The L4 interconnect uses the same ConnID as L3.

5.9.2 Endianness Management

Both L4 interconnects are little-endian only. Any initiator accessing the L4 interconnect module must consider byte ordering and perform a conversion, if necessary.

5.9.3 L4 Security and Firewalls

5.9.3.1 Protection Mechanism

The following two parameters are used to set up access permission because of the large address spaces and the number of peripherals connected to the L4 interconnects:

- Programmable groups for initiators:
 - 8 protection groups for the L4-Core interconnect
 - 8 protection groups for the L4-Per interconnect
 - 6 protection groups for the L4-Emu interconnect
- Each segment is divided into regions of 2K bytes:
 - 100 regions for the L4-Core interconnect
 - 43 regions for the L4-Per interconnect
 - 26 regions for the L4-Emu interconnect

Note: Regions and segments are present for the L4-Wakeup interconnect but cannot be programmed. The L4-Wakeup protection is done through the L4-Core and L4-Emu interconnects.

A protection group is a group of targets that have the same security settings. Initiator access is defined by CONNID_BIT_VECTOR field L4_AP_PROT_GROUP_k_L[15:0]. The initiators have the same access permission to all regions in this group.

A region is programmed to allow access to a unique selectable protection group by using PROT_GROUP_ID field L4_AP_REGION_I_H[22:20].

Note: k denotes the protection group number.

l denotes the region number.

5.9.3.2 Protection Group

A protection group defines which initiators with a given MReqInfo can access the targets agent protected by this group.

The CONNID_BIT_VECTOR field L4_AP_PROT_GROUP_MEMBERS_k[15:0] (see [Figure 5-15](#)) is a 1-bit vector that sets up initiator permission access regions. A protection group is accessible by an initiator if the bit position corresponding to its ConnID is set to one in the CONNID_BIT_VECTOR field.

The ENABLE field L4_AP_PROT_GROUP_ROLES_k[31:0] lists all possible MReqInfo combinations. Setting a Req bit in this register determines the type of access allowed to the initiator. See [Section 5.4.3.4, REQ_INFO_PERMISSION Configuration](#), for more information. MReqInfo is used in L4 the same way it is used in the L3 firewall configuration.

Note: Permissions are identical for read and write accesses in L4 interconnect targets.

Figure 5-15 shows an example of CONNID_BIT_VECTOR.

Figure 5-15. Example of CONNID_BIT_VECTOR

Setting bits 1 and 4 in the PROT_GROUP_ID_1 defines a group initiator able to access targets in protection group 1, and includes:

- MPU SS
- IVA2.2 MMU

Protection group 1 (PG1) can be applied to multiple protection regions without limitation. Each protection region I that is configured with PG1 enables permission access to these two initiators only.

The firewall default configuration for the L4-Core interconnect contains eight protection groups to ensure security:

- Most regions are, by default, set with protection group 7 (PG7), which is configured for all access (see [Table 5-103](#)).
- Protection group 0 (PG0) is restricted to the MPU subsystem in public.
- By default, the hardware crypto-processors (DES, SHA1-MD5, AES, FPKA, RNG, and WDTIMER1 not available in GP device) are attached to PG1 and are publicly accessible by all the initiators that can access the L4-Core.
- The LCD is attached to protection group 2 (PG2).
- The Camera is attached to protection group 3 (PG3).
- The GPTIMER12 of the L4-Wakeup interconnect is attached to protection group 4 (PG4) (not available in GP device).
- By default, PG5 to PG7 are configured for all access.

Note: System control module and secure watchdog timer have an embedded firewall.

The L4-Per interconnect contains eight protection groups:

- By default, PG0 to PG7 are configured for all access.
- By default, most regions are set with PG7, which is configured for all access (see [Table 5-104](#)).

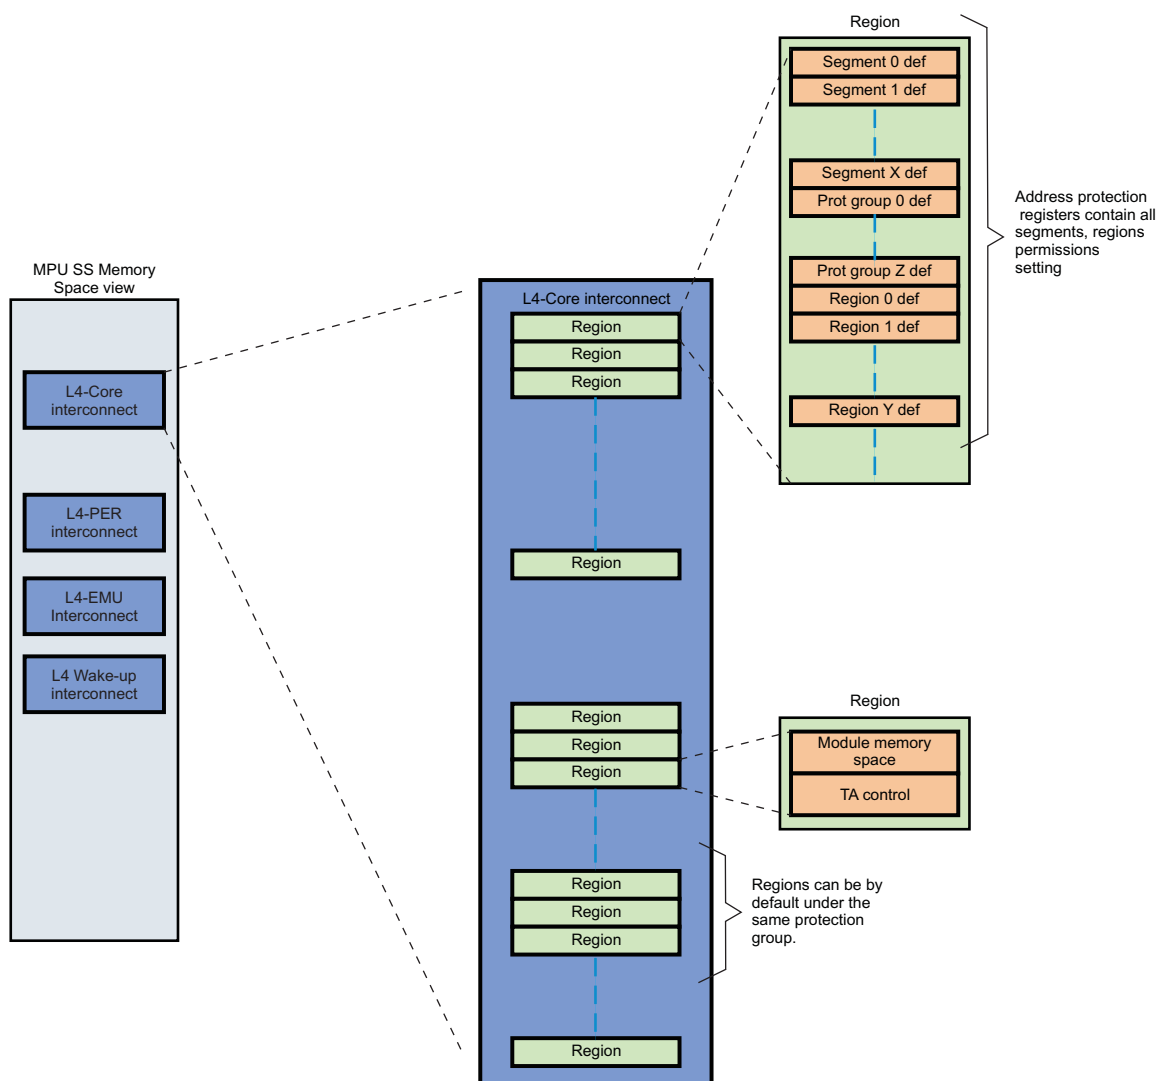

The L4-Emu interconnect contains six protection groups:

- By default, most regions are set with PG5, which is configured for all access (see [Table 5-105](#)).
- The AP is attached to PG0.
- The WDTIMER1 is attached to PG1 (not available in GP device).
- The GPTIMER12 is attached to PG2 (not available in GP device).
- The emulation organs are attached to PG3.

5.9.3.3 Segments and Regions

The protection mechanism for L4 interconnects is based on a hierarchical segmentation (see [Figure 5-16](#)). By default, some regions are attached to a specific protection group. This specificity allows the user to set up the permission access for certain types of modules that require the same access protection without managing the region allocation.

Figure 5-16. L4 Firewall Overview

100-018

All interconnect address spaces are covered by regions. [Table 5-103](#) to [Table 5-105](#) list the module mapping, including the address, region number, and default protection group allocated to it.

By setting ENABLE bit L4_AP_REGION_y_H[0] to 0, the region becomes inactive and therefore inaccessible. Setting the bit to 1 activates the region.

Table 5-103. Region Allocation for L4-Core Interconnect

Device Name	Start Address (hex)	Description	Region Number	Default Protection Group

5.9.3.4 L4 Firewall Address and Protection Registers Setting

[Table 5-106](#) lists the settings of the AP registers for an L4 interconnect firewall. These values are computed based on the physical implementation of each L4 interconnect.

Table 5-106. L4 Firewall Register Description Overview

Register Type	Register Name	Bits	Field	Description
Segment	L4_AP_SEGMENT_I_L	23:0	Base	Segment base address
	L4_AP_SEGMENT_I_H	4:0	SIZE	Segment size equals to 2 power of SIZE
Protection groups	L4_AP_PROT_GROUP_MEMBERS_k_L	15:0	CONNID_BIT_VECTOR	See Section 5.9.1 for L4ConnID).
	L4_AP_PROT_GROUP_ROLES_k_L	15:0	ENABLE	Refer to Table 5-22 for MReq description
Region setting	L4_AP_REGION_I_L	23:0	BASE	Define the base address of region in respect to its respective segment base address
	L4_AP_REGION_I_H	27:24	SEGMENT_ID	Segment ID number of the region
		22:20	PROT_GROUP_ID	The protection group attached to the region
		19:17	BYTE_DATA_WIDTH_EXP	Determine the number of bytes in an access
		5:1	SIZE	Size of the region equals to 2 power of SIZE
		0	ENABLE	Enable the region protection

5.9.4 Error Handling

5.9.4.1 Overview

The L4 interconnect provides mechanisms for handling either internally detected errors or errors reported by modules attached to the L4 target ports. Hardware support facilitates logging errors and cleaning up the state to allow error recovery software to treat the error.

As an L3 target, the L4 interconnect reports errors to the L3 interconnect in-band whenever possible. In-band error reporting is the default and recommended configuration. It is assumed that INBAND_ERROR_REP bit [L4_IA_AGENT_CONTROL_L\[27\]](#) is set to 1.

Note: *L4_IA* denotes which interconnect is considered: L4-Core, L4-Per, L4-Emu, or L4-Wakeup.

L4_TA denotes the module name, such as UART1, McBSP1, etc.

The L4 interconnects handle three types of errors:

- No target core found or address hole
- Request protection violation
- Failure of the target to service a request before a time-out expires

5.9.4.2 Error Logging

5.9.4.2.1 No Target Core Found/Address Hole

This error indicates that a request was addressed to a hole in the L4 address map.

When this occurs, an in-band error response is returned to the L3 level.

The error is also logged into the INBAND_ERROR bit [L4_IA_AGENT_STATUS_L\[27\]](#).

Additionally, an address hole error code is logged into the CODE field [L4_IA_ERROR_LOG_L\[25:24\]](#).

The L4_IA_ERROR_LOG register also includes MULTI bit [L4_IA_ERROR_LOG_L\[31\]](#), which is asserted when multiple errors are detected. In this case, the error code corresponds to the first error that occurs.

5.9.4.2.2 Protection Violation

This error indicates that an initiator has accessed a restricted region. This error is reported using an in-band error. It is written to the INBAND_ERROR field. A protection violation error code is also saved in the CODE field [L4_IA_ERROR_LOG_L\[25:24\]](#).

The security violation is also logged in the CONTROL_SEC_ERR_STATUS [7] register of the system control module.

Note: There is no specific error signal for the security violation that goes out from the L4 interconnects. The out-band error that goes to the system control module indicates a SECURITY_VIOLATION, but it also indicates normal interconnect errors.

5.9.4.2.3 Time-Out

This section gives information about all modules and features in the high-tier device. See the *OMAP35x Family* chapter to check availability of modules and features. To flag interconnect response being blocked, the time-out of target agents attached to unavailable modules can be enabled with the lowest setting.

A time-out mechanism can be enabled on a per-target basis in the [L4_TA_AGENT_CONTROL_L](#) register. If the mechanism is enabled for a TA, and commands are not accepted or responses are not returned within the expected delay, the L4 interconnect generates an error event.

The error is logged in the target agent REQ_TIMEOUT bit [L4_TA_AGENT_STATUS_L\[8\]](#). The affected TA enters an error state that causes it to send error responses to any new request targeted at it. To recover from this state, the TA must be reset by system software. The time-out is counted starting from the moment a command is presented to the target, regardless of how the target responds to the command.

The L4 interconnect implements a centralized time-base circuit that broadcasts a set of four periodic pulse signals to all connected TAs. These four signals are referred to as 1X-time base, 4X-time base, 16X-time base, and 64X-time base.

The time-base circuit offers four possible sets of time-base signals. Selection is done by programming TIMEOUT_BASE field [L4_LA_NETWORK_CONTROL_L\[10:8\]](#). [Table 5-107](#) lists the values in the number of L4 clock cycles.

Table 5-107. L4 Time-Out Link and TA Programming

TIMEOUT_BASE[2:0]	REQ_TIMEOUT[2:0]				
	0	1	2	3	4
0	All L4 time-out features are disabled.				
1	Locally disabled	64	256	1024	4096
2		256	1024	4096	16384
3		1024	4096	16384	65536
4		4096	16384	65536	262144

The reset value is 0x4, resulting in the longest possible time-out.

The selected time-base signals are available at any TA. Each TA can be programmed to refer to one of these four time-base signals, by using REQ_TIMEOUT field [L4_TA_AGENT_CONTROL_L\[10:8\]](#) (see [Table 5-108](#)).

Table 5-108. L4 Time-Out TA Programming

REQ_TIMEOUT	Target Agent Time-out Reference
0	Time-out locally disabled
1	1X-base cycle
2	4X-base cycle
3	16X-base cycle
4	64X-base cycle

A time-out condition is detected when the command acceptance or the response is not received after a delay of between one and three time-base periods.

Example:

- L4 frequency = 100 MHz
- TIMEOUT_BASE = 4 in the [L4_LA_NETWORK_CONTROL_L](#) register
- REQ_TIMEOUT = 2 in the [L4_TA_AGENT_CONTROL_L](#) for target agent A
- REQ_TIMEOUT = 4 in the [L4_TA_AGENT_CONTROL_L](#) for target agent B

At agent A, the time-base unit is 16384 cycles. A time-out is issued when a request to the attached module is not accepted or no response is sent after a delay of 164 μ s to 492 μ s.

At agent B, the time-base unit is 262,144 cycles. A time-out is issued when a request to the attached module is not accepted or no response is sent after a delay of 2.6 ms to 7.8 ms.

On detection of a time-out condition, the agent automatically generates an error response to the inter_IA, which is forwarded to the L3. The agent also logs the time-out to REQ_TIMEOUT bit [L4_TA_AGENT_STATUS_L\[8\]](#).

After the time-out has been detected and logged, the behavior of the attached module is ignored. A new request targeting the module arriving at the timed out TA receives an error response. If the request is addressed to the agent internal registers, it is processed normally.

To recover from a time-out error, the software is assumed to reset first the faulty module by using its internal soft reset bit, and then the TA by using OCP_RESET bit [L4_TA_AGENT_CONTROL_L\[0\]](#).

5.9.4.3 TA Software Reset

Writing 1 to OCP_RESET bit [L4_TA_AGENT_CONTROL_L\[0\]](#) initiates the software reset period. The software reset must be asserted for at least 16 cycles of the target module OCP clock, which can be a divided clock with respect to the L4 clock.

During the software reset period the following occur:

- Requests sent to the target module receive error responses. Therefore, if the faulty request is part of a DMA transfer, it is necessary to stop the DMA to avoid getting unwanted errors.

- The attached module must then be reset to complete the recovery.

- Timeout error generation is enabled at each TA.
- Timeout error and target in-band errors are only reported in-band to the L3 initiator.
- Protection violations are reported out-of-band. Error steering is used to distinguish between application or debug errors.

The diagram illustrates the Error Log Architecture. At the bottom, three **Target** boxes send **Sresp=ERR** signals to three **Target Agent** boxes. Each Target Agent contains a **timeout** block and a switch. The switch routes signals to a central **Initiator Agent** box. The Initiator Agent contains an **Error Log** box and a switch. The switch routes signals to an **L3** box and an **SCM** box. The L3 box receives **Sresp=ERR** signals and reports **Firewall, timeout and target in-band errors** to the SCM. The SCM receives **Firewall - App** and **Firewall - Debug** signals. The SCM also reports **Firewall errors also reported out-of-band, but separately**. The Initiator Agent also has an **ERROR LOG ADDR** block.

Firewall, timeout and target in-band errors are reported to L3 in-band ONLY. Conversion to out-of-band in L3

Firewall errors also reported out-of-band, but separately

Timeout out-of-band errors are discarded - recreated from in-band error in L3

5.10 L4 Interconnects Registers

A summary of the hardware interface for the L4-Core, L4-Per, L4-Emu and L4-Wkup interconnects is given in [Table 5-109](#) to [Table 5-112](#). Each module instance in the design is shown with the module register map and bit definitions for each bit field.

Table 5-109. L4- Core Instance Summary

Module Name	Base Address	Size

5.10.1 L4 Initiator Agent (L4 IA) Register Mapping Summary

This section provides information on the L4 IA module. Each of the registers within the module instance is described separately in [Table 5-113](#) to [Table 5-114](#).

The initiator OCP interface register block (IA) consists of the status, control, and error log registers that can be used to configure the interface of an initiator OCP. There can be only one register block for each initiator OCP interface.

Table 5-113. L4 IA Register Mapping Summary (1)

Register Name	Type	Register Width (Bits)	CORE_IA Physical Address	PER_IA Physical Address	EMU_IA_L3 Physical Address
L4_IA_AGENT_CONTROL_L	RW	32	0x4804 0820	0x4900 0820	0x5400 6820
L4_IA_AGENT_STATUS_L	RW	32	0x4804 0828	0x4900 0828	0x5400 6828
L4_IA_ERROR_LOG_L	RW	32	0x4804 0858	0x4900 0858	0x5400 6858

Table 5-114. L4 IA Register Mapping Summary (2)

Register Name	Type	Register Width (Bits)	EMU_IA_DAP Physical Address	WKUP_IA_EMU Physical Address	WKUP_IA_CORE Physical Address
L4_IA_AGENT_CONTROL_L	RW	32	0x5400 8020	0x4832 8820	0x4832 A020
L4_IA_AGENT_STATUS_L	RW	32	0x5400 8028	0x4832 8828	0x4832 A028

5.10.2 L4 Initiator Agent (L4 IA) Register Descriptions

5.10.2.1 L4_IA_AGENT_CONTROL_L

Table 5-115. L4_IA_AGENT_CONTROL_L

Address Offset	0x020
Physical address	Please refer from Table 5-113 to Table 5-114
Description	Enable error reporting on an initiator interface. The error reporting mechanism is enabled when the INBAND_ERROR_REP bit field is set to 1. The out-of-band OCP MError reporting mechanism is enabled when the MERROR_REP bit field is set to 1.
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				INBAND_ERROR_REP	Reserved		MERROR_REP	Reserved																							

Bits	Field Name	Description	Type	Reset
31:28	Reserved	Read returns 0.	R	0x0
27	INBAND_ERROR_REP	Setting this field to 1 reports on in-band errors using the INBAND_ERROR log bit of IA.AGENT_STATUS register.	R	1
26:25	Reserved	Read returns 0.	R	0x0
24	MERROR_REP	Enable MError reporting	R	0x0
23:0	Reserved	Read returns 0.	R	0x00000000

5.10.2.2 L4_IA_AGENT_STATUS_L

Table 5-117. L4_IA_AGENT_STATUS_L

Address Offset	0x028
Physical address	Please refer from Table 5-113 to Table 5-114
Description	Stores status information for an initiator. The INBAND_ERROR and MERROR fields are read/write and are implemented as log bits.
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				INBAND_ERROR_REP	Reserved		MERROR_REP	Reserved																							

Bits	Field Name	Description	Type	Reset
31:28	Reserved	Read returns 0.	R	0x0
27	INBAND_ERROR_REP	0x0 No In-Band error present. 0x1 In-Band error present.	R 1toClr	0x0
26:25	Reserved	Read returns 0.	R	0x0
24	MERROR_REP	0x0 No MError error present. 0x1 MError error present.	R	0x0
23:0	Reserved	Read returns 0.	R	0x0000000

5.10.2.3 L4_IA_ERROR_LOG_L

Table 5-119. L4_IA_ERROR_LOG_L

Address Offset	0x058
Physical address	Please refer from Table 5-113 to Table 5-114
Description	Log information about error conditions. The CODE field logs any protection violation or address hole errors detected by the initiator subsystem while decoding a request.
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MULTI	Reserved					CODE	Reserved																								

Bits	Field Name	Description	Type	Reset
31	MULTI	While the CODE field is not zero, the MULTI bit is asserted whenever an additional error is detected. Once set by hardware, the MULTI bit can only be cleared by writing a 1 to it while writing a value other than zero to the CODE field.	RW	0
30:26	Reserved	Read returns 0.	R	0x00
25:24	CODE	The error code of an initiator request. 0x00: No errors 0x01: Reserved 0x10: Address hole 0x11: Protection violation The CODE field, once set by hardware, can only be cleared by writing a non-zero value to it, in conjunction with writing a 1 to the MULTI bit field.	RW	0x0
23:0	Reserved	Read returns 0.	R	0x000000

5.10.3 L4 Target Agent (L4 TA) Register Mapping Summary

This section provides information on the L4 Target agent (TA) register module. Each of the registers within the module instance is described separately in [Table 5-121](#) to [Table 5-149](#).

[Table 5-121](#) to [Table 5-150](#) provide information on the L4 Target Agent having two supplementary registers OCP_CONTROL and OCP_STATUS

The TA register block consists of the status and control registers that can be used to configure the interfaces of the targets.

5.10.6.5 L4_LA_NETWORK_CONTROL_H

Table 5-168. L4_LA_NETWORK_CONTROL_H

Address Offset	0x024
Physical address	Please refer to Table 5-157
Description	Control interconnect global power control
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							CLOCK_GATE_DISABLE	Reserved		THREAD0_PRI	Reserved							EXT_CLOCK	Reserved												

Bits	Field Name	Description	Type	Reset
31:25	Reserved	Read returns 0.	R	0x00
24	CLOCK_GATE_DISABLE	When set to 1 this field disables all clock gating.	RW	0
23:21	Reserved	Read returns 0.	R	0x0
20	THREAD0_PRI	Sets thread priority. If the field is set to 0, the default, all initiator threads are treated the same. Setting the THREAD0_PRI field to 1 assigns a higher arbitration priority to thread 0 of the first initiator OCP interface. To avoid starvation, arbitration is imposed by the initiator subsystem. When multiple requests from different initiator threads are dispatched to targets simultaneously, the oldest request is dispatched first. If thread 0 is assigned a higher priority, a request on thread 0 always wins arbitration. Assigning thread 0 of the first initiator OCP the highest priority on a request or response can result in the starvation of other threads.	R	1
19:9	Reserved	Read returns 0.	R	0x000
8	EXT_CLOCK	When set to 1, the ext_clk_off_i signal on the initiator subsystem instructs the entire L4 to shut off.	R	1
7:0	Reserved	Read returns 0.	R	0x00

Interprocessor Communication (IPC) Module

This chapter describes the interprocessor communication (IPC) module in the OMAP35x Applications Processor.

Topic	Page
6.1 IPC Overview	776
6.2 IPC Integration	777
6.3 IPC Mailbox Functional Description	780
6.4 IPC Mailbox Basic Programming Model	783
6.5 IPC Mailbox Use Cases and Tips	788
6.6 IPC Mailbox Registers	794

6.1 IPC Overview

Communication between the on-chip processors of the device uses a queued mailbox-interrupt mechanism.

The queued mailbox-interrupt mechanism allows the software to establish a communication channel between two processors through a set of registers and associated interrupt signals by sending and receiving messages (mailboxes).

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

Figure 6-1 shows a block diagram of the interprocessor communication (IPC) module.

Figure 6-1. Simplified Block Diagram of the IPC

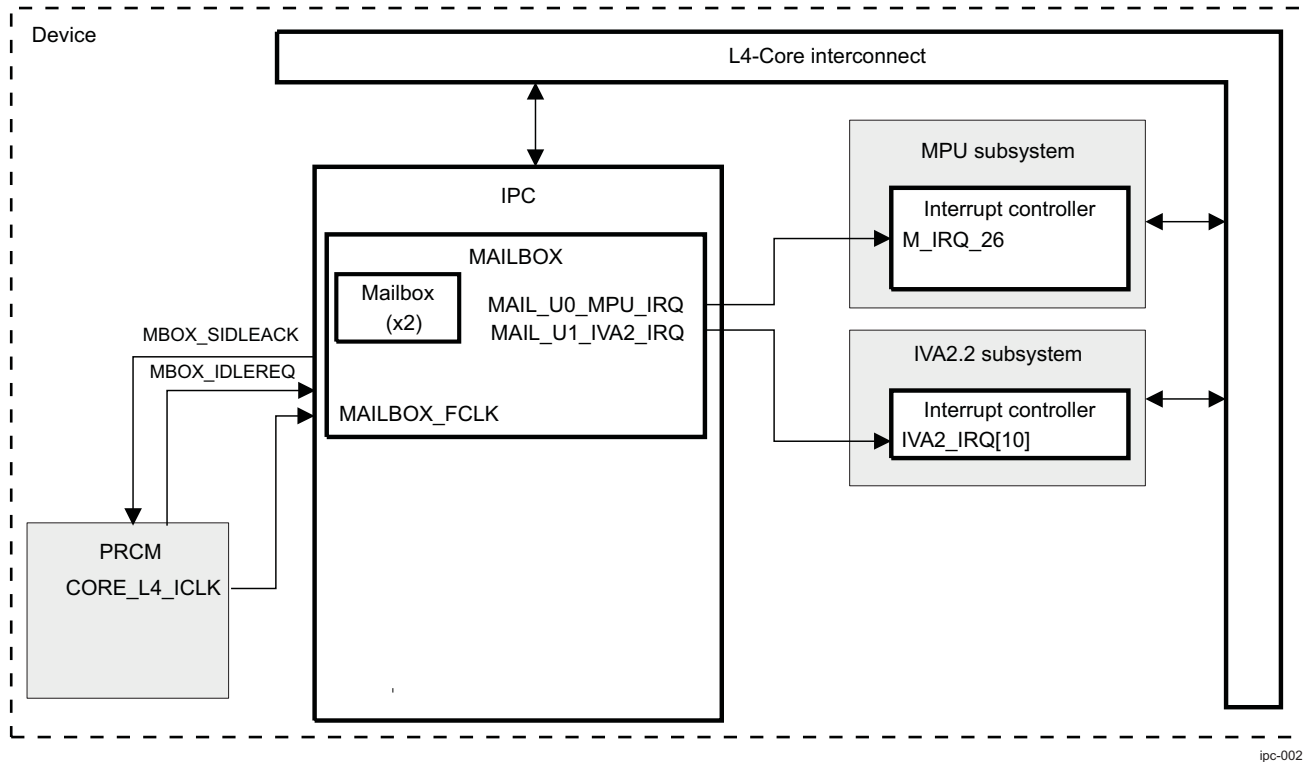

The mailbox module includes these features:

- Two mailbox message queues for microprocessor unit (MPU) and imaging video and audio accelerator (IVA2.2) communications.
- Flexible assignment of receiver and sender for each mailbox through interrupt configuration
- 32-bit message width
- Four-message FIFO depth for each message queue
- Message reception and queue-not-full notification using interrupts
- Support of 16-/32-bit addressing scheme
- Power management support
- Automatic idle mode for power savings

6.2 IPC Integration

Figure 6-2 highlights the IPC integration in the device.

Figure 6-2. IPC Integration

6.2.1 Clocking, Reset, and Power-Management Scheme

6.2.1.1 Clocks

6.2.1.1.1 Module Clocks

The mailbox module receives one input clock, **CORE_L4_ICLK**, from the power, reset, and clock management (PRCM) module. **CORE_L4_ICLK** is gated internally and can be turned off to lower operating power when a module is not active. The exact frequency of this clock depends on PRCM programming.

6.2.1.2 Resets

The IPC supports both a hardware reset and a software reset.

6.2.1.2.1 Hardware Reset

The mailbox module receives its reset signal, **CORE_RST** (the reset signal of the CORE power domain), from the PRCM module.

6.2.1.2.2 Software Reset

The mailbox module supports a software reset by accessing the **MAILBOX.MAILBOX_SYSCONFIG[1] SOFTRESET** bit (0: normal mode, 1: module is reset).

6.2.1.3 Power Domains

The mailbox module connects to the CORE power domain.

6.2.1.4 Power Management

6.2.1.4.1 System Power Management

This section describes system power management for the mailbox module.

As part of the system-wide power-management scheme, the mailbox module supports a communication protocol with the PRCM that allows the PRCM to request the mailbox to enter a low-power state. When the mailbox module acknowledges a low-power-mode request from the PRCM, the clock to the module is gated off at the PRCM clock generator. Because the clock is disabled at the source, the low-power mode offers lower power consumption than the internal clock-gating method in the local power management.

The PRCM.CM_ICLKEN1_CORE[7] EN_MAILBOXES bit in the PRCM module controls the mailbox clock. When this bit is 1, the clock to the mailbox module is enabled; otherwise, the clock is disabled (see the *Power, Reset, and Clock Management* chapter for more information).

The mailbox module can be configured using the MAILBOX.MAILBOX_SYSCONFIG[4:3] SIDLEMODE field to one of the following acknowledgment modes:

- No-idle mode: The mailbox module never enters the idle state.
- Force-idle mode: The mailbox module immediately enters the idle state on receiving a low-power-mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state.
- Smart-idle mode: After receiving a low-power-mode request from the PRCM module, the mailbox module enters the idle state only after all asserted output interrupts are acknowledged.

Table 6-1 describes the mailbox power-management modes.

Table 6-1. Mailbox Power Management Modes

Power-Management Mode Requested by the PRCM	MAILBOX.MAILBOX_SYSCONFIG[4:3] SIDLEMODE Field (Offset: 0x010)
Force-idle	00
No-idle	01
Smart-idle	10
Reserved (not used)	11

Note: The mailbox idle status can be read from the PRCM.CM_IDLEST1_CORE[7] ST_MAILBOXES bit. When this bit is 0, the mailbox module cannot be accessed; otherwise, the mailbox module can be accessed (see the *Power, Reset, and Clock Management* chapter for more information).

6.2.1.4.2 Module Power Management

This section describes local power management for the mailbox module.

To conserve power, the mailbox module supports an automatic idle mode whenever no activity is detected on the mailbox L4-Core interconnect interface. The automatic idle mode is enabled or disabled through the MAILBOX.MAILBOX_SYSCONFIG[0] AUTOIDLE bit.

When the MAILBOX.MAILBOX_SYSCONFIG[0] AUTOIDLE bit is asserted, the automatic idle mode is enabled in cases in which no activity is detected on the L4-Core interconnect interface, and the mailbox clock is disabled internally to the module, thus reducing power consumption.

When new activity is detected on the L4-Core interconnect interface, the clock is restarted with no latency penalty. After reset, the automatic idle mode is disabled; therefore, it is recommended that software enable the automatic idle mode for reduced power consumption.

Note: The PRCM.CM_AUTOIDLE1_CORE[7] AUTO_MAILBOXES bit controls whether the mailbox interface clock is enabled or disabled in synchronization with the CORE power domain state transition (see *the Power, Reset, and Clock Management* chapter for more information).

6.2.2 Hardware Requests

6.2.2.1 Interrupt Requests

The mailbox module can generate two interrupts:

- MAIL_U0_MPU_IRQ, mapped on M_IRQ_26 of the MPU subsystem interrupt controller
- MAIL_U1_IVA2_IRQ, mapped on IVA2_IRQ[10] of the IVA2.2 subsystem interrupt controller

Each interrupt allows the user (MPU subsystem or IVA2.2 subsystem) of the mailbox to be notified when a message is received or when the message queue is not full. There is one interrupt per user.

6.2.2.2 Idle Handshake Protocol

The PRCM module handles an idle handshake protocol for the mailbox module. The PRCM requires the mailbox module to enter idle mode. The mailbox module acknowledges when it is ready.

6.3 IPC Mailbox Functional Description

Note: In the mailbox functional description, u is the user number from 0 to 1 and m is the mailbox number from 0 to 1.

The mailbox module provides a means of communication through message queues among the MPU and the IVA2.2. The two individual mailbox modules, or FIFOs, can associate with any of the processors using the MAILBOX.MAILBOX_IRQENABLE_ u registers.

The mailbox module includes the following two user subsystems:

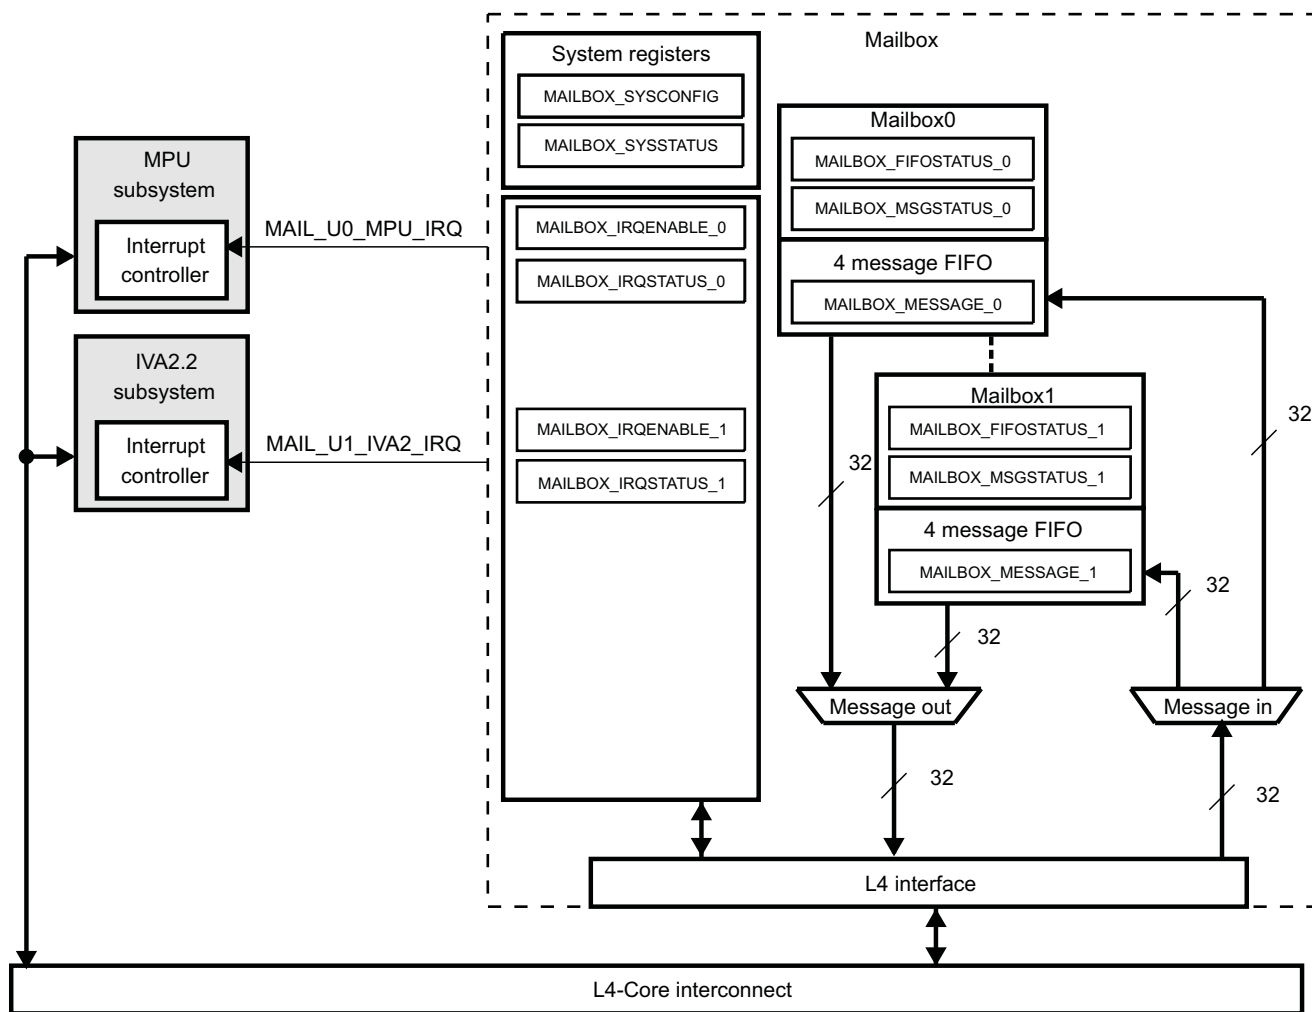

- User 0: MPU subsystem ($u = 0$)
- User 1: IVA2.2 subsystem ($u = 1$)

Each user has a dedicated interrupt signal from the mailbox module and a dedicated pair of interrupt enabling and status registers. Each MAILBOX.MAILBOX_IRQSTATUS_ u interrupt status register corresponds to a particular user. A user can query its interrupt status register through the L4-Core interconnect.

6.3.1 Block Diagram

Figure 6-3 shows the mailbox block diagram.

Figure 6-3. Mailbox Block Diagram

ipc-003

6.3.2 Mailbox Assignment

6.3.2.1 Description

To assign a receiver to a mailbox, set the new message interrupt enable bit corresponding to the desired mailbox in the MAILBOX.MAILBOX_IRQENABLE_u register. The receiver reads the MAILBOX.MAILBOX_MESSAGE_m register to retrieve a message from the mailbox.

An alternate method for the receiver that does not use the interrupts is to poll the MAILBOX.MAILBOX_FIFOSTATUS_m and/or MAILBOX.MAILBOX_MSGSTATUS_m registers to know when to send or retrieve a message to or from the mailbox. This method does not require assigning a receiver to a mailbox. Because this method does not include the explicit assignment of the mailbox, the software must avoid having multiple receivers use the same mailbox, which can result in incoherency.

To assign a sender to a mailbox, set the queue-not-full interrupt enable bit of the desired mailbox in the MAILBOX.MAILBOX_IRQENABLE_u register, where *u* is the number of the receiving user. However, direct allocation of a mailbox to a sender is not recommended because it can cause the sending processor to be constantly interrupted.

It is recommended that register polling be used to:

- Check the status of either the MAILBOX.MAILBOX_FIFOSTATUS_m or MAILBOX.MAILBOX_MSGSTATUS_m registers
- Write the message to the corresponding MAILBOX.MAILBOX_MESSAGE_m register, if space is available.

The sender should use the queue-not-full interrupt when the initial mailbox status check indicates the mailbox is full. In this case, the sender can enable the queue-not-full interrupt for its mailbox in the appropriate MAILBOX.MAILBOX_IRQENABLE_u register. This allows the sender to be notified by interrupt only when a FIFO queue has at least one available entry.

Reading the MAILBOX.MAILBOX_IRQSTATUS_u register determines the status of the new message and the queue-not-full interrupts for a particular user. Writing 1 to the corresponding bit in the same register location acknowledges, and subsequently clears, an interrupt.

CAUTION

Assigning multiple senders or multiple receivers to the same mailbox is not recommended.

6.3.3 Sending and Receiving Messages

6.3.3.1 Description

When a 32-bit message is written to the MAILBOX.MAILBOX_MESSAGE_m register, the message is appended into the FIFO queue. This queue holds four messages. If the queue is full, the message is discarded.

Queue overflow can be avoided by first reading the MAILBOX.MAILBOX_FIFOSTATUS_m register to check that the mailbox message queue is not full before writing a new message to it.

Reading the MAILBOX.MAILBOX_MESSAGE_m register returns the message at the beginning of the FIFO queue and removes it from the queue. If the FIFO queue is empty when the MAILBOX.MAILBOX_MESSAGE_m register is read, the value 0 is returned.

The new message interrupt is asserted when at least one message is in the mailbox message FIFO queue. To determine the number of messages in the mailbox message FIFO queue, read the MAILBOX.MAILBOX_MSGSTATUS_m register.

6.3.4 16-Bit Register Access

6.3.4.1 Description

So that 16-bit processors can access the mailbox module, the device allows 16-bit register read and write access, with restrictions for the MAILBOX.MAILBOX_MESSAGE_m registers. The 16-bit half-words are organized in little endian fashion; that is, the least-significant 16 bits are at the low address and the most-significant 16 bits are at the high address (low address + 0x02).

All mailbox module registers can be read or written to directly using individual 16-bit accesses with no restriction on interleaving, except the MAILBOX.MAILBOX_MESSAGE_m registers, which must always be accessed by either single 32-bit accesses or two consecutive 16-bit accesses.

CAUTION

When using 16-bit accesses, it is critical to ensure that the mailbox used has only one assigned receiver and only one assigned sender.

When using 16-bit accesses to the MAILBOX.MAILBOX_MESSAGE_m registers, the order of access must be the least-significant half-word first (low address) and the most-significant half-word last (high address). This requirement is due to the update operation by the message FIFO of the MAILBOX.MAILBOX_MSGSTATUS_m registers. The update of the FIFO queue contents and the associated status registers and possible interrupt generation occurs only when the most-significant 16 bits of a MAILBOX.MAILBOX_MESSAGE_m are accessed.

6.4 IPC Mailbox Basic Programming Model

6.4.1 Initialization Flow for the Mailbox Module

The initialization flow for the mailbox module consists of the following steps:

1. Perform a software reset of the mailbox module (see [Section 6.4.1.1, Software Reset](#)).
2. Set the idle mode and clock configuration of the mailbox module (see [Section 6.4.1.2, Idle Mode and Clock Configuration](#)).

6.4.1.1 Software Reset

To perform a software reset, write 1 in the MAILBOX.MAILBOX_SYSCONFIG[1] SOFTRESET bit. The MAILBOX.MAILBOX_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1.

When the software reset completes, the MAILBOX.MAILBOX_SYSCONFIG[1] SOFTRESET bit is automatically reset. The software must ensure that the software reset completes before doing mailbox operations.

CAUTION

When performing a software reset by writing 1 in the MAILBOX.MAILBOX_SYSCONFIG[1] SOFTRESET bit, 0 must be written in the other bits of the MAILBOX.MAILBOX_SYSCONFIG register.

6.4.1.2 Idle Mode and Clock Configuration

The idle mode and clock configuration is done by setting the MAILBOX.MAILBOX_SYSCONFIG[4:3] SIDLEMODE field and the MAILBOX.MAILBOX_SYSCONFIG[0] AUTOIDLE bit (see [Section 6.6, Mailbox Registers](#), for more information).

6.4.2 Mailbox Assignment

Before communicating, mailboxes can be explicitly assigned to a user using the appropriate MAILBOX.MAILBOX_IRQENABLE_u register. The software must ensure that only one sender and one receiver are assigned per mailbox.

For example, to assign mailbox 1 ($m = 1$) to the MPU ($u = 0$, see [Section 6.3, Mailbox Functional Description](#), for the user number) as a receiver, set the MAILBOX.MAILBOX_IRQENABLE_0[2] NEWMSGENABLEUUMB1 bit to generate an interrupt to the MPU when a new message is received in mailbox 1.

To assign mailbox 0 ($m = 0$) to the MPU ($u = 0$) as a sender, set the MAILBOX.MAILBOX_IRQENABLE_0[1] NOTFULLENABLEUUMB0 bit to generate an interrupt to the MPU when the message queue of mailbox 0 is not full.

6.4.3 Mailbox Communication Preparation

Before communicating with another user, the sender must first use one of the following methods to determine that the mailbox message FIFO queue is not full:

- Poll the MAILBOX.MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB bit or the MAILBOX.MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB field to determine if there is an open slot available to write a message.

- If the queue-not-full interrupt is enabled by setting the corresponding bit in the MAILBOX.MAILBOX_IRQENABLE_u register, an interrupt to the sender indicates that the mailbox has an available slot. To avoid continuous interrupt to the sender, it is recommended that the software waits until the message queue is full by reading the MAILBOX.MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB field before enabling the interrupt in the MAILBOX.MAILBOX_IRQENABLE_u register. When a queue-not-full interrupt is generated to the sender, the interrupt should be disabled until the message queue is full for the same reason.

The receiver can also detect new messages from another user using two methods:

- Poll the MAILBOX.MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB bit or the MAILBOX.MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB field.
- Use a new message ISR (interrupt service routine). In this case, the receiver must enable the appropriate interrupt in the MAILBOX.MAILBOX_IRQENABLE_u register.

Note: After an interrupt is generated, and before exiting the ISR, write 1 in each bit responsible for this generation in the MAILBOX.MAILBOX_IRQSTATUS_u register, thereby clearing these bits.

6.4.4 Mailbox Communication Sequence

When a message slot is available in the mailbox, a message can be transmitted by a sender to a receiver using the following steps:

1. The sender writes a message in the MAILBOX.MAILBOX_MESSAGE_m register. This results in the following actions:
 - The message is stored at the tail of the FIFO queue of mailbox *m*, and the MAILBOX.MAILBOX_FIFOSTATUS_m and MAILBOX.MAILBOX_MSGSTATUS_m registers are updated.
 - If the FIFO queue was previously empty, a new message interrupt can be generated to the receiver to which the mailbox is allocated; otherwise, the interrupt is already asserted and remains so.
2. The receiver can either use an ISR or poll the MAILBOX.MAILBOX_FIFOSTATUS_m or MAILBOX.MAILBOX_MSGSTATUS_m registers to detect new messages and read them by accessing the MAILBOX.MAILBOX_MESSAGE_m register.
 - If using interrupts, the receiver enters the ISR when it detects the new message interrupt. The receiver checks both the MAILBOX.MAILBOX_IRQSTATUS_u register to determine the source of the interrupt and the MAILBOX.MAILBOX_MSGSTATUS_m register(s) to determine the number of messages in the FIFO queue.
 - The receiver can poll the appropriate MAILBOX.MAILBOX_MSGSTATUS_m register(s) to check the status and determine if there are any pending messages to read. The receiver can read the MAILBOX.MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB field to determine how many messages are available.
3. Using either ISR or polling method, when the receiver determines that it has a message pending in a mailbox, it repeatedly reads the MAILBOX.MAILBOX_MESSAGE_m register to remove all messages from the FIFO queue until a read in the MAILBOX.MAILBOX_MSGSTATUS_m register indicates no more messages are available (MAILBOX.MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB field = 0x00).
4. After reading all of the messages, the receiver can acknowledge the new message interrupt by writing 1 in the appropriate bit of the MAILBOX.MAILBOX_IRQSTATUS_u register to clear the interrupt flag before exiting the ISR.

6.4.5 Example of Communication

This example shows how communication is established between the MPU and IVA2.2 subsystems in the device. The MPU subsystem sends messages to the IVA2.2 subsystem through mailbox 0, and the IVA2.2 subsystem sends messages to the MPU subsystem through mailbox 1.

To establish communication, the software follows these steps:

1. Turn on the automatic idle feature by writing 1 in the MAILBOX.MAILBOX_SYSCONFIG[0] AUTOIDLE bit.
2. Configure the mailbox in smart-idle mode by setting the MAILBOX.MAILBOX_SYSCONFIG[4:3] SIDLEMODE field in smart-idle mode (smart-idle is the recommended mode; see [Section 6.6, Mailbox Registers](#), for more information). Smart-idle mode allows the PRCM low-power-mode requests to be acknowledged only after clearing any pending interrupts.
3. Write 1 in the MAILBOX.MAILBOX_IRQENABLE_1[0] NEWMSGENABLEUUMB0 bit to enable interrupts to the IVA2.2 subsystem when a new message is received in mailbox 0.
4. Write 1 in the MAILBOX.MAILBOX_IRQENABLE_0[2] NEWMSGENABLEUUMB1 bit to enable interrupts to the MPU subsystem when a new message is received in mailbox 1.
5. Enable interrupts in the corresponding subsystems.

6.4.5.1 Sending a Message (Polling Method)

To send a message using the polling method, the MPU or IVA2.2 subsystem follows these steps:

1. The MPU subsystem (or IVA2.2 subsystem) determines if the message queue of mailbox 0 (or mailbox 1 for the IVA2.2 subsystem) is full by reading the MAILBOX.MAILBOX_FIFOSTATUS_0[0] FIFOFULLMB bit (or the MAILBOX.MAILBOX_FIFOSTATUS_1[0] FIFOFULLMB bit for the IVA2.2 subsystem).
2. If the MAILBOX.MAILBOX_FIFOSTATUS_0[0] FIFOFULLMB bit (or the MAILBOX.MAILBOX_FIFOSTATUS_1[0] FIFOFULLMB bit for the IVA2.2 subsystem) is 0, mailbox 0 (or mailbox 1 for the IVA2.2 subsystem) has a message slot available to store a new message; go to step 4.
3. If the MAILBOX.MAILBOX_FIFOSTATUS_0[0] FIFOFULLMB bit (or the MAILBOX.MAILBOX_FIFOSTATUS_1[0] FIFOFULLMB bit for the IVA2.2 subsystem) is 1, mailbox 0 (or mailbox 1 for the IVA2.2 subsystem) is full; go back to step 1.
4. The MPU subsystem (or IVA2.2 subsystem) can send a message by writing it into the MAILBOX.MAILBOX_MESSAGE_0 register (or the MAILBOX.MAILBOX_MESSAGE_1 register for the IVA2.2 subsystem).

6.4.5.2 Sending a Message (Interrupt Method)

To send a message using the interrupt method, the MPU or IVA2.2 subsystem follows these steps:

1. To avoid continuous interruption, the MPU subsystem (or the IVA2.2 subsystem) must determine if mailbox 0 (or mailbox 1 for the IVA2.2 subsystem) is full by reading the MAILBOX.MAILBOX_FIFOSTATUS_0[0] FIFOFULLMB bit (or the MAILBOX.MAILBOX_FIFOSTATUS_1[0] FIFOFULLMB bit for the IVA2.2 subsystem).
2. If mailbox 0 (or mailbox 1 for the IVA2.2 subsystem) is full, the MPU subsystem (or the IVA2.2 subsystem) can enable the queue-not-full interrupt by setting the MAILBOX.MAILBOX_IRQENABLE_0[1] NOTFULLENABLEUUMB0 bit (or the MAILBOX.MAILBOX_IRQENABLE_1[3] NOTFULLENABLEUUMB1 bit for the IVA2.2 subsystem), and perform another task before an interrupt occurs; go to step 4).
3. If mailbox 0 (or mailbox 1 for the IVA2.2 subsystem) is not full, the MPU can go back to step 1 and wait for mailbox 0 (or mailbox 1 for the IVA2.2 subsystem) to fill, or the MPU can send a message, if necessary, by writing in the MAILBOX.MAILBOX_MESSAGE_0 register (or the MAILBOX.MAILBOX_MESSAGE_1 register for the IVA2.2 subsystem).
4. After receiving an interrupt, the MPU subsystem (or the IVA2.2 subsystem) enters the ISR and reads the MAILBOX.MAILBOX_IRQSTATUS_0[1] NOTFULLSTATUSUUMB0 bit (or the MAILBOX.MAILBOX_IRQSTATUS_1[3] NOTFULLSTATUSUUMB1 bit for the IVA2.2 subsystem) to determine if mailbox 0 (or mailbox 1 for the IVA2.2 subsystem) is not full and thus send its message. The MPU subsystem writes the message in the MAILBOX.MAILBOX_MESSAGE_0 register (or the MAILBOX.MAILBOX_MESSAGE_1 register for the IVA2.2 subsystem). The MPU subsystem (or the IVA2.2 subsystem) then acknowledges the interrupt by writing 1 in the MAILBOX.MAILBOX_IRQSTATUS_0[1] NOTFULLSTATUSUUMB0 bit (or the MAILBOX.MAILBOX_IRQSTATUS_1[3] NOTFULLSTATUSUUMB1 bit for the IVA2.2 subsystem).

Note: To send several messages, a subsystem or processor must determine if the message queue of mailbox *m* has enough available slots by checking the MAILBOX.MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB field before writing all of the messages in this mailbox (see [Section 6.6](#), *Mailbox Registers*, for more information).

6.4.5.3 Receiving Messages (Interrupt Method)

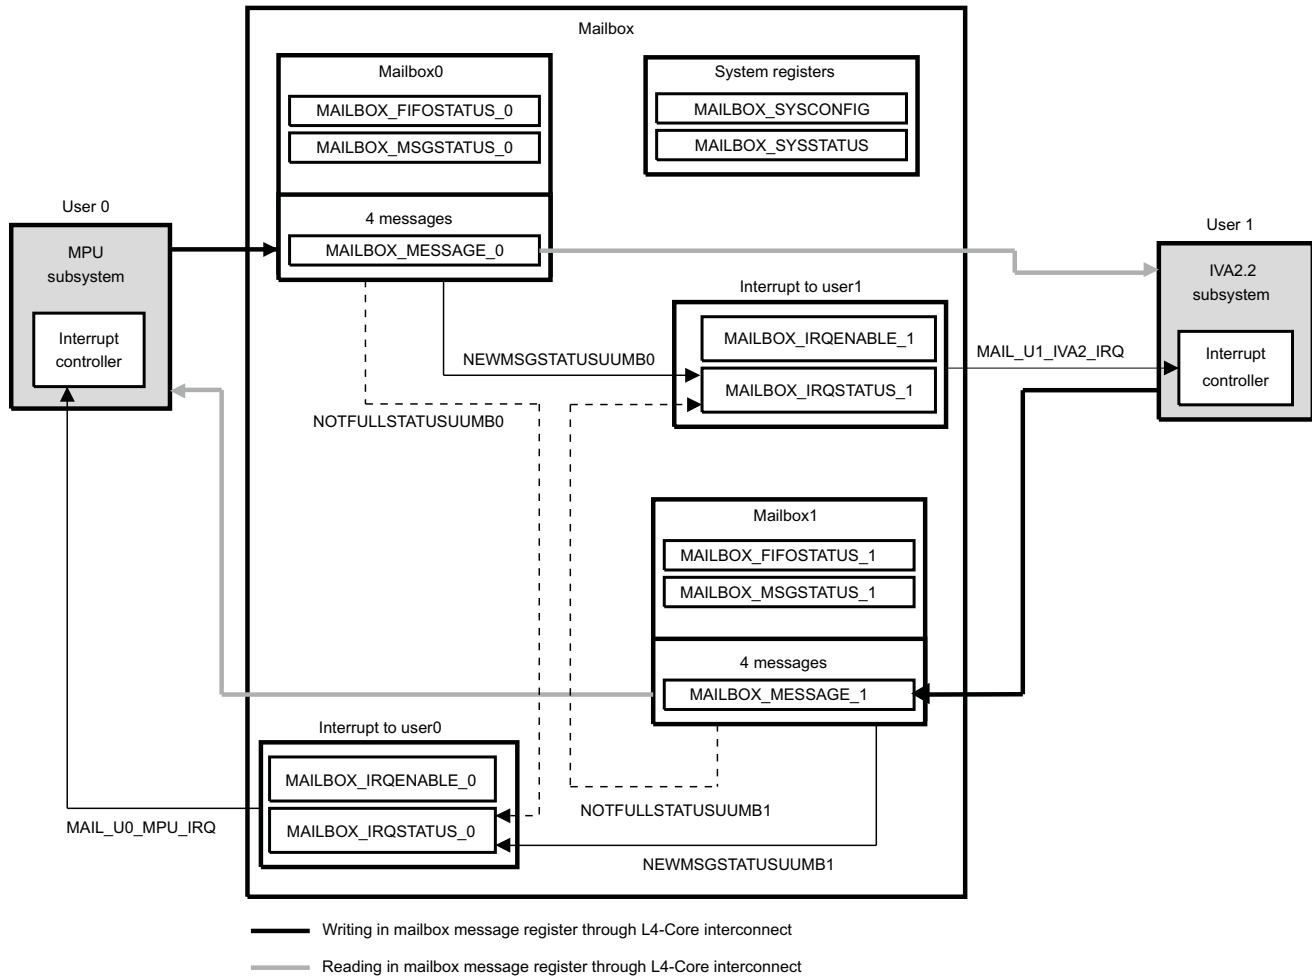

After receiving an interrupt indicating that a new message is received, the MPU or IVA2.2 subsystem follows these steps:

1. The MPU subsystem (or the IVA2.2 subsystem) determines how many messages are stored in the message queue of mailbox 1 by reading the MAILBOX.MAILBOX_MSGSTATUS_1[2:0] NBOFMSGMB field (or the MAILBOX.MAILBOX_MSGSTATUS_0[2:0] NBOFMSGMB field for the IVA2.2 subsystem).
2. The MPU subsystem (or the IVA2.2 subsystem) reads the MAILBOX.MAILBOX_MESSAGE_1 register (or the MAILBOX.MAILBOX_MESSAGE_0 register for the IVA2.2 subsystem) as many times as there are messages in mailbox 1 (or mailbox 0 for the IVA2.2 subsystem).
3. Finally, the MPU subsystem (or the IVA2.2 subsystem) acknowledges the interrupt by writing 1 in the MAILBOX.MAILBOX_IRQSTATUS_0[2] NEWMSGSTATUSUUMB1 bit (or the MAILBOX.MAILBOX_IRQSTATUS_1[0] NEWMSGSTATUSUUMB0 bit for the IVA2.2 subsystem).

Note: After the interrupt is acknowledged, if the mailbox message queue is not empty, the interrupt is reasserted.

[Figure 6-4](#) shows an example of communication:

Figure 6-4. Example of Communication

ipc-004

6.5 IPC Mailbox Use Cases and Tips

6.5.1 Camcorder Use Case: How to Configure the Mailbox Module for Communication Between the MPU and the IVA2.2 Subsystems

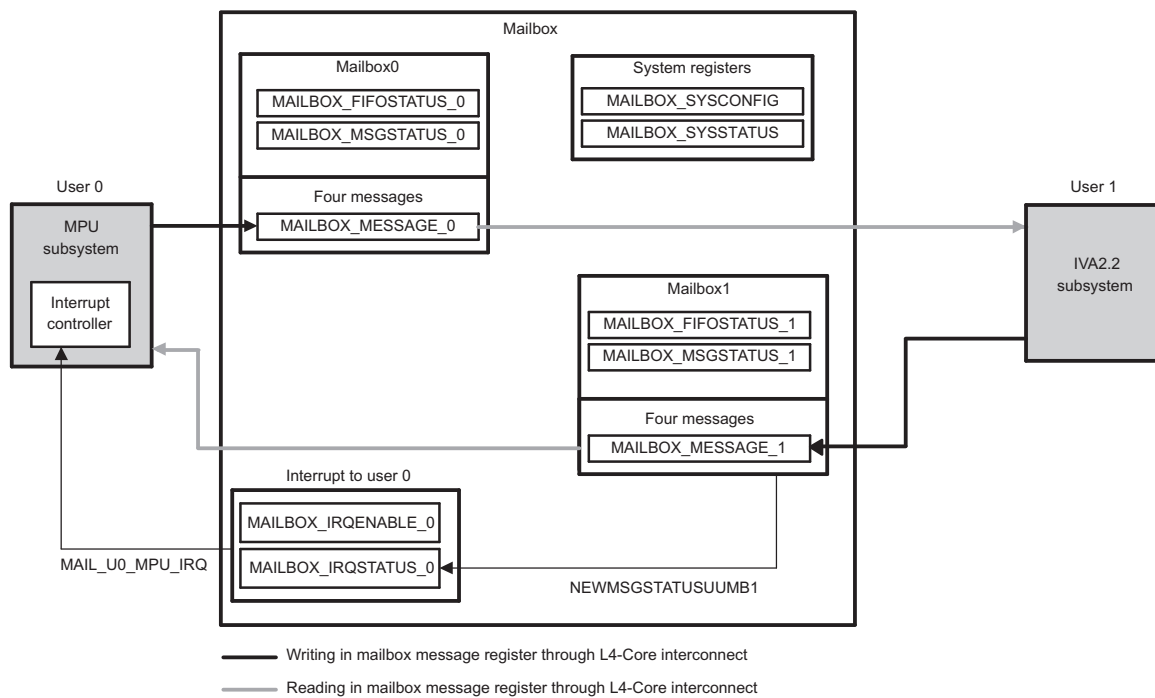

6.5.1.1 Overview

In a whole Camcorder use case, the mailbox module is in charge of the communication between the MPU and the IVA2.2 subsystems in the device.

The MPU subsystem send messages to the IVA2.2 subsystem through mailbox 0: typically, an audio or video compression request (a command and a memory address). And the IVA2.2 subsystem sends messages to the MPU subsystem through mailbox 1: typically, a compression completion message with error management.

Figure 6-5 shows an overview of the use of the mailbox module in the case of the Camcorder use case.

Figure 6-5. Overview

ipc-005

For the Camcorder use case, the configuration is the following:

- 32-bit message width
- Use of polling method for MPU subsystem message sending (mailbox 0), IVA2.2 subsystem message receiving (mailbox 0), and IVA2.2 subsystem message sending (mailbox 1)
- Use of interrupt method for MPU subsystem message receiving (mailbox 1)
- NewMessage interrupt to the MPU subsystem indicating a new message is received on mailbox 1

6.5.1.2 Programming Flow

6.5.1.2.1 Initial Configuration

The initialization of the mailbox module is done in two parts:

1. Mailbox module initialization
2. Interrupt enabling

The two subsections below describe each of these initialization parts.

See [Figure 6-6](#) for the corresponding programming flowchart.

6.5.1.2.1.1 Mailbox Module Initialization

To initialize the mailbox module, the following steps must be done:

1. Enable the clock for the mailbox module (set the PRCM.CM_ICLKEN1_CORE[7] EN_MAILBOXES bit to 1)
2. Set the MAILBOX.MAILBOX_SYSCONFIG[1] SOFTRESET bit to 1. This bit is automatically reset by the hardware
3. Poll the MAILBOX.MAILBOX_SYSSTATUS[0] RESETDONE bit until it is set to 1 by the mailbox module to indicate that the mailbox module is complete

[Table 6-2](#) shows all the registers to be configured for the mailbox module initialization.

Table 6-2. Register Print after the Mailbox Module Initialization

Register Name	Physical Address	Value	Value Description
PRCM.CM_ICLKEN1_CORE	0x4800 4A10	0x0000 0080	EN_MAILBOXES bit set to 1 to enable the mailbox clock
MAILBOX.MAILBOX_SYSCONFIG	0x4809 4010	0x0000 0002	SOFTRESET bit set to 1 to reset the mailbox module
MAILBOX.MAILBOX_SYSSTATUS	0x4809 4014	0x0000 0001	The RESETDONE bit is set to 1 by the mailbox module when the software reset is complete

6.5.1.2.1.2 Interrupt Enabling

The NewMessage interrupt is asserted when at least one message is in the mailbox message FIFO queue.

To generate an interrupt to the MPU subsystem when a new message is received on mailbox 1, set the MAILBOX.MAILBOX_IRQENABLE_0[2] NEWMSGENABLEUUMB1 bit to 1.

[Table 6-3](#) shows all the registers to be configured for the interrupt enabling.

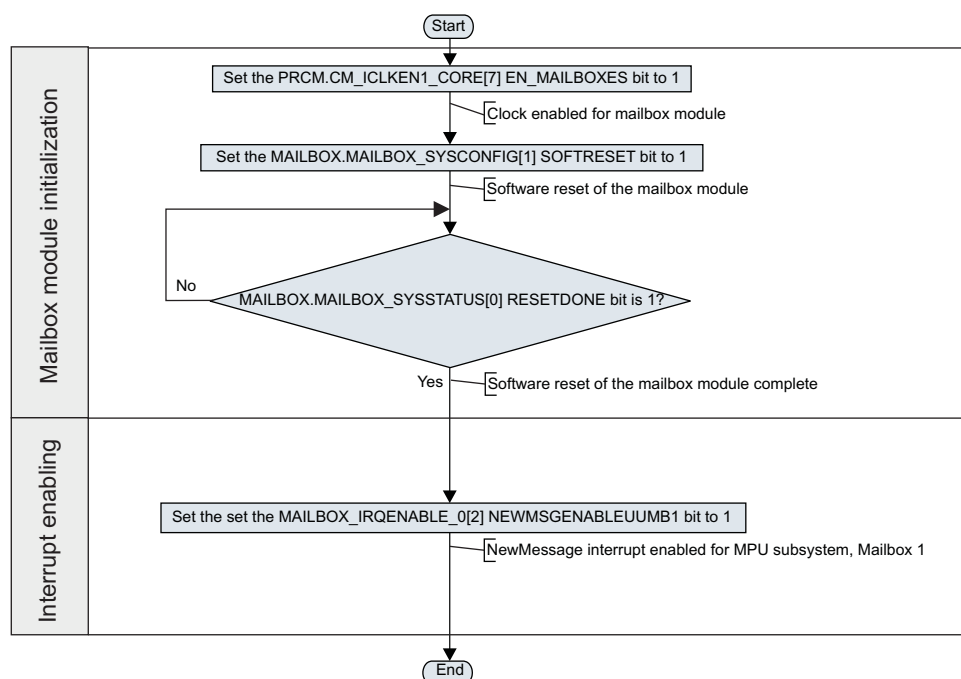

Table 6-3. Register Print after the Interrupt Enabling

Register Name	Physical Address	Value	Value Description
MAILBOX.MAILBOX_IRQENABLE_0	0x4809 4104	0x0000 0004	NEWMSGENABLEUUMB1 bit is set to 1 to enable the NewMessage interrupt to the MPU subsystem on mailbox 1

6.5.1.2.1.3 Initial Configuration Flowchart

Figure 6-6 describes the programming flowchart corresponding to the initial configuration.

Figure 6-6. Initial Configuration Flowchart

ipc-006

6.5.1.2.2 Operational Mode

For the Camcorder use case, the communication between the MPU and the IVA2.2 subsystems is done in four parts:

1. MPU subsystem message sending (polling method)
2. IVA2.2 subsystem message receiving (polling method)
3. IVA2.2 subsystem message sending (polling method)
4. MPU subsystem message receiving (interrupt method)

6.5.1.2.2.1 MPU Subsystem Message Sending (Polling Method)

To send a message with mailbox 0 using the polling method, the MPU subsystem follows these steps:

1. Poll the MAILBOX.MAILBOX_FIFOSTATUS_0[0] FIFOFULLMB bit until it is cleared to 0 by the mailbox module to indicate that the mailbox 0 message queue is not full
2. Write the message into the MAILBOX.MAILBOX_MESSAGE_0 register

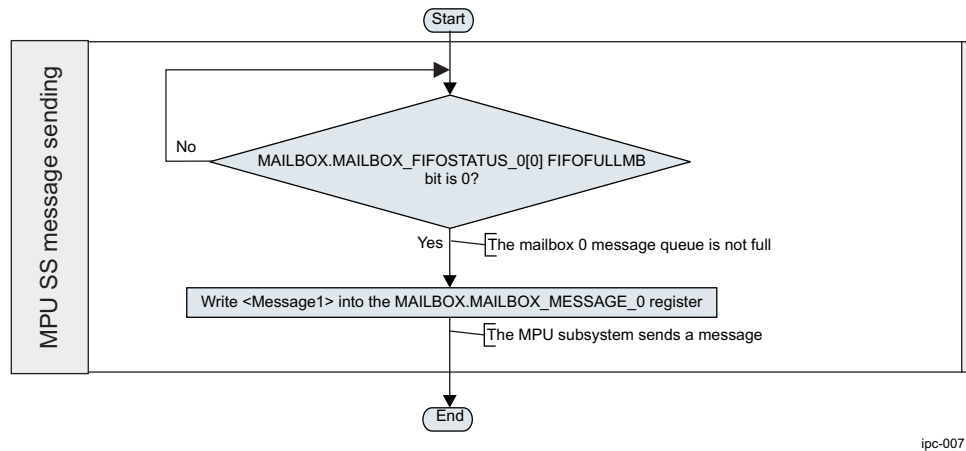

Table 6-4 shows all the registers to be configured for the MPU subsystem message sending.

Table 6-4. Register Print after the MPU Subsystem Message Sending

Register Name	Physical Address	Value	Value Description
MAILBOX.MAILBOX_FIFOSTATUS_0	0x4809 4080	0x0000 0000	FIFOFULLMB bit is cleared to 0 when the mailbox 0 message queue is not full
MAILBOX.MAILBOX_MESSAGE_0	0x4809 4040	<Message1>	<Message1> is written into the MAILBOX.MAILBOX_MESSAGE_0 register

Figure 6-7 describes the programming flowchart corresponding to the MPU subsystem message sending.

Figure 6-7. MPU Subsystem Message Sending Flowchart

6.5.1.2.2.2 IVA2.2 Subsystem Message Receiving (Polling Method)

To receive a message with mailbox 0 using the polling method, the IVA2.2 subsystem follows these steps:

1. Poll the MAILBOX.MAILBOX_MSGSTATUS_0[2:0] NBOFMSGMB field until it is set to 0x1 to detect a new message in mailbox 0
2. Read the message into the MAILBOX.MAILBOX_MESSAGE_0 register

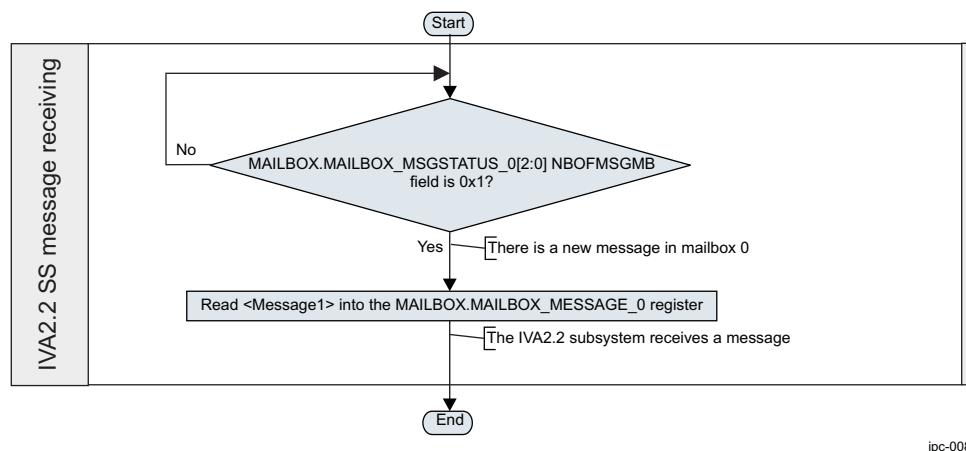

Table 6-5 shows all the registers to be configured for the IVA2.2 subsystem message receiving.

Table 6-5. Register Print after the IVA2.2 Subsystem Message Receiving

Register Name	Physical Address	Value	Value Description
MAILBOX.MAILBOX_MSGSTATUS_0	0x4809 40C0	0x0000 0001	NBOFMSGMB field is set to 0x1. <Message1> is received.
MAILBOX.MAILBOX_MESSAGE_0	0x4809 4040	<Message1>	<Message1> is read into the MAILBOX.MAILBOX_MESSAGE_0 register

Figure 6-8 describes the programming flowchart corresponding to the IVA2.2 subsystem message receiving.

Figure 6-8. IVA2.2 Subsystem Message Receiving Flowchart

6.5.1.2.2.3 IVA2.2 Subsystem Message Sending (Polling Method)

When the IVA2.2 subsystem data processing is done, use of mailbox 1 to send a message. After sending the message, a NewMessage interrupt is generated and received by the MPU subsystem. To send a message with mailbox 1 using the polling method, the MPU subsystem follows these steps:

1. Poll the MAILBOX.MAILBOX_FIFOSTATUS_1[0] FIFOFULLMB bit until it is cleared to 0 by the mailbox module to indicate that the mailbox 0 message queue is not full
2. Write the message into the MAILBOX.MAILBOX_MESSAGE_1 register

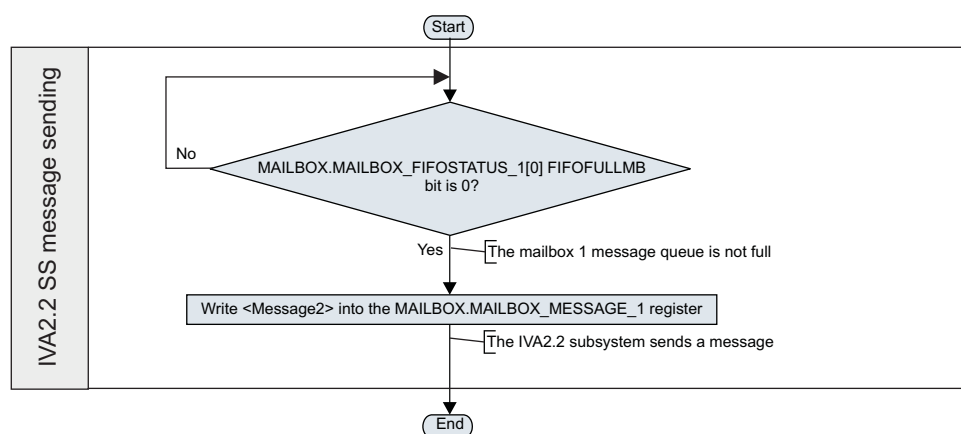

Table 6-6 shows all the registers to be configured for the IVA2.2 subsystem message sending.

Table 6-6. Register Print after the IVA2.2 Subsystem Message Sending

Register Name	Physical Address	Value	Value Description
MAILBOX.MAILBOX_FIFOSTATUS_1	0x4809 4084	0x0000 0000	FIFOFULLMB bit is cleared to 0 when the FIFO is not full
MAILBOX.MAILBOX_MESSAGE_1	0x4809 4044	<Message2>	<Message2> is written into the MAILBOX.MAILBOX_MESSAGE_1 register

Figure 6-9 describes the programming flowchart corresponding to the IVA2.2 subsystem message sending. See Section 6.5.1.2.2.3 for more information.

Figure 6-9. IVA2.2 Subsystem Message Sending Flowchart

ipc-009

6.5.1.2.2.4 MPU Subsystem Message Receiving (Interrupt Method)

After receiving a NewMessage interrupt (indicating a new message is received), the MPU subsystem reads the message from the IVA2.2 subsystem. To receive a message with mailbox 0 using the polling method, the IVA2.2 subsystem follows these steps:

1. Read the MAILBOX_IRQSTATUS_0[2] NEWMSGSTATUSUMB1 bit
2. Read the message into the MAILBOX_MESSAGE_1 register
3. Set the MAILBOX_IRQSTATUS_0[2] NEWMSGSTATUSUMB1 bit to 1 to clear the interrupt flag

Table 6-7 shows all the registers to be configured for the MPU subsystem message receiving.

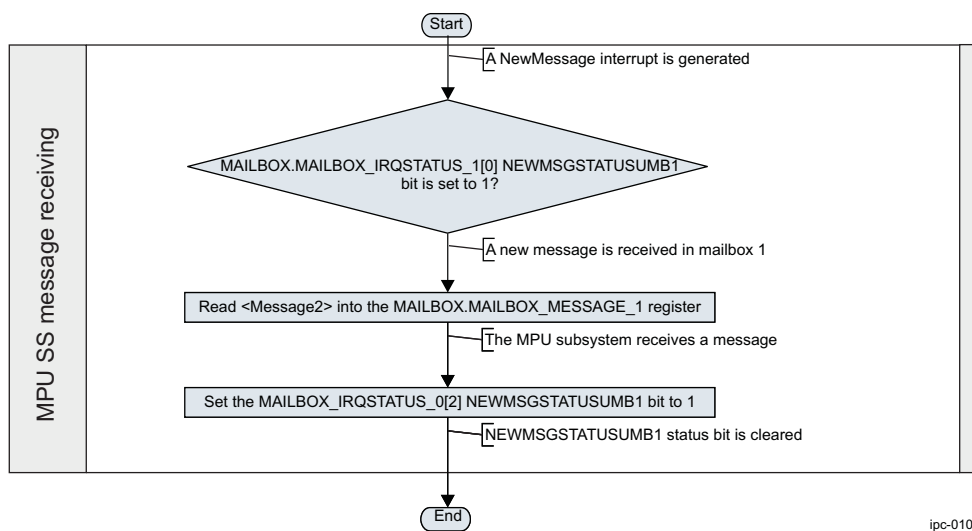

Table 6-7. Register Print after the MPU Subsystem Message Receiving

Register Name	Physical Address	Value	Value Description
MAILBOX.MAILBOX_IRQSTATUS_0	0x4809 4100	0x0000 0004	A NewMessage interrupt is generated. NEWMSGSTATUSUMB1 status bit is set to 1.

Table 6-7. Register Print after the MPU Subsystem Message Receiving (continued)

Register Name	Physical Address	Value	Value Description
MAILBOX.MAILBOX_MESSAG E_1	0x4809 4044	<Message2>	<Message2> is read into the MAILBOX.MAILBOX_MESSAG E_1 register
MAILBOX.MAILBOX_IRQSTAT US_0	0x4809 4100	0x0000 0000	NEWMSGSTATUSUMB1 status bit is cleared

Figure 6-10 describes the programming flowchart corresponding to the MPU subsystem message receiving. See [Section 6.5.1.2.2.4](#) for more information.

Figure 6-10. MPU Subsystem Message Receiving Flowchart

6.6 IPC Mailbox Registers

Table 6-8 summarizes the mailbox instance.

Table 6-8. Mailbox Instance Summary

Module Name	Base Address	Size
MLB	0x4809 4000	4K bytes

6.6.1 Mailbox Register Mapping Summary

Table 6-9 summarizes the MLB registers.

Table 6-9. MLB Register Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address
MAILBOX_SYSCONFIG	RW	32	0x010	0x4809 4010
MAILBOX_SYSSTATUS	R	32	0x014	0x4809 4014
MAILBOX_MESSAGE_m	RW	32	0x040- 0x044	0x4809 4040- 0x4809 4044
MAILBOX_FIFOSTATUS_m	R	32	0x080- 0x084	0x4809 4080- 0x4809 4084
MAILBOX_MSGSTATUS_m	R	32	0x0C0- 0x0C4	0x4809 40C0- 0x4809 40C4
MAILBOX_IRQSTATUS_u	RW	32	0x100- 0x108	0x4809 4100- 0x4809 4108
MAILBOX_IRQENABLE_u	RW	32	0x104- 0x10C	0x4809 4104- 0x4809 410C

Note: In MAILBOX_MESSAGE_0, MAILBOX_MESSAGE_1, MAILBOX_FIFOSTATUS_0, MAILBOX_FIFOSTATUS_1, MAILBOX_MSGSTATUS_0, and MAILBOX_MSGSTATUS_1 register names, 0 or 1 is the mailbox number.

In MAILBOX_IRQSTATUS_0, MAILBOX_IRQSTATUS_1, MAILBOX_IRQENABLE_0, and MAILBOX_IRQENABLE_1 register names, 0 or 1 is the user number:

- User 0: MPU subsystem
- User 1: IVA2.2 subsystem

System Control Module

This document describes the system control module for the OMAP35x Applications Processor.

Note: This chapter gives information about all modules and features in the high-tier device. See Chapter 1, the *OMAP35x Family* section, to check availability of modules and features. Unavailable module and feature pins are not functional.

7.4 System Control Module Functional Description	808
7.5 System Control Module Programming Model	889
7.6 System Control Module Registers	902
7.7 Revision History	1027

7.1 System Control Module Overview

The system control module (SCM) allows software control of the various static modes supported by the device. The SCM is on the L4-Core interconnect, but it is sensitive only to the device internal power-on reset. It is not affected by the L4-Core reset.

For emulator devices, the power-on reset can also be controlled by the debugger through the JTAG interface.

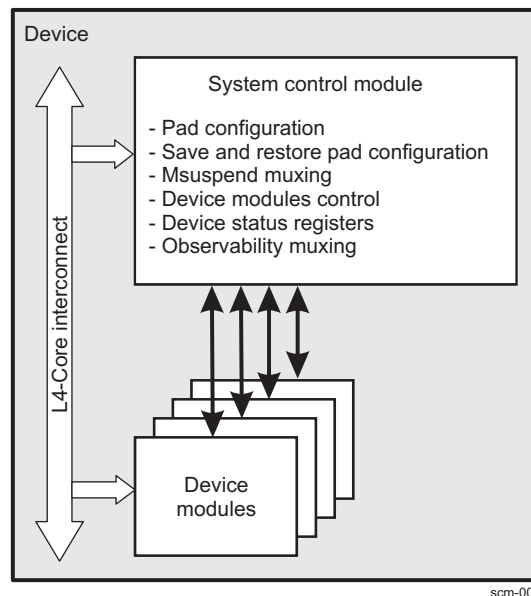

The device uses the SCM as the primary point of control for these areas:

- Functional I/O multiplexing
- Pad configuration (pull-up or pull-down enable)
- Secure mode configuration and emulation controls
- Device status
- Peripheral sensitivity to the MPU and/or the DSP (IVA2.2) MSuspend signals
- Static device configuration
- Debug and observability I/O multiplexing
- Save-and-restore pad configuration

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

Figure 7-1 provides an overview of the SCM.

Figure 7-1. System Control Module Overview

The SCM primarily implements a bank of registers accessible by the software. Some are read-only registers that carry status information, and others are fully accessible (read/write).

The read/write registers are divided into the following classes:

- Pad functional multiplexing and configuration registers (32-bit registers, one register per two pins)
- Debug and observability I/O multiplexing register (32-bit read/write register)
- Static device configuration registers (32-bit read/write registers for module specific configuration)
- Security and emulation control registers (32-bit registers accessible only in secure privilege mode with

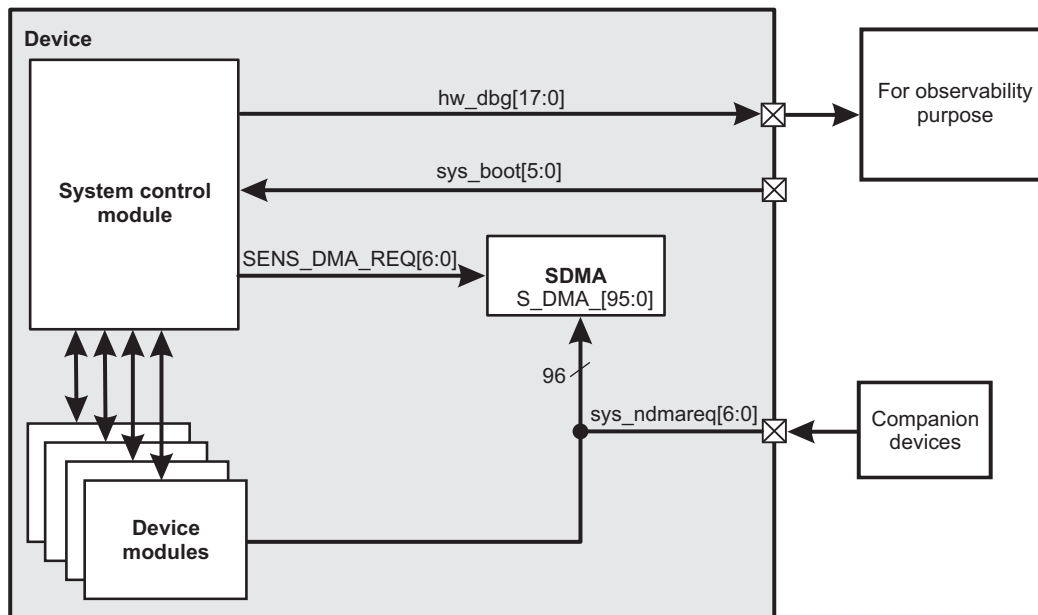

- read/write, read/write once, or read/write to clear capability)
- Scratchpad memory bank (256* 32-bit)

7.2 System Control Module Environment

The SCM allows the setting of external system DMA (sDMA) request pin sensitivity and controls the multiplexing of device internal modules signals routed to external pins for hardware debug purposes. The SCM also integrates the decoding logic of sys_boot[5:0].

Figure 7-2 shows an overview of the SCM environment.

Figure 7-2. System Control Module Environment Overview

108-002

The seven sys_ndmareq[6:0] pins are optional external direct memory access (DMA) requests that can be managed directly by the sDMA controller. The SCM can configure these requests to either level sensitive (active low) or edge sensitive (falling edge) through the correct setting of the SENS DMA REQ N bit (where N is between 0 and 6) in the CONTROL.DEVCONF0 and CONTROL.DEVCONF1 registers.

The sys_boot[5:0] pins are read-accessible in a status register (SYSBOOT field CONTROL.STATUS[5:0]) following a power-on reset. The SCM does not use sys_boot[6].

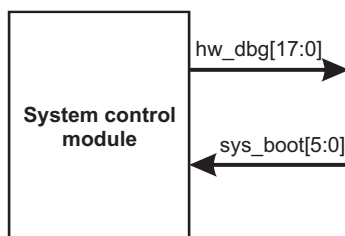

With the correct pad configuration, the SCM maps the hw_dbg[17:0] pins at the device boundary to observe hardware debug signals from device modules. The internal observable signals are PRCM signals, DMA requests, and interrupts.

7.2.1 Functional Interfaces

7.2.1.1 Basic System Control Module Pins

Figure 7-3 shows the SCM functional interface configured to observe device module debug signals.

Figure 7-3. System Control Module Interface Signals

108-003

7.2.1.2 System Control Module Interface Description

Table 7-1 lists the SCM input and output configured to observe device module debug signals.

Table 7-1. SCM I/O Description

Signal Name	I/O ⁽¹⁾	Description	Reset Value
hw_dbg[17:0]	O	Debug signals 0 to 17	N/A
sys_boot[5:0]	I	Boot configuration mode bits 0 to 5	Unknown

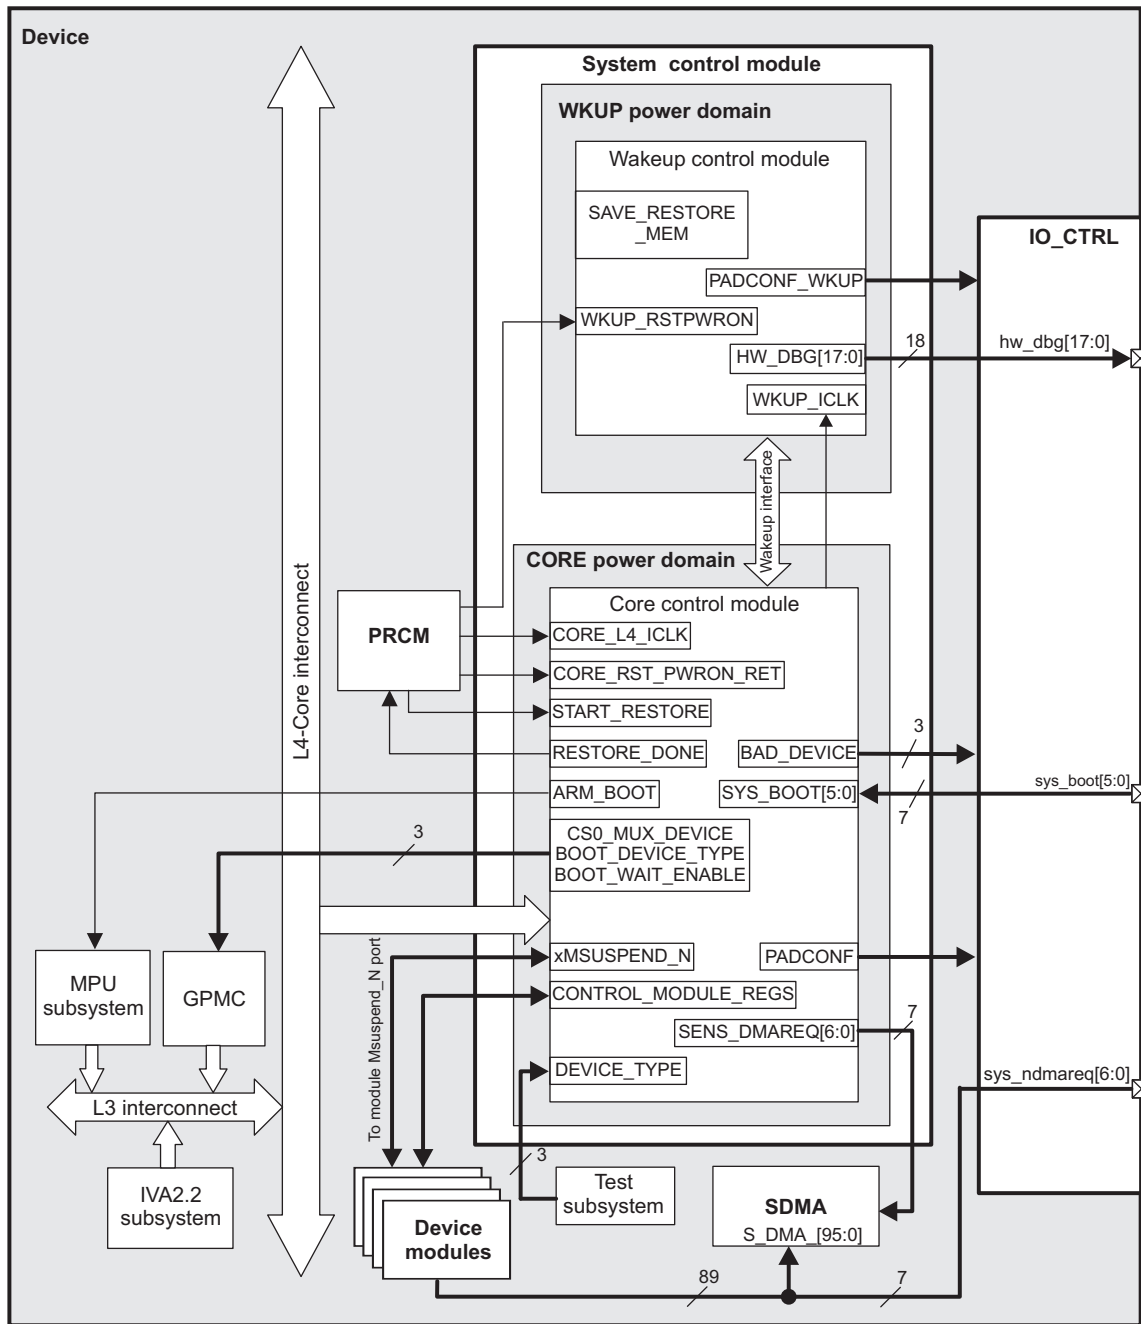

⁽¹⁾ I = Input, O = Output

7.3 System Control Module Integration

This section describes the integration of the SCM within the device.

Figure 7-4 shows the SCM integration in the device.

Figure 7-4. System Control Module Integration

108-004

The SCM is split into two blocks: the core control module in the CORE power domain, and the wake-up control module in the WKUP power domain. The wake-up control module contains the save-and-restore memory, some observability multiplexing, pad configurations, and security registers. For further information on the wake-up control module, see [Section 7.4.3, Wake-up Control Module](#).

The software sets the configuration registers to the desired values depending on the configuration of the requested device. Static device configuration registers can be set by the software at any time and are effective immediately.

The SCM is connected on the L4-Core interconnect. The power, reset, and clock management (PRCM) module provides the module interface clock (CORE_L4_ICLK) and the power-on reset signal. The PRCM generates one global reset per power domain (CORE_RST_PWRON_RET for the CORE power domain and WKUP_RSTPWRON for the WKUP power domain). The SCM does not respond to a warm reset or to an L4 reset.

7.3.1 Clocking, Reset, and Power-Management Scheme

7.3.1.1 Clock

The main sequential logic within the SCM is accessible in a register file through the L4-Core. The only clock provided to the SCM is the interface clock, CORE_L4_ICLK. This clock comes from the PRCM module and is controlled by the EN_OMAPCTRL bit PRCM.CM_ICLKEN1_CORE[6] (0 = disables the clock, 1 = enables the clock) and the AUTO_OMAPCTRL bit PRCM.CM_AUTOIDLE1_CORE[6] (enables/disables automatic control of the interface clock).

The wake-up control module is configured through the L4-Core interface of the core control module and is accessed from the core control module through a dedicated interface. This interface uses the L4-Core interface clock (CORE_L4_ICLK) divided by 4 or 2 according to the WKUPCTRLCLOCKDIV bit CONTROL.CONTROL_PADCONF_OFF[2]. Only this wake-up interface clock (WKUP_ICLK) is propagated to the wake-up control module.

For further information, see the *Power, Reset, and Clock Management* chapter.

7.3.1.2 Resets

The SCM responds only to the internal power-on reset and to the device type (secure, emulator, general-purpose, test, or bad). The SOFTRESET bit CONTROL.CONTROL_SYSCONFIG[1] has no effect; the SCM is not affected by a warm reset.

The internal power-on reset is not a direct image of the power-on reset input pin (SYS_NRESPWRON). The PRCM module generates an internal power-on reset signal per power domain and activates the internal power-on reset when the eFuse-related settings (such as the device type) are initialized. The core control module of the CORE power domain responds to the CORE power-on reset (CORE_RST_PWRON_RET). The wake-up control module of the WKUP power domain responds to the power-on reset (WKUP_RSTPWRON).

Note: References in the TRM to the power-on reset refer to the internal power-on reset as seen by the SCM.

On emulator devices, the debugger can also control the internal power-on reset signal though the JTAG interface.

For further information, see the *Power, Reset, and Clock Management* chapter.

7.3.1.3 Power Domain

The SCM is split into two blocks: the core control module, which is attached to the CORE power domain and can be in either active, retention, or off state, and the wake-up control module, which belongs to the WKUP power domain.

Note: The System Control Module is fully built with retention Flip-Flop.

For further information, see the *Power, Reset, and Clock Management* chapter.

7.3.1.4 Power Management

7.3.1.4.1 System Power Management

The PRCM module can require the SCM to be idled to save power. The SCM enters idle mode through the IDLEMODE field CONTROL.CONTROL_SYSCONFIG[4:3].

The PRCM module requests idle mode, and the SCM always accepts an idle command. Idle mode can be configured to either force-idle or smart-idle mode.

When the SCM is in force-idle mode (IDLEMODE bits CONTROL.CONTROL_SYSCONFIG[4:3] = 0b00) and it receives an idle request from the PRCM module (PRCM.CM_ICLKEN1_CORE[6] set to 0 or PRCM.CM_AUTOIDLE1_CORE[6] set to 1 and the L4-Core interface clock idle transitions), the SCM waits unconditionally for active system clock gating by the PRCM module. Active system clock gating occurs only when all peripherals supplied by the same L4-Core interface clock domain are also ready for idle.

In smart-idle mode (IDLEMODE bits CONTROL.CONTROL_SYSCONFIG[4:3] = 0b10), an idle command is accepted only when the save mechanism completes.

In idle mode (when the PRCM module has gated the interface clock), the SCM is not active and the interface clock paths are gated.

Note: The ST_OMAPCTRL bit PRCM.CM_IDLEST1_CORE[6] (0b0 = active, 0b1 = idle) can check the SCM idle state.

The SCM idle mode is a function of the EN_OMAPCTRL bit PRCM.CM_ICLKEN1_CORE[6] configuration and can be controlled automatically with hardware, depending on the AUTO_OMAPCTRL bit PRCM.CM_AUTOIDLE1_CORE[6] configuration.

7.3.1.4.2 Module Power Saving

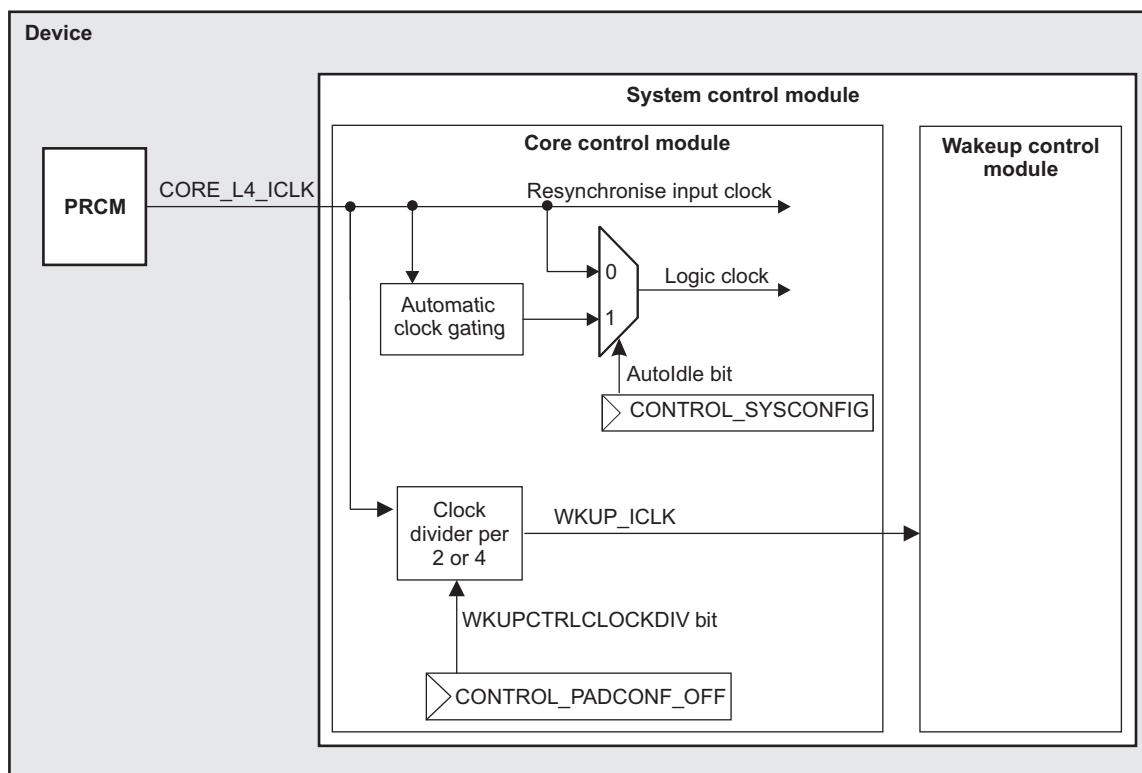

An internal interface clock-gating feature provides SCM local power management. The clock for the logic within the module can be gated when there is no access to the module according to the AUTOIDLE bit CONTROL.CONTROL_SYSCONFIG[0]. Otherwise, this logic is free-running on the interface clock CORE_L4_ICLK.

The L4-Core interface clock (CORE_L4_ICLK) is also used to synchronize and resample module inputs. The clock for those functions must always be free-running. Therefore, it is not gated.

The wake-up control module is clocked only by a local wake-up interface clock from the core control module. The wake-up interface clock (WKUP_ICLK) uses the L4-Core interface clock (CORE_L4_ICLK) divided by 4 or 2 to reduce power consumption according to the WKUPCTRLCLOCKDIV bit CONTROL.CONTROL_PADCONF_OFF[2] (0 = divided by 4, 1 = divided by 2).

Figure 7-5 shows the SCM internal clock implementation.

Figure 7-5. Internal Clock Implementation

108-005

7.3.2 Hardware Requests

The SCM does not generate interrupt or wake-up requests.

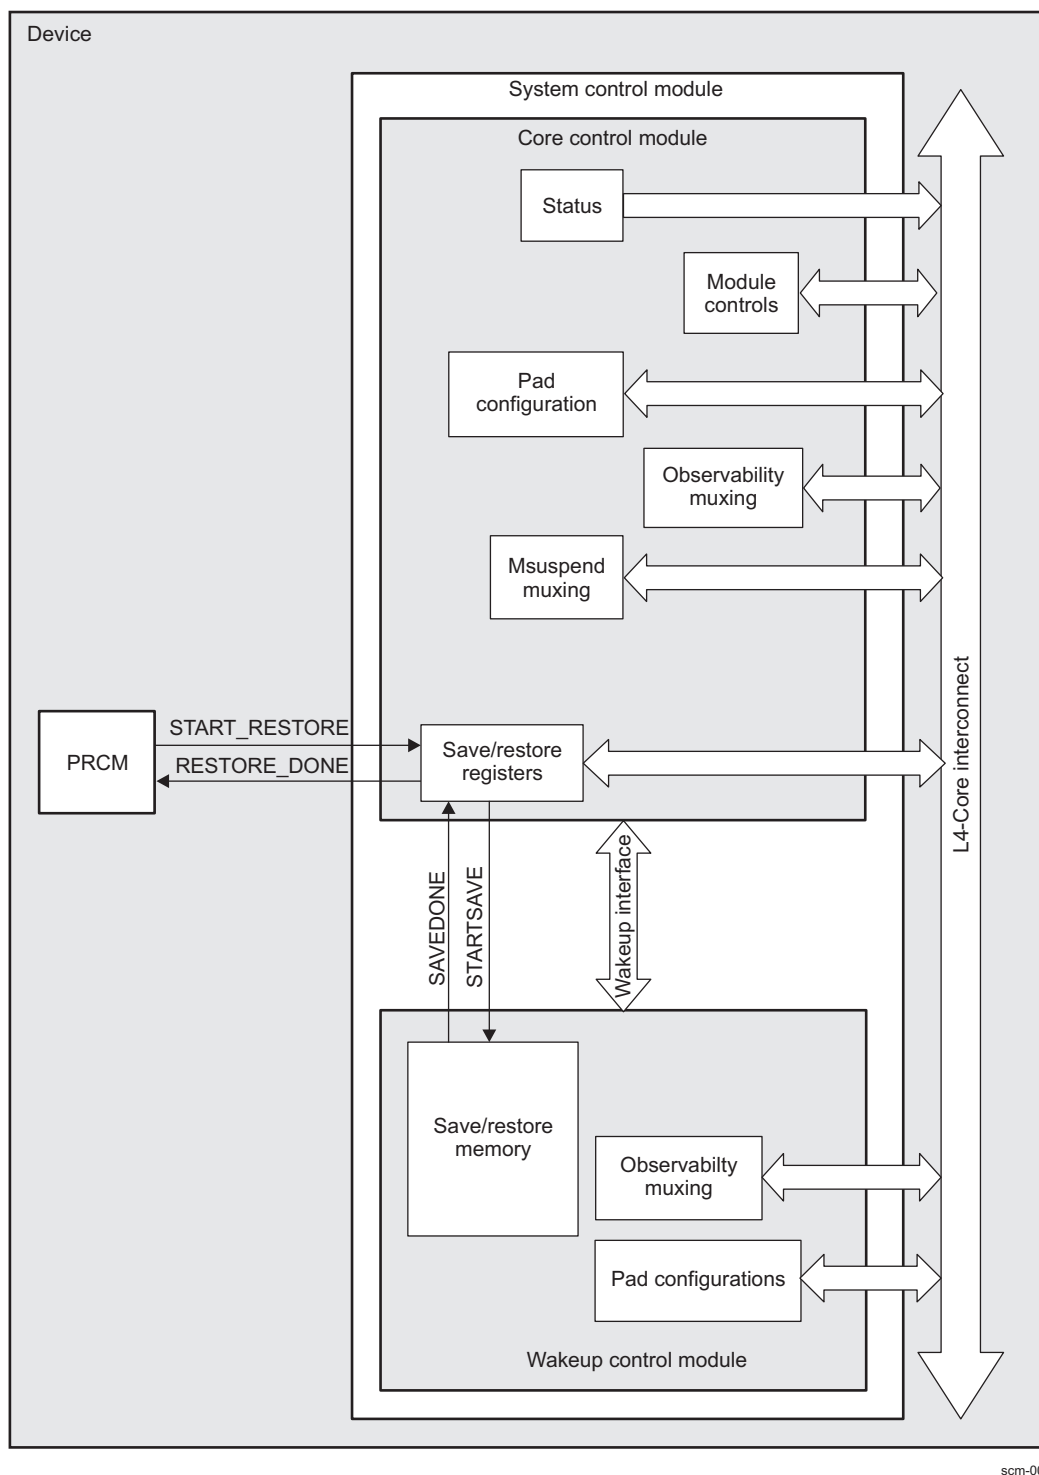

7.4 System Control Module Functional Description

7.4.1 Block Diagram

The SCM controls various device modules settings through register configuration and internal signals. It also controls the pad configuration and multiplexing and the routing of internal signals (such as PRCM signals or DMA requests) to observable pins for debug.

Figure 7-6 shows the SCM block diagram.

Figure 7-6. System Control Module Block Diagram

The following sections describe the functionality of the SCM registers.

7.4.2 System Control Module Initialization

The SCM responds only to the internal power-on reset and to the device type. At power-on, reset values for the registers define the safe state for the device. In the initialization mode, only modules used at boot time are associated with the pads. Other module inputs are internally tied, and outputs pads are turned off each time the feature is available.

For the pad configuration, pull-up/pull-down fields are set according to the device pin list. For further information, see the pin list tables in your device-specific data manual.

The device type (for example, emulator, secure, general-purpose) affects the reset values and access rights for some emulation and security-related configuration bits (see [Section 7.6](#), *SCM Registers*).

General-purpose devices (that is, those with no secure mode available) include features that are inaccessible or unavailable. These inaccessible registers define the default or fixed device configuration or behavior.

This technical reference manual focuses only on GP devices. To determine if a HS version of your device is available and for more information on HS devices, please refer to your device-specific data manual.

7.4.3 Wake-Up Control Module

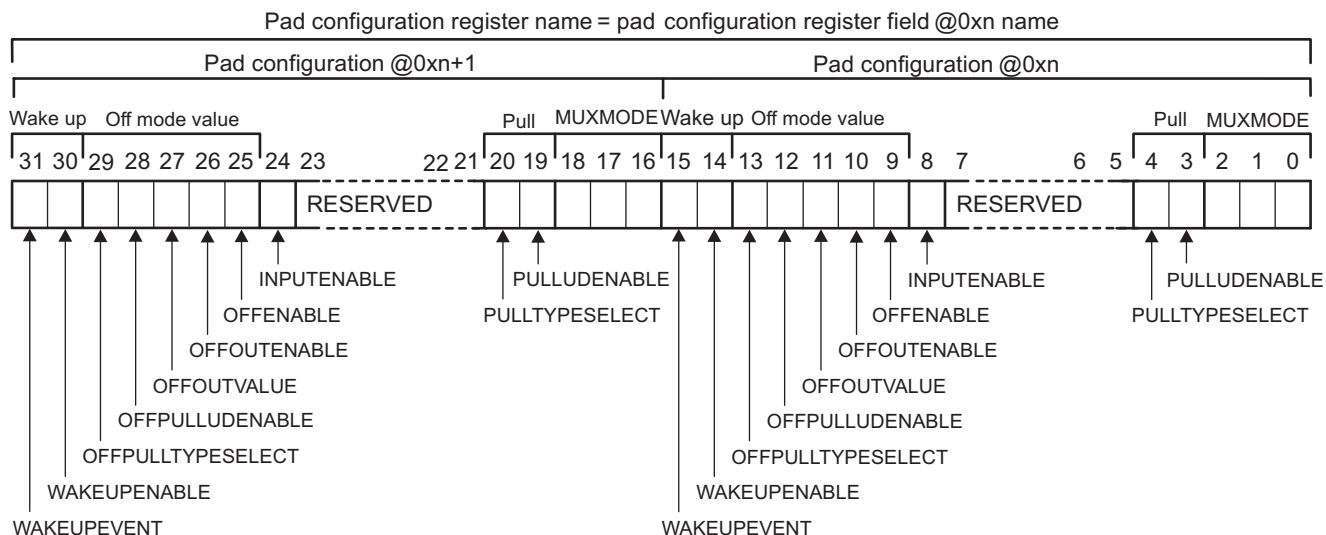

The wake-up control module in the SCM belongs to the WKUP power domain. It contains a 1K-byte memory in which to save the pad configuration registers in the core control module before going to off mode. Pad configuration registers driving the I/O pad control in the WKUP power domain are also instantiated in the wake-up control module. In this module, there is also a subset of observability multiplexing registers dedicated to PRCM observable signals and security registers (CONTROL.[CONTROL_SEC_TAP](#) and CONTROL.[CONTROL_SEC_EMU](#)).

The wake-up control module is configured through the L4-Core interface in the core control module and is accessed from the core control module through a dedicated interface. This interface between the core control module and the wake-up control module uses the CORE_L4_ICLK clock divided by 4 or 2 to reduce power consumption in the WKUP power domain.

7.4.4 Pad Functional Multiplexing and Configuration

After power-on reset, the software sets the pad functional multiplexing and configuration registers to the requested device pad configurations. Data written in these registers command directly the multiplexing of the pad configuration logic.

Each pin is configurable by software using its associated pad configuration register field, which is 16 bits wide (see [Figure 7-7](#)).

Figure 7-7. Pad Configuration Register Functionality

scm-008

One pad configuration register field is available for each pin. Each 32-bit pad configuration register is grouped into two 16-bit pad configuration register fields. One pad configuration register provides control for two different pins.

Some pad configuration registers control the configuration of pads in the CORE power domain. These registers are instantiated in the CORE power domain of the SCM (core control module, physical addresses 0x4800 2030 to 0x4800 2260). Pad configuration registers also control the configuration of pads in the WKUP power domain. These registers are instantiated in the WKUP power domain of the SCM (wake-up control module, physical addresses 0x4800 2A00 to 0x4800 2A4C).

Write access to these registers can be restricted to secure privilege mode only through the PADCONFACCDISABLE bit [CONTROL.CONTROL_SEC_CTRL\[3\]](#).

Note: These registers can be accessed using 8-, 16-, and 32-bit operations.

The functional bits of a pad configuration register field are divided into the following five fields:

- MUXMODE (3 bits) defines the multiplexing mode applied to the pin. A mode corresponds to the selection of the functionality mapped on the pin with six (0 to 5) possible functional modes for each pin.
- PULL (2 bits) for combinational pull-up/pull-down configuration:
 - PULLTYPESELECT: Pull-up/pull-down selection for the pin.
 - PULLUDENABLE: Pull-up/pull-down enable for the pin.
- INPUTENABLE (1 bit) drives an input enable signal to the I/O CTRL.
 - INPUTENABLE = 0: Input Disable. Pin is configured in output only mode.
 - INPUTENABLE = 1: Input Enable. Pin is configured in bi-directional mode.
- Off mode values (5 bits) override the pin state when the OFFENABLE bit [CONTROL.CONTROL_PADCONF_X](#) is set and off mode is active ([FORCEOFFMODEEN](#) bit [CONTROL_PADCONF_OFF\[0\]](#) = 0b1). This feature allows having separate configurations for the pins when in off mode:
 - OFFENABLE: Off mode pin state override control.
 - OFFFOUTENABLE: Off mode output enable value. This is an active low signal.
 - OFFFOUTVALUE: Off mode output value.
 - OFFPULLUDENABLE: Off mode pull-up/pull-down enable
 - OFFPULLTYPESELECT: Off mode pull-up/pull-down selection
- Wake-up bits (2 bits):
 - WAKEUPENABLE: Enable wake-up detection on input. It is also the OFF mode input enable value.

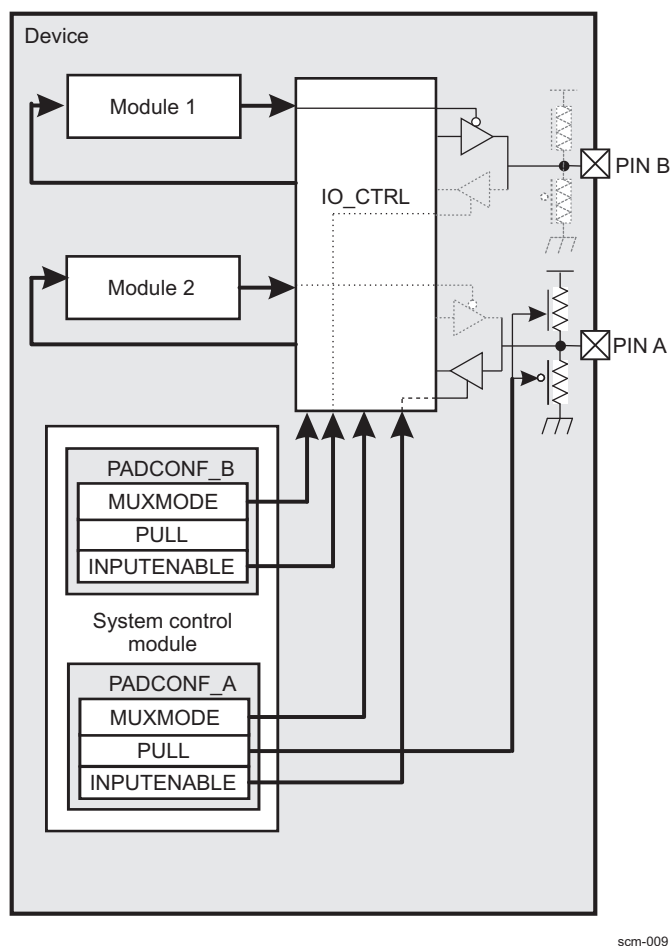

- WAKEUPEVENT: Wake-up event status for the pin.

CAUTION

The software has in charge to configure the OFF mode pads configuration. It must be careful on the Input/Output capability enabled for each pin.

Figure 7-8 shows the pad configuration functionality when off mode is inactive. For further information on off mode, see [Section 7.4.4.4, Off Mode](#).

Figure 7-8. Pad Configuration Diagram

7.4.4.1 Mode Selection

[Table 7-2](#) lists the multiplexing modes and settings.

Table 7-2. Mode Selection

MUXMODE	Selected Mode
0b000	Primary mode = Mode 0
0b001	Mode 1
0b010	Mode 2
0b011	Mode 3
0b100	Mode 4

Table 7-2. Mode Selection (continued)

MUXMODE	Selected Mode
0b101	Mode 5
0b110	Mode 6
0b111	Safe mode = Mode 7

The MUXMODE field CONTROL.[CONTROL_PADCONF_X](#) defines the multiplexing mode applied to the pad. Modes are referred to by their decimal (from 0 to 7) or binary (from 0b000 to 0b111) representation. Functional modes are defined from 0b000 to 0b101; mode 0b111 is referred to as the safe mode.

For most pads, the reset value for the MUXMODE field CONTROL.[CONTROL_PADCONF_X](#) is 0b111. The exceptions are pads to be used at boot time to transfer data from selected peripherals to the external flash memory.

Mode 0 is the primary mode. When mode 0 is set, the function mapped to the pin corresponds to the name of the pin.

Mode 1 to mode 6 are possible modes for alternate functions. On each pin, some modes are used effectively for alternate functions, while other modes are unused and correspond to no functional configuration.

The safe mode avoids any risk of electrical contention by configuring the pin as an input with no functional interface mapped to it. The safe mode is used mainly as the default mode for all pins containing no mandatory interface at the release of power-on reset.

For more information about the configurable mode on each pin, see [Table 7-4](#) through [Table 7-6](#).

7.4.4.2 Pull Selection

Whichever pull value is configured, pulls are automatically disabled when a pin is configured as an output (see [Table 7-3](#)).

Table 7-3. Pull Selection

PULL		Pin Behavior
PULLTYPESELECT	PULLUDENABLE	
0b0	0b0	Pull-down selected but not activated
0b0	0b1	Pull-down selected and activated if pin configured in input
0b1	0b0	Pull-up selected but not activated
0b1	0b1	Pull-up selected and activated if pin configured in input

For more information on the pull available on each pin, see [Table 7-4](#) through [Table 7-6](#).

7.4.4.3 Pad Multiplexing Register Fields

Table 7-4 through Table 7-6 provide for each pad configuration register field the address offset, reset values, and associated signal name for each multiplexing mode (as set by bit field MUXMODE). Mode 0 is always defined. Modes with no signal name are undefined for the given pad.

Notes:

- Pad configuration registers are split into three types, which correspond to the following three tables:
 - Table 7-4 lists the pad configuration registers instantiated in the CORE power domain that drive the pads in the CORE power domain.
 - Table 7-5 lists the pad configuration registers instantiated in the CORE power domain that drive the D2D pads. These pads are available in stacked mode only.
 - Table 7-6 lists the pad configuration registers instantiated in the WKUP power domain that drive the pads in the WKUP power domain.
- In Table 7-4 through Table 7-6 the following are indicated:
 - In the MUX Reset States column and PUPD Reset States column, a dash (-) indicates that the field is hardwired to logic 0. No corresponding control block ports are implemented for these bits.
 - An empty cell indicates that the mode or pull is not available for this pin.

Table 7-4. Core Control Module Pad Configuration Register Fields

Register Name	Physical Address	Mode 0	Mode 1	Mode 2	Mode 3	Mode 4	Mode 5	Mode 6	Mode 7

⁽¹⁾ The D2D_swakeup pad is available in stacked mode only.

Note: Pad names are signal names available in mode 0.

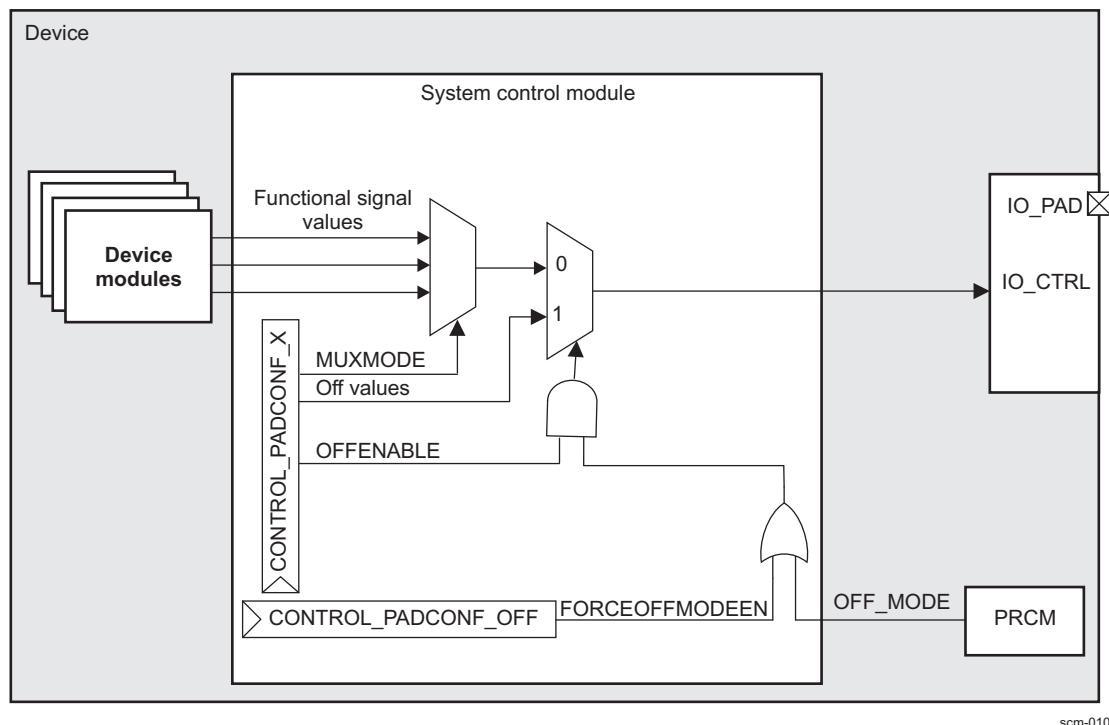

For more information on the pad default states, please refer to your device-specific data manual.

7.4.4.4 Off Mode

When off mode is active (PAD_OFF_MODE = 0b1 from PRCM or FORCEOFFMODEENABLE bit CONTROL.CONTROL_PADCONF_OFF[0] = 0b1), the off mode values field CONTROL.CONTROL_PADCONF_X overrides the pad state when OFFENABLE bit CONTROL.CONTROL_PADCONF_X is set.

Figure 7-9 shows the off mode pad control.

Figure 7-9. Off Mode Pad Control Overview

For further information on the OFF mode, see the *Power, Reset and Clock Management* chapter.

For further information on the preliminary settings that must be done before to perform OFF <-> ON transitions, refer to [Section 7.5.3](#) of this chapter.

7.4.4.4.1 Save-and-Restore Mechanism

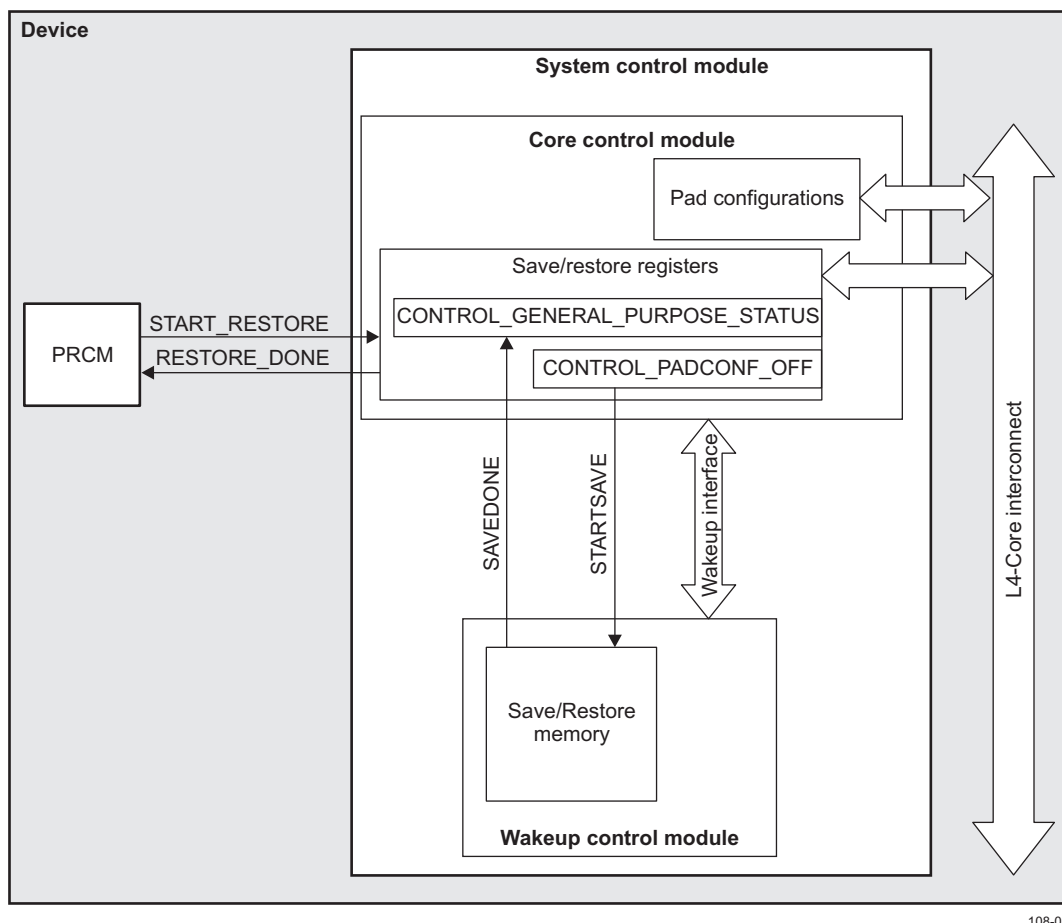

Before going to OFF mode there is a context saving of the device. The save-and-restore mechanism saves the pad configuration registers (in the CORE power domain) in a WKUP power domain memory (physical addresses 0x4800 2600 to 0x4800 29FC) before going to off mode, and restores those registers when returning from off mode. This mechanism uses the dedicated wake-up interface between the core control module and the wake-up control module.

The save mechanism in the pad configuration registers is activated by setting the STARTSAVE bit CONTROL.CONTROL_PADCONF_OFF[1]. When all pad configuration registers have been saved to the wake-up memory, the status SAVEDONE bit CONTROL.CONTROL_GENERAL_PURPOSE_STATUS[0] is set. In smart-idle mode, the idleAck is returned when the save process is complete.

When returning from off mode, the registers are restored after the PRCM module asserts the START_RESTORE signal. The SCM returns a RESTORE_DONE signal to the PRCM module when the restore process completes.

Figure 7-10 shows an overview of the save-and-restore mechanism in off mode.

Figure 7-10. Save-and-Restore Mechanism Overview

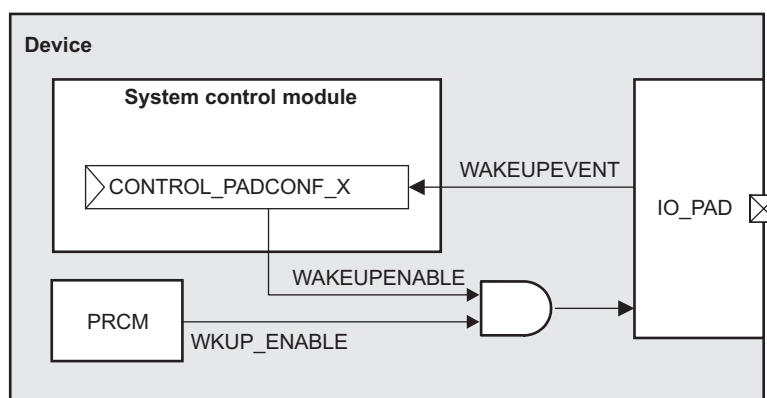

108-011

7.4.4.4.2 Wake-up Event Detection

In off mode, wake-up event detection can also be enabled on an input pad. The pad wake-up event is latched in the WAKEUPEVENT bit [CONTROL.PADCONF_X](#).

The OFF mode IO pads wake-up scheme is enabled by setting the EN_IO bit PRCM.PM_WKEN_WKUP[8]. The wake-up scheme status is transmitted by the WKUP_ENABLE signal. The wake-up event detection capability of each IO pad of the device is individually enabled/disabled by writing WAKEUPENABLE bit [CONTROL.PADCONF_X](#).

Figure 7-11. Wake-up Event Detection Overview

108-012

For further information on the Wake-up sequences, see the *Power, Reset and Clock Management* chapter.

Note: When the wake-up detection is enabled for a pad, this pad is configured as input. So do not forget to write 0b1 in the OFFOUTENABLE bit CONTROL.CONTROL_PADCONF to disable the output capability.

Table 7-7 lists the bit directions of the CONTROL_PADCONF_x registers.

Table 7-7. Bit Directions for CONTROL_PADCONF_x Registers

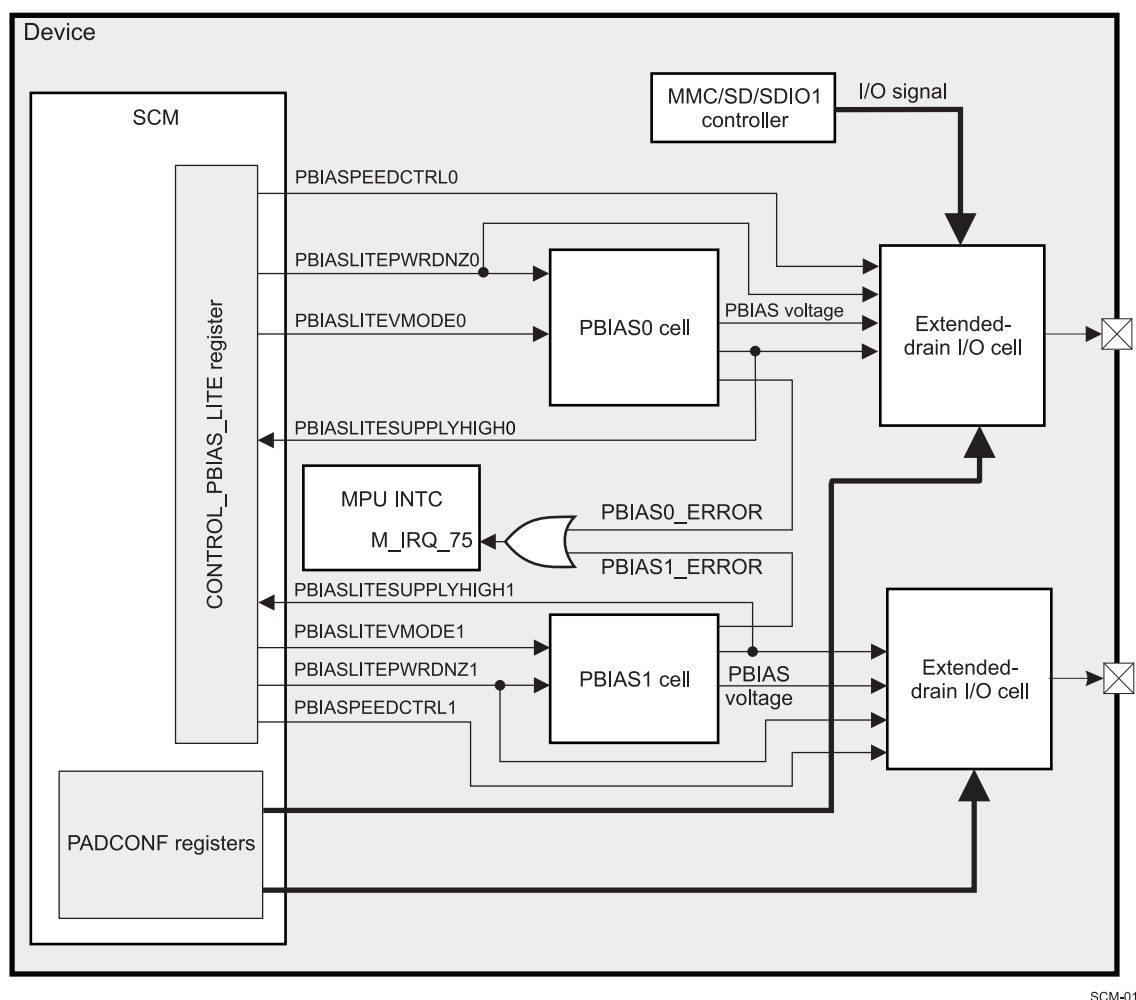

CONTROL_PADCONF_x Bit	Bit Direction	
	0	1
PULLUDENABLE	Not activated	Activated
PULLTYPESELECT	Pulldown	Pullup
INPUTENABLE	Input enable signal inactive	Input enable signal active
OFFENABLE	Off mode values are invalid.	Off mode values are valid.
OFFOUTENABLE	Output	Input
OFFOUTVALUE	Low	High
OFFPULLUDENABLE	Not activated	Activated
OFFPULLTYPESELECT	Pulldown	Pullup
WAKEUPENABLE	Disable I/O wake-up function.	Enable I/O wake-up function.
WAKEUPEVENT	Wake-up event not detected	Detect wake-up event.

7.4.5 Extended-Drain I/O Pin and PBIAS Cell

The device mainly supports 1.8-V I/O voltage on its interfaces, with the exception of MMC/SD/SDIO1 interfaces, which support both 1.8-V and 3.0-V voltages via internal PBIAS generation and extended-drain I/Os.

The need for embedded extended-drain I/Os on MMC/SD/SDIO1 interfaces imposes the use of embedded PBIAS cells to provide 1.8-V or 3.0-V reference voltage. The PBIAS cells and the extended-drain I/Os are software-controlled by bits located in the CONTROL.CONTROL_PBIAS_LITE register of the SCM. See [Section 7.6.4, Register Descriptions](#), for the description of this register.

Figure 7-12 shows the functional block diagram between the PBIAS cells and the extended I/O cells.

Figure 7-12. Functional Block Diagram

SCM-014

Table 7-8 describes the **CONTROL.PBIAS_LITE** bit control for the PBIAS and the extended-drain I/O cells.

Table 7-8. PBIAS Cell and Extended-Drain I/O Pin CONTROL_PBIAS_LITE Bit Control

Control Signal for MMC/SD/SDIO1	Control Signal for PBIAS1	Description
PBIASLITEPWRDNZ0	PBIASLITEPWRDNZ1	Protects the I/O cell when the VDDSD voltage is not stable. Software must keep this signal to 0b0 when the VDDSD signal is ramping. When this bit is at 0, the PAD is floating.
PBIASLITEVMODE0	PBIASLITEVMODE1	Controls the VDDSD voltage level. The default state of this bit is HIGH, indicating that VDDSD = 3.0 V.
PBIASLITESUPPLYHIGH0	PBIASLITESUPPLYHIGH1	Describes whether the VDDSD supply is 3.0 V or 1.8 V
PBIASLITEVMODEERROR	PBIASLITEVMODEERROR1	Indicates whether the software-programmed VMODE level matches the SUPPLY_HI output signal
PBIAS0_ERROR	PBIAS1_ERROR	Determines whether the software-programmed xPBIASLITEVMODE level matches the xPBIASLITESUPPLYHIGH. This signal is generated only when xPBIASLITEVMODEEN is HIGH.

Table 7-9 lists the power supplies for the PBIAS and the extended-drain I/O cells.

Table 7-9. Power Supplies

Name	Description
VDD (VDD2 power pin)	Core voltage supply
VDDS (MMC1_VDDS or VMMC1a_VDDS power pin)	I/O supply voltage nominal 1.8 V/ 3.0 V
VSUP_18	1.8-V supply for the input buffer

7.4.5.1 PBIAS Cell

The PBIAS cell provides a bias for the extended-drain I/O cell used with high voltage for MMC/SD/SDIO1 interfaces. The PBIAS cell provides a voltage reference (PBIAS voltage) for biasing the extended-drain in the MMC/SD/SDIO1 I/O cell. Besides generating the bias voltage, the cell can detect the supply voltage (VDDS) value (1.8 V or 3.0 V) and update, with its status, the PBIASLITESUPPLYHIGH0 or PBIASLITESUPPLYHIGH1 bit.

CAUTION

The PBIAS cell lets the MMC/SD/SDIO1 peripheral support 1.8-V and 3.0-V voltages. The PBIAS cell is not a part of the MMC/SD/SDIO1 peripheral, but a part of the device I/O to which the MMC/SD/SDIO1 peripheral is internally connected. These device I/Os are not exclusive to the MMC/SD/SDIO1 peripheral; through I/O multiplexing they can be connected to other internal signals. It is necessary to configure the PBIAS to enable the I/Os, regardless of how I/O multiplexing is configured for these device I/Os. In other words, independently of which signal is internally connected to a device I/O powered by MMC1_VDDS or VMMC1a_VDDS, the PBIAS must be configured.

7.4.5.2 Extended-Drain I/O

On the device, the following extended-drain I/Os are used by I/Os from the MMC/SD/SDIO1 and USIM modules:

- MMC/SD/SDIO1 module: mmc1_clk, mmc1_cmd, and mmc1_dati (where i = 0 to 7).
- USIM module: sim_io, sim_clk, sim_pwrctrl, sim_rst.

Figure 7-13 describes the extended-drain I/O cell.

Figure 7-13. Extended-Drain I/O

The extended-drain I/O cell has the following I/O signals:

- Output signal, input signal, and oe, which comes from the MMC/SD/SDIO1 or USIM module with the correct MODE field [CONTROL_PADCONF_X](#) configuration.

Note: MMC/SD/SDIO1 or USIM extended-drain I/Os are muxed I/Os with mode and pull-up/pull-down configurations programmable in the SCM.

- The PBIAS voltage is a voltage reference for biasing the extended-drain in the MMC/SD/SDIO1 or USIM I/O cell.
- The PBIASLITEPWRDNZ0 or PBIASLITEPWRDNZ1 bits are used to protect the I/O cell when the VDD5 voltage is not stable.

CAUTION

Software must keep this signal to 0b0 whenever the VDD5 signal is ramping. When PBIASLITEPWRDNZ0 or PBIASLITEPWRDNZ1 is 0, the PAD is floating (the PAD may not reflect the state of the output signal, and the input signal may not reflect the state of the PAD).

- The PBIASPEEDCTRL0 or PBIASPEEDCTRL1 bits control the speed of I/O cells and can be used to reduce dynamic current if fast rise/fall times are not required.
- The PBIASLITESUPPLYHIGH0 or PBIASLITESUPPLYHIGH1 bits are status bits on the VDD5 value and is used to inform the cell on the value of VDD5 signal.

For further information on the software configurations of the extended-drain I/O and PBIAS cell, see [Section 7.5.2, Extended-Drain I/Os and PBIAS Cell Programming Guide](#).

7.4.6 Functional Register Description

7.4.6.1 Static Device Configuration Registers

Table 7-10 describes the static device configuration registers.

Table 7-10. Static Device Configuration Registers

Physical Address	Register Name	Description	Access
0x4800 2274	CONTROL_DEVCONF0	Module dedicated configurations	R/W
0x4800 22D8	CONTROL_DEVCONF1	Module dedicated configurations	R/W

These registers allow the static configuration of device modules such as USB, McBSP, and I²C. For example, they allow selecting external or internal clocks for McBSP modules.

7.4.6.2 Control CSIRXFE Register

Table 7-11 describes the [CONTROL_CSIRXFE](#) register, which controls some CSIRXFE analog cell settings. The CSIRXFE analog cell is used in the interface between a digital camera module and a mobile engine phone.

Table 7-11. Control CSIRXFE Register

Physical Address	Register Name	Description	Access
0x4800 22DC	CONTROL_CSIRXFE	Controls settings for CS1a and CS1b interface pins	R/W

7.4.6.3 MPU and/or DSP (IVA2.2) MSuspend Configuration Registers

Table 7-12 describes the MPU and/or DSP (IVA2.2) MSuspend configuration registers.

Table 7-12. MSuspendMux Control Registers

Physical Address	Register Name	Description	Access
0x4800 2290	CONTROL_MSUSPENDMUX_0	Control the use of MSuspend signals at module level	R/W
0x4800 2294	CONTROL_MSUSPENDMUX_1		R/W
0x4800 2298	CONTROL_MSUSPENDMUX_2		R/W
0x4800 229C	CONTROL_MSUSPENDMUX_3		R/W
0x4800 22A0	CONTROL_MSUSPENDMUX_4		R/W
0x4800 22A4	CONTROL_MSUSPENDMUX_5		R/W

These registers provide an entry for each module that must consider the MSuspend signals from the processors (MPU and/or DSP). For each module, the sensitivity to the MSuspend signals is defined within five possibilities (coded using 3 bits):

- 0b000: No sensitivity; no MSuspend signal reaches the module.
- 0b001: Sensitivity to the MPU MSuspend signal (the DSP signal is ignored)
- 0b010: Sensitivity to the DSP MSuspend signal (the MPU signal is ignored)
- 0b011: Sensitivity to the logical ORed MPU and DSP MSuspend signals
- 0b100: Sensitivity to the logical ANDed MPU and DSP MSuspend signals
- Other values: No sensitivity; no MSuspend signal reaches the module.

The logic used to combine the MSuspend signals from the processors is implemented within the SCM. MSuspend signals are active low.

CAUTION

Use care when using combined sensitivity settings (ANDing or ORing DSP and MPU MSuspend signals).

ORing the DSP and MPU MSuspend signals creates a situation where the module is suspended when at least one processor is under debug; therefore, when one processor is halted, stepping within the code of the other one does not change the module suspended state.

Not all modules use the MSUSPEND signal. See the TRM chapter for each module to determine whether the module supports the MSUSPEND signal.

All MSUSPEND signals coming out of the MPU and DSP are resynchronized within the SCM by using the control module interface clock.

7.4.6.4 IVA2.2 Boot Registers

Table 7-13 describes the IVA2.2 boot registers.

Table 7-13. IVA2.2 Boot Registers

Physical Address	Register Name	Description	Access
0x4800 2400	CONTROL_IVA2_BOOTADDR	IVA2.2 boot loader address register	R/W
0x4800 2404	CONTROL_IVA2_BOOTMOD	IVA2.2 boot mode register	R/W

The [CONTROL_IVA2_BOOTADDR](#) register defines the physical address for the IVA2 boot loader and drives the IVA2_BOOTADDR[21:0] signals out from the control block to the IVA2 subsystem.

The [CONTROL_IVA2_BOOTMOD](#) register defines the IVA2 boot mode and drives the IVA2_BOOTMOD[3:0] signals out from the control block to the IVA2.2 subsystem. Based on the value of IVA2_BOOTMOD[3:0], the ROM boot loader executes different boot modes of IVA2.2.

Table 7-14 lists the IVA2.2 boot modes.

Table 7-14. IVA2.2 Boot Modes

IVA2_BOOTMOD[3:0] Value	Meaning
0x0	Direct boot: The ROM loader is not executed. Instead, IVA2.2 directly starts executing the bootstrap at the address contained in the CONTROL_IVA2_BOOTADDR register.
0x1	Idle boot: The boot loader executes the IDLE instruction.
0x2	Wait in self-loop boot: The boot loader puts IVA2.2 in a self-loop.
0x3	User-defined bootstrap mode: The boot loader copies the boot strap into internal memory and branches to it.
0x4	The boot loader executes the default context restore code, which is part of the ROM boot loader.

For further information, see the *IVA2.2 Subsystem* chapter.

7.4.6.5 PBIAS LITE Control Register

Table 7-15 describes the [CONTROL_PBIAS_LITE](#) register, which controls some settings of PBIAS LITE cells for MMC/SD/SDIO interface.

Table 7-15. PBIAS Control Register

Physical Address	Register Name	Description	Access
0x4800 2520	CONTROL_PBIAS_LITE	Control settings for PBIAS LITE MMC/SD/SDIO1 pins	R/W

For further details on the PBIAS cells please refer to [Section 7.4.5, Extended-Drain I/O Pin and PBIAS Cell](#).

7.4.6.6 CSI Receiver Control Register

[Table 7-16](#) describes the `CONTROL_CSI` register, which controls the CS1b receiver trimming override.

Table 7-16. CSI Receiver Control Register

Physical Address	Register Name	Description	Access
0x4800 2530	<code>CONTROL_CSI</code>	CS1b receiver trimming override	R/W

7.4.7 Security Registers

The security registers in the SCM allow the configuration of the system-level security of the device. This configuration includes reset values and debug and test properties.

This technical reference manual focuses only on GP devices. Therefore, only the general-purpose features on security registers are explained in this chapter.

To determine if a HS version of your device is available and for more information on HS devices, please refer to your device-specific data manual.

Secure registers have the following characteristics:

- Secure registers can be accessed (read or write) only when the MPU is in secure privilege mode.
- When the MPU is not in secure privilege mode, reads to these registers return 0.
- When the MPU is in secure privilege mode, reads to these registers return the current programmed value.
- All secure registers are reset by the power-on reset, the values of which are device-type dependent.
- Some secure registers are restricted for public or secure privilege accesses by using lock bits. When the lock is high, the registers can be accessed only by secure accesses. When the lock is low, the registers can be accessed by both public and secure transactions.

Some bits also depend on the public or secure privilege mode and the device type configured:

- S: Secure device
- T: Test device
- E: Emulator device
- B: Bad device
- G: General-purpose device

7.4.7.1 Security Control Registers

[Table 7-17](#) describes the security control registers.

Table 7-17. Security Control Registers

Physical Address	Register Name	Description	Access	
			Device Type	
			G	S/T/E/B
0x4800 22B0	<code>CONTROL_SEC_CTRL</code>	Security control register	Public and secure (R/OCO ⁽¹⁾)	Secure privilege (R/OCO) and public (R)
0x4800 2A64	<code>CONTROL_SEC_EMU</code>	Emulation security control register	Public and secure (R)	Secure privilege (R/OCO) and public (R)
0x4800 2A60	<code>CONTROL_SEC_TAP</code>	Tap controllers security control register	Public and secure (R/OCO)	Secure privilege (R/OCO) and public (R)

⁽¹⁾ R/OCO: Read/one-change-only

Table 7-17. Security Control Registers (continued)

Physical Address	Register Name	Description	Access	
			Device Type	
			G	S/T/E/B
0x4800 2A7C	CONTROL_SEC_DAP	Force DAP qualifiers for ease of FW programming	Public and secure (R/W)	Public and secure (R/W)

The [CONTROL.CONTROL_SEC_CTRL](#) and [CONTROL.CONTROL_SEC_TAP](#) registers are public accessible on G devices, and secure privilege accessible on S/T/E/B devices.

The [CONTROL.CONTROL_SEC_EMU](#) register can be accessed (read or write) only when the MPU is in secure privilege mode. Otherwise, a read to this register returns 0.

The reset values and write capabilities of these registers differ according to the device type.

The [CONTROL.CONTROL_SEC_DAP](#) register is accessible on public and secure privilege devices. Accesses to this register are restricted according to the SECDAPWRDISABLE bit [CONTROL.CONTROL_SEC_DAP](#)[31].

The reset values and write capabilities of this register do not depend on the device type.

Some bits in these registers are one-change-only (OCO):

- Write actions that do not change the bit reset value are not considered.
- The first write action that changes the bit reset value is considered; any subsequent write action is ignored. No more write actions are effective until the next power-on reset.

7.4.7.2 Security Status Registers

[Table 7-18](#) lists the status registers.

Table 7-18. Security Status Registers

Physical Address	Register Name	Description	Access
0x4800 22E0	CONTROL_SEC_STATUS	Security status register	Public (R) and secure privilege (R/W)
0x4800 22E4	CONTROL_SEC_ERR_STATUS	Security error status register	Public (R) and secure privilege (R/W)
0x4800 22E8	CONTROL_SEC_ERR_STATUS_DEBUG	Security error status register debug	Public (R) and secure privilege (R/W)

These registers do not depend on the device type.

The [CONTROL.CONTROL_SEC_STATUS](#), [CONTROL.CONTROL_SEC_ERR_STATUS](#), and [CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG](#) registers can be read in public and secure privilege mode, and can be written only in secure privilege mode.

The individual bits are cleared on a write access (same value written) in secure privilege mode. These bits are also cleared when the L3 and L4 firewall embedded error log registers are cleared. All bits in these registers reflect device internal events related to the device security.

On a specific event (signal rising edge), the corresponding bit is set. On a rising edge, the input signal must stay high for at least two interface clocks periods to be recognized. The software must clear each bit after reviewing the events.

When a security violation occurs, the following bits are set :

- In application mode
 - [CONTROL.CONTROL_SEC_ERR_STATUS](#) [00] = OCM-ROM security violation
 - [CONTROL.CONTROL_SEC_ERR_STATUS](#) [01] = OCM-RAM security violation
 - [CONTROL.CONTROL_SEC_ERR_STATUS](#) [02] = GPMC security violation
 - [CONTROL.CONTROL_SEC_ERR_STATUS](#) [04] = SMS security violation

- CONTROL.CONTROL_SEC_ERR_STATUS [06] = IVA2.2 security violation
- CONTROL.CONTROL_SEC_ERR_STATUS [07] = L4-Core security violation
- CONTROL.CONTROL_SEC_ERR_STATUS [12] = L3 RT security violation
- CONTROL.CONTROL_SEC_ERR_STATUS [15] = D2D security violation
- CONTROL.CONTROL_SEC_ERR_STATUS [16] = L4-Peri security violation
- CONTROL.CONTROL_SEC_ERR_STATUS [17] = L4-Emu security violation
- In debug mode
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [00] = OCM-ROM security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [01] = OCM-RAM security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [02] = GPMC security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [03] = SMS security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [06] = IVA2.2 security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [12] = L3 RT security violation

For more information, please refer to the *Interconnect* chapter.

7.4.7.3 Device Status Registers

Table 7-19 lists the status registers.

Table 7-19. Device Status Registers

Physical Address	Register Name	Description	Access
0x4800 22F0	CONTROL_STATUS	Device status register	Public and secure privilege (R)
0x4800 22F4	CONTROL_GENERAL_PURPOSE_STATUS	Status bits reflecting device internal states	Public and secure privilege (R)

These registers do not depend on the device type.

The CONTROL.CONTROL_STATUS and CONTROL.CONTROL_GENERAL_PURPOSE_STATUS registers are read-only registers and have no access restriction.

Note: Depending on the DEVICE_TYPE and sys_boot[5:0] input signals, the SCM provides the six output signals listed in Table 7-20.

Table 7-20. System Control Module I/O Signals

Signal Name	I/O	Width	Description
sys_boot[5:0]	I	6	System boot input 0 to 5, from pad; this is latched at reset.
DEVICE_TYPE	I	3	Device type (from test_sub_system) sampled at reset
BOOT_WAIT_ENABLE	O	1	Dedicated to GPMC controller
ARM_BOOT	O	1	Dedicated to MPU subsystem
BAD_DEVICE	O	3	Used by I/O pads gating logic (I/O core)
CS0_MUX_DEVICE	O	1	Dedicated to GPMC controller
BOOT_DEVICE_SIZE	O	1	Dedicated to GPMC controller
INTERNAL_BOOT	O	1	Internal or external boot selection

- ARM_BOOT <= (((DeviceType == Emulator) or (DeviceType == Test)) and (sys_boot[4:0] == 0b111111)):

Determines whether it is external boot and authorizes it only for general-purpose and emulation
- BOOT_WAIT_ENABLE <= (sys_boot[5:0] == 0b111111):

Allows indicating whether or not the attached memory uses a wait active low
- BAD_DEVICE <= DeviceType if (DeviceType == Bad)

- CS0_MUX_DEVICE <= 1:
Allows indicating whether it is multiplexed or nonmultiplexed FLASH
- BOOT_DEVICE_SIZE <= 1 (16 bits)
- INTERNAL_BOOT <= Not ARM_BOOT:
Determines whether or not the attached memory uses a wait active low

The lower three sys_boot[4:0] pins allow the selection of the booting sequence of interfaces or devices for ROM code when booting. sys_boot[5] switches between memory (0) and peripheral (1) booting.

For further information on the configuration of the sys_boot pins, see the *Multimedia Device Initialization* chapter.

After booting, these pins can be used optionally for other functions. When the pins are reused, the associated sysboot registers are not modified by the new functionality. It is recommended that the output function on the sys_boot pins be reused.

7.4.7.4 Secure SDRC Registers

Table 7-21 lists the secure SDRAM controller (SDRC) registers, which export reset values to the SDRC registers.

Table 7-21. Secure SDRC Registers

Physical Address	Register Name	Description	Access
0x4800 2460	CONTROL_SECURE_SDRC_SHARING	SDRC sharing configuration	R/W
0x4800 2464	CONTROL_SECURE_SDRC_MCFG0	SDRC configuration register 0	R/W
0x4800 2468	CONTROL_SECURE_SDRC_MCFG1	SDRC configuration register 1	R/W

The secure SDRC registers are public and can be accessed without any restriction.

When the SECURE_SDRC_x_WDISABLE bit [CONTROL.CONTROL_SECURE_SDRC_x\[31\]](#) is set, the register [CONTROL.CONTROL_SECURE_SDRC_x](#) is locked and becomes read only.

At reset, the following occur:

- [CONTROL.CONTROL_SECURE_SDRC_SHARING\[30:0\]](#) copies into [SDRC.SDRC_SHARING\[30:0\]](#).
- [CONTROL.CONTROL_SECURE_SDRC_MCFG0\[30:0\]](#) copies into [SDRC.SDRC_MCFG_0\[30:0\]](#).
- [CONTROL.CONTROL_SECURE_SDRC_MCFG1\[30:0\]](#) copies into [SDRC.SDRC_MCFG_1\[30:0\]](#).

When LOCK bit [SDRC.SDRC_SHARING\[30\]](#) is set, a copy of [SDRC.SDRC_SHARING\[30:0\]](#) is made into [CONTROL.CONTROL_SECURE_SDRC_SHARING\[30:0\]](#).

When LOCK bit [SDRC.SDRC_MCFG_0\[30\]](#) is set, a copy of [SDRC.SDRC_MCFG_0\[30:0\]](#) is made into [CONTROL.CONTROL_SECURE_SDRC_MCFG0\[30:0\]](#).

When LOCK bit [SDRC.SDRC_MCFG_1\[30\]](#) is set, a copy of [SDRC.SDRC_MCFG_1\[30:0\]](#) is made into [CONTROL.CONTROL_SECURE_SDRC_MCFG1\[30:0\]](#).

7.4.7.5 OCMROM Secure Debug Register

Table 7-22 describes the OCMROM secure debug register, which configures the secure ROM access for debug.

Table 7-22. OCMROM Secure Debug Register

Physical Address	Register Name	Description	Access
0x4800 24C0	CONTROL_OCMROM_SECURE_DEBUG	Secure ROM code debug configuration	Secure privilege (R/W) and public (R)

This register does not depend on the device type and can be accessed (read or write) only when the MPU is in secure privilege mode. Otherwise, a read to this register returns 0.

The OCMROM_SECURE_DEBUG bit [CONTROL_OCMROM_SECURE_DEBUG\[0\]](#) must be set only when the secure debug is activated.

7.4.7.6 Firewall Configuration Locked Register (Stacked Mode Only)

[Table 7-23](#) describes the firewall configuration locked register, which allows locking the configuration of all firewall registers that have configuration registers exported from the SCM. This register pertains only to stacked mode.

Table 7-23. Firewall Configuration Lock Register

Physical Address	Register Name	Description	Access	
			FWCONFIGURATIONLOCK	
			0	1
0x4800 246C	CONTROL_MODEM_FW_CONFIGURATION_LOCK	Control module locking mechanism	Public and secure privilege (R/W)	Secure privilege (R/W) and public (R)

The reset value and the write capabilities of this register differ according to the device type.

The debug must be activated before writing the FWCONFIGURATIONLOCK bit [CONTROL_CONTROL_MODEM_FW_CONFIGURATION_LOCK\[0\]](#).

7.4.7.7 GPMC Boot Code Register (Stacked Mode Only)

[Table 7-24](#) describes the general-purpose memory controller (GPMC) boot code register, which configures the size of the flash boot code. This register pertains only to stacked mode.

Table 7-24. GPMC Boot Code Register

Physical Address	Register Name	Description	Access	
			FWCONFIGURATIONLOCK	
			0	1
0x4800 2480	CONTROL_MODEM_GPMC_BOOT_CODE	GPMC flash boot code protection	Public and secure privilege (R/W)	Secure privilege (R/W) and public (R)

This register does not depend on the device type. Access to this register is restricted according to the FWCONFIGURATIONLOCK bit [CONTROL_CONTROL_MODEM_FW_CONFIGURATION_LOCK\[0\]](#).

[Table 7-25](#) lists the GPMC boot code sizes.

Table 7-25. GPMC Boot Code Size

GPMC_BOOT_CODE_SIZE field CONTROL_CONTROL_GPMC_BOOT_CODE[4:0]	Size
0x0	Firewall deactivated (0x0)
0x1	1K byte
0x2	2K bytes
0x3	4K bytes
0x4	8K bytes
0x5	16K bytes
0x6	32K bytes
0x7	64K bytes
0x8	128K bytes

Table 7-25. GPMC Boot Code Size (continued)

GPMC_BOOT_CODE_SIZE field CONTROL.CONTROL_GPMC_BOOT_CODE[4:0]	Size
0x9	256K bytes
0xA	512K bytes
0xB	1M byte
0xC	2M bytes
0xD	4M bytes
0xE	8M bytes
0xF	16M bytes
0x10	32M bytes
0x11	64M bytes
0x12	128M bytes
0x13	256M bytes
0x14	512M bytes
0x15	1G byte
0x16	2G bytes
0x17	4G bytes
others	Not allowed

7.4.7.8 Modem Memory Resources Configuration Register (Stacked Mode Only)

[Table 7-26](#) describes the modem memory resources configuration register. This register pertains only to stacked mode.

Table 7-26. Modem Memory Resources Configuration Register

Physical Address	Register Name	Description	Access	
			FWCONFIGURATIONLOCK	
			0	1
0x4800 2470	CONTROL_MODEM_MEMORY_RESOURCES_CONF	Modem memory resources allocation	Public and secure privilege (R/W)	Secure privilege (R/W) and public (R)

This register does not depend on the device type. Access is restricted based on the FWCONFIGURATIONLOCK bit [CONTROL.CONTROL_MODEM_FW_CONFIGURATION_LOCK\[0\]](#).

7.4.7.9 GPMC Modem Firewall Registers (Stacked Mode Only)

[Table 7-27](#) describes the GPMC modem firewall registers, which export reset values to the GPMC firewall region 1. These registers pertain only to stacked mode.

Table 7-27. GPMC Modem Firewall Registers

Physical Address	Register Name	Description	Access	
			FWCONFIGURATIONLOCK	
			0	1
0x4800 2474	CONTROL_MODEM_GPMC_DT_FW_REQ_INFO	Exported value to the GPMC modem firewall region 1 REQ_INFO_PERMISSION_1 field	Public and secure privilege (R/W)	Secure privilege (R/W) and public (R)
0x4800 2478	CONTROL_MODEM_GPMC_DT_FW_RD	Exported value to the GPMC modem firewall region 1 READ_PERMISSION_1 field	Public and secure privilege (R/W)	Secure privilege (R/W) and public (R)
0x4800 247C	CONTROL_MODEM_GPMC_DT_FW_WR	Exported value to the GPMC modem firewall region 1 WRITE_PERMISSION_1 field	Public and secure privilege (R/W)	Secure privilege (R/W) and public (R)

The GPMC modem firewall registers do not depend on the device type. Access is restricted according to the FWCONFIGURATIONLOCK bit [CONTROL.CONTROL_MODEM_FW_CONFIGURATION_LOCK\[0\]](#).

Before the FWCONFIGURATIONLOCK bit [CONTROL.CONTROL_MODEM_FW_CONFIGURATION_LOCK\[0\]](#) is set, [CONTROL.CONTROL_MODEM_GPMC_DT_FW_RD](#) and [CONTROL.CONTROL_MODEM_GPMC_DT_FW_WR](#) must be reprogrammed to authorize only the modem subsystem for read ([CONTROL.CONTROL_MODEM_GPMC_DT_FW_RD](#)) or write ([CONTROL.CONTROL_MODEM_GPMC_DT_FW_WR](#)) accesses.

7.4.7.10 SMS Modem Firewall Registers (Stacked Mode Only)

[Table 7-28](#) describes the SMS modem firewall registers, which export reset values to the SMS firewall region 1. These registers pertain only to stacked mode.

Table 7-28. SMS Modem Firewall Registers

Physical Address	Register Name	Description	Access	
			FWCONFIGURATIONLOCK	
			0	1
0x4800 2484	CONTROL_MODEM_SMS_RG_ATT1	Exported value to the SMS modem firewall region 1 SMS_RG_ATT1 field	Public and secure privilege (R/W)	Secure privilege (R/W) and public (R)
0x4800 2488	CONTROL_MODEM_SMS_RG_RDPERM1	Exported value to the SMS modem firewall region 1 SMS_RG_RDPERM1 field	Public and secure privilege (R/W)	Secure privilege (R/W) and public (R)
0x4800 248C	CONTROL_MODEM_SMS_RG_WRPERM1	Exported value to the SMS modem firewall region 1 SMS_RG_WRPERM1 field	Public and secure privilege (R/W)	Secure privilege (R/W) and public (R)

The SMS modem firewall registers do not depend on the device type. Access is restricted according to the FWCONFIGURATIONLOCK bit [CONTROL.CONTROL_MODEM_FW_CONFIGURATION_LOCK\[0\]](#).

On general-purpose devices, before the FWCONFIGURATIONLOCK bit [CONTROL.CONTROL_MODEM_FW_CONFIGURATION_LOCK\[0\]](#) is set, these registers must be reprogrammed to authorize only the modem subsystem.

7.4.7.11 D2D Firewall Stacked Device Security Registers (Stacked Mode Only)

[Table 7-29](#) and [Table 7-30](#) describe the D2D firewall stacked device security registers. These registers pertain only to stacked mode.

Table 7-29. D2D Firewall Stacked Device Security Registers

Physical Address	Register Name	Description	Access	
			Device Type	
			G	S/T/E/B
0x4800 24D8	CONTROL_D2D_FW_STACKED_DEVICE_SECURITY	D2D reset and MPU IRQ acknowledge	Public and secure privilege (R/W)	Secure privilege (R/W) and public (R)
0x4800 24C4	CONTROL_D2D_FW_STACKED_DEVICE_SEC_DEBUG	D2D stacked device IRQ for firewall violation debug	Public and secure privilege (R/W)	

The reset values and write capabilities of the [CONTROL.CONTROL_D2D_FW_STACKED_DEVICE_SECURITY](#) register differ according to the device type.

The [CONTROL.CONTROL_D2D_FW_STACKED_DEVICE_SEC_DEBUG](#) register does not depend on the device type.

Table 7-30. Modem D2D Firewall Stacked Device Debug Mode Register

Physical Address	Register Name	Description	Access	
			FWCONFIGURATIONLOCK	
			0	1
0x4800 2490	CONTROL_MODEM_D2D_FW_DEBUG_MODE	D2D firewall debug mode	Public and secure privilege (R/W)	Secure privilege (R/W) and public (R)

[CONTROL_MODEM_D2D_FW_DEBUG_MODE](#) does not depend on the device type. Access is restricted according to the FWCONFIGURATIONLOCK bit [CONTROL_MODEM_FW_CONFIGURATION_LOCK](#)[0].

This register configures only the D2D bridge debug accesses between the modem and the application engine (APE) subsystem. The [CONTROL_MODEM_GPMC_DT_FW_REQ_INFO](#) and SMS_RG_ATT1 registers must be configured accordingly.

7.4.7.12 APE Firewall Default Secure Lock Register

[Table 7-31](#) describes the APE firewall default secure lock register.

Table 7-31. APE Firewall Default Secure Lock Register

Physical Address	Register Name	Description	Access
0x4800 24BC	CONTROL_APE_FW_DEFAULT_SECURE_LOCK	Firewall default region configuration	Secure privilege (R/W) and public (R)

[CONTROL_APE_FW_DEFAULT_SECURE_LOCK](#) does not depend on the device type and can be accessed (read or write) only when the MPU is in secure privilege mode. Otherwise, a read to this register returns 0.

7.4.7.12.1 External Security Control Register

[Table 7-32](#) describes the external security control register.

Table 7-32. External Security Control Register

Physical Address	Register Name	Description	Access	
			G/B/S	T/E
0x4800 24D4	CONTROL_EXT_SEC_CONTROL	External security control	Public (R) and secure privilege (R/W)	Public and secure privilege (R)

[CONTROL_EXT_SEC_CONTROL](#) can be accessed (read or write) only when the MPU is in secure privilege mode. Otherwise, a read to this register returns 0.

The reset value and write capabilities of this register differ according to the device type.

7.4.7.13 Keys Access Registers

[Table 7-33](#) describes the keys access registers.

Table 7-33. Keys Access Registers

Physical Address	Register Name	Description	Access
0x4800 2300+4.x	CONTROL_RPUB_KEY_H_x	Root public key hash	Public & Secure privilege (R)
0x4800 2318+4.x	CONTROL_RAND_KEY_x	Random keys	Secure privilege (R)
0x4800 2328+4.x	CONTROL_CUST_KEY_x	Customer keys	Secure privilege (R)
0x4800 2370+4.x	CONTROL_USB_CONF_x	USB conf	Public & Secure privilege (R)
0x4800 2380+4.x	CONTROL_FUSE_OPP_x	Fuse OPP/Fuse SR1/Fuse SR2	Public & Secure privilege (R)

These registers are part of the device eFuse configuration on the interconnect. Reading at the address of one of these registers provides a direct view into a part of the eFuse chain. The eFuse chain is valid and stable before the SCM comes out of reset state (internal power-on reset).

In case of eFuse chain reload, the device is kept in warm reset state; therefore, access through the interconnect interface to capture transient values is not possible.

These registers do not depend on the device type and are read-only registers and have no access restriction except `CONTROL.CONTROL_RAND_KEY_x`, `CONTROL.CONTROL_CUST_KEY_x`, and `CONTROL_TEST_KEY_x` registers

`CONTROL.CONTROL_RAND_KEY_x`, `CONTROL.CONTROL_CUST_KEY_x`, and `CONTROL_TEST_KEY_x` registers can be accessed only while the MPU is in secure privilege mode. In secure privilege mode, these registers can be accessed only if the `SECKEYACCENABLE` bit `CONTROL.CONTROL_SEC_CTRL[2]` is set to 1. They cannot be accessed on general-purpose devices. Outside secure privilege mode or when `SECKEYACCENABLE` bit `CONTROL.CONTROL_SEC_CTRL[2]` is not set, a read attempt to these registers results in an interface access error and no value is returned. These registers have no access restriction.

Some other Customer Keys are accessible from the System Control Module:

- `CONTROL_CEK_x` (with $x=0$ to 3)
- `CONTROL_CEK_BCH_x` (with $x=0$ to 4)
- `CONTROL_MSV_0`
- `CONTROL_MSV_BCH_x` (with $x=0$ or 1)
- `CONTROL_SWRV_x` (with $x=0$ to 4)

These registers only apply to the HS device. To determine if a HS version of your device is available and for more information on HS devices, please refer to your device-specific data manual.

7.4.7.14 Memory DFT Read/Write Control Registers

Table 7-34 describes the memory DFT read/write control registers.

These registers can be accessed (read or write) only while the MPU is in secure privilege mode. They cannot be accessed on general-purpose devices.

Outside secure privilege mode, a read to these registers returns 0. In secure privilege mode, a read to these registers returns the current programmed value.

Table 7-34. Memory DFT Read/Write Control Registers

Physical Address	Register Name	Description	Access
0x4800 2278	CONTROL_MEM_DFTRW0	DFT read and write controls for memory blocks	Public (R) and secure privilege (R/W)
0x4800 227C	CONTROL_MEM_DFTRW1	DFT read and write controls for memory blocks	Public (R) and secure privilege (R/W)

7.4.7.15 Control Dynamic Power Framework Registers

Table 7-35 lists the dynamic power framework control registers.

Table 7-35. Control DPF Region Registers

Physical Address	Register Name	Description	Access
0x4800 2498	<code>CONTROL_DPF_OCM_RAM_FW_ADDR_MATCH</code>	OCM-RAM dynamic power framework handling	Public (R) and secure privilege (R/W)
0x4800 249C	CONTROL_DPF_OCM_RAM_FW_REQINFO	OCM-RAM dynamic power framework handling	Public (R) and secure privilege (R/W)

Table 7-35. Control DPF Region Registers (continued)

Physical Address	Register Name	Description	Access
0x4800 24A0	CONTROL_DPF_OCM_RAM_FW_WR	OCM-RAM dynamic power framework handling	Public (R) and secure privilege (R/W)
0x4800 24A4	CONTROL_DPF_REGION4_GPMC_FW_ADDR_MATCH	GPMC dynamic power framework handling	Public (R) and secure privilege (R/W)
0x4800 24A8	CONTROL_DPF_REGION4_GPMC_FW_REQINFO	GPMC dynamic power framework handling	Public (R) and secure privilege (R/W)
0x4800 24AC	CONTROL_DPF_REGION4_GPMC_FW_WR	GPMC dynamic power framework handling	Public (R) and secure privilege (R/W)
0x4800 24B0	CONTROL_DPF_REGION1_IVA2_FW_ADDR_MATCH	IVA2 dynamic power framework handling	Public (R) and secure privilege (R/W)
0x4800 24B4	CONTROL_DPF_REGION1_IVA2_FW_REQINFO	IVA2 dynamic power framework handling	Public (R) and secure privilege (R/W)
0x4800 24B8	CONTROL_DPF_REGION1_IVA2_FW_WR	IVA2 dynamic power framework handling	Public (R) and secure privilege (R/W)
0x4800 2538	CONTROL_DPF_MAD2D_FW_ADDR_MATCH	MAD2D dynamic power framework handling	Public (R) and secure privilege (R/W)
0x4800 253C	CONTROL_DPF_MAD2D_FW_ADDR_MATCH	MAD2D dynamic power framework handling	Public (R) and secure privilege (R/W)
0x4800 2540	CONTROL_DPF_MAD2D_FW_ADDR_MATCH	MAD2D dynamic power framework handling	Public (R) and secure privilege (R/W)

These registers do not depend on the device type. They can be accessed (read or write) only while the MPU is in secure privilege mode. They cannot be accessed on general-purpose devices.

Outside secure privilege mode, a read to these registers returns 0. In secure privilege mode, a read to these registers returns the current programmed value.

7.4.8 Debug and Observability

7.4.8.1 Description

Note: This feature is restricted to emulator devices.

[Figure 7-14](#) shows an overview of observability multiplexing, which minimizes the number of signals exchanged at the power domain boundary.

Figure 7-14. Overview of the Debug and Observability Register Functionality

Two layers of multiplexer are used to select the set of internal observable signals (PRCM signals, DMA requests, and interrupts) to be routed to the pins dedicated to the hardware debug.

The first layer is in the CORE power domain. It is controlled by the core control module registers and selects the set of internal signals from the CORE power domain to be routed. The second layer is in the WKUP power domain. It is controlled by the wake-up control module registers and selects the set of internal signals from the WKUP power domain.

The pads used for the hardware debug must be properly configured by selecting the hardware debug function (hw_dbgN) of the pad. To configure the pads, select mode 5 (0b101) in the MUXMODE bit field of the CONTROL.CONTROL_PADCONF_CAM_x register (only for hw_dbg0 to hw_dbg11), or select mode 7 (0b111) in the MUXMODE bit field of the CONTROL.CONTROL_PADCONF_ETK_x register (for all hw_dbgN).

Before selecting the CORE signals, the WKUPOBSMUX field of the CONTROL.CONTROL_WKUP_DEBOBS_n registers must be set to 0.

Note: The pads used for the hardware debug must be properly configured by selecting the hardware debug function (hw_dbgN) of the pad. To configure the pads, select mode 5 (0b101) in the MUXMODE bit field of the CONTROL.CONTROL_PADCONF_CAM_x register (only for hw_dbg0 to hw_dbg11), or select mode 7 (0b111) in the MUXMODE bit field of the CONTROL.CONTROL_PADCONF_ETK_x register (for all hw_dbgN).

Table 7-36. Observability Registers

Physical Address	Register Name	Description	Access	
			Device Type	
			E/T/G	S/B
0x4800 2420	CONTROL_DEBOBS_0	Set and configure CORE observable signals 1 and 0	R/W	R
0x4800 2424	CONTROL_DEBOBS_1	Set and configure CORE observable signals 3 and 2	R/W	R
0x4800 2428	CONTROL_DEBOBS_2	Set and configure CORE observable signals 5 and 4	R/W	R
0x4800 242C	CONTROL_DEBOBS_3	Set and configure CORE observable signals 7 and 6	R/W	R
0x4800 2430	CONTROL_DEBOBS_4	Set and configure CORE observable signals 9 and 8	R/W	R
0x4800 2434	CONTROL_DEBOBS_5	Set and configure CORE observable signals 11 and 10	R/W	R
0x4800 2438	CONTROL_DEBOBS_6	Set and configure CORE observable signals 13 and 12	R/W	R
0x4800 243C	CONTROL_DEBOBS_7	Set and configure CORE observable signals 15 and 14	R/W	R
0x4800 2440	CONTROL_DEBOBS_8	Set and configure CORE observable signals 17 and 16	R/W	R
0x4800 2A68	CONTROL_WKUP_DEBOBS_0	Set and configure WKUP observable pins 3, 2, 1, 0	R/W	R
0x4800 2A6C	CONTROL_WKUP_DEBOBS_1	Set and configure WKUP observable pins 7, 6, 5, 4	R/W	R
0x4800 2A70	CONTROL_WKUP_DEBOBS_2	Set and configure WKUP observable pins 11, 10, 9, 8	R/W	R
0x4800 2A74	CONTROL_WKUP_DEBOBS_3	Set and configure WKUP observable pins 15, 14, 13, 12	R/W	R
0x4800 2A78	CONTROL_WKUP_DEBOBS_4	Set and configure WKUP observable pins 17, 16	R/W	R

The write capabilities of these registers differ according to the device type.

Perform the following steps to configure observability:

1. To configure the pads properly for hardware debug and observability, select the hardware debug (hw_dbg) function mode 5 in the MUXMODE field of the CONTROL.CONTROL_PADCONF_CAM_x or mode 7 in the MUXMODE field of the CONTROL.CONTROL_PADCONF_ETK_X registers.
2. For the observability pads, set the proper values of the WKUPOBSMUX field CONTROL.CONTROL_WKUP_DEBOBS_n. Up to 5 bits are used to select the signal set to be observed (0x00 selection sets the output to CORE_OSMUXn signal). For more information, see the description of each register in [Section 7.4.8.2, Observability Tables](#).
3. To observe the CORE_OSMUXn signals from the first layer of the multiplexer, set the WKUPOBSMUX field CONTROL.CONTROL_WKUP_DEBOBS_n to 0x00, and then set the proper values of the OBSMUX field CONTROL.CONTROL_DEBOBS_n. A maximum of 7 bits is used to select the signal set to be observed (0b0000000 selection sets the output to 0).

For more information, see the description of each register in [Section 7.4.8.2, Observability Tables](#).

The observability feature of CONTROL.CONTROL_DEBOBS_n registers can be gated using the OBSERVABILITYDISABLE bit CONTROL.[CONTROL_SEC_CTRL](#)[5]. When set, this bit forces the internal signals CORE_OBSMUXn to 0 as if the OBSMUX field CONTROL.CONTROL_DEBOBS_n is set to 0x000.

The observability feature of the CONTROL.CONTROL_WKUP_DEBOBS_n registers can be gated using the OBSERVABILITYDISABLE bit CONTROL.[CONTROL_WKUP_DEBOBS_4](#)[31]. When set, if the pads are configured for the hardware debug, outputs are set to 0.

7.4.8.2 Observability Tables

This section gives information about all modules and features in the high-tier device. See Chapter 1, the *OMAP35x Family* section, to check availability of modules and features. Unavailable module and feature pins are not functional.

Table 7-37 through Table 7-72 define the mapped internal signals for each OBSMUX and WKUPOBSMUX value.

Table 7-37. Internal Signals Multiplexed on OBSMUX0

Out Signal Name	Muxed Signal Name	OBSMUX0 Field CONTROL.CONTROL_DEBOBS_0 [22:16] (dec)	Description	High State	Low State
CORE_OBSMUX0 ⁽¹⁾	tie_low	0	-	-	-
	CM_96_FCLK	1	96 MHz functional clock of the CM module.	-	-
	CM_32K_CLK	2	32 kHz functional clock of the CM module.	-	-
	Reserved	3	-	-	-
	PRCM_CAM_domainFreeze	4	Indicates if the CAM domain is frozen.	Domain is frozen	Domain is not frozen
	PRCM_NEON_forceWakeup	5	Indicates if a wakeup of the NEON domain is forced.	Wakeup is forced	Wakeup is not forced
	PRCM_COREL4_domainNready	6	Indicates if the CORE_L4 domain is ready. In other words, is domain transition on-going ?	Domain is not ready	Domain is not ready
	PRCM_WKUP_domainNready	7	Indicates if the WKUP domain is ready. In other words, is domain transition on-going ?	Domain is not ready	Domain is not ready
	PRCM_STATE_IS_OFF_IVA2	8	Indicates to the global Power Manager FSM that the IVA2 domain power state is ON	FSM state is OFF	FSM state is not OFF
	Reserved	(16:9)	-	-	-
	sdma_PI_DMAREQ	(87:17)	DMA requests lines mapped to the System DMA module. See the <i>DMA</i> chapter for more information about the System DMA request mapping.	-	-

	PRCM_CAM_RST	3	Reset signal for CAM module.	Reset not active	Reset active
	PRCM_SECURE_WD_RS T	4	Reset signal for SECURE Watchdog.	Reset not active	Reset active
	PRCM_MPU_domainsOn	5	Indicates to the global Power Manager FSM that the MPU domain power state is ON.	State is ON	State is not ON
	PRCM_mpu_domain_is_in active	6	Indicates if the MPU domain is active or not.	Domain is inactive	Domain is active
	PRCM_mpu_domain_is_ret ention	7	Indicates to the global Power Manager FSM that the MPU domain power state is RETENTION.	State is RETENTIO N	State is not RETENTIO N
	PRCM_mpu_domain_is_off	8	Indicates to the global Power Manager FSM that the MPU domain power state is OFF.	State is OFF	State is not OFF
	PRCM_SYS_CLKREQ_in	9	When SYS_CLKREQ is used as an input, it is used to control the SYS.CLKOUT1 (and the internal oscillator).	-	-
	PRCM_vdd1_domain_go_o ff_mode	10	Indicates a transition of the VDD1 domain to OFF_MODE.	Transition initiated	No transition
	PRCM_MPU_SRAMRETO NIN[1]	11	SRAM retention on signal to MPU power domain (bit 1).	Retention is ON	Retention is OFF
	PRCM_IVA2_SRAMAGOO DOUT[2]	12	IVA2 array Powergood indication from SRAM to PSCON (bit 2).	Power is stable	Power is not stable
	PRCM_CORE_POWER_G OOD[3]	13	Indicates if the CORE power switches status (bit 3).	Power is stable	Power is not stable
	PRCM_CORE_SRAMRET ONIN[4]	14	SRAM retention on signal to CORE power domain (bit 4).	Retention is ON	Retention is OFF
	PRCM_SGX_SRAMAONIN [0]	15	SRAM array power control input (bit 2) for SGX power domain.	Array is powered	Array is not powered
	PRCM_CAM_POWER_GO OD[2]	16	Indicates if the CAM power switches status (bit 2).	Power is stable	Power is not stable
	PRCM_DPLL1_POWER_G OOD[0]	17	Indicates if the DPLL1 power switches status (bit 0).	Power is stable	Power is not stable
	PRCM_PER_POWER_RE T	18	PER domain switch command for power-retention.	Retention is ON	Retention is OFF
	PRCM_FORCEACTIVECO RE	19	If asserted, the CORE domain is unable to start a sleep transition.	Sleep transition impossible	Sleep transition possible
	PRCM_GPIO2_SWAKEUP	20	GPIO2 asserts this signal to initiate a transition to WAKEUP mode.	Transition initiated	Wakeup conditions not reached
	Reserved	(31:21)	-	-	-

7.4.9 Electromagnetic Interference Reduction for Clocking Generation (Spreading)

7.4.9.1 Overview

There are two major forms of digital signals: digital-data and digital-clock (CLK). Digital signals are the principal signal form in today's digital electronic products.

- A digital-data signal can be viewed as a sequence of pulses with different pulse widths
- A clock (CLK) signal is usually a string of rectangular pulses with the same pulse width

In the case of a clock, the generated signal has a predetermined frequency. Electromagnetic radiations such as radio frequency emissions are also generated from the constant frequency clock signals and their harmonics. Unfortunately, a problem exists with some devices such as communication devices for example in that the system clock generates unwanted spurious signals that interfere with the decoding of information from received signals by a receiver of the communication device. Note that data periodicity also causes interference.

This periodicity generates a significant power peak at the selected frequency, which in turn causes an EMI disturbance to the environment.

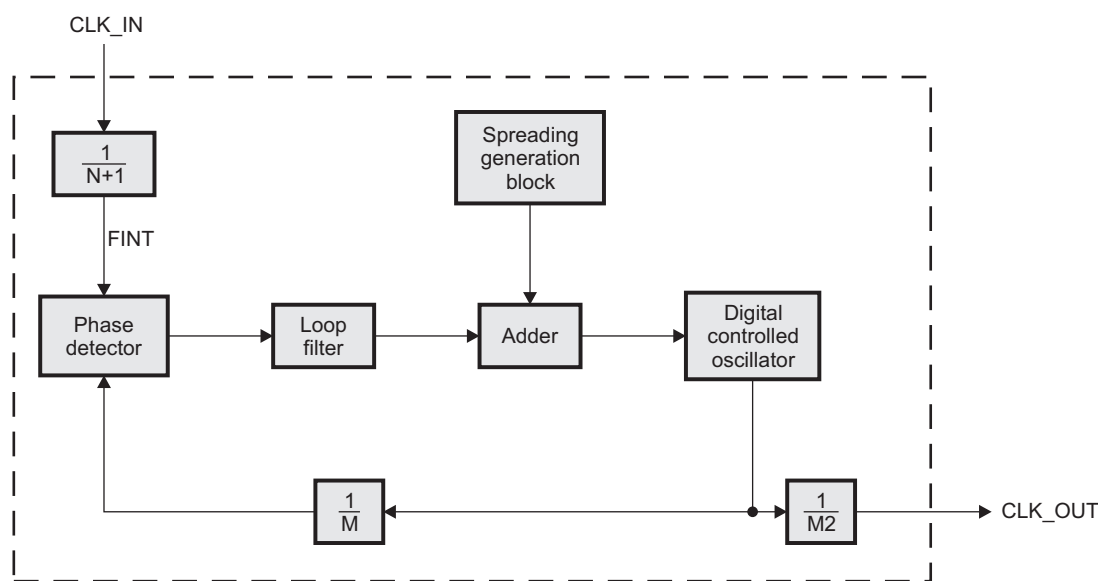

The harmonics of the generated signal system clock radiates in the other modules of the device, and the spurious energy can be enough to cause enough interference, which results in performance degradation (in the form of high bit error rates in case of a wireless communication interface for example).

In order to reduce the power peaks (and thus the energy of the electromagnetic noise generated for a specific frequency), an internal frequency modulation of the DPLL is used to distribute the energy to many different frequencies, thus reducing the power peaks.

This frequency modulation feature is directly integrated in some DPLLs of the device. The DPLLs that support this additional feature are called DPLL-D in the following.

Figure 7-15 shows a diagram of a DPLL that supports the EMI reduction feature.

Figure 7-15. DPLL with EMI Reduction Feature

108-033

The additional features of the DPLL compliant with EMI reduction are:

- EMI Reduction using Triangular frequency modulation, also called Spread Spectrum Clocking (SSC).

7.4.9.2 Integration

The four following DPLLs/Domains of the devices that support the EMI reduction feature are:

- DSS/DSI DPLL
- CORE domain DPLL
- PER domain DPLL
- USBHOST DPLL

Figure 7-16 highlights the four DPLL-D integration in the device.

Figure 7-16. DPLL-D Integration

The control of the DPLL is done both by the PRCM and the System Control Module:

- The PRCM controls the clocking generation of the DPLL. For more information, see the *Power Reset and Clock Management* chapter.
- The System Control Module contains all necessary bits that controls the EMI Reduction feature (Spread Spectrum Clocking).

7.4.9.2.1 Clocking, Reset, and Power Management Scheme

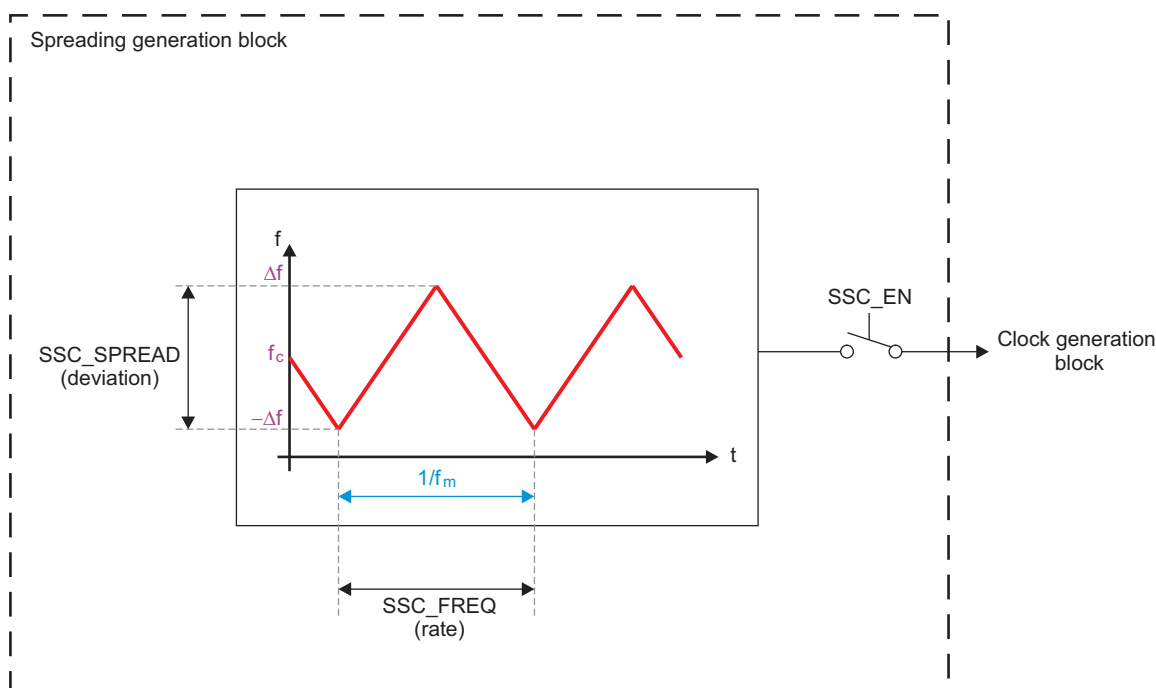

Please see the *Power Reset and Clock Management* chapter.

7.4.9.3 Functional Description

7.4.9.3.1 Spreading Generation Block

Figure 7-17 shows a diagram of the Spreading Generation block.

Figure 7-17. Spreading Generation Block Diagram

108-035

Note: Δf is the deviation from the center frequency. The total spreading deviation is equal to twice Δf .

f_c is the original clock frequency.

f_m is the spreading frequency.

This additional block generates the required waveform used to reduce EMI. This waveform is then modulated with the initial signal in order to add some controlled deviation in the clock signal frequency, which spreads the energy of the clock and its harmonics into a band of frequencies, and then reduces the Electromagnetic Interferences.

The **SSC_SPREAD** value handles the deviation (amplitude) of the generated signal from the original signal. It is controlled by the CONTROL.CONTROL_XXX_DPLL_SPREADING[3:2] XXX_SPREADING_AMPLITUDE bitfield of the corresponding registers (where XXX is the name of the concerned DPLLs). Note that this register contains only a spreading ratio K , which is equal to $\Delta f / f_m$.

The **SSC_FREQ** value controls the rate of the generated signal. It is controlled by the CONTROL.CONTROL_XXX_DPLL_SPREADING[1:0] XXX_SPREADING_RATE bitfield of the corresponding registers (where XXX is the name of the concerned DPLLs).

The **SSC_EN** signal enables/disables the frequency modulation feature of the DPLL. It is controlled by the CONTROL.CONTROL_XXX_DPLL_SPREADING[4] XXX_SPREADING_ENABLE bitfield of the corresponding registers (where XXX is the name of the concerned DPLLs).

In any case the frequency modulation will be programmed in the System Control Module and it is not generally something that needs to be changed in real time.

7.4.9.3.2 Spread Spectrum Clocking (SSC)

7.4.9.3.2.1 Definition

The aim of the Spread Spectrum Clocking is to add a variation in the frequency of an original clock, which spreads the generated interferences over a larger band of frequency.

In theory, Spread Spectrum Clocking means that the clock signal is varied around the desired frequency. For example, for a 1 GHz clock, the frequency might be 999.5 Mhz at one moment in time and 1.0005 GHz at another. Doing this constantly causes the power of the tone to be "spread" out more over a broader band of tight frequencies (centered at the desired tone). To realize this constant variation on the original signal, a modulation with an additional signal (called spreading waveform) is realized.

Creating a spread-spectrum clock by spreading the initial clock frequency is done by defining the following parameters:

- The spreading frequency (deviation), which is the ratio of the range of spreading frequency over the original clock frequency.
- The modulation rate (f_m), which is used to determine the clock-frequency spreading-cycling rate, and is the time during which the generated clock frequency varies through Δf and returns to the original frequency.
- The modulation waveform, which describes the variation curve in term of time.

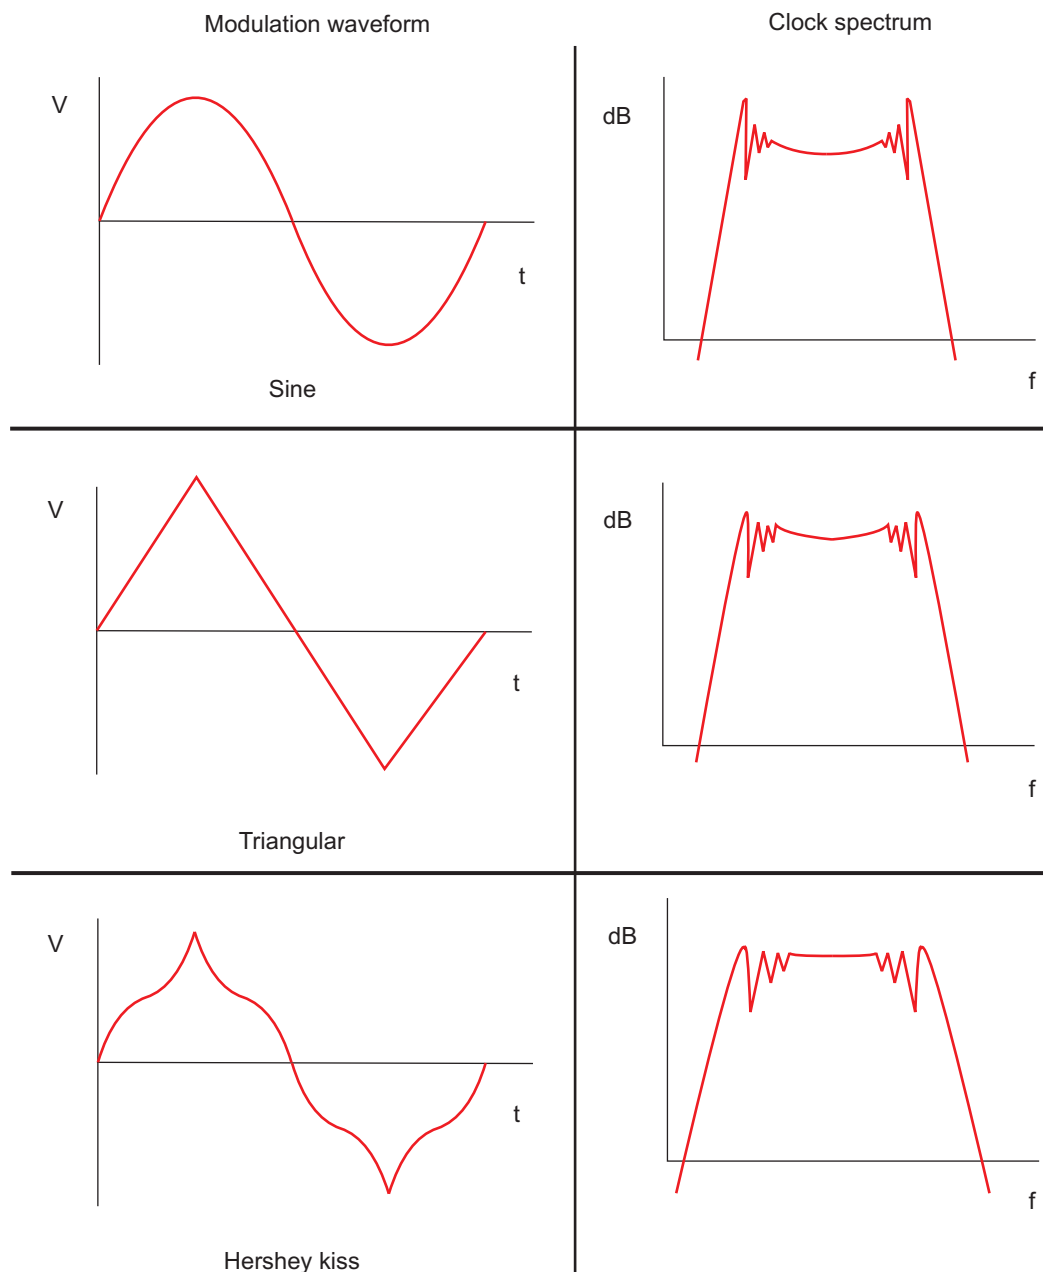

The spectral power reduction in the DPLL clocks is dependent on the Modulation Index (K) which is a ratio of spreading frequency, calculated from the frequency deviation (Δf) and the modulation rate (f_m) .

7.4.9.3.2.2 The modulation waveforms

The shape (profile) of the generated clock signal depends on the modulation waveform that is used during the frequency modulation. Several profiles can be used, according to the desired shaping for the energy spreading.

[Figure 7-18](#) shows three examples of modulation waveforms and the spectrum of the corresponding modulated clock signal.

Figure 7-18. Modulation Profiles

108-036

The triangular wave gives a relatively flat spectrum and is also easy to generate. The triangular waveform is used by the DPLL-D.

7.4.9.3.2.3 Effects on the Clock Signal

Figure 7-19 gives an example of the effect of a triangular spreading on a clock signal.

Figure 7-19. Effect of the SSC in Frequency

Figure 7-19 highlights the power reduction of the main peak, but also the flatter aspect of the modulated signal. One could notify that the minimum level of the second signal is higher than the first one. This effect is normal and is due to the "noise" added for the modulation.

Note: The spreading technique "scatters" the energy of the peaks on the other frequencies, which reduces the power of the peaks but increases the global "noise" of the signal.

Figure 7-20 shows the effect of a triangular spreading on a clock signal in the Time Domain.

Figure 7-20. Effect of the SSC in the Time Domain

108-039

7.4.9.3.2.4 Estimation of the EMI Reduction Level

Figure 7-21 shows the effect of the spreading on a clock and its harmonics.

Figure 7-21. Peaks Reduction Due to Spreading

108-037

The electromagnetic interference reduction can be estimated with the following equation:

$$(1) \text{ Peak_power_reduction} = 10 * \log ((\text{Deviation} * f_c) / f_m)$$

With:

- Peak_power_reduction in dB
- Deviation in % of the initial clock frequency (f_c), equals to $\Delta f / f_c$
- f_c is the original clock frequency, in MHz
- f_m is the spreading frequency, in MHz

According to equation (1), it is also possible to compute the deviation, and then Δf , for a required peak power reduction:

$$(2) \text{ Deviation} = (f_m / f_c) * 10^{(\text{Peak_power_reduction} / 10)}$$

Example:

For $f_c=400\text{MHz}$, Deviation =1% peak from f_c ($\Delta f = 4\text{MHz}$) and $f_m=400\text{kHz}$, the estimated peak power reduction is 10dB.

7.4.9.3.2.5 Bandwidth Calculation (Carson Bandwidth Rule)

Carson's bandwidth rule defines the approximate bandwidth requirements of communications system components for a carrier signal that is frequency modulated by a continuous or broad spectrum of frequencies rather than a single frequency.

Carson's bandwidth rule is expressed by the relation $\text{CBR} = 2 * (\Delta f + f_m)$ where CBR is the bandwidth requirement, Δf is the peak frequency deviation, and f_m is the highest frequency in the modulating signal.

For example, an FM signal with 5kHz peak deviation, and a maximum audio frequency of 3 kHz, would require an approximate bandwidth $2*(5+3) = 16$ kHz.

Theoretically any FM signal will have an infinite number of sidebands and hence an infinite bandwidth but in practice all significant sideband energy (98% or more) is concentrated within the bandwidth defined by Carson's rule.

7.4.9.3.3 Frequency Limitations

There are some limitations on the use of the Spreading feature. [Figure 7-22](#) shows the supported Spreading frequency and deviation.

Figure 7-22. Supported Spreading Frequency and Deviation

		SPREADING_AMPLITUDE (bits [3:2])			
		00	01	10	11
		K			
		4	6	8	10
SPREADING_RATE (bits [1:0])	Min to Max rate (kHz)	Frequency deviation +/- kHz			
00	62.5 to 125	250 to 500	375 to 750	500 to 1000	625 to 1250
01	125 to 250	500 to 1000	750 to 1500	1000 to 2000	1250 to 2500
10	250 to 500	1000 to 2000	1500 to 3000	2000 to 4000	2500 to 5000
11	500 to 1000	2000 to 4000	3000 to 6000	4000 to 8000	5000 to 10000

 Not recommended. PLL jitter degradation and modulation amplitude not a linear function of FM.

108-040

Even if all the previous frequencies and deviations are supported by the DPLL-D, a range of "Safe operating regions" has been defined according to its impact on jitter.

[Figure 7-22](#) shows the supported safe operating regions supported by the DPLL-D.

Figure 7-23. Supported Safe Operating Regions and Jitter Impact

CLKOUT FREQUENCY (25–900 MHz)	Recommended safe operating region				Max jitter impact in % due to spreading
400–900					+/- 1.25%
200–399					+/- 1.25%
100–199					+/- 1.25%
50–99					+/- 1.00%
25–49					+/- 2.00%

108-041

(1) Please see [Figure 7-22](#) for color coding)

7.4.9.4 Basic Programming Model

7.4.9.4.1 Spread Spectrum Clocking Configuration

The configuration of the spreading feature is not mandatory when programming the DPLL. This feature is usually enabled when the DPLL clocks generate harmonics which can potentially interfere with the GSM carrier frequencies.

Once the "clock generation control" registers are configured, it is possible to configure the spreading on the clock signal.

The first thing to do is to calculate the *Deviation* and/or the *Spreading Rate* according to the desired peak power reduction. In addition to this, it is necessary to have K (modulation index), which value is equal to $\Delta f / f_m$.

Then, both XXX_SPREADING_AMPLITUDE and XXX_SPREADING_RATE bitfields can be configured with the calculated values.

Finally, the spreading has to be enabled using the XXX_SPREADING_ENABLE bit.

Note: It is necessary to carefully configure the spreading on a clock in order to avoid adding some "noise" on frequencies that are used by another module. For example, adding spreading on a clock to reduce noise on GSM frequencies can "move" the generated noise to the memory controller's frequency, and then degrade its performances.

Example:

For $f_c=400\text{MHz}$, Deviation = 1% peak from f_c ($\Delta f = 4\text{MHz}$) and $f_m=400\text{kHz}$, the estimated peak power reduction is 10dB. K is then equal to 10. The DPLL can be configured as follow:

- XXX_SPREADING_RATE = 10 (250 to 500 KHz)
- XXX_SPREADING_AMPLITUDE = 11 ($K = 10$)
- XXX_SPREADING_ENABLE = 1

The state of the modulation feature can be monitored with the XXX_SPREADING_ENABLE_STATUS bit of the corresponding register.

Notes:

- To support the spreading feature the DPLL Bandwidth is restricted to a max of 70KHz. This implies the Reference Clock frequency to be in range 0.75MHz to 2.1MHz, and then the XXX_DPLL_FREQSEL[3:0] bitfield to be in range "0011" to "0111".
 - The required Δf (Frequency deviation) is targeted on the CLKOUT Frequency is achieved when M2 is programmed to 1. Otherwise the frequency deviation will be scaled down by the factor of M2 value. However, this does not affect the deviation, so frequency change of harmonics at GSM frequencies is the same.
 - The spread of modulation frequency within each range is due to an internal auto-ranging function and specific frequencies cannot be selected.
 - The lowest range (62.5 to 125 KHz) should only be selected when Reference Clock (PLL internal reference frequency) < 1.1 MHz is being used, to prevent the PLL feedback loop from canceling the modulation.
-

When deactivating the spreading (XXX_SPREADING_ENABLE = 0), the End-of-Spreading is synchronous to the internal spreading cycle. So there is no residual average frequency error.

7.5 System Control Module Programming Model

7.5.1 Feature Settings

7.5.1.1 Force Pad Configuration MuxMode by High-Speed USB

The two pads hsub0_data0 and hsub0_data1 can force pad configuration MuxMode when the CARKITEN signal is generated:

- CARKITHSUB0DATA0AUTOEN bit CONTROL.[CONTROL_DEVCONF1](#)[19]:
0: The hsub0_data0 MuxMode signal is driven by MUXMODE1 bit CONTROL.CONTROL_PADCONF_HSUSB0_NXT[18:16].
1: The hsub0_data0 MuxMode signal is forced to 0x2 when the CARKITEN signal is active.
- CARKITHSUB0DATA1AUTOEN bit CONTROL.[CONTROL_DEVCONF1](#)[20]:
0: The hsub0_data1 MuxMode signal is driven by MUXMODE0 bit CONTROL.CONTROL_PADCONF_HSUSB0_DATA[2:0].
1: The hsub0_data1 MuxMode signal is forced to 0x2 when the CARKITEN signal is active.

Note: Associated pad configuration registers remain unchanged.

For more details on High-Speed USB, see the *High-Speed USB Controllers* chapter.

7.5.1.2 Video Driver

This section gives information about all modules and features in the high-tier device. See Chapter 1, the *OMAP35x Family* section, to check availability of modules and features. Unavailable module and feature pins are not functional.

- TVOUTBYPASS bit CONTROL.[CONTROL_DEVCONF1](#)[18]:
0b0: Dual 10-bit video DAC TV out bypass disable
0b1: Dual 10-bit video DAC TV out bypass enable
- TVACEN bit CONTROL.[CONTROL_DEVCONF1](#)[11]:
0b0: Enables dc coupling for TV output
0b1: Enables ac coupling for TV output

For more details on video DACs, see the *Display Subsystem* chapter.

7.5.1.3 McBSP1 Internal Clock

The McBSP1 internal clock gates the internal interconnect clock and selects the FSR, CLKR, and CLKS input for the McBSP1.

- MCBSP1_FSR bit CONTROL.[CONTROL_DEVCONF0](#)[4]:
0: FSR is from the pin mcbasp1_fsr.
1: FSR is from the pin mcbasp1_fsx.
- MCBSP1_CLKR bit CONTROL.[CONTROL_DEVCONF0](#)[3]:
0: CLKR is from the pin mcbasp1_clkr.
1: CLKR is from the pin mcbasp1_clkx.
- MCBSP1_CLKS bit CONTROL.[CONTROL_DEVCONF0](#)[2]:
0: CLKS is from the PRCM functional clock.
1: CLKS is from the pin mcbasp1_clks.

For more details on McBSP, see the *Multichannel Serial Port Interface* chapter.

7.5.1.4 McBSP2 Internal Clock

The McBSP2 internal clock gates the internal interconnect clock and selects the FSR, CLKR, and CLKS input for the McBSP2. The McBSP2 does not have mcbasp2_clkr and mcbasp2_fsr external pins. Clock input is from the mcbasp2_clkx pin; FSR input is from the mcbasp2_fsx pin.

- MCBSP2_CLKS register bit CONTROL.[CONTROL_DEVCONF0\[6\]](#):
 - 0: Clock is from the PRCM functional clock.
 - 1: Clock is from the external pin mcbasp_clks.

For more details on McBSP, see the *Multichannel Serial Port Interface* chapter.

7.5.1.5 McBSP3 Internal Clock

The McBSP3 internal clock gates the internal interconnect clock and selects the FSR, CLKR, and CLKS input for the McBSP3. The McBSP3 does not have mcbasp3_clkr and mcbasp3_fsr external pins. Clock input is from the mcbasp3_clkx pin; FSR input is from the mcbasp3_fsx pin.

- MCBSP3_CLKS register bit CONTROL.[CONTROL_DEVCONF1\[0\]](#):
 - 0: Clock is from the PRCM functional clock.
 - 1: Clock is from the external pin mcbasp_clks.

For more details on McBSP, see the *Multichannel Serial Port Interface* chapter.

7.5.1.6 McBSP4 Internal Clock

The McBSP4 internal clock gates the internal interconnect clock and selects the FSR, CLKR, and CLKS input for the McBSP4. The McBSP4 does not have mcbasp4_clkr and mcbasp4_fsr external pins. Clock input is from the mcbasp4_clkx pin; FSR input is from the mcbasp4_fsx pin.

- MCBSP4_CLKS register bit CONTROL.[CONTROL_DEVCONF1\[2\]](#):
 - 0: Clock is from the PRCM functional clock.
 - 1: Clock is from the external pin mcbasp_clks.

For more details on McBSP, see the *McBSP* chapter.

7.5.1.7 McBSP5 Internal Clock

The McBSP5 internal clock gates the internal interconnect clock and selects the FSR, CLKR, and CLKS input for the McBSP5. The McBSP5 does not have mcbasp5_clkr and mcbasp5_fsr external pins. Clock input is from the mcbasp5_clkx pin; FSR input is from the mcbasp5_fsx pin.

- MCBSP5_CLKS register bit CONTROL.[CONTROL_DEVCONF1\[4\]](#):
 - 0: Clock is from the PRCM functional clock.
 - 1: Clock is from the external pin mcbasp_clks.

For more details on McBSP, see the *McBSP* chapter.

7.5.1.8 MMC/SD/SDIO1 Module Input Clock Selection

- MMCSDIO1ADPCLKISEL bit CONTROL.[CONTROL_DEVCONF0\[24\]](#):
 - 0: Input clock is from the external pin.
 - 1: Internal loopback, module input clock is copied from the module output clock.

7.5.1.9 MMC/SD/SDIO2 Module Input Clock Selection

- MMCSDIO2ADPCLKISEL bit CONTROL.[CONTROL_DEVCONF1\[6\]](#):
 - 0: Input clock is from the external pin.
 - 1: Internal loopback, module input clock is copied from the module output clock.

7.5.1.10 Setting Sensitivity on SYS_NDMAREQ[6:0] Input Pins

The seven SYS_NDMAREQ0 to SYS_NDMAREQ6 input pins can be either level or edge sensitive.

- SENSDMAREQ0 bit CONTROL.CONTROL_DEVCONF0[0]:
0: Level sensitivity
1: Edge sensitivity
- SENSDMAREQ1 bit CONTROL.CONTROL_DEVCONF0[1]:
0: Level sensitivity
1: Edge sensitivity
- SENSDMAREQ2 bit CONTROL.CONTROL_DEVCONF1[7]:
0: Level sensitivity
1: Edge sensitivity
- SENSDMAREQ3 bit CONTROL.CONTROL_DEVCONF1[8]:
0: Level sensitivity
1: Edge sensitivity
- SENSDMAREQ4 bit CONTROL.CONTROL_DEVCONF1[21]:
0: Level sensitivity
1: Edge sensitivity
- SENSDMAREQ5 bit CONTROL.CONTROL_DEVCONF1[22]:
0: Level sensitivity
1: Edge sensitivity
- SENSDMAREQ6 bit CONTROL.CONTROL_DEVCONF1[23]:
0: Level sensitivity
1: Edge sensitivity

For more details on DMA, see the *DMA* chapter.

7.5.1.11 I²C I/O Internal Pull-up Enable

The I/O internal pull-up of I2C1, I2C2, and I2C3 can be enabled:

- I2C1HSMASER bit CONTROL.CONTROL_DEVCONF1[12]:
0: I2C1 I/O internal pull-up disable
1: I2C1 I/O internal pull-up enable
- I2C2HSMASER bit CONTROL.CONTROL_DEVCONF1[13]:
0: I2C2 I/O internal pull-up disable
1: I2C2 I/O internal pull-up enable
- I2C3HSMASER bit CONTROL.CONTROL_DEVCONF1[14]:
0: I2C3 I/O internal pull-up disable
1: I2C3 I/O internal pull-up enable

Note: This feature is used for the master component.

For more details on I²C, see the *Inter-Integrated Circuit* chapter.

7.5.1.12 SDRC I/O Drive Strength Selection

- SDRC_LOWDATA bit CONTROL.SCM_CONTROL_PROG_IO0[31] selects data[15:0] DQS0, DQS1, DM0 and DM1 I/O drive strength:
0: Load range = [2 pF - 6 pF]
1: Load range = [6 pF - 12 pF]
- SDRC_HIGHDATA bit CONTROL.SCM_CONTROL_PROG_IO0[30] selects data[31:16] DQS2, DQS3, DM2 and DM3 I/O drive strength:

- 0: Load range = [2 pF - 6 pF]
- 1: Load range = [6 pF - 12 pF]
- SDR_C_ADDRCRTL bit CONTROL.SCM_CONTROL_PROG_IO0[29] selects address NRAS, NCAS, NWE, NCLK, CLK, BA0 and BA1 I/O drive strength:
 - 0: Load range = [2 pF - 6 pF]
 - 1: Load range = [6 pF - 12 pF]
- SDR_C_NCS0 bit CONTROL_PROG_IO0[28] selects NCS0 and CKE0 I/O drive strength
- SDR_C_NCS1 bit CONTROL_PROG_IO0[27] selects NCS1 and CKE1 I/O drive strength

7.5.1.13 GPMC I/O Drive Strength Selection

- GPMC_A1 bit CONTROL.CONTROL_PROG_IO0[26] selects GPMC_A1 I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_A2 bit CONTROL.CONTROL_PROG_IO0[25] selects GPMC_A2 I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_A3 bit CONTROL.CONTROL_PROG_IO0[24] selects GPMC_A3 I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_A4 bit CONTROL.CONTROL_PROG_IO0[23] selects GPMC_A4 I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_A5 bit CONTROL.CONTROL_PROG_IO0[22] selects GPMC_A5 I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_A6 bit CONTROL.CONTROL_PROG_IO0[21] selects GPMC_A6 I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_A7 bit CONTROL.CONTROL_PROG_IO0[20] selects GPMC_A7 I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_A8 bit CONTROL.CONTROL_PROG_IO0[19] selects GPMC_A8 I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_A9 bit CONTROL.CONTROL_PROG_IO0[18] selects GPMC_A9 I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_MIN_CFG bit CONTROL.CONTROL_PROG_IO0[16] selects data[7:0] I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_D8_D15 bit CONTROL.CONTROL_PROG_IO0[15] selects data[15:8], NOE, NWE, NADV_ALE and WAIT0 I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_NCS0 bit CONTROL.CONTROL_PROG_IO0[14] selects GPMC_NCS0 I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_NCS1 bit CONTROL.CONTROL_PROG_IO0[13] selects GPMC_NCS1 I/O drive strength
 - 0: Load range = [2pf : 6pf]

- 1: Load range = [6pf : 12pf]
- GPMC_NCS2 bit CONTROL.CONTROL_PROG_IO0[12] selects GPMC_NCS2 I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_NCS3 bit CONTROL.CONTROL_PROG_IO0[11] selects GPMC_NCS3 I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_NCS4 bit CONTROL.CONTROL_PROG_IO0[10] selects GPMC_NCS4 I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_NCS5 bit CONTROL.CONTROL_PROG_IO0[9] selects GPMC_NCS5 I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_NCS6 bit CONTROL.CONTROL_PROG_IO0[8] selects GPMC_NCS6 I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_NCS7 bit CONTROL.CONTROL_PROG_IO0[7] selects GPMC_NCS7 I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_CLK bit CONTROL.CONTROL_PROG_IO0[6] selects GPMC_CLK I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_NBE0_CLE bit CONTROL.CONTROL_PROG_IO0[5] selects GPMC_NBE0_CLE I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_NBE1 bit CONTROL.CONTROL_PROG_IO0[4] selects GPMC_NBE1 I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_NWP bit CONTROL.CONTROL_PROG_IO0[3] selects GPMC_NWP I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_WAIT1 bit CONTROL.CONTROL_PROG_IO0[2] selects GPMC_WAIT1 I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_WAIT2 bit CONTROL.CONTROL_PROG_IO0[1] selects GPMC_WAIT2 I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]
- GPMC_WAIT3 bit CONTROL.CONTROL_PROG_IO0[0] selects GPMC_WAIT3 I/O drive strength
 - 0: Load range = [2pf : 6pf]
 - 1: Load range = [6pf : 12pf]

7.5.1.14 MCBSP2 I/O Drive Strength Selection

- MCBSP2_MIN_CTL field CONTROL.CONTROL_PROG_IO1[7:6] selects FSX, CLKX, DR and DX I/O drive strength
 - 0: 8 mA
 - 1: 6 mA
 - 2: 4 mA
 - 3: 2 mA

7.5.1.15 MCSPI1 I/O Drive Strength Selection

- MCSPI1_MIN_CTL field CONTROL.CONTROL_PROG_I01[5:4] selects CLK, SOMI, SIMO and CS0 I/O drive strength
0: 8 mA
1: 6 mA
2: 4 mA
3: 2 mA
- MCSPI1_CS1 field CONTROL.CONTROL_PROG_I01[3:2] selects CS1 I/O drive strength
0: 8 mA
1: 6 mA
2: 4 mA
3: 2 mA
- MCSPI1_CS2 field CONTROL.CONTROL_PROG_I01[1:0] selects CS2 I/O drive strength
0: 8 mA
1: 6 mA
2: 4 mA
3: 2 mA

7.5.1.16 Force MPU Writes to Be Nonposted

MPUFORCEWRNP bit CONTROL.CONTROL_DEVCONF1[9] bit is for debugging only. When this bit is set to 1 (for debugging), all writes are forced to nonposted and the cache attributes are ignored. By default, this bit should be set to 0 (posted writes). For the best performance, keep this bit at 0.

7.5.2 Extended-Drain I/Os and PBIAS Cell Programming Guide

Note: The device can be supplied by an external power IC. Texas Instruments provides such a global solution to its customers with the TPS65950 power IC. Contact your TI representative for more information on the TPS65950 power IC.

If the device is associated with the TPS65950 power IC, before using MMC/SD/SDIO1 or USIM interfaces, the software must program the TPS65950 to enable the VMMC1 or VMMC1a (for MMC/SD/SDIO1 module), LDO and to provide a 1.8-V/3.0-V voltage. This is done by software via the I²C interface that links the device and TPS65950 IC.

If the application does not want the MMC/SD/SDIO1 interface running at 3.0 V, software users must then assert the VMODE signal to low for 1.8-V activity: in this case, the PBIAS is connected to ground. (see [Figure 7-24](#))

[Table 7-73](#) lists the control signal with the corresponding control bits from the CONTROL.CONTROL_PBIAS_LITE (physical address: 0x4800 2520) register to configure the PBIAS and the extended drain I/O cells. These signals can be software controlled.

Table 7-73. Control Signal

Control Signals Name	Bit Register for MMC/SD/SDIO1 Module using PBIAS0 cell	Bit Register for MMC/SD/SDIO1 Module using PBIAS1 cell	Reset Value
PWRDNZ	CONTROL.CONTROL_PBIAS_LITE[1] PBIASLITEPWRDNZ0 bit	CONTROL.CONTROL_PBIAS_LITE[9] PBIASLITEPWRDNZ1 bit	0
VMODE	CONTROL.CONTROL_PBIAS_LITE[0] PBIASLITEVMODE0 bit	CONTROL.CONTROL_PBIAS_LITE[8] PBIASLITEVMODE1 bit	1
SUPPLY_HIGH	CONTROL.CONTROL_PBIAS_LITE[7] PBIASLITESUPPLYHIGH0 bit	CONTROL.CONTROL_PBIAS_LITE[15] PBIASLITESUPPLYHIGH1 bit	0
SPEEDCTRL	CONTROL.CONTROL_PBIAS_LITE[2] PBIASLITESPEEDCTRL0 bit	CONTROL.CONTROL_PBIAS_LITE[10] PBIASLITESPEEDCTRL1 bit	0

Table 7-73. Control Signal (continued)

Control Signals Name	Bit Register for MMC/SD/SDIO1 Module using PBIAS0 cell	Bit Register for MMC/SD/SDIO1 Module using PBIAS1 cell	Reset Value
VMODEERROR	CONTROL. CONTROL_PBIAS_LITE [3] PBIASLITEVMODEERROR0 bit	CONTROL. CONTROL_PBIAS_LITE [11] PBIASLITEVMODEERROR1 bit	0

The PBIAS cell supports two ranges of I/O VDDS: 1.8 V, typical for low-voltage applications, and 3.0 V, typical for high-voltage applications. For each supply voltage range, the cell generates suitable bias voltage (PBIAS) for extended-drain PMOS devices.

CAUTION

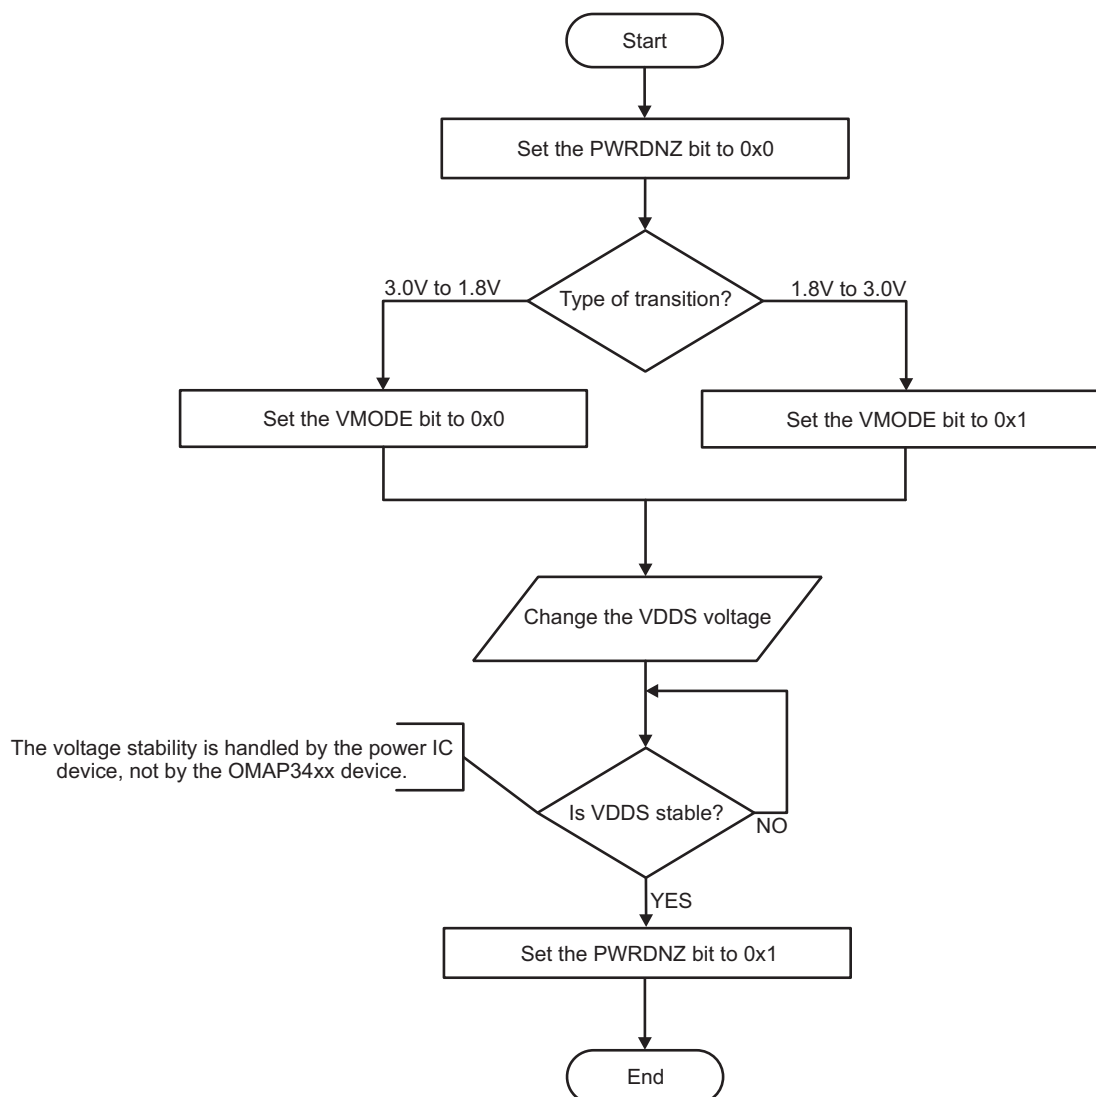

The PBIAS cell must be programmed according to peripheral power supply voltage. Refer to [Table 7-74](#)

Table 7-74. Voltage Configuration

PBIASLITEVMODE Configuration	VDDS Voltage	Reset Value
1.8 V	1.8 V	Normal 1.8-V operation
1.8 V	3.0 V	Damaging configuration
3.0 V	1.8 V	Degraded functionality
3.0 V	3.0V	Normal 3.0-V operation

Figure 7-24 describes the programming flow to go from 3.0 V to 1.8 V, and vice versa.

Figure 7-24. Flowchart

108-019

The PBIAS output is the same as VDDS when the PWRDNZ bit is LOW. Once the VDDS supply settles, the software releases the PWRNDZ (pulls it HIGH). This then starts up the PBIAS cell work to generate the PBIAS voltage. During the complete process the MMC/SD/SDIO1 I/O cannot be used for transmitting data.

Note: In the case of a damaging configuration, hardware system protection prevents deterioration of the associated extended-drain I/Os.

CAUTION

The following are critical requirements for the cell:

- The VMODE bit must be defined before the PWRNDZ bit is made HIGH (cell is brought out of PWRNDZ).
- The default state of VMODE bit must be HIGH (to indicate 3.0-V operation).
- PWRNDZ bit must be kept LOW whenever the VDDS supply is ramping up (PWRNDZ bit is not required to be kept LOW during ramp down of the supply). This could be damaging.

7.5.2.1 PBIAS Error Generation

[Table 7-75](#) summarizes the generation of the PBIAS error interrupt (PBIAS0_ERROR and PBIAS1_ERROR) depending on the various CONTROL.[CONTROL_PBIAS_LITE](#) bits control. The row highlighted in grey is a potential condition that could cause potential reliability issue if not detected. To prevent this reliability issue, the PBIAS voltage is kept a VDDS level when the PBIAS error signal is HIGH.

Table 7-75. PBIAS Error Signal Truth Table

VMODE	PWRNDZ	SUPPLY_HIGH	PBIAS ERROR
X	X	X	0
0	0	X	0
0	1	0	0
0	1	1	1
X	1	X	1
1	0	X	0
1	1	0	1
1	1	1	0

Note: PBIAS ERROR = 1: VMODE level not same as SUPPLY_HIGH

PBIAS ERROR = 0: VMODE level same or VMODE not considered

The PBIAS error are merged and connected to the MPU Subsystem interrupt controller.

The CONTROL.[CONTROL_PBIAS_LITE](#)[i] VMODEERROR bits (with i=3 or 11) also indicates if this kind of error occurs.

7.5.2.2 Critical Timing Requirements

It is crucial that the PWRNDZ bit is de-asserted (made 1 from 0) only after VDDS is stable. The cells support the cases when VDD ramps up before VSUP_18, or when VSUP_18 ramps up before VDD. However, VDDS must come up after both VDD and VSUP_18.

[Figure 7-25](#) and [Figure 7-26](#) show the expected behavior of PWRNDZ bit with regard to supply ramp up. [Figure 7-25](#) shows the case when VDD ramps up before VSUP_18, and [Figure 7-26](#) shows the case when VSUP_18 ramps up before VDD.

Figure 7-25. VDD Ramps Up Before VSUP_18

Figure 7-26. VSUP_18 Ramps Up Before VDD

7.5.2.3 Speed Control and Voltage Supply State

There are two other control bits in the CONTROL.[CONTROL_PBIAS_LITE](#) register:

- SPEEDCTRL bit can be used to reduce dynamic current if fast rise/fall times are not needed.
- SUPPLYHIGH bit signal is used to inform the cell on the value of VDDS signal. (0b0 = 1.8 V and 0b1 = 3.0 V)

7.5.3 OFF Mode Preliminary Settings

The following actions must be performed once, and remain valid for all device OFF <-> ON transitions:

- Program a valid device OFF pads configuration, by setting in each CONTROL.[CONTROL_PADCONF_X](#) registers all OFF mode values bits: OFFPULLTYPESELECT (OFF mode pull type), OFFPULLUDENABLE (OFF mode pull enabling), OFFOUTVALUE (OFF mode output value), OFFOUTENABLE (OFF mode output enabling), OFFENABLE (OFF mode pad state override control) .
- Program a valid device ACTIVE pads configuration by setting pertinent bits in each CONTROL.[CONTROL_PADCONF_X](#) register (see [Section 7.5.4, Pad Configuration Programming Points](#)).
- Perform a device ACTIVE pads configuration saving in the save and restore memory from Wake-up Control Module by asserting the STARTSAVE bit CONTROL.[CONTROL_PADCONF_OFF](#)[1].
- Set the SCM in smart idle mode by setting the IDLEMODE field CONTROL.[CONTROL_SYSCONFIG](#)[4:3] (this will ensure that its clocks can not be cut until the save procedure has completed).
- Enable/disable the wake-up event detection capability of the pads by setting the WAKEUPENABLE bit CONTROL.[CONTROL_PADCONF_X](#).

Note: When the wake-up detection is enabled for a pad, this pad is configured as input. So do not forget to write 0b1 in the OFFOUTENABLE bit CONTROL.[CONTROL_PADCONF_X](#) to disable the output capability.

For further information, see the *Power, Reset and Clock Management* chapter.

7.5.4 Pad Configuration Programming Points

You must be careful to the following points to configure the pad configuration:

- Identify signals required on the interface based on the target application.
Example: You want to configure UART1 interface on balls. The required signals are: uart1_tx, uart1_rts, uart1_cts, and uart1_rx.
- Choose the pads used for those signals. Because some signals could be available on several pads and/or may be multiplexed with other signals that can be need for an other application. Refer to [Section 7.4.4.3, Pad Multiplexing Register Fields](#).
Example: Each UART1 interface signals are available on two pads.
- Identify the pad configuration registers associated to the pads you will use in your application. Refer to [Section 7.4.4.3, Pad Multiplexing Register Fields](#).
Example: With the previous hypothesis the pad configuration registers to program are:
 - uart1_cts: CONTROL.CONTROL_PADCONF_DSS_DATA0[15:0]
 - uart1_rts: CONTROL.CONTROL_PADCONF_DSS_DATA0[31:16]
 - uart1_tx: CONTROL.CONTROL_PADCONF_DSS_DATA6[15:0]
 - uart1_rx: CONTROL.CONTROL_PADCONF_DSS_DATA6[31:16]

Note: In that configuration, dss_datan (where n = 0) signals will not be available on these balls.

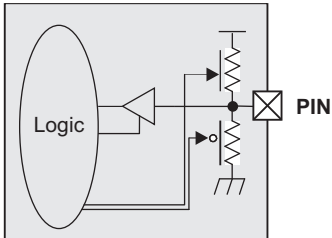

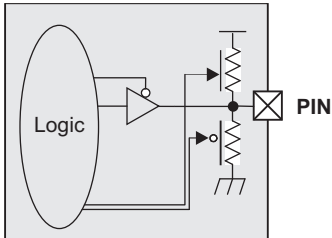

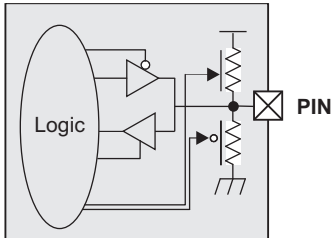

- Configure the MUXMODE field of each pad configuration registers (CONTROL.CONTROL_PADCONF_X) associated to the pads used. [Section 7.4.4.3, Pad Multiplexing Register Fields](#) lists the entire mode available for each pin. Write the binary value of the mode used in the MUXMODE field of the pad configuration registers.
Example: UART1 signals are available in mode 2. So you should write 0b010 in the corresponding MUXMODE field of pad configurations registers to program.
- Configure the pull of the pad when you use it as input. When the pad is used as output the pull is automatically disabled. [Section 7.4.4.3, Pad Multiplexing Register Fields](#) lists the pull available on each pad and it reset value. Set the appropriate value for PULLYPESELECT bit of the pad configuration register to set the pull value (0b0 = Pull Down selected, 0b1 = Pull Up selected) and set the PULLUDENABLE bit of the pad configuration register to enable the pull on the pad (0b0 = pull disabled, 0b1 = pull enabled)
Example: uart1_rts and uart1_tx are output signals, so the pull will be automatically disabled on the pad. uart1_cts and uart1_rx are input signals, so you should configure the pull for these pads:
 - uart1_cts: enable pull-up (write 0b1 in the PULLYPESELECT bit and 0b1 in the PULLUDENABLE bit of the corresponding pad configuration register)
 - uart1_rx: enable pull-down (write 0b0 in the PULLYPESELECT bit and 0b1 in the PULLUDENABLE bit of the corresponding pad configuration register)
- Set the INPUTENABLE bit of the pad configuration register if your pin is use as input.
Example: uart1_rts and uart1_tx are output signals, so clear the INPUTENABLE bit of the corresponding pad configuration register. uart1_cts and uart1_rx are input signals, so set the INPUTENABLE bit of the corresponding pad configuration register.

Note: The order is unimportant for the previous setting of the pad configuration bits.

7.5.5 I/O Power Optimization

In order to optimize I/O power, it is important to avoid unconnected or incorrectly-pulled pins. According to the type of the pins, the way to reduce power consumption is different. [Table 7-76](#) shows the 3 available pin (or ball) types.

Table 7-76. Existing Pin Types

Input	Output	Bidirectional
		

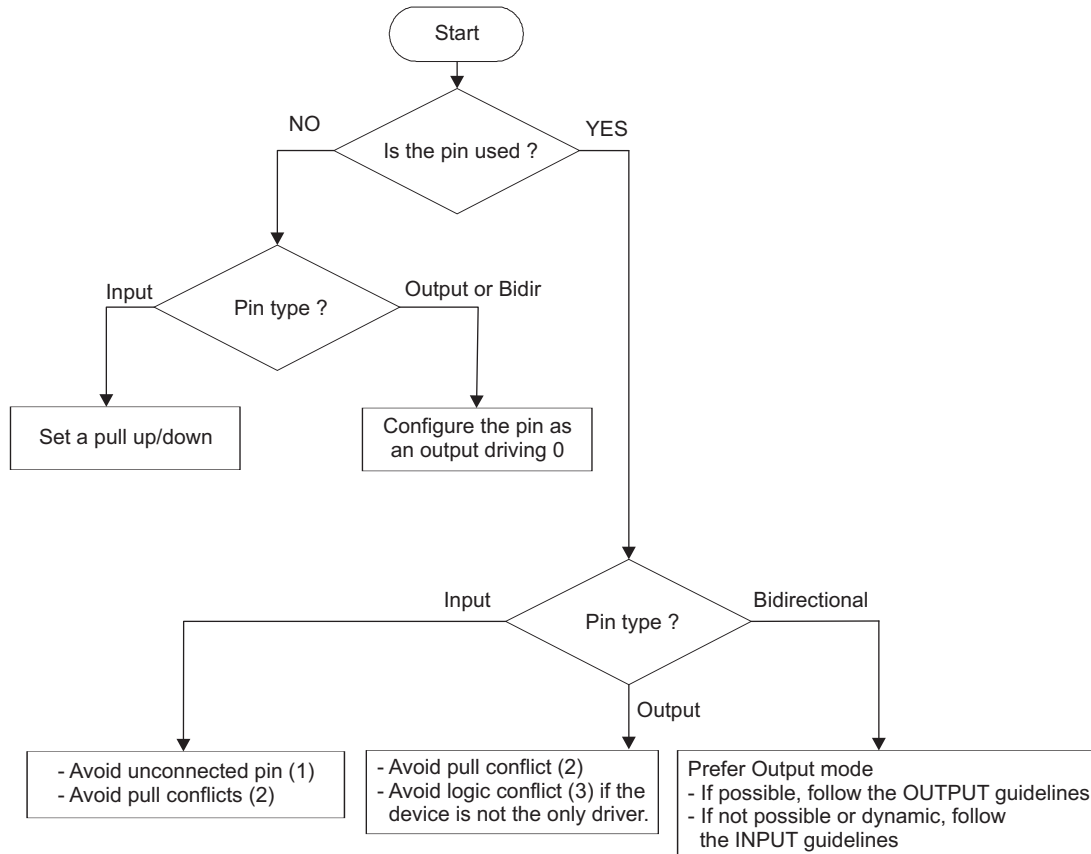

Each pin type requires a specific configuration. The following describes some pieces of advice which can be useful to avoid extra current leakage:

- For input pins, use a pull up/down when possible.
- For output pins, check existing pulls to avoid conflicts.
- For bidirectional pins, reconfigure the pin as an output driving 0 when possible.

Some I/O configurations involve modifications during the software setup of I/Os and sometimes require several hardware updates.

[Figure 7-27](#) resumes how to correctly configure I/Os for power optimization.

Figure 7-27. I/O Power Optimization Flowchart

The following notes give additional explanations about the pin configuration.

1. In order to avoid unconnected pins, the configuration depends on its use:
 - If the pin is not driven externally, a pull up/down is required.
 - Otherwise, a pull up/down is not necessary.
2. Pull conflicts occur when there are different pulls on the same line. In order to correctly configure the pin, avoid external and internal pull together.
3. Logic conflicts consist in different electrical levels at the same time on one line. This can occur when several devices are connected to the same line. The two possible cases are:
 - If no external device drives the line, configure the pin to drive a '0'.
 - If another device drives the line, either the same value has to be driven or the pin has to be disconnected (HZ).

Note: It is advised to use high impedance logical state either on the device or the external component when the line is driven by both components.

The I/O pads are software-controlled by:

- Writing to the CONTROL.CONTROL_PADCONF_X registers in the Control Module for input/output and pull up/down configuration.
- Writing to the GPIOi.GPIO_OE registers in the GPIO module for input/output configuration.

For more information about how to configure the I/O pads, see [Chapter 7](#), *System Control Module*.

For more information about the GPIO module, see the *General-Purpose Interface* chapter.

Note: For a correct configuration of each pin direction (input, output, bidirectional), both the CONTROL.CONTROL_PADCONF_X and the GPIOi.GPIO_OE registers have to be written.

7.6 System Control Module Registers

This section gives information about all modules and features in the high-tier device. See Chapter 1, the *OMAP35x Family* section, to check availability of modules and features. Unavailable module and feature pins are not functional.

Table 7-77 lists the base address and address space for the SCM instances.

Table 7-77. Instance Summary

Module Name	Base Address	Size
INTERFACE	0x4800 2000	36 bytes
PADCONFS	0x4800 2030	564 bytes
GENERAL	0x4800 2270	767 bytes
MEM_WKUP	0x4800 2600	1K byte
PADCONFS_WKUP	0x4800 2A00	80 bytes
GENERAL_WKUP	0x4800 2A60	31 bytes

Some register description tables in this section are divided into different device types and ModeSP according to their access rights and reset value. For example, CONTROL.CONTROL_EXT_SEC_CONTROL is divided into seven tables named "TypeAModeB Bitfield Details" where:

- A can take different expressions depending on the device type:
 - E: EMULATOR device
 - G: General-purpose device
 - T: TEST device
 - S: SECURE device
 - B: BAD device
 - X: DON'T CARE device
 These access rights are enumerated in register descriptions as needed.
- B can take different expressions depending on the mpu mode:
 - SP: SECURE PRIVILEGE mode
 - NSP: NON SECURE PRIVILEGE mode
 - X: DON'T CARE mode

7.6.1 System Control Module Register Mapping Summary

Note: All module registers are 8-, 16-, or 32-bit accessible through the L4 interconnect (little endian encoding).

Table 7-78 lists the INTERFACE registers.

Table 7-78. INTERFACE Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address
CONTROL_REVISION	R	32	0x0000 0000	0x4800 2000
CONTROL_SYSCONFIG	RW	32	0x0000 0010	0x4800 2010

Table 7-79 lists the PADCONFS registers.

Table 7-79. PADCONFS Registers Mapping Summary

7.6.2 INTERFACE Register Descriptions

Table 7-84 through Table 7-84 describe the interface register bits.

7.6.2.1 Control System Configuration Register (CONTROL_SYSCONFIG)

Table 7-84. Control System Configuration Register (CONTROL_SYSCONFIG)

Address Offset	0x10																																
Physical address	0x4800 2010																Instance	INTERFACE															
Description	Set various parameters relative to the Idle mode of the Control module																																
Type	RW																																
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
RESERVED																												IDLEMODE		ENAWAKEUP	SOFTRESET	AUTOIDLE	

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Read returns reset value.	R	0x00000000
4:3	IDLEMODE	Power Management, req/ack control 0x0: Force-idle. An idle request is acknowledged unconditionally 0x1: Reserved 0x2: Smart-idle. Acknowledgement to an idle request is given based on the internal activity of the module 0x3: Reserved	R/W	0x0
2	ENAWAKEUP	Wake-up enable. Not used in the module	R	0x0
1	SOFTRESET	Software reset. Not used in the module	R	0x0
0	AUTOIDLE	Internal interface clock gating strategy 0x0: Interface clock is free-running 0x1: Automatic interface clock gating strategy is applied, based on the interconnect interface activity	R/W	0x0

According to the pad type, some features are configurable or not. [Table 7-85](#) gives the description of a fully configurable pad.

Table 7-85. CONTROL PADCONF X

Address Offset		0x0000 0000 - 0x0000 05C8															
Physical address		See Table 7-79				Instance		SYSC_PADCONFS									
Description		Pad configuration register															
Type		RW															

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bits	Field Name	Description	Type	Reset
31	WAKEUPEVENT1	Pad_x wake-up event status latched in the I/O: 0: No wake-up event occurred 1: A wake-up event occurred	R	0
30	WAKEUPENABLE1	Input pad wake-up enable (and OFF mode input enable value) for pad_x: 0: wake-up detection on low level 1: wake-up detection on high level	R/W	0
29	OFFPULLTYPESELECT1	Off mode Pull-Up/Down selection for pad_x: 0: Pull-Down selected 1: Pull-Up selected	R/W	0
28	OFFPULLUDENABLE1	Off mode Pull-Up/Down enable for pad_x: 0: Pull-Up/Down disabled 1: Pull-Up/Down enabled	R/W	0
27	OFFOUTVALUE1	Off mode pad_x output value	R/W	0
26	OFFOUTENABLE1	Off mode pad_x output enable value: (Warning: This is an active low signal.) 0: output enabled 1: output disabled	R/W	0
25	OFFENABLE1	Off mode pad_x state override control: 0: Off mode disabled 1: Off mode enabled	R/W	0
24	INPUTENABLE1	Input enable value for pad_x	R/W	1
23:21	RESERVED	Reserved	R	0
20	PULLTYPESELECT1	Pull-Up/Down selection for pad_x: 0: Pull-Down selected 1: Pull-Up selected	R/W	Pad dependent
19	PULLUDENABLE1	Pull-Up/Down enable for pad_x: 0: Pull-Up/Down disabled 1: Pull-Up/Down enabled	R/W	Pad dependent
18:16	MUXMODE1	Functional multiplexing selection for pad_x	R/W	Pad dependent

Bits	Field Name	Description	Type	Reset
15	WAKEUPEVENT0	Pad_y wake-up event status latched in the I/O: 0: No wake-up event occurred 1: A wake-up event occurred	R	Pad dependent
14	WAKEUPENABLE0	Input pad wake-up enable (and OFF mode input enable value) for pad_y: 0: wake-up detection on low level 1: wake-up detection on high level	R/W	0
13	OFFPULLTYPESELECT0	Off mode Pull-Up/Down selection for pad_y: 0: Pull-Down selected 1: Pull-Up selected	R/W	0
12	OFFPULLUDENABLE0	Off mode Pull-Up/Down enable for pad_y: 0: Pull-Up/Down disabled 1: Pull-Up/Down enabled	R/W	0
11	OFFOUTVALUE0	Off mode pad_y output value	R/W	0
10	OFFOUTENABLE0	Off mode pad_y output enable value: (Warning: This is an active low signal.) 0: Off mode enabled. 1: Off mode disabled	R/W	0
9	OFFENABLE0	Off mode pad_y state override control: 0: Off mode disabled. 1: Off mode enabled	R/W	0
8	INPUTENABLE0	Input enable value for pad_y	R/W	1
7:5	RESERVED	Reserved	R	0
4	PULLTYPESELECT0	Pull-Up/Down selection for pad_y: 0: Pull-Down selected 1: Pull-Up selected	R/W	Pad dependent
3	PULLUDENABLE0	Pull-Up/Down enable for pad_y: 0: Pull-Up/Down disabled 1: Pull-Up/Down enabled	R/W	Pad dependent
2:0	MUXMODE0	Functional multiplexing selection for pad_y	R/W	Pad dependent

Note: The Bits field gives the field number for the pairs of pads gathered in each register.

[Table 7-86](#) describes the reset values, the capabilities, and the corresponding register for each pad.

Notes:

- All '-' assume that the corresponding bit is not available. These bits are considered as Reserved.
- The reset value for Reserved bits is 0.
- In the MUX Reset States and PU/PD Reset States columns of [Table 7-86](#), a dash (-) indicates that the field is hardwired to logic 0. No corresponding control block ports are implemented for these bits.

Table 7-86. CONTROL_PADCONF_CAPABILITIES

7.6.4 GENERAL Register Descriptions

Table 7-87 through Table 7-360 describe the GENERAL registers bits.

7.6.4.1 CONTROL_PADCONF_OFF

Table 7-87. CONTROL_PADCONF_OFF

Address Offset	0x0000 0000	Instance	GENERAL
Physical address	0x4800 2270		
Description	Off mode pad configuration register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																WKUPCTRLCLOCKDIV		STARTSAVE		FORCEOFFMODEEN											

Bits	Field Name	Description	Type	Reset
31:3	RESERVED	Read returns reset value.	R	0x00000000
2	WKUPCTRLCLOCKDIV	Wkup_ctrl module clock divider 0x0: Clock is divided by 4 0x1: Clock is divided by 2	R/W	0x0
1	STARTSAVE	Start pad configuration registers save mechanism 0x0: Save is not started 0x1: Save is running. This bit is auto-cleared after 8 interface clock cycles.	R/W	0x0
0	FORCEOFFMODEEN	Force OFF mode active 0x0: OFF mode is not forced active 0x1: OFF mode is forced active	R/W	0x0

Bits	Field Name	Description	Type	Reset
31	SECCTRLWRDISABLE	Security Control Register write disable control 0x0: Write in Security Control Register is allowed 0x1: Write in Security Control Register is forbidden	Refer to Table 7-111	0x0
30	SECUREMODEINITDONE	Used by software to indicate complete secure mode initialization 0x0: Secure Mode initialization not done 0x1: Secure Mode initialization done	Refer to Table 7-111	0x0
29:28	CORERAMSECURESAVE	Used for indicating the nature of secure content save 0x0: No secure content saved 0x1: Secure content saved for retention operation 0x2: Secure content saved for Low Iddq operation 0x3: Unused	Refer to Table 7-111	0x0
27:13	RESERVED	Read returns reset value	R	0x00000
12	CPEFUSEDECODEDN	Used for indicating the encoded state of the MSV and CEK 0x0: MSV and CEK Values are BCH decoded 0x1: MSV and CEK Values are not BCH decoded	Refer to Table 7-111	Refer to Table 7-112
11	CPEFUSEWRDISABLE	Used to indicate if it is allowed to write in the SWEV registers 0x0: CUST_EFUSE SWRV write is allowed 0x1: CUST_EFUSE SWRV write is not allowed	Refer to Table 7-111	Refer to Table 7-112
10	CPEFUSEAUTOLOADDONE	Used by software to indicate complete secure mode initialization 0x0: CUST_EFUSE Auto-load currently in progress or not started 0x1: CUST_EFUSE Auto-load is done	Refer to Table 7-111	0x0
9	BSCDISABLED	Control the use of BSC 0x0: BSC is disabled 0x1: BSC is enabled	Refer to Table 7-111	Refer to Table 7-112
8	RESERVED	Read returns reset value	R	0x0
7	DMLSYSTEMENABLE	Control the use of DML module (Direct Memory Load Execute Dump) 0x0: DML is disabled 0x1: DML is enabled	Refer to Table 7-111	Refer to Table 7-112
6	RESERVED	Read returns reset value	R	0x0

Bits	Field Name	Description	Type	Reset
5	OBSERVABILITYDISABLE	Control the observability feature 0x0: Observability can be configured through the ObsMux bit field in CONTROL_DEBOBS register 0x1: Observability is disabled. If pads are configured for the 'hardware debug', output is tied low	Refer to Table 7-111	Refer to Table 7-112
4	RESERVED	Read returns reset value	R	0x0
3	PADCONFACCDISABLE	Control the write access to the pad configuration registers (CONTROL_PADCONF_X) 0x0: Write access is unrestricted 0x1: Write access is allowed only in secure mode	Refer to Table 7-111	0x0
2	SECKEYACCENABLE	Random Key and Customer Key and Test_key eFuse access control in Secure Mode 0x0: Access to C-field and Test_key forbidden in Secure Mode 0x1: Access to C-field and Test_key allowed in Secure Mode	Refer to Table 7-111	Refer to Table 7-112
1	WDREGENABLE	Secure watchdog registers update access control 0x0: Access is never allowed 0x1: Access is allowed only in Secure Mode	Refer to Table 7-111	Refer to Table 7-112
0	WDOPDISABLE	Secure Watchdog operation enable control 0x0: Watchdog timer is running 0x1: Watchdog timer is frozen	Refer to Table 7-111	Refer to Table 7-112

Bits	Field Name	Description	Type	Reset
31:24	RESERVED	Read returns reset value	R	0x0
23	SENSDMAREQ6	Set sensitivity on SYS.nDMAREQ6 input pin 0x0: Level sensitivity 0x1: Edge sensitivity	R/W	0x0
22	SENSDMAREQ5	Set sensitivity on SYS.nDMAREQ5 input pin 0x0: Level sensitivity 0x1: Edge sensitivity	R/W	0x0
21	SENSDMAREQ4	Set sensitivity on SYS.nDMAREQ4 input pin 0x0: Level sensitivity 0x1: Edge sensitivity	R/W	0x0
20	CARKITHSUB0DATA1AUTOEN	Enable force from HSUB0 DATA1 pad configuration MuxMode when CARKITEN is generated: 0x0: HSUB0 DATA1 pad MuxMode is driven by HSUB0 DATA1 pad configuration register. 0x1: HSUB0 DATA1 pad MuxMode is forced to 0x2 when CARKITEN signal is active.	R/W	0x0
19	CARKITHSUB0DATA0AUTOEN	Enable force from HSUB0 DATA0 pad configuration MuxMode when CARKITEN is generated 0x0: HSUB0 DATA0 pad MuxMode is driven by HSUB0 DATA1 pad configuration register 0x1: HSUB0 DATA0 pad MuxMode is forced to 0x2 when CARKITEN signal is active.	R/W	0x0
18	TVOUTBYPASS	Active high enable Dual 10-bit video DAC TV out bypass	R/W	0x0
17:15	RESERVED	Read returns reset value.	R	0x0
14	I2C3HSMASER	Active-high enable of I2C3 IO internal pull-up (used for master component)	R/W	0x0
13	I2C2HSMASER	Active-high enable of I2C2 IO internal pull-up (used for master component)	R/W	0x0
12	I2C1HSMASER	Active-high enable of I2C1 IO internal pull-up (used for master component)	R/W	0x0
11	TVACEN	TV AC coupled load enable for TV output	R/W	0x0
10	RESERVED	Read returns reset value.	R	0x0
9	MPUFORCEWRNP	Force MPU writes to others to be non posted 0x0: Posted writes 0x1: Non posted writes	R/W	0x0
8	SENSDMAREQ3	Set sensitivity on SYS.nDMAREQ3 input pin 0x0: Level sensitivity 0x1: Edge sensitivity	R/W	0x0

Bits	Field Name	Description	Type	Reset
7	SENSDMAREQ2	Set sensitivity on SYS.nDMAREQ2 input pin 0x0: Level sensitivity 0x1: Edge sensitivity	R/W	0x0
6	MMCSPIO2ADPCLKISEL	MMC/SDIO2 Module Input Clock selection 0x0: Input clock is from the external pin 0x1: Internal loop-back; module input clock is copied from the module output clock	R/W	0x0
5	RESERVED	Read returns reset value.	R	0x0
4	MCBSP5_CLKS	Select the CLKS input for the module McBSP5 0x0: CLKS is from the PRCM functional clock 0x1: CLKS is from the external pin McBSP_CLKS	R/W	0x0
3	RESERVED	Read returns reset value.	R	0x0
2	MCBSP4_CLKS	Select the CLKS input for the module McBSP4 0x0: CLKS is from the PRCM functional clock 0x1: CLKS is from the external pin McBSP_CLKS	R/W	0x0
1	RESERVED	Read returns reset value.	R	0x0
0	MCBSP3_CLKS	Select the CLKS input for the module McBSP3 0x0: CLKS is from the PRCM functional clock 0x1: CLKS is from the external pin McBSP_CLKS	R/W	0x0

7.6.5 MEM_WKUP Register Descriptions

0x4800 2600 to 0x4800 29FC physical addresses are memories mapped for save and restore location (1Kbytes).

- 0x4800 2600 - 0x4800 2830: non accessible (pad configuration)
- 0x4800 2834 - 0x4800 29FC: user accessible

7.6.6 PADCONFS_WKUP Register Description

Each 32-bit PADCONF register gathers the configuration of two pads. For example, CONTROL.CONTROL_PADCONF_GPMC_7 is used to configure gpmc_7 pad (bits [15:0]) and gpmc_8 pad (bits [32:16]). See [Figure 7-8](#) for more information about PADCONF registers.

According to the pad type, some features are configurable or not. [Table 7-85](#) gives the description of a fully configurable pad.

[Table 7-361](#) describes the reset values, the capabilities, and the corresponding register for each pad.

Notes:

- All '-' assume that the corresponding bit is not available. These bits are considered as Reserved.
 - The reset value for Reserved bits is 0.
 - In the MUX Reset States and PU/PD Reset States columns of [Table 7-361](#), a dash (-) indicates that the field is hardwired to logic 0. No corresponding control block ports are implemented for these bits.
-

	Removed the CONTROL_SRAMLDO4 register.
	Removed the CONTROL_SRAMLDO5 register.

Memory Management Units (MMUs)

This chapter describes the memory management units (MMUs) for the OMAP35x Applications Processor.

Topic	Page
8.1 MMU Overview	1030
8.2 MMU Integration	1031
8.3 MMU Functional Description	1034
8.4 MMU Basic Programming Model.....	1046
8.5 MMU Registers	1053
8.6 Revision History	1069

8.1 MMU Overview

The OMAP35x device contains three memory management units (MMUs):

- Microprocessor unit (MPU) MMU
- Camera MMU
- Image Video and Audio accelerator (IVA2.2) MMU

The camera MMU and IVA2.2 MMU share the same architecture and are both described in this chapter. The MPU MMU, which implements a different architecture, is covered in the *ARM® Cortex™-A8 Technical Reference Manual* which can be downloaded via the internet at <http://infocenter.arm.com>.

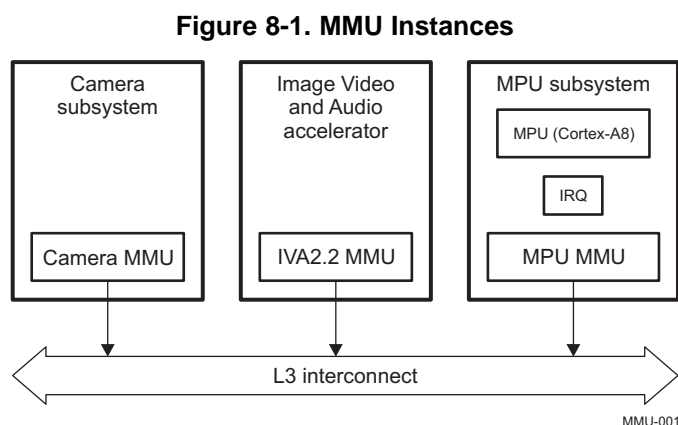

Note: The MMUn prefix provides information about the register instantiation, where n = 1 for the camera MMU, and n = 2 for the IVA2.2 MMU.

The MMU instances include the following main features:

- N entries fully associative translation look-aside buffer (TLB) with N = 8 for the camera MMU and N = 32 for the IVA2.2 MMU
- 1 interrupt line out to the MPU subsystem
- 32-bit virtual addresses, 32-bit physical address
- Mapping size: 4KB and 64KB pages, 1MB section, and 16MB supersection
- Predefined (static) or table-driven (hardware table walker) software translation strategies

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

Figure 8-1 shows the MMU instances in the OMAP35x device.

8.2 MMU Integration

The MMU communicates accesses from the requestor (either the camera subsystem or the IVA2.2) to the L3 main interconnect, performing virtual to physical address translation. The camera MMU is programmed through the L4-core interconnect. The IVA2.2 MMU is programmed through the L3 interconnect. Both MMU error conditions are signaled as interrupts to the system master processor (that is, the MPU).

Figure 8-2 and Figure 8-3 show the system integration of the camera MMU instance and the IVA2.2 MMU instance.

Figure 8-2. Camera MMU System Integration

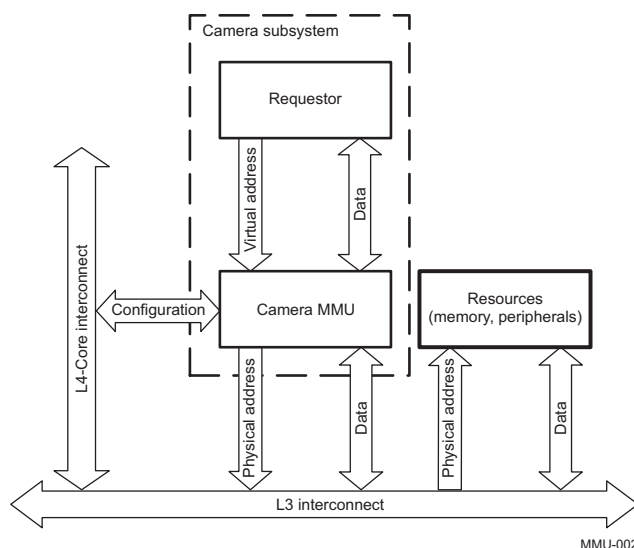

Figure 8-3. IVA2.2 MMU System Integration

8.2.1 Clock Domains

The camera MMU instance has two clock domains: the functional clock domain for the MMU, which is synchronous to the L3 interconnect clock, and the L4 interconnect clock, which is used to configure the MMU instance. Both camera MMU clocks are derived from a common reference clock generated by the power reset and clock management (PRCM) module.

The IVA2.2 MMU instance has only one clock domain: the functional clock domain for the MMU. The IVA MMU clock is generated by the DPLL2 embedded in IVA2.2, but controlled by PRCM registers.

8.2.2 Power Management

The OMAP35x functional units are grouped into power domains. Each power domain is a section of the device with independent and dedicated power rails. Fifteen different power domains exist. For information about OMAP35x power management, see the *Power, Reset, and Clock Management* chapter.

The MMU instances belong to different power domains. [Table 8-1](#) shows the correspondence between the MMU instance and power domains.

Table 8-1. Power Domains of the MMU Instances

MMU Instance	Power Domain
MMU1 (camera MMU)	CAM
MMU2 (IVA2.2 MMU)	IVA2

8.2.2.1 System Power Management

As part of the OMAP35x system-wide power management scheme, each MMU instance supports a communication protocol with the PRCM module that allows the PRCM module to request an MMU instance to enter a low-power state. When the MMU instance acknowledges a low-power mode request from the PRCM module, the clock to the instance is gated off at the PRCM clock generator. Because the clock is disabled at the source, the low-power mode offers lower power consumption than the internal clock gating method in the local power management.

The MMU instance can be configured through the MMUn.MMU_SYSCONFIG[4:3] IDLEMODE field as one of the following acknowledgement modes:

- No-idle mode: The MMU instance never enters the idle state.
- Force-idle mode: The MMU instance immediately enters the idle state after receiving a low-power mode request from the PRCM module. In this mode, the software must ensure that there are no pending interrupts before requesting this mode to go into the idle state; otherwise, an error can occur.
- Smart-idle mode: After receiving a low-power mode request from the PRCM module, the MMU instance enters the idle state only after all interrupts are acknowledged.

[Table 8-2](#) describes the MMU power management modes. For details, see the [MMU_SYSCONFIG](#) register.

Table 8-2. Power Domains of the MMU Instances

Power Management Mode Requested by the PRCM	MMUn.MMU_SYSCONFIG[4:3] IDLEMODE field
Force-idle	00
No-idle	01
Smart-idle	10
Reserved	11

8.2.2.2 Module Power Saving

To conserve power, the MMU instance supports an automatic idle mode whenever activity is not detected on the configuration register port of the MMU instance. The automatic idle mode is enabled or disabled through the MMUn.MMU_SYSCONFIG[0] AUTOIDLE bit.

If the MMUn.MMU_SYSCONFIG[0] AUTOIDLE bit is asserted, the automatic idle mode is enabled when activity is not detected on the configuration register port, and the MMU instance clock is disabled internally to the module, thereby reducing power consumption.

When new activity is detected on the configuration register port, the clock is restarted with no latency penalty. After reset, the automatic idle mode is disabled; therefore, it is recommended to enable the automatic idle mode to reduce power consumption.

8.2.3 Reset

The MMU instances are reset together with their respective reset domains. [Table 8-3](#) shows the correspondence between the MMU instances and the reset domains.

Table 8-3. Reset Domains of the MMU Instances

MMU Instance	Reset Domain
MMU1 (camera MMU)	CAM_RST
MMU2 (IVA2.2 MMU)	IVA_RST2

Software reset is applied when the MMUn.MMU_SYSCONFIG[1] SOFTRESET is set to 1. The MMUn.MMU_SYSSTATUS[0] RESETDONE bit can be polled to know the reset status.

When an MMU instance is released from reset, its TLB is empty and the MMU is disabled.

Note: IVA2.2 MMU can be accessed from the L3 interconnect (configuration registers) even if the DSP is still under reset (IVA_RST1 active).

8.2.4 Interrupts

Each MMU instance can generate an interrupt to the MPU on the occurrence of the following predefined set of events:

- Multi-hit fault
There is more than one TLB entry for the given virtual address.
- Table walk fault
A table walk data read generated an error.
- Emulation miss
A TLB miss was caused by an emulation access.
- Translation fault
No translation is found for the given virtual address. The hardware table walker is enabled but no valid page table entry exists for the requested address.
- TLB miss with table walk disabled
No translation is found in the TLB for the given virtual address and the table walking logic is disabled.

Each of these events can be individually enabled and disabled using the MMUn.MMU_IRQENABLE register. If an event occurs and is enabled, an interrupt is generated to the MPU. The MPU can use the MMUn.MMU_IRQSTATUS register to find the precise cause of the interrupt.

The MMUn.MMU_FAULT_AD register holds the virtual address of the translation that causes the interrupt. The MMUn.MMU_EMU_FAULT_AD indicates the address of the last emulation event causing an MMU interrupt.

[Table 8-4](#) shows the generated interrupt versus the MMU instance.

Table 8-4. Interrupts of the MMU Instances

MMU Instance	MMU Interrupt Name	MMU Interrupt Mapping
MMU1 (camera MMU)	CAM_IRQ0	M_IRQ_24
MMU2 (IVA2.2 MMU)	IVA2_MMU_IRQ	M_IRQ_28

Note: The IVA2_MMU_IRQ (MMU2 instance) interrupt is a dedicated interrupt to the MPU subsystem.
The *Camera Subsystem* and the *IVA2.2 Subsystem* chapters outline details about interrupt generation in the camera and IVA2.2 subsystems. For details about the MPU interrupt scheme, see the *Interrupt Controller* chapter.

8.3 MMU Functional Description

The MMUs handle the translation from virtual into physical addresses. The requestor (either the camera subsystem or the DSP mega cell or the EDMA module for IVA2.2) issues virtual addresses to the respective MMU (MMU1 for the camera subsystem and MMU2 for the IVA2.2). The MMU translates these virtual addresses into physical addresses to access the actual resource (memory) when the MMU instance is enable. That is when MMUn.MMU_CNTL[1] MMUENABLE is set to 1. MMU does not translate the virtual address into physical address when MMU is disabled. When MMUn.CNTL[1].MMUENABLE is cleared to 0, the physical address is the same as the virtual address.

Figure 8-4 shows the relationship between the physical address, the virtual address, and the MMU.

Figure 8-4. MMU Address Translation

8.3.1 MMU Benefits

The MMU offers two major benefits:

- Memory defragmentation: Fragmented physical memory can be translated into contiguous virtual memory without moving data.
- Memory protection: Illegal, that is, non-allowed accesses to memory locations can be detected and prevented.

Figure 8-5 shows two typical MMU use cases.

Figure 8-5. MMU Usage Examples

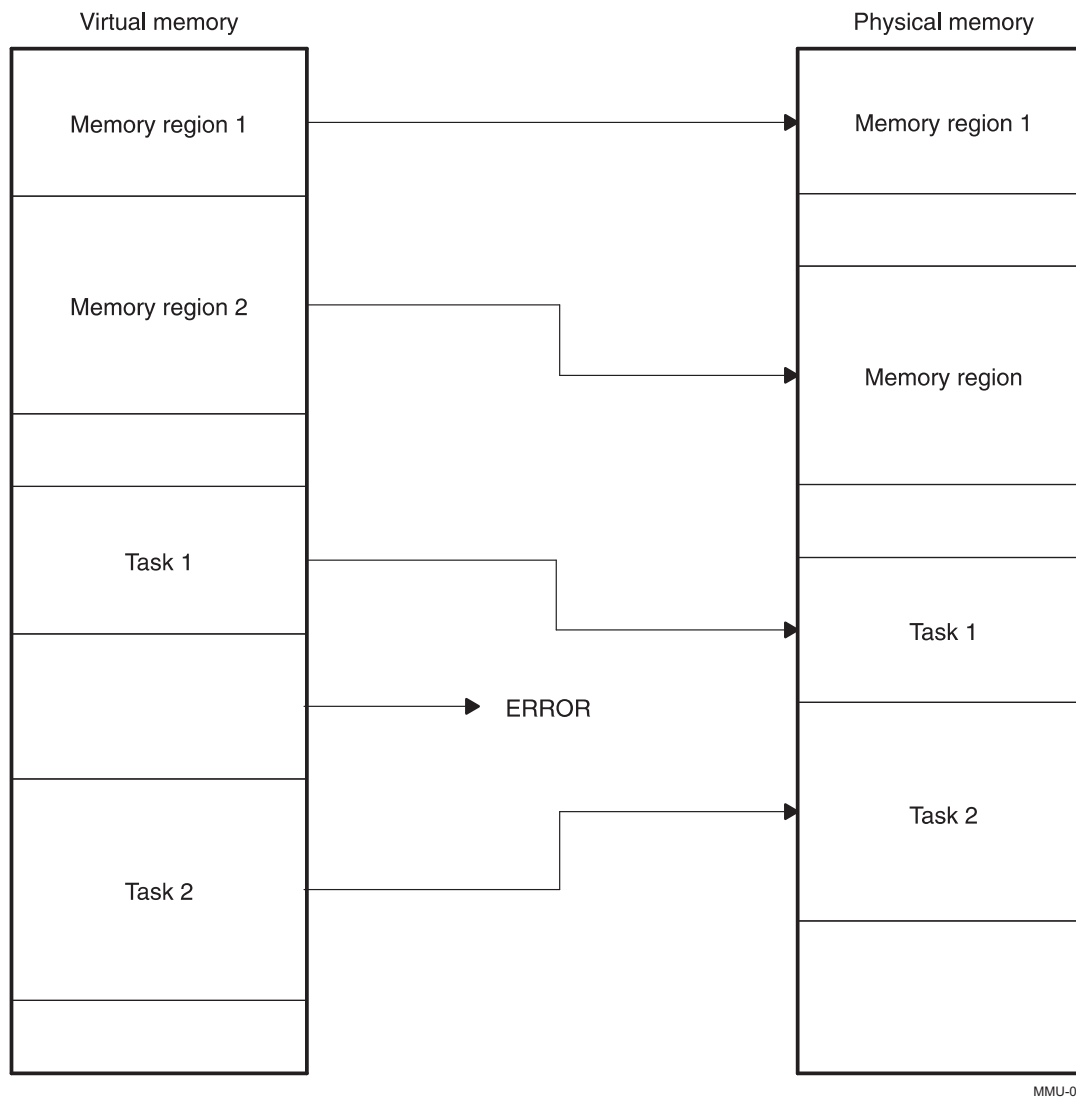

Figure 8-5 shows two benefits of using an MMU. Memory region 1 and memory region 2 are fragmented in physical memory. Using the MMU, they appear as one contiguous memory region in the virtual memory space.

On the other hand, task 1 and task 2 are located adjacent to each other in physical memory. In systems without an MMU, there is a danger that task 1 can accidentally write into the memory area allocated to task 2 and vice versa. Allocating task 1 and task 2 into two separate virtual memory regions prevents this problem, because a region of unmapped memory separates the two tasks. Any erroneous access to this region results in an error that can be detected easily.

8.3.2 MMU Architecture

The MMU translation process is based on translation entries stored in translation tables. One first-level translation table can exist with several optional second-level translation tables.

Each table entry describes the translation of one contiguous memory region. For a description of the structure of these tables, see [Section 8.3.3, Translation Tables](#).

Two major functional units exist in the MMU to provide address translation automatically based on the table entries:

- The table walker automatically retrieves the correct translation table entry for a requested translation. If two-level translation is used (for the translation of small memory pages), the table walker also automatically reads the required second-level translation table entry.
- The TLB stores recently used translation entries, acting like a cache of the translation table.

This basic architecture is outlined in [Figure 8-6](#).

Figure 8-6. MMU Architecture

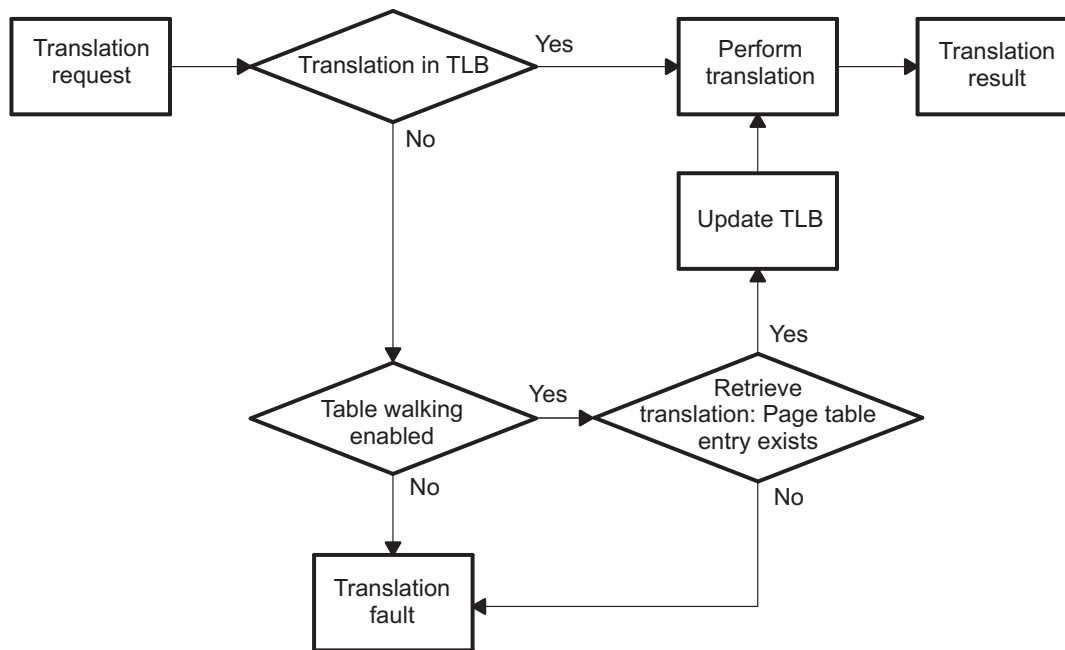

8.3.2.1 MMU Address Translation Process

Whenever an address translation is requested (that is, for every access with the MMU enabled), the MMU first checks whether the translation is already contained in the TLB, which acts like a cache storing recent translations. The TLB can also be programmed manually to ensure that time-critical data can be translated without delay.

If the requested translation is not in the TLB, the table-walking logic retrieves this translation from the translation table(s), and then updates the TLB. The address translation is then performed. [Figure 8-7](#) summarizes the process.

Figure 8-7. Translation Process

MMU-007

8.3.3 Translation Tables

The translation of virtual to physical addresses is based on entries in translation tables that define the following properties:

- Address translation, that is, the correspondence between virtual and physical addresses
- Size of the memory region the entry translates
- Endianness, data access size, and the mixed property of this memory region

The virtual addresses index the translation tables. Each virtual address corresponds to exactly one entry in the translation table.

8.3.3.1 Translation Table Hierarchy

When developing a table-based address translation scheme, one of the most important design parameters is the memory page size described by each translation table entry. MMU instances support 4KB and 64KB pages, a 1MB section, and a 16MB supersection. Using bigger page sizes means a smaller translation table.

Using a smaller page size greatly increases the efficiency of dynamic memory allocation and defragmentation. That is why many operating systems (OSs) can operate on memory blocks as small as 4KB; however, the smaller size implies a more complex table structure.

A quick calculation shows that using 4KB memory pages with one translation table would require one million entries to span the entire 4GB address range. The table itself would be 32MB, a size that is not feasible.

However, using bigger pages greatly reduces the functionality of the OS memory management. Implementing a two-level hierarchy reconciles these two requirements. Within this hierarchy, one first-level translation table describes the translation properties based on 1MB memory regions.

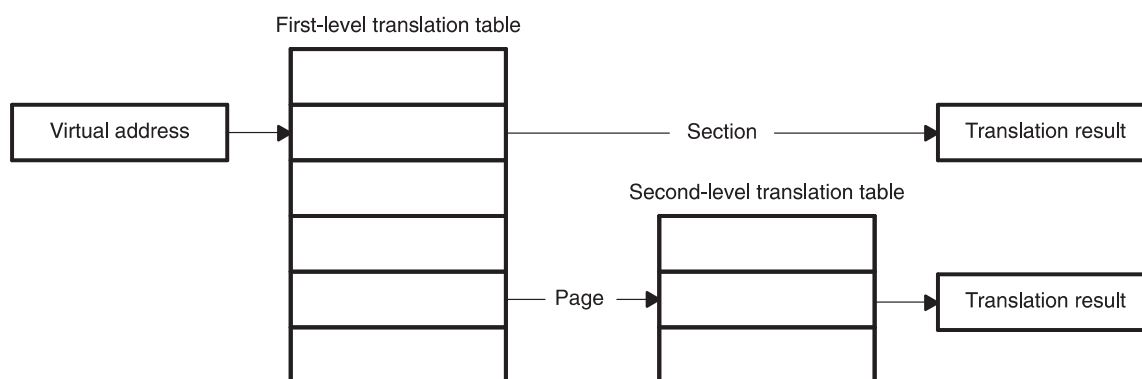

Each of the entries in this first-level translation table can specify the following:

- The translation properties for a big memory section. This memory section can be either 1MB (section) or 16MB (supersection). In this case, all translation parameters are specified in the first-level translation table entry.

- A pointer to a second-level translation table that specifies individual translation properties based on smaller pages within the 1MB page of memory. These pages can be either 64KB (large page) or 4KB (small page). In this case, the actual translation parameters are specified in the second-level translation table entry. The first-level translation table entry specifies only the base address of the second-level translation table.

This hierarchical approach means that additional translation information for smaller pages must be provided only when the pages are actually used. [Figure 8-8](#) shows this hierarchy.

Figure 8-8. Translation Hierarchy

MMU-008

The structure of the first and second-level translation tables and their entries are described in more detail in [Section 8.3.3.2, First-Level Translation Table](#), and [Section 8.3.3.3, Two-Level Translation](#).

8.3.3.2 First-Level Translation Table

The first-level translation table describes the translation properties for 1MB sections. To describe a 4GB address range requires 4096 32-bit entries (so-called first-level descriptors).

The first-level translation table start address must be aligned on a multiple of the table size with a 128-byte minimum. Consequently, an alignment of at least 16K bytes is required for a complete 4096-entry table; that is, at least the last fourteen address bits must be zero.

The start address of the first-level translation table is specified by the so-called translation table base. The table is indexed by the upper 12-bits of the virtual address. This mechanism is shown in [Figure 8-9](#).

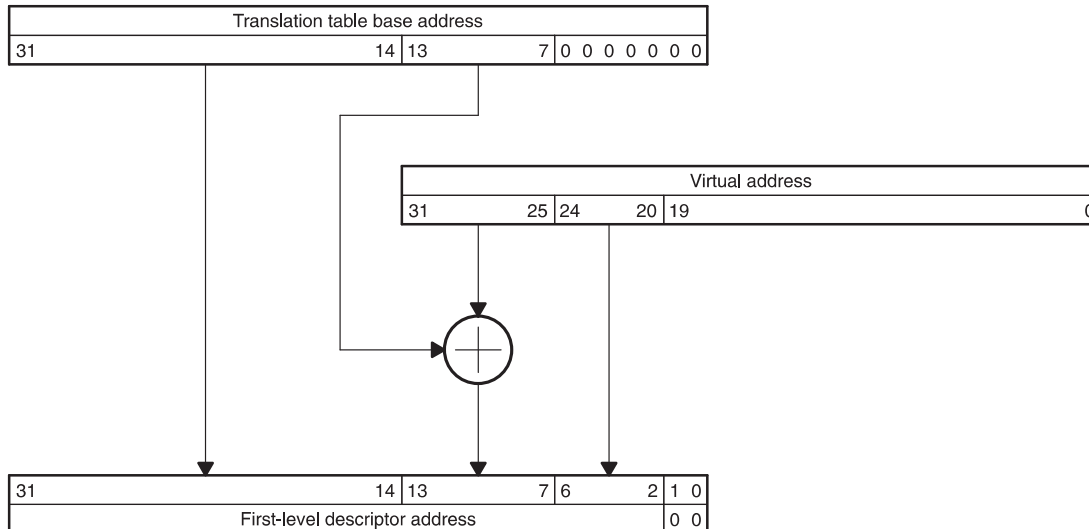

Figure 8-9. First-level Descriptor Address Calculation

MMU-009

To summarize, the translation table base and the translation table index together define the first-level descriptor address. [Figure 8-10](#) outlines the precise mechanism used to calculate this address.

Figure 8-10. Detailed First-level Descriptor Address Calculation

MMU-010

As an example of this mechanism, consider a translation table base address of 0x8000:0000 and a virtual address of 0x1234:5678. In this case, the first-level descriptor address is $0x8000:0000 + (0x123 \ll 2) = 0x8000:048C$.

8.3.3.2.1 First-Level Descriptor Format

Each first-level descriptor provides either the complete address translation for 1MB or 16MB sections or provides a pointer to a second-level translation table for 4KB or 64KB pages. The first-level descriptor format is shown in [Table 8-5](#).

Table 8-5. First-Level Descriptor Format

First-Level Descriptor Format												
31:24	23:20	19	18	17	16	15	14:12	11:10	9:2	1	0	
X										0	0	Fault
Second-Level Translation Table Base Address									X	0	1	Page
Section Base Address	X	0	M	X	E ⁽¹⁾	X	ES	X	X	1	0	Section
Supersection Base Address	X	1	M	X	E	X	ES	X	X	1	0	Supersection
X										1	1	Fault

⁽¹⁾ See [Table 8-32](#) for endianness limitations.

M = Mixed region: 0 = Page-based access-size, 1 = Access-based access-size

E = Endianness: 0 = Little endian, 1 = Big endian (endianness is locked on little endian)

ES = Element Size: 00 = 8-bit, 01 = 16-bit, 10 = 32-bit, 11 = No endianness conversion

X = Don't care

8.3.3.2.2 First-Level Page Descriptor Format

If a translation granularity smaller than 1MB is required, a two-level translation process is used. In this case, the first-level block descriptor specifies only the start address of a second-level translation table. The second-level translation table entries specify the actual translation properties.

8.3.3.2.3 First-Level Section Descriptor Format

Each section descriptor in the first-level translation table specifies the complete translation properties for a 1MB section or a 16MB supersection.

Note: Supersection descriptors must be repeated 16 times, because each descriptor in the first-level translation table describes 1MB of memory. If an access points to a descriptor which is not initialized, MMU will behave in an unpredictable way.

In addition to the address translation itself, three parameters are specified in the section descriptors:

- **Endianness**
The *endianness* parameter specifies whether the memory section uses a big- or little-endian data format. This parameter is locked to little endian. See [Table 8-32](#) for more information.
- **Element size**
The *element size* parameter can optionally specify the data access size (8, 16, or 32 bits) for all data items in the defined section.
- **Mixed region**
The *mixed region* parameter specifies whether the information about the data access size is detected from the access itself (access-based detection) or if the specified element size parameter is used (page-based detection). For example, the specified element size parameter can be used when several smaller sized accesses are packed into a bigger sized access, such as two 16-bit accesses packed into one 32-bit access. In this case, with no specified data access size, 32 bits would be the access size detected, leading to an incorrect result. To avoid this problem, specify the data access size for the memory section.

8.3.3.2.4 Section Translation Summary

Sections and supersections can be translated based solely on the information in the first-level translation table. [Figure 8-11](#) summarizes the address translation process for a section.

Figure 8-11. Section Translation Summary

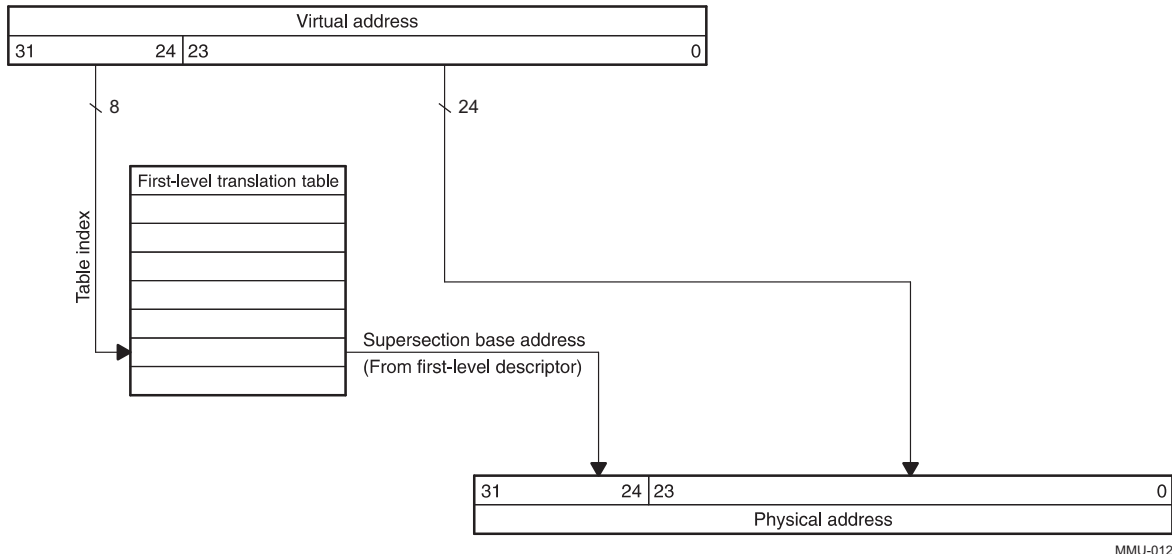

MMU-011

8.3.3.2.5 Supersection Translation Summary

The translation of a supersection is similar to the translation of a section. The difference is that for a supersection only bits 31 to 24 index into the first-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a supersection.

[Figure 8-12](#) shows the translation mechanism for a supersection.

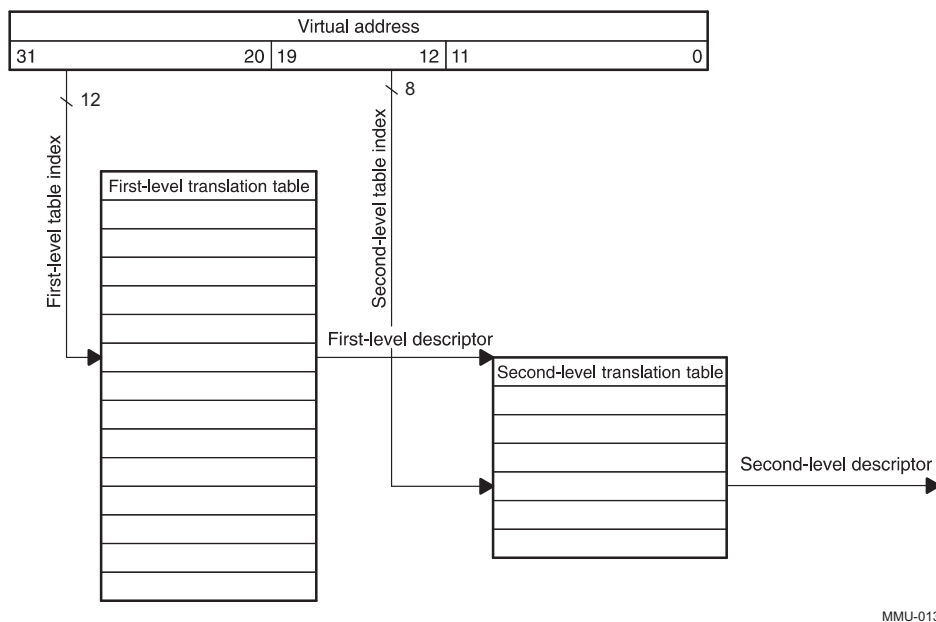

Figure 8-12. Supersection Translation Summary

8.3.3.3 Two-Level Translation

Two-level translation is used when fine-grain granularity is required, that is when memory sections smaller than 1MB are needed. In this case, the first-level descriptor provides a pointer to the base address of a second-level translation table. This second-level table is indexed by bits 19 to 12 of the virtual address. [Figure 8-13](#) shows this indexing mechanism.

Figure 8-13. Two-Level Translation

Each second-level translation table describes the translation of 1MB of address space in pages of 64KB (large page) or 4KB (small page). It consists of 256 second-level descriptors describing 4KB each.

Note: In the case of a large page, the same descriptor must be repeated 16 times. If an access points to a descriptor which is not initialized, MMU will behave in an unpredictable way.

8.3.3.3.1 Second-Level Descriptor Format

Similar to first-level section descriptors, second-level descriptors provide all of the necessary information for the translation of a large or small page. Table 8-6 shows the format of second-level descriptors. The translation parameters (endianness, element size, and mixed region) have the same meaning as those for sections.

Table 8-6. Second-Level Descriptor Format

Second-Level Descriptor Format										
31:16	15:12	11	10	9	8:6	5:4	3:2	1	0	
X									0	0
Large Page Base Address	X	M	X	E ⁽¹⁾	X	ES	X	0	1	Large Page
Small Page Base Address		M	X	E	X	ES	X	1	X	Small Page

⁽¹⁾ See Table 8-32 for endianness limitations.

M = Mixed region: 0 = Page-based access-size, 1 = Access-based access-Fsize

E = Endianness: 0 = Little-endian, 1 = Big-endian (endianness is locked on little endian)

ES = Element Size: 00 = 8-bit, 01 = 16-bit, 10 = 32-bit, 11 = No endianness conversion

X = Don't care

8.3.3.3.2 Small Page Translation Summary

Figure 8-14 summarizes the translation process for small pages.

Figure 8-14. Small Page Translation Summary

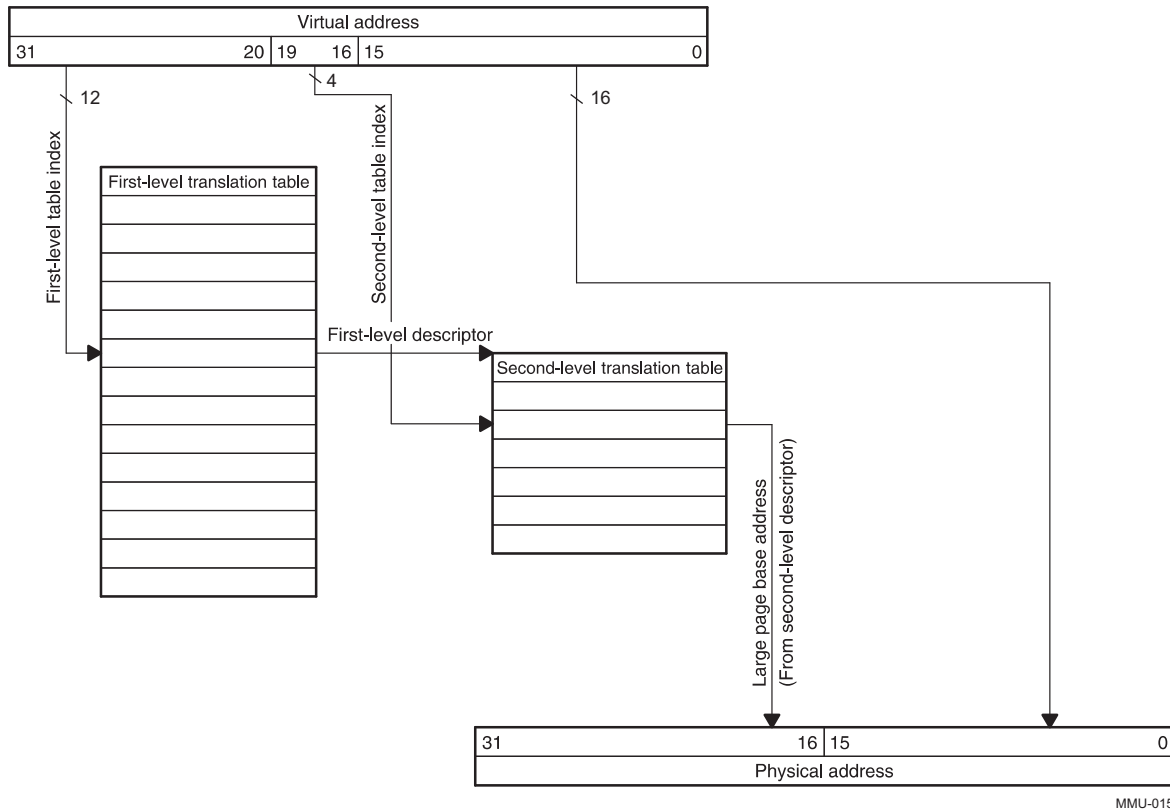

MMU-014

8.3.3.3.3 Large Page Translation Summary

The translation of a large page is similar to the translation of a small page. The difference is that, for a large page, only bits 19 to 16 index into the second-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a large page. This is shown in [Figure 8-15](#).

Figure 8-15. Large Page Translation Summary

MMU-015

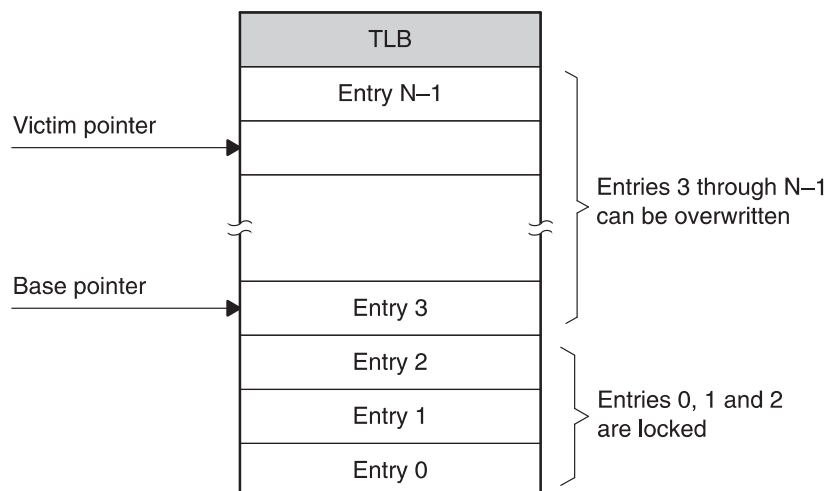

8.3.4 Translation Lookaside Buffer

Translating virtual to physical addresses is required for each memory access in systems using an MMU. To accelerate this translation process, a cache, or TLB, holds the result of recent translations.

For every translation, the MMU internal logic first checks whether the requested translation is already cached in the TLB. If the translation is cached, this translation is used; otherwise the translation is retrieved from the translation tables and the TLB is updated. If the TLB is full, one of its entries must be replaced. This entry is selected on a random basis.

The first n TLB entries, where $n < \text{Total Number } N \text{ of TLB Entries}$, can be protected (locked) against being overwritten by setting the TLB base pointer to n . When this mechanism is used, only unprotected entries can be overwritten. The victim pointer indicates the next TLB entry to be written. [Figure 8-16](#) shows an example of TLB with N TLB entries (ranging from 0 to $N-1$). The base pointer contains the value "3" protecting Entry 0, Entry 1, and Entry 2 and the victim pointer points to the next TLB entry to be updated.

Note: The last TLB entry (Entry $N-1$, where $N = 8$ for the camera MMU and $N = 32$ for the IVA2.2 MMU) always remains unprotected.

Figure 8-16. TLB Entry Lock Mechanism

MMU-016

The table walking logic automatically writes the TLB entries. The entries can also be manually written, which is done typically to ensure that the translation of time-critical data accesses is already present in the TLB so that they execute as fast as possible. The entries must be locked to prevent them from being overwritten.

8.3.4.1 TLB Entry Format

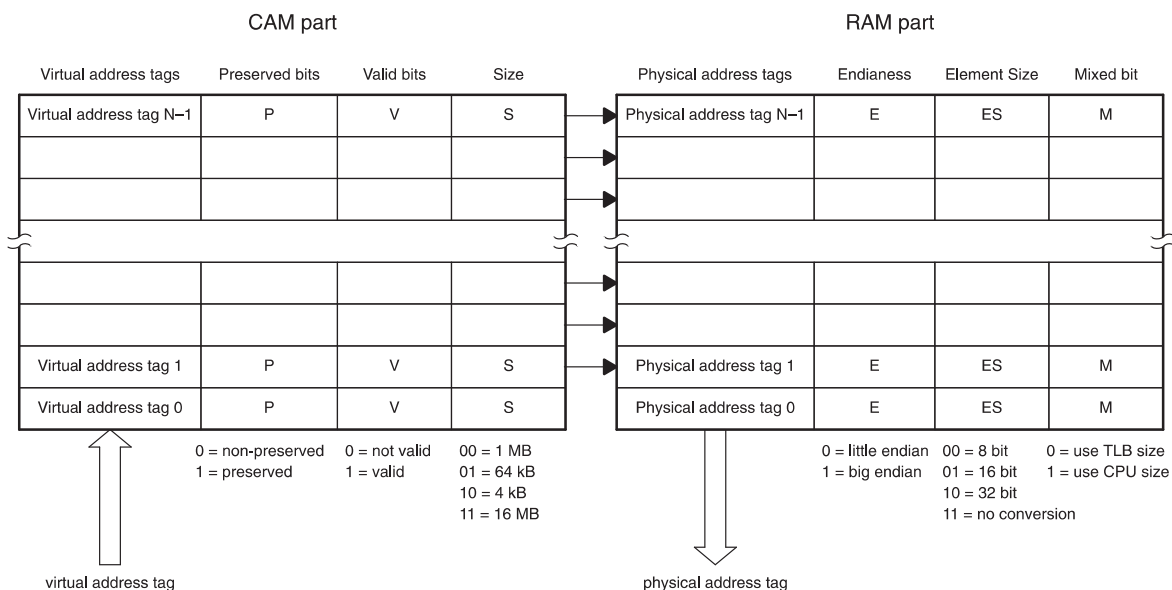

TLB entries consist of two parts:

- The CAM part contains the virtual address tag used to determine if a virtual address translation is in the TLB. The TLB acts like a fully associative cache addressed by the virtual address tag. The CAM part also contains the section/page size, as well as the preserved and the valid parameters. See the [MMU_CAM](#) register table for more details.
- The RAM part contains the address translation that belongs to the virtual address tag as well as the endianness, element size, and mixed parameters described in [Section 8.3.3.2](#). See the [MMU_RAM](#) register table for more details.

The valid parameter specifies whether an entry is valid or not. The preserved parameter determines the behavior of an entry in the event of a TLB flush. If an entry is set as preserved, it is not deleted when a TLB is flushed, that is when [MMU_GFLUSH\[0\]](#) GLOBALFLUSH is set to 1. Preserved entries must be deleted manually. [Section 8.3.3.2](#) describes the procedure to delete TLB entries.

[Figure 8-17](#) shows the TLB entry structure.

Figure 8-17. TLB Entry Structure

MMU-017

8.3.5 MMU Error Handling

The following types of faults can occur:

- **TLB miss with table walker disabled**
No translation is found for the virtual address required. If the hardware table walker is disabled, a fault is generated.
- **Translation fault**
No translation is found for the virtual address required (TLB miss). The table walker is enabled but a page table entry does not exist for the given virtual address.
- **Table walk fault**
A table walk results in a memory read error.
- **Multi-hit fault**
More than one valid entry exists in the TLB for the given virtual address.

When a fault occurs and its corresponding interrupt is enabled, an interrupt is signaled to the MPU. The interrupt service routine (ISR) is then responsible for fault recovery. The requestor is stalled by the MMU while the fault is handled. For example, for a TLB miss, the ISR might load the missing entry into the TLB.

The ISR can determine the cause of the fault interrupt by reading the MMU's [MMU_IRQSTATUS](#) register. The virtual address that caused the fault can be determined by reading the MMU's [MMU_FAULT_AD](#) register.

In the case of a TLB miss, the MMU continues servicing the request as soon as a valid TLB entry is written. In the case of a translation fault, table walk fault, or multi-hit fault, the ISR first addresses the cause of the fault and then releases the MMU by writing to the interrupt status register. The MMU then continues servicing the request.

8.3.6 MMU Instance Design Parameters

The various MMU instances have different design parameters, most notably the size of the virtual address space and the number of TLB entries. [Table 8-7](#) shows the correspondence between the MMU instances and the design parameters.

Table 8-7. Design Parameters of the MMU Instances

MMU Instance	Virtual Address Space	TLB Entries
MMU1 (camera MMU)	4GB	8 entries
MMU2 (IVA2.2 MMU)	4GB	32 entries

8.4 MMU Basic Programming Model

MMU instances handle translation from virtual into physical addresses. Virtual addresses are issued by the Camera or the IVA2.2 subsystems to the MMU, which converts them into physical addresses. These physical addresses correspond to actual memory resource. Refer to the *Memory Mapping* chapter for more information on the device memory mapping.

MMU instances can be used dynamically or statically, in other words, MMU can be managed by the MPU software or configured directly.

An MMU is configured dynamically when a software subroutine writes translation tables into the appropriate physical memory space. Translation tables are most likely stored in external SDRAM. They are automatically written by the MPU OS (symbian, Linux,...). Operating System may limit the memory section size to page or sections. A MPU memory management software treats all information concerning addressing. Sub-set tables can be copied into external SDRAM to automatically create a given MMU translation table. Features such as mixed region, endianness, element size are then overwritten in SDRAM to match one's need and customize Camera or IVA2.2 subsystems' need (8-bit exchange in little-endian format for example). Note that 16MB sections and 64KB page table entries must be duplicated 16 times with the same content in translation tables. This process avoids a second read operation when an access points to another element than first one in the table. If they are not copied the MMU will behave in an unpredictable way.

When an MMU is configured statically, translation tables are not used, and TLB entries are written directly by the programmer.

[Figure 8-18](#) shows the configuration strategies: static, dynamic and mixed use of MMU.

Figure 8-18. MMU Configuration Strategies

MMU-018

MMU components must be set up before the MMU can be used for address translation. The following steps are required:

- Initialize translation tables and the table walker logic if translation tables are used.
- Write TLB entries if required.
- Enable MMU.

Next paragraph explains how to configure the IVA2.2 MMU by directly writing the entries in the Translation Look-aside Buffer (TLB). The focus of this example is to explain the required configuration steps rather than to provide the most efficient implementation.

8.4.1 Writing TLB Entries Statically

This example deals with predefined translation strategy, that is, entries are “statically” written in the TLB.

This method avoids the need to write Translation tables in memory and is commonly used for relatively small address spaces. It ensures that the translation of time-critical data accesses execute as fast as possible with entries already present in the TLB. These entries must be locked to prevent them from being overwritten. To setup the MMU follow those steps:

1. Reset MMU: write `MMU_SYSCONFIG[1] SOFTRESET=1` and wait for the system reset completion by polling `MMU_SYSSTATUS[0] RESETDONE` until it is equal to 1.
2. Set `MMU_SYSCONFIG[0] AUTOIDLE` bit to enable power saving via automatic interface clock gating. After reset the Table walking logic remain disabled (`MMU_CNTL[2] TWLENABLE=0`), the TLB is empty and the victim pointer points to the first TLB entry, Entry 0 (`MMU_LOCK[8:4] CURRENTVICTIM` at 0). To initialize a TLB entry, follow those steps:
 3. Load the Virtual Address (VATAG), the preserved (P=1) and valid (V=1) bits and the page size (small or large page, section, supersection) into `MMU_CAM` register.
 4. Load the Physical Address (PHYSICALADDRESS), the endianness (ENDIANNESS=0), element size

- (ELEMENTSIZE) and mixed page attributes bits (MIXED) into [MMU_RAM](#) register.
5. Specify the TLB entry you want to write by setting the [MMU_LOCK\[8:4\]](#) CURRENTVICTIM pointer. Start with TLB Entry 0 and increment this pointer for each subsequent entry you want to write.
 6. Load the specified entry in the TLB by setting [MMU_LD_TLB\[0\]](#) LDTLBITEM=1.
 7. Repeat steps 3 to 6 for all entries you want to write.
Remember to increment the [MMU_LOCK\[8:4\]](#) CURRENTVICTIM pointer with each entry you are writing. To prevent replacement of TLB entries see [Section 8.4.1.1](#), Protecting TLB Entries.
To enable error handling when more than one valid entry exists in the TLB for the given virtual address or when no translation is found for the virtual address required (with the Table walking logic disabled):
 8. Enable Multi-hit fault and TLB miss with table walker disabled interrupts by writing 1 in [MMU_IRQENABLE\[4\]](#) MULTIHITFAULT and [MMU_IRQENABLE\[0\]](#) TLBMISS.
 9. To determine the cause of the fault interrupt the interrupt service routine (ISR) can read corresponding [MMU_IRQSTATUS](#) bits. The virtual address that caused the fault can be determined by reading [MMU_FAULT_AD](#).

Note: MMU errors result in a memory stall; the MMU will not process any request until the cause of the error has been addressed.

To enable memory translations enable MMU (virtual addresses are treated as physical addresses when MMU is disabled):

10. Set [MMU_CNTL\[1\]](#) MMUENABLE=1 to enable memory translations enable the MMU (virtual addresses are treated as physical addresses when the MMU is disabled).

8.4.1.1 Protecting TLB Entries

The first n TLB entries (with $n <$ total number of TLB entries) can be protected from being overwritten with new translations. This is useful to ensure that certain commonly used or time-critical translations are always in the TLB and do not require retrieval via the table walking process.

The entry protection mechanism is shown in [Figure 8-16](#). To protect the first n TLB entries, set the [MMU1.MMU_LOCK\[12:10\]](#) BASEVALUE field for the camera MMU ([MMU2.MMU_LOCK\[14:10\]](#) BASEVALUE field for the IVA2.2 MMU) to n .

8.4.1.2 Deleting TLB Entries

Two mechanisms exist to delete TLB entries. All unpreserved TLB entries, i.e., TLB entries that were written with the preserved bit set to zero, can be deleted by invoking a TLB flush. Such a TLB flush is invoked by setting the [MMUn.MMU_GFLUSH\[0\]](#) GLOBALFLUSH bit.

Individual TLB entries can be flushed, regardless of the preserved bit setting, by specifying its virtual address in the [MMUn.MMU_CAM](#) register and setting the [MMUn.MMU_FLUSH_ENTRY\[0\]](#) FLUSHENTRY bit.

The preserved bit should only be used on protected TLB entries, as it does not prevent replacement by the table walking logic.

8.4.1.3 Reading TLB Entries

TLB entries can be read by you to determine the TLB content at runtime. In doing so, the TLB entry number is specified by setting the [MMUn.MMU_LOCK\[8:4\]](#) CURRENTVICTIM pointer. CAM and RAM parts of the TLB entry can then be read in the [MMUn.MMU_READ_CAM](#) and [MMUn.MMU_READ_RAM](#) registers, respectively.

8.4.2 Programming the MMU Dynamically

When translation tables are used for MMU address translation they must be properly set up and the table walking logic must be enabled.

The following page sizes are supported:

- Supersection: 16M bytes
- Section: 1M bytes
- Large page: 64K bytes
- Small page: 4K bytes

The memory location of these sections or pages (the Physical Address) is found by reading the Translation Table Hierarchy using a combination of the Virtual Address and the Translation Table Base address. [Figure 8-19](#) illustrates the MMUn translation table hierarchy, with first-level descriptors (L1D) and second-level descriptors (L2D).

Figure 8-19. MMUn Translation Table Hierarchy

MMU-019

The first step is to build translation tables (first- and second-level translation tables depending on translation strategy) and place them into memory.

The start address of translation tables must always be aligned according to their size. For example, a 4096-entry first-level translation table must be aligned on a 16KB boundary (4096 Entries * 4 bytes = 16KB), that is, the lower 14 bits of the translation table start address (MMUn.MMU_TTB[13:0]) must be zero. For more details see [Section 8.3.3.2](#).

After the translation tables have been written to memory the translation table base address, i.e. the most significant bits of the first-level translation table start address must be set. This is done using the MMUn.MMU_TTB[31:7] TTBADDRESS field. See [Section 8.5](#) for a complete description of the MMU control registers.

Once the translation tables have been written to memory and the translation table base is set, the table walking logic can be enabled. This is done by setting the MMUn.MMU_CNTL[2] TWLENABLE bit.

8.4.2.1 Programming the MMU Using First- and Second-Level Translation Tables

Translation tables must be setup and written in memory. Each TLB entry contains a memory page size: 1MB section or 16MB supersection. When page size is smaller, 4KB or 64KB, second-level translation tables are necessary. To setup the MMU follow the same steps as in previous example but write the first- and second-level descriptors in physical memory.

The first-level translation table describes the translation properties for 1MB sections. 4096 32-bit entries (so-called first-level descriptors) are required to describe a 4GB address range with 1MB sections. The first-level translation table start address must be aligned on a multiple of the table size with a 128-byte minimum. Consequently, an alignment of at least 16K bytes is required for a complete 4096-entry table, that is, at least the last 14 address bits must be zero. The start address of the first-level translation table is specified by the so-called translation table base. The table is indexed by the upper 12-bits of the virtual address. [Figure 8-20](#) through [Figure 8-23](#) shows how the physical address is built from the virtual address as a function of the page sizes and hierarchy.

8.5 MMU Registers

The MMU1 (camera ISP MMU) and MMU2 (IVA2.2 MMU) instances are programmed using two identical sets of configuration registers. [Table 8-8](#) lists the base address of each register set.

Table 8-8. MMU Instance Summary

MMU Instance	Base Address	Size
MMU1 (Camera ISP MMU)	0x480B D400	256 bytes
MMU2 (IVA2.2 MMU)	0x5D00 0000	256 bytes

Note: The MPU MMU is configured using register CP15. For more information, please download the *ARM® Cortex™-A8 Technical Reference Manual* via the internet at <http://infocenter.arm.com>.

8.5.1 MMU Register Mapping Summary

Each MMU instance (except the MPU MMU) is programmed using a set of 18 configuration registers. [Table 8-9](#) lists these registers and their access type, access size, and offset against their respective base address.

Note: The registers and their bit fields in this set are identical for the two instances except the MMUn.MMU_LOCK register, which has bit fields for the MMU1 (camera ISP MMU) that are different from the MMU2 (IVA2.2 MMU).

CAUTION

MMU2 instance (IVA2.2 MMU) registers are limited to 32-bit data accesses. Data access of 16-bit and 8-bit are not allowed and can corrupt register content.

Table 8-9. MMU Register Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	MMU1 (Camera MMU) Physical Address	MMU2 (IVA2.2 MMU) Physical Address
MMU_SYSCONFIG	RW	32	0x10	0x480B D400	0x5D00 0010
MMU_SYSSTATUS	R	32	0x14	0x480B D414	0x5D00 0014
MMU_IRQSTATUS	RW	32	0x18	0x480B D418	0x5D00 0018
MMU_IRQENABLE	RW	32	0x1C	0x480B D41C	0x5D00 001C
MMU_WALKING_ST	R	32	0x40	0x480B D440	0x5D00 0040
MMU_CNTL	RW	32	0x44	0x480B D444	0x5D00 0044

System Direct Memory Access (SDMA)

This chapter describes the system direct memory access (SDMA) of the OMAP35x Applications Processor.

Note: This chapter gives information about all modules and features in the high-tier device. See Chapter 1, the *OMAP35x Family* section, to check availability of modules and features. Ensure that DMA requests of unavailable modules and features are masked in DMA subsystems.

9.8 Revision History	1141

9.1 SDMA Module Overview

The System Direct Memory Access (SDMA), also called DMA4, performs high-performance data transfers between memories and peripheral devices without microprocessor unit (MPU) support during transfer. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

The device also embeds dedicated DMA controllers: the camera image signal processor (ISP) DMA; the enhanced DMA (EDMA), which is embedded in the IVA2.2 subsystem; the display DMA; and the universal serial bus (USB) high-speed (HS) DMA. For more information, see *Camera ISP Subsystem*, *IVA Subsystem*, *Display Subsystem*, and *High-Speed USB Controllers* chapters.

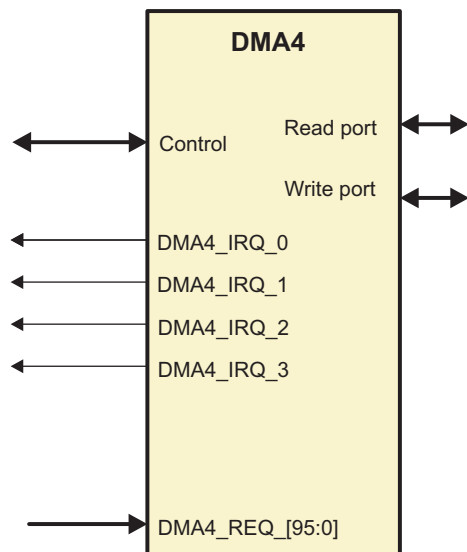

The DMA controller includes the following main features:

- Data transfer support in either direction between:
 - Memory and memory
 - Memory and peripheral device
- 32 logical DMA channels supporting:
 - Multiple concurrent transfers
 - Independent transfer profile for each channel
 - 8-bit, 16-bit, or 32-bit data element transfer size
 - Software-triggered or hardware-synchronized transfers
 - Flexible source and destination address generation
 - Burst read and write
 - Chained multiple-channel transfers
 - Endianism conversion
 - Per-channel secure transaction attribute (not available on GP device)
- First-come, first-serve DMA scheduling with fixed priority
- Up to 96 DMA requests
- Constant fill
- Transparent copy
- Four programmable interrupt request output lines
- Software or hardware enabling
- FIFO depth: 256 x 32-bits
- Data buffering
- FIFO budget allocation
- Power-management support
- Auto-idle power-saving support
- Implementation of retention flip-flops (RFFs) to support dynamic power saving (DPS) between system power modes without MPU involvement
- Initiators for secure transactions on the L3 and L4 interconnect (not available on GP device)

Note: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

Figure 9-1 shows an overview of the SDMA module.

Figure 9-1. SDMA Overview

108-001

The SDMA module has two ports—one read and one write—and provides multiple logical channel support. A dynamically allocated FIFO queue memory pool provides buffering between the read and write ports.

The MPU configures the SDMA through the L4 interconnect.

9.2 SDMA Controller Environment

9.2.1 Environment Overview

The read and write ports of the SDMA controller are connected to the device through the L3 interconnect. The control port is connected to the L4 interconnect. The SDMA interrupt lines are connected to the interrupt lines of the MPU interrupt controller. The SDMA can handle up to 96 DMA requests, including four external hardware DMA requests.

9.2.2 SDMA Request Scheme

The hardware DMA request line schemes can be either edge-sensitive or transition-sensitive.

The sensitivity selection of the DMA request line can be configured in the system control module with the following register bits:

- CONTROL.CONTROL_DEVCONF0[0] SENSDMAREQ0 register bit for sys_ndmareq0
- CONTROL.CONTROL_DEVCONF0[1] SENSDMAREQ1 register bit for sys_ndmareq1
- CONTROL.CONTROL_DEVCONF1[7] SENSDMAREQ2 register bit for sys_ndmareq2
- CONTROL.CONTROL_DEVCONF1[8] SENSDMAREQ3 register bit for sys_ndmareq3

The default scheme is transition sensitive. All internal peripherals of the device use the transition-sensitive scheme.

Figure 9-2 shows the DMA request captured on a falling edge in the edge-sensitive scheme.

Figure 9-2. Edge-Sensitive DMA Request Scheme

108-013

For a transition-sensitive DMA request (see Figure 9-3), the line must be maintained low (asserted) until the first DMA access is complete, after which the line must be maintained high (de-asserted) for a minimum of one clock cycle (CORE_L3_ICLK):

When the de-assertion time is less than one clock cycle, the SDMA might not detect the de-assertion.

When the channel is enabled one cycle after a DMA request is disabled, the channel detects the DMA request and starts the corresponding transfer.

When the channel is enabled two cycles after the DMA request is disabled, the channel does not detect the DMA request.

Figure 9-3. Transition-Sensitive DMA Request Scheme

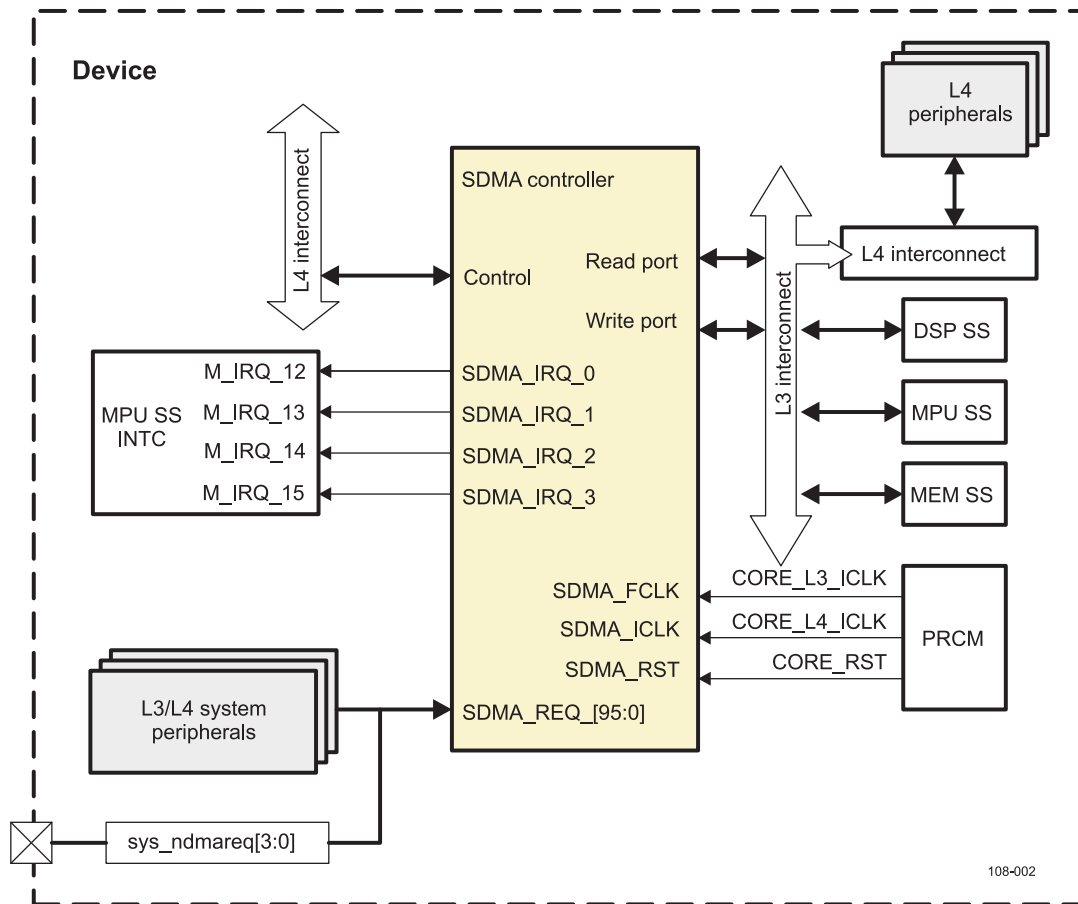

108-012

9.3 SDMA Module Integration

Figure 9-4 highlights the SDMA controller integration.

Figure 9-4. SDMA Controller Integration

9.3.1 External SDMA Request Interface Description

The sys_ndmareq pins are optional external DMA requests used by external devices to establish direct hardware synchronization with the SDMA controller. A logical channel can be configured to respond to an external synchronization request. These requests can be configured to either active low on level or falling edge active by the control module.

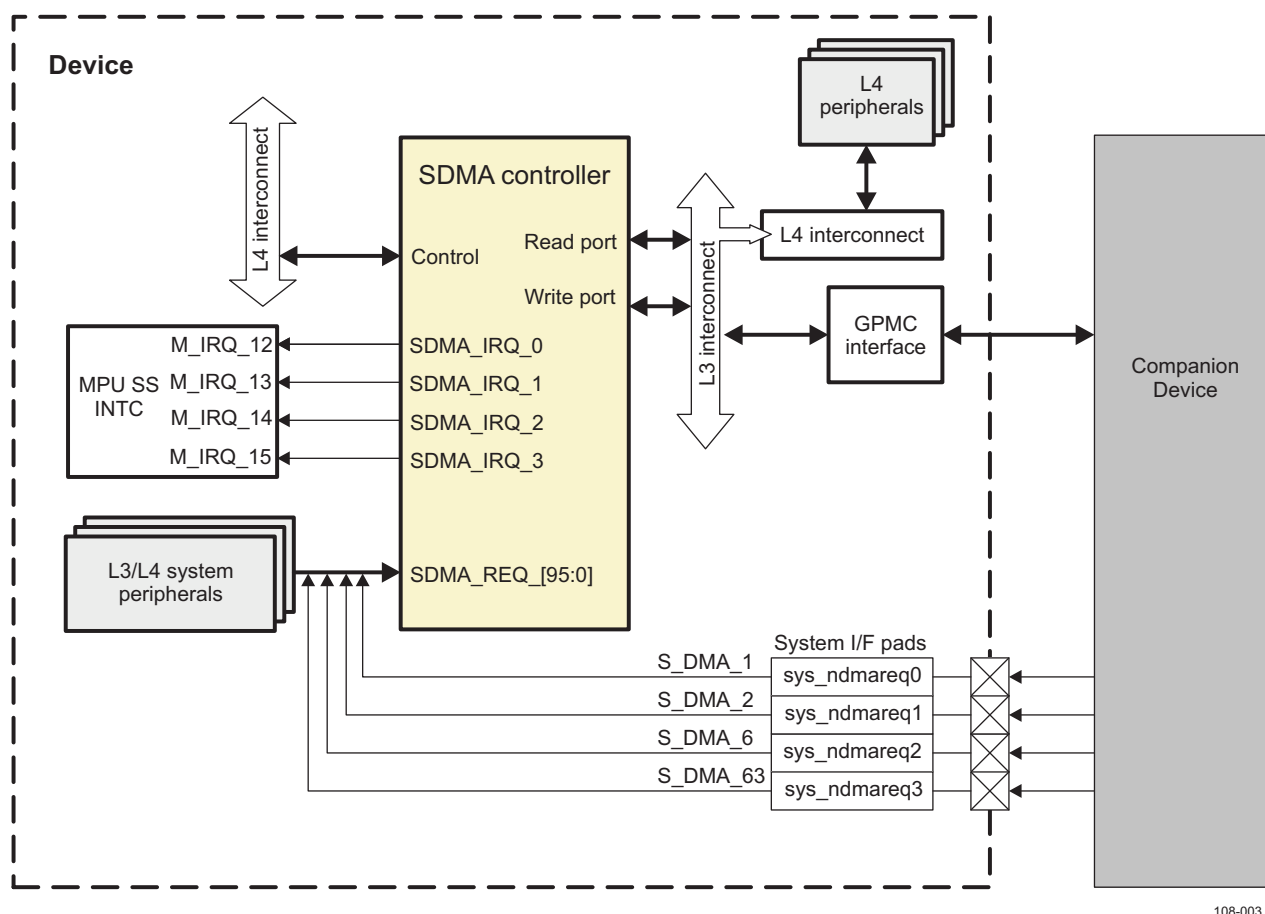

Table 9-1 shows the I/O description of the external DMA request pin.

Table 9-1. Description External DMA Request Pin

Signal Name	IO	Description	Reset
sys_ndmareq0	I	External DMA request to the SDMA controller	Unknown
sys_ndmareq1	I	External DMA request to the SDMA controller	Unknown
sys_ndmareq2	I	External DMA request to the SDMA controller	Unknown
sys_ndmareq3	I	External DMA request to the SDMA controller	Unknown

Figure 9-5 shows the SDMA environment with an example of how to use the external hardware DMA request pins.

Figure 9-5. Example of External DMA Requests to the SDMA Controller

108-003

For example, an external device can use the external DMA request pins to start a logical channel transfer over the general-purpose memory controller (GPMC) interface. The transfer can be a memory-to-memory transfer in which the source memory is in the external device.

The external DMA request signals are not available on external pins by default after cold reset. See the *System Control Module* chapter for instructions on multiplexing out the seven signal lines to pins.

9.3.2 Clocking, Reset, and Power-Management Scheme

9.3.2.1 Clocking

The SDMA controller uses two clock domains:

- CORE_L4_ICLK supports the configuration port.
- CORE_L3_ICLK is both a functional clock for all internal logic and for the two master read and write ports.

The SDMA controller supports a software-controlled standby mode with an input clock shutoff. Setting the PRCM.CM_IDLEST1_CORE[2] ST_DMA status bit to 1 allows detection of the SDMA power mode.

For more information about power management and clock idle, see [Section 9.4.20, Power Management](#).

9.3.2.2 Resets

9.3.2.2.1 Asynchronous Hardware Reset

The SDMA controller is part of the CORE_RST reset domain.

9.3.2.2.2 Software Reset through the Configuration Port

The SDMA controller can be reset independently by software through the SDMA.DMA4_OCP_SYSCONFIG[1] SOFTRESET bit. Setting the bit to 1 enables an active software reset that is functionally equivalent to a hardware reset.

Hardware and software resets initialize all of the logic in the SDMA module and the global registers and some of the per-channel registers (such as the enable bit hardware request line number and link bit field) implemented in flip-flops. However, all remaining per-channel registers are memory-based and, therefore, are not reset.

9.3.2.3 Power Domain

The SDMA controller is part of the CORE power domain.

9.3.3 Hardware Requests

9.3.3.1 Interrupts to the MPU Subsystem
